Subject: RE: Sycamore Marsh Farm Recharge PMA Comments

Ben;
Thank you for your comments and providing your family's background in the project area. Your comments will be added to the Admin. Record. I have also been contacted by the Dunlaps who are interested in participating in recharge projects in the area and they have submitted a PMA Solicitation Form.

As you know, projects in the Plan that the GSAs will oversee will not be implemented until they are vetted, refined and approved by the GSA boards. At that time, any coordination or integration with other project proponents can be defined.

Thank you,
Mary

Hi Mary and Grant,

I was able to see the PMA submission for the Sycamore Marsh Farm Recharge Project. It seems like a great project but I wanted to point out that part of the project area is land that is owned by T&M King Farms LLC which is owned and managed by me. I have included the map that was part of Appendix 2C and circled the portion of the parcel owned by T&M on the east side of the Colusa Basin Drain. I also want to mention that there should be close coordination with the land owned by John and Tina Dunlap directly to the south of the Marsh project area since it is also part of the Sycamore Slough. Since the project includes the Sycamore Slough the whole of the Slough south of Grimes Arbuckle road will have to be included in the project since it is part of the same waterway and ecosystem. I know this area well

because the Dunlap property and parts of the Marsh property because it was originally owned by my great grandparents as part of the Sherer and King pioneer farms.

We would love to be included on this project.

Best Regards,

Ben

Date: Thursday, November 4, 2021 9:18:45 AM

Hi Corin;
See below, questions from the October 13 virtual SGMA Series meeting (she watched the recording), for the admin record.

I also have some information to share from our legal counsel regarding what comments need to be documented in the record and in Appendix 2A. Maybe we can discuss on the call today if that is still on?

Thanks,
Mary

Subject: RE: Public Meeting Follow Up

Hi Ashley;
To answer your questions:
Was follow-up information provided on how the groundwater pumping fees will be calculated?
There have been no decisions regarding a pumping fee. Those discussions will start happening early next year. It is still to be determined how/if fees will be instated. Those discussions and decisions will happen at public GSA Board meetings. There may be other subcommittee meetings where recommendations for the Boards will be developed.

Also, how easy is it to adjust our compliance markers (e.g. minimum thresholds)? Is there a formal process, is the public included, and does the state have to approve changes?
The GSAs are required to report annually on their progress and to update the Plans every five years. They can adjust the Sustainable Management Criteria during these updates. Any adjustments will need to be justified to DWR with data and reasoning, and DWR will have to approve any changes. It will be a public process, likely similar to what has been done the last couple years with information coming to the Technical Advisory Committees at public meetings and then to the Boards at their public meetings for final decisions.

I hope that answered your questions. Let me know if anything is not clear.
Thank you,
Mary

Hi Mary!

Thank you for sharing the meeting recording. I finally had enough time to watch it this morning, and a lot of my questions were answered. I appreciate the recording and you sharing it.

I do have a couple more questions, and I am wondering if you can answer them. Was follow-up information provided on how the groundwater pumping fees will be calculated? If not, where can I find that information? Also, how easy is it to adjust our compliance markers (e.g. minimum thresholds)? Is there a formal process, is the public included, and does the state have to approve changes?

Thank you, again, and have a wonderful day!

Ashley

Subject:	Arsenic and Connate Sea Water Contamination around the Sutter Buttes
Date:	Monday, July 06, 2020 1:17:17 PM
Attachments:	Sutter_County_Final_GMP_20120319 (1).pdf Sutter County GMP Figures.pdf CA-Arsenic-Report.pdf

CAUTION: This email originated from outside of the organization. Do not click links or open attachments unless you recognize the sender and know the content is safe.

Hi Mary, Paul and Christina,

I wanted to follow up regarding my public comment on the last Butte Basin call. As mentioned in my call, my concern is that the connate seawater under the Sutter Buttes is contaminating groundwater and drinking water quality.

I have previously sent the SWCB Bulletin No. 6 from 1952 and the PHD Paper by George Curtin from 1971. Bulletin No. 6 reported that pumping depressions were drawing salt brines to the surface causing groundwater contamination. Curtin's paper proposes that the connate seawater is moving laterally through faults around the Buttes and researched several hundred gas well logs to express this opinion.

According to the Sutter County GMP on Page 23 "The Sutter Buttes Rampart consists largely of gravel, sand, silt and clay sediments which were deposited circumferentially around the Buttes as a geologic apron. These sediments may extend up to 15 miles north and west beyond the Sacramento River. " On Page 32 the GMP addresses the arsenic contamination issue - "… recent data analysis suggest a possible correlation between elevated arsenic concentrations and the presence of volcaniclastic material of the Sutter Buttes Rampart formation." Since the Colusa and Butter Basins are within the 15 mile circumference of the Sutter Buttes this would impact the analysis for Lower Water Quality and potentially Seawater Intrusion SGMA Sustainability metrics. I am mentioning the Seawater Intrusion metric because of the hydraulic components of pumping depressions and the physics of natural occurring contaminants moving laterally from higher elevations to lower elevations in combination of the force of pulling water to the surface by the operation of groundwater wells.

You will see the elevated EC levels and arsenic levels in the GMP Figures attachments. On Figure 19, there was an observation at T15NR3E of arsenic at 350 ppm and an EC of 1126. To the south at 14NR2E the observation of arsenic at 370 ppm and an EC of 1400. Since this study was focused on Sutter County there were not observations for Colusa County and Butter County. For Colusa County – the attached report regarding Arsenic contamination in public drinking water systems has the Grimes water district at 23.9 ppm which is the worse levels of toxicity of any public system in the Sacramento Valley. To the northwest of the Buttes there is a USGS Gamma well ESAC 21 which seems to be located in the Colusa County portion of the Butte Basic which has an arsenic reading of 80 ppm. Finally ESAC 11 which is due north of the Buttes and appears to be located in Grey Lodge

has an arsenic level of 70.

I can also note that the EPA assessment of the wastewater treatment facility for Yuba City reported that the high levels of arsenic in the wastewater was apparently from the portion of the Yuba infrastructure. Since most of the source of the water for Yuba City is surface water from the Feather River the arsenic contamination is pronounced where ground water is used. Finally as I mentioned in the past you probably are aware that the EPA has entered into an mitigation agreement with Sutter County regarding the arsenic contamination at Robbins. As you know Robins is at lower elevation and due south of the Buttes which would explain the contamination so far away from the Buttes. Robbins arsenic levels are less than the levels observed at Grimes.

I will send the Yuba City EPA report and the USGS Gamma documents next.

My suggestion would be to pick up where the SWRCB left off in 1952 and examine salt water and arsenic levels within a 15 mile circumference around the Buttes and set up a monitoring network to monitor changes in ground water quality going forward. This would not only focus on the southern part of the Buttes but within the whole circumference.

Thank you for your time and consideration.

Best Regards,

Ben

Hi Mary, Paul and Christina

The 2006 USGS Study presents the observations wells on Figure 3 – Page . I have attached a photo of the link to the USGS GAMMA website sorting for Arsenic. I have also include USGS Laux Road which is ESAC 21 and USGS Gray Lodge which is ESAC 11. On the website you can see the actual locations on the satellite imagery.

The 2004 EPA assessment for the Yuba City Sewage infrastructure addresses the arsenic issue on Page 10. It ascribes more than half of the arsenic contamination to groundwater.

Thanks again for your time and consideration

Subject: RE: Arsenic and Connate Sea Water Contamination around the Sutter Buttes

Hi Ben,

Thanks for the information and additional reports. I did reference some of the reports you had sent me earlier in the draft of the HCM for the Butte subbasin. That document will hit the street for public comment later this summer.

I will pass your emails and attachments along to the consultant team (Davids Engineering) for their reference and consideration as they continue supporting GSP development and completion.

I will also forward your emails to Tania Carlone, the facilitator for the Butte Advisory Board (BAB), so she can include it as correspondence in the future to the BAB since this is helpful follow up to the comment you made at their last meeting.

Best,
Christina

Subject: Arsenic and Connate Sea Water Contamination around the Sutter Buttes

ATTENTION: This message originated from outside **Butte County**. Please exercise judgment before opening

attachments, clicking on links, or replying.

I wanted to follow up regarding my public comment on the last Butte Basin call. As mentioned in my call, my concern is that the connate seawater under the Sutter Buttes is contaminating groundwater and drinking water quality.

I have previously sent the SWCB Bulletin No. 6 from 1952 and the PHD Paper by George Curtin from 1971. Bulletin No. 6 reported that pumping depressions were drawing salt brines to the surface causing groundwater contamination. Curtin's paper proposes that the connate seawater is moving laterally through faults around the Buttes and researched several hundred gas well logs to express this opinion.

According to the Sutter County GMP on Page 23 "The Sutter Buttes Rampart consists largely of gravel, sand, silt and clay sediments which were deposited circumferentially around the Buttes as a geologic apron. These sediments may extend up to 15 miles north and west beyond the Sacramento River. " On Page 32 the GMP addresses the arsenic contamination issue - "… recent data analysis suggest a possible correlation between elevated arsenic concentrations and the presence of volcaniclastic material of the Sutter Buttes Rampart formation." Since the Colusa and Butter Basins are within the 15 mile circumference of the Sutter Buttes this would impact the analysis for Lower Water Quality and potentially Seawater Intrusion SGMA Sustainability metrics. I am mentioning the Seawater Intrusion metric because of the hydraulic components of pumping depressions and the physics of natural occurring contaminants moving laterally from higher elevations to lower elevations in combination of the force of pulling water to the surface by the operation of groundwater wells.

You will see the elevated EC levels and arsenic levels in the GMP Figures attachments. On Figure 19, there was an observation at T15NR3E of arsenic at 350 ppm and an EC of 1126. To the south at 14NR2E the observation of arsenic at 370 ppm and an EC of 1400. Since this study was focused on Sutter County there were not observations for Colusa County and Butter County. For Colusa County – the attached report regarding Arsenic contamination in public drinking water systems has the Grimes water district at 23.9 ppm which is the worse levels of toxicity of any public system in the Sacramento Valley. To the northwest of the Buttes there is a USGS Gamma well ESAC 21 which seems to be located in the Colusa County portion of the Butte Basic which has an arsenic reading of 80 ppm. Finally ESAC 11 which is due north of the Buttes and appears to be located in Grey Lodge has an arsenic level of 70.

I can also note that the EPA assessment of the wastewater treatment facility for Yuba City reported that the high levels of arsenic in the wastewater was apparently from the portion of the Yuba infrastructure. Since most of the source of the water for Yuba City is surface water from the Feather River the arsenic contamination is pronounced where ground water is used. Finally as I mentioned in the past you probably are aware that the EPA has entered into an mitigation agreement with Sutter County regarding the arsenic contamination at Robbins. As you know Robins is at lower elevation and due south of the Buttes which would explain the contamination so far away

from the Buttes. Robbins arsenic levels are less than the levels observed at Grimes.

I will send the Yuba City EPA report and the USGS Gamma documents next.

My suggestion would be to pick up where the SWRCB left off in 1952 and examine salt water and arsenic levels within a 15 mile circumference around the Buttes and set up a monitoring network to monitor changes in ground water quality going forward. This would not only focus on the southern part of the Buttes but within the whole circumference.

Thank you for your time and consideration.

Ben

2B-4. Projects and Management Actions Submittal Forms

(THIS PAGE LEFT BLANK INTENTIONALLY)

COLUSA SUBBASIN

Colusa Subbasin GSP Projects and Management Actions (PMAs) Submittal Form

Overview

The purpose of this form is to gather ideas for potential projects and management actions (PMAs) that could be evaluated and ultimately included in the Colusa Subbasin GSP. Once ideas are gathered, an initial screening and evaluation process will be conducted, followed by ranking of potential PMAs for more detailed evaluation and inclusion in the initial GSP.

Potential PMAs may fall under several categories, including but not limited to the following:

- Recharge projects
- Supply augmentation projects
- Water conservation projects
- Projects to reduce non-beneficial consumptive use
- Groundwater pumping allocations
- Monitoring programs (groundwater pumping, water levels, stream flows, etc.)

Please provide supporting documentation and/or links to that documentation for each question, if available. **NOTE: It is recognized that much of the requested information may not be available at this time. Please provide as much information as you can.**

Project Name and Contact

Project or Management Action Name: Boards In Program

Contact Person: Lewis Bair or Bill Vanderwaal

Organization/Affiliation (Project Proponent): RD-108

Contact Phone: 530.437.2221

Contact Email: wvanderwaal@rd108.org

Project or Management Action Description and Status

Project or Management Action Description:

Institute a voluntary or financially incentivized program to have landowners leave their spill board in place during the winter to capture rainfall and hold it on the fields for recharge.

COLUSA SUBBASIN

Project or Management Action Location (please provide a map if available): Any fields with spill boards throughout the subbasin.

Which Sustainability Indicator(s) does this Project or Management Action address:

1. Groundwater levels

Project or Management Action Status (Conceptual, In Design, Ready for Implementation):

Ready for implementation

Has a feasibility assessment been conducted? If so, please list the agency and provide the documentation (or provide web link to download).
Not required for a voluntary program.

Estimated Cost:
Zero for voluntary program.

Potential Funding Sources:

Management Action or Project Yield (e.g. water contributed to the groundwater system, acre-feet per year):
Depends on rainfall and infiltration rate of field. It might be low for high clay content fields but still better than letting the precipitation runoff.

Please describe any required Permitting and Regulatory Process and status of permitting and CEQA/NEPA compliance:
N/A for voluntary program.

Does this Management Action or Project serve a disadvantaged community? If so, which one(s)?

Byron,

I attached some files on recharge projects the District has participated in. OAWD has a group of farmers who are investigating annexing over 7,000 acres into the District. They will be looking to integrate recharge projects to make the annexation more appealing. We are in the early stages but it is something to be thinking about.

Stony Creek Fan
Conjunctive Water Management Program

Feasibility Investigation

---

1. Plan Formulation
2. Existing and Baseline Conditions
3. Project Alternatives

Prepared for:

Glenn-Colusa Irrigation District
Orland-Artois Water District
Orland Unit Water Users' Association

Prepared by:

Grant Davids, Davids Engineering
Roger Putty, MWH
Susan Burke, MWH

February 2004
(DRAFT)

NOTE TO READERS:

This volume represents a major milestone in development of the Stony Creek Fan Feasibility Investigation. It contains the following three major sections:

1. **PLAN FORMULATION** is a statement of the goals and objectives of the SCF Partners and Partnership, along with a general discussion of the approach to development of conjunctive water management programs and of the physical and institutional factors that influence alternatives formulation. While additional editing needs to be done to smooth this section out, it is critical that this section be read and understood, because it explains why the alternatives take the shape that they do.

2. **EXISTING AND BASELINE CONDITIONS** documents and expands on information presented to the Partners in both group and one-on-one meetings. Remember that the baseline condition is hypothetical...it is a reference condition used to measure and compare the benefits of project alternatives. The key things to review are the projected land uses and water demands associated with the Baseline; these are the potential future water demands that the alternatives are designed to meet. Note that the description of existing and baseline conditions for the groundwater-only areas with the SCF Project Area have not yet been prepared.

3. **PROJECT ALTERNATIVES** describes the alternative actions that could be taken under the Program to meet the Partner's goal and objectives. Emphasis is placed on the "Solo Alternative", which initially would not involve actual physical sharing of resources among the Partners, but nonetheless could (and should) be viewed as a coordinated SCF Partnership effort. The collaborative alternatives are not as beneficial to each partner as the Solo Alternative *under present basin conditions.* Bear in mind that these materials simply describe the alternatives; no effort has been made yet to compare, evaluate and "fine tune" the alternative formulation. This work comes next and will likely lead to a SCF Preferred Alternative.

SECTION 1. PLAN FORMULATION

INTRODUCTION

The Stony Creek Fan Partnership (the Partnership) was established to investigate the potential for a conjunctive water management program to mutually benefit one or all of the entities that comprise the partnership. The three individual entities that comprise the partnership are the Orland Unit Water Users' Association (OUWUA), the Orland-Artois Water District (OAWD), and the Glenn-Colusa Irrigation District (GCID). The basis for this partnership, as with any partnership, is that each individual entity is able to make better use of its resources by operating within the partnership rather than operating outside the partnership. The partners agreed, through a Phase I Agreement, dated September 6, 2001, to cooperatively pursue development of the Stony Creek Fan Conjunctive Water Management Program (Program). A map of the Study Area is attached.

To determine the feasibility and practicality of developing a conjunctive water management program and related facilities the partners began the Stony Creek Fan Feasibility Investigation. The purpose of this investigation is to evaluate the potential conjunctive water management opportunities in the Stony Creek Fan area. The planning approach to completing this investigation is the focus of Section 1 of this document. The plan formulation describes the goals and objectives of the SCF Partners and Partnership, a discussion of the general approach to developing conjunctive water management programs, and of the physical and institutional factors that influenced the plan formulation process for the Stony Creek Fan Conjunctive Water Management Program.

COMMON GOALS AND INDIVIDUAL NEEDS

From the very beginning, it was recognized that the three Partners share some common goals, but also have different individual needs that they hope to fulfill, in whole or in part, through participation in the SCF Conjunctive Water Management Program (**Table 1-1**). Common goals include the following:

- **Protect local surface water and groundwater resources consistent with Glenn County ordinances**, specifically the Glenn County Groundwater Management Plan Basin Management Objectives (BMOs) and State and federal laws. This ensures that any plan to more fully utilize available water resources to meet the Partner's needs recognizes and allows for the needs of other water users within and neighboring the SCF Project Area.
- **Pursue opportunities to maximize Program benefits through strategic, synergistic linkages with other regional water management activities and authorities**. Increasingly, water management initiatives are being approached and implemented at a regional scale. While the SCF Partnership purposely began and has been maintained thus far with only three members, the Partners recognize that linkages with other water management initiatives and parties can provide mutual benefit. Potential linkages exist with Glenn County and the independent pumpers within and neighboring the SCF project area, as well as regional initiatives such as the Sacramento Valley Water Management Program and the State Water Project and Central Valley Project.
- **Secure water supply reliability locally and provide opportunities for improved water supply reliability for water users elsewhere in the State**. Fundamentally, the SCF Partnership exists to provide reliable, affordable water supplies to local users. However, the Partners understand that a proactive stance toward addressing regional and Statewide water supply reliability ultimately yields benefits to local initiatives. Thus, the Partner's will look for opportunities to participate in regional and Statewide initiatives that are consistent with the goals of the Partnership

- **Seek ways to achieve environmental benefits that are compatible with Program operations.** The Partners recognize that water management initiatives that also yield environmental benefit are more widely supported by the public and environmental advocates, and stand a better chance of attracting public financial support. Where feasible, the Partners will look for opportunities to fold environmental purposes into project formulation.

Table 1-1. Common Goals and Individual Needs

Common Goals		
• Protect local surface water rights and contract entitlements of each individual partner. • Manage groundwater resources consistent with Glenn County ordinances, specifically the Glenn County Groundwater Management Plan Basin Management Objectives (BMOs) and State and federal laws. • Pursue opportunities to maximize benefits through strategic, synergistic linkages with other regional water management activities and authorities. • Secure water supply reliability locally and provide opportunities for improved water supply reliability for water users elsewhere in the State. • Seek ways to achieve environmental benefits that are compatible with Program operations.		
Individual Needs		
GCID	**OAWD**	**OUWUA**
Improved reliability and increased flexibility through integration of basin surface and groundwater resources.	Secure reliable, affordable water supply in all years.	Enhanced management of surface water resources. Improvements to aging and obsolete irrigation infrastructure.

The individual needs of the Partners are very different. GCID has a relatively reliable water supply, being subject to shortages of only 25% in critically dry years. Therefore, the District's water supply reliability emphasis is on improving the ability to recapture system and farm losses in years of shortage. Additionally, the District's facilities are extensive and prone to ordinary deterioration, posing a significant and growing ongoing maintenance expense as costs generally escalate.

OAWD faces dual problems of water supply adequacy and affordability. Over recent years, the District has derived about half of its total water supply from its CVP water supply contract and half from groundwater supplies pumped by private landowners. Looking to the future, however, the amount of water available under its CVP contract is expected to decrease while water demands increase. This will lead to a supply mix of about one-third surface water and two-thirds groundwater, which may or may not be sustainable or affordable. At the same time, CVP water costs are escalating much more rapidly than other costs, raising concerns about the affordability of CVP water over the long-term. Thus, OAWD's primary need is adequate, affordable water.

Finally, the OUWUA is fortunate to have an extremely reliable water supply, but its storage, conveyance and distribution facilities are approaching obsolescence. For example, the Association's distribution system is capable of operating only on a rotation schedule, which is generally adequate for forage crop production, but not for production of high value crops and modern irrigation systems. Here the need is primarily to generate financial revenues to fund system modernization.

While the individual conditions and needs of the Partners are very different, they can be expressed in terms of either *new water* that would be used directly to achieve water supply reliability, and *financial revenues* derived from water transfers. Fundamentally, the challenge to the Partnership is to generate water supplies for direct use or for transfer to generate financial revenues.

GENERAL DISCUSSION OF CONJUNCTIVE USE AND PROTECTING BASIN

Conjunctive use involves the coordinated use of groundwater and surface water to minimize the impacts of shortages and increase supply reliability. Coordinated use means using groundwater to meet demand in dry years (when surface water supplies are limited) and using surface water to meet demand in wet years (when surface water supplies are not limited). Generally, one of the goals of a conjunctive use program is to maintain and protect the health of the groundwater basin. Basin Management Objectives (BMOs) are often established for this purpose.

In some geographic areas, basin health can be maintained without a formalized program if the rate of groundwater extraction is less than or equal to the rate of natural recharge. If, on the other hand, the groundwater extraction rate is greater than the natural recharge rate, then the health of the groundwater aquifer may be compromised. In such a case a formalized conjunctive use program may be required. A formalized conjunctive use program often develops methods to artificially recharge the groundwater aquifer. Artificial recharge can occur either through in-lieu programs or through direct recharge. These artificial recharge programs, combined with natural recharge, maintain the health of the groundwater aquifer.

A year in which artificial recharge occurs is often referred to as a 'put' year. Whereas, a year in which groundwater is extracted is called a 'take' year. It is the combination of these put and take years that characterize the conjunctive use cycle.

This conjunctive use cycle is shown in **Figure 1-1**, exhibiting an idealized pattern of alternating put and take cycles, which, operating in conjunction with one another would ensure the health of the basin as measured by long-term groundwater levels (i.e. long-term basin management objectives are met).

Because groundwater basins are complex, dynamic physical systems, the pattern of put and take cycles varies considerably among basins and with time. **Figure 1-2** is an hypothetical example where basin groundwater levels start out above a hypothetical BMO and remain above that level for several cycles (years) despite continued groundwater pumping from the basin. Perhaps during these years favorable hydrologic conditions have ensured the health of the basin, or perhaps the inflow (natural recharge) to the basin is adequate under the groundwater pumping circumstances. **Figure 1-2** suggests that eventually, however, the basin groundwater levels drop below the BMO levels. At that time the basin enters a put-cycle phase and implementing artificial recharge through in-lieu or direct means, or both, ensure that BMO objectives are achieved. For example, perhaps here-to-for unutilized winter flows could be redirected and recharged into the basin. Or, available dry-year surface water supplies could be used for in-lieu recharge.

Figure 1-3 shows the same types of hypothetical conjunctive use program, however in this example the initial basin elevation is below the long-term average BMO. In this hypothetical example the program would begin with put-years in order to recharge the basin until groundwater elevations approach the long-term average BMO elevation. Once the groundwater elevation begins to approach the long-term average BMO elevations then the basin would be managed with put and take cycles as needed to maintain the average condition.

The SCF investigation was designed to explore the basin's characteristics, including the basins ability to be operated under put and take cycles. The findings from this investigation influenced the plan formulation process and subsequent alternatives. This outcome is discussed in the following section.

FACTORS INFLUENCING THE APPROACH TO FORMULATING SCF CONJUNCTIVE USE ALTERNATIVES

Over the course of the feasibility investigation, new information regarding different and very unique physical aspects of the area combined with the institutional aspects arising from the SCF Partnership arrangement served as fundamental drivers of the alternatives formulation process. In particular, a field

investigation undertaken as part of the SCF study revealed new information about the Project Area's hydrogeologic and recharge characteristics. This new information improved each partner's understanding of the resources available to him or her and how best to manage those resources. And, more importantly, the fact that a conjunctive use program alternative must consider and serve the needs of three Partners, not a single entity, required an approach capable of revealing individual benefits to each partner's involvement in an integrated conjunctive use program as compared to operating independent of the partnership. Each of these factors is discussed further below.

Discussion of Physical Factors Influencing Alternatives Formulation

The basic components of a conjunctive use system are shown in **Figure 1-4**. Of paramount importance to a system of this type are, one, the basin's ability to produce groundwater without undesirable effects, and, secondly, the degree to which this ability can be enhanced by replenishing depleted groundwater supplies with artificial recharge. The Stony Creek Fan area would appear to be well suited for development of a conjunctive use system given the following characteristics[1]:

- Existing distribution and extraction facilities well positioned to support groundwater production and in-lieu recharge operations;
- The presence of the Stony Creek Fan, formerly thought of as the primary subsurface geologic feature beneath the Project Area, thought to have extensive groundwater storage and yield properties as well as highly permeable and transmissive properties capable of accepting natural and artificial recharge at relatively rapid rates;
- Viable surface water supply sources for storage and replenishment of groundwater through direct and/or in-lieu artificial recharge; and
- A strategic institutional alliance formed between GCID, OAWD, and OUWUA, bringing these key physical elements together.

As mentioned previously, "Put" and "Take" cycles govern the operation of a conjunctive water management project. The Stony Creek Fan Feasibility Investigation developed an understanding of the overall goals and needs of the districts, the water sources potentially available to the project, the various legal and institutional factors that effect the management of district resources, and an improved understanding of the groundwater basin and its response to hydrologic variations, pumping, and recharge. This analysis process is shown conceptually in **Figure 1-5a** and described in the following paragraphs.

Determine Yield Allocation: Project configurations are defined principally by the magnitude and allocation of Project yield, which shape the Project's extraction, or "Take" cycles (see **Figure 1-5a**, Determine Yield Allocation). Basic options include allocation to satisfy district unmet water demands, or to meet market demand. These options help define the primary features that drive the formulation of the project alternatives.

Assess Basin Response: The hydrogeology of the Stony Creek Fan is not well known, and a major objective of the feasibility investigation was to characterize the factors that influence groundwater behavior in the Study Area. Determining how to maximize project yield by strategic pumping or artificial recharge, thereby maintaining healthy groundwater conditions, are critical to the plan formulation process. The outcome of these evaluations will guide formulation of recharge and recovery strategies.

Determine Feasibility of Artificial Recharge: Depending on basin response to different project yield configurations, artificial recharge can be a critical component of a project configuration. The feasibility of

[1] It was recognized that the geology of the Stony Creek Fan was not well known, and a major objective of the feasibility investigation would be to characterize the factors that influence groundwater management in SCF Study Area. The outcome of these investigations changed the above thinking considerably, which is discussed further below.

artificial recharge depends largely upon the surface water supply sources and their compatibility with the recharge mechanism, in-lieu or direct recharge. Compatibility is measured both in physical terms which is governed by hydrology and also institutional terms which is governed by legal and contractual characteristics unique to each source. Also critically important are is the groundwater basins physical characteristics and hydrologic conditions, both of which govern the potential benefit of artificial recharge. For instance, a full basin may receive very limited benefit from artificial recharge in terms of long-term groundwater storage.

Figure 1-5a does not reveal the multitude of steps critical to the formulation and analysis of conjunctive use projects alternatives. These detailed steps are shown in flowchart form in **Figure 1-5b** ("Put" Cycle) and **Figure 1-5c** ("Take" Cycle). The following sections use these flowcharts to discuss the factors that influenced path followed by Stony Creek Fan Feasibility Investigation.

Assessment of Artificial Recharge Potential ("Put" Cycle)

The in-lieu leg of the flowchart (see **Figure 1-5b**) begins with the question "History of groundwater pumping per district?" If the answer is no, in-lieu recharge is not possible because there is no pumping to stop in order to achieve the in-lieu recharge. If the answer to the question is yes, then an assessment of the volume of surface water available for use as a substitute during the in-lieu recharge period is required. Finally, the assessment of surface water would be combined with the estimates of historical pumping volumes in order to estimate the size of the in-lieu potential.

The SCF investigation initially estimated the historical volume of groundwater extracted by each district to the as an initial assessment of the feasibility of in-lieu recharge. **Table 1-2** summarizes these findings.

Table 1-2
Summary of District Groundwater Pumping

District	Approximate Number of Groundwater Wells	Range of Historical Annual Groundwater Pumping (1000 AF/Yr)	Approximate In-lieu Capability (1000 AF/Yr)
GCID	200	4 to 17	17
OAWD	400	5 to 55	55
OUWUA	50	3 to 13	13
Total	**650**	**12 to 85**	**85**

The results of this initial review suggested that in-lieu recharge was possible given the amount of historical pumping. A review of surface water supplies that could be used in-lieu of pumping groundwater revealed two possible sources: unused Base Supply; and unappropriated Stony Creek water. These findings helped further shape the conjunctive use alternatives. More detailed discussion of this source identification and the characteristics of these potential in-lieu sources is provided later in this report.

The other method of artificial recharge represented on the flowchart is direct recharge. Following the "Direct Recharge" leg of the flowchart the first question asks whether or not favorable infiltration rates exist. If the answer were "No" then direct recharge would not be viable. For instance, soils consisting of fine sand to silty clay conditions are typically unsuitable for artificial recharge due to relatively low infiltration rates.

A field investigation of the Stony Creek Fan area was completed to determine infiltration characteristics within the Project Area and to help asses the feasibility of recharging the groundwater basin using constructed direct recharge basins. Candidate sites were identified throughout the area and were evaluated

based on specific site selection criteria[2]. Three sites were ultimately chosen for pilot recharge testing[3]. The three sites are considered to be representative of areas favorable for groundwater recharge throughout the Project Area.

The pilot recharge tests were conducted over a several week period under varied conditions. Infiltration rates varied from several feet per day to ten's of feet per day. The range of infiltration rates are summarized in **Table 1-3**. These infiltration rates are considered highly favorable for direct recharge operations.

Table 1-3
Pilot Recharge Test Infiltration Rates

Site	Long Term Infiltration Rate (ft/d)	
	Spreading Basin	Flooded Field
Van Tol	22	2
Jasper	45	6
Olivarez	10	0.5

1 Spreading basins are shallow ponds excavated to relatively shallow depths (2 to 6 feet) through low permeability soils and/or through shallow hardpan.
2 A flooded field refers to the groundwater recharge technique of applying shallow water to a bermed field (approximate berm height, 2 feet).

With the finding that favorable infiltration rates exist in the Project Area, the next logical question along the "Direct Recharge" path is "Does recharge water reach the target aquifer?" If the answer is "yes' then proceed to the next step. If the answer is "No", then direct recharge may not be effective. The SCF investigation found that the recharge water, under the existing state of the basin, might not be reaching the target aquifer, the Tehama formation.[4] Instead the recharge water appears to enter the Stony Creek Fan alluvium, where it may only reside in storage for a relatively short period - weeks or months as opposed to several months to several years – before being discharged from the area. It is postulated that the high conductivities associated with the alluvial materials result in lateral movement and lateral spreading of the recharge water, and little downward migration. This is evident by the shallow, mid, and deep groundwater level hydrographs shown for the Van Tol site. The groundwater levels associated with the shallow monitoring well show evidence of the recharge water reaching the surface of the water table, however, the mid and deep monitoring wells are not effected. This observation is typical of the monitored groundwater levels at all three pilot recharge testing sites. Furthermore, recent field work completed by the Northern District of the California Department of Water Resources suggests that the hydrogeology of the Stony Creek Fan alluvium is a relatively thin water-bearing zone of layered sands and gravels 50 to 80 feet thick (see **Figure 1-6**). This relatively thin "veneer" is layered on top of relatively impermeable clays comprising the Tehama formation; there is believed to be little interconnection between the alluvium and this formation.[5] This proposed distinction is in stark contrast to the previously accepted theory that the Stony Creek Fan aquifer consisted of sand and gravel layers associated with the younger alluvial

[2] The Pilot Recharge Test Site Selection Criteria are: soils and geologic conditions; groundwater conditions; land availability; water availability; site access; environmental issues; geographic variability. For a complete description refer to Stony Creek Pilot Test Site Selection Criteria Memorandum, MWH, October 2001.
[3] See Technical Memorandum 2:Pilot Recharge Test Designs and Monitoring Program, MWH, August 2002
[4] The Tehama Formation typically includes confined (or semi-confined) water-bearing layers occurring at multiple depths, which are believed to be the source of groundwater pumped by most irrigation wells in the Study Area.
[5] This is partly corroborated by results of well interference tests that suggest there is little interaction between the unconfined surface layer (Stony Creek Fan Alluvium) and the deeper confined aquifers (the Tehama formation) (personal communication with Toccoy Dudley, DWR-ND).

materials interbedded and interconnected with the silts and clays that are characteristic of the older alluvium, or Tehama formation.

The results of the field work described above suggests that in-lieu recharge may be more effective than direct recharge in managing the long-term health of groundwater resources in the Project Area. Assuming the artificial recharge water reaches the target aquifer, the next question on the flowchart is "Does the recharge water appear to positively impact the storage of the basin?" In other words, does the recharge water improve basin conditions (e.g. groundwater elevations) or does the recharge water appear to run-off? If the answer to this question is "Yes" then artificial recharge appears viable. If the answer to the question is "No" then recharge water is being rejected possibly because the basin is already "full."

The term "full", as used here, is referring to groundwater conditions that are relatively stable, or in balance. Under these conditions water leaving the basin is approximately equal to water entering the basin on a long-term average annual basis. For instance, groundwater storage conditions in the Project Area have varied over the course of the last 30 years due to varied hydrologic and water supply conditions, however, the cumulative change in storage conditions has been minimal. This is supported by the following information:

- A water balance completed for the Project Area shows a net recharge on average of approximately 1.1 acre-feet per acre per year; and
- Review of groundwater level hydrographs throughout the region indicate groundwater levels typically return to pre-pumping conditions the following spring.

Based on the above findings, it was concluded that average annual natural recharge to the basin has generally exceeded average annual extractions from the basin, and artificial recharge at this time would not provide any additional direct benefit. However, as described previously, operating the basin in a "take" mode could require additional artificial recharge at some point in the future. For this reason, consideration of artificial recharge using in-lieu methods is pursued as part of the conjunctive use alternatives formulation effort.

Assessment of Additional Groundwater Yield Potential

[This section needs further discussion of the need to transfer water for the purposes of revenue generation to help each District achieve their goals/needs as discussed at the beginning of Section 1.]

The 'take' cycle, shown n **Figure 1-5c**, begins by asking "Transfer dry-year water?" If the answer to the question is no then the pumped groundwater would be used to meet local demand. Note that both legs of the flow chart could be followed and some water could be used to meet local demand while some could be reserved for transfer. If the answer to the transfer question is 'Yes' then a series of questions must be answered.

The first question is, does the groundwater pumping entity have access to dry year surface water supply to transfer. If there is no dry-year supply then a transfer is not possible. If the answer to the question is yes then the question is, "Is there conveyance for the transfer?" For example, both GCID and OAWD have relatively efficient conveyance for transfer water. Both districts would leave water in the Sacramento River. OUWUA is relatively more challenged for conveyance. The Stony Creek is believed to be a losing creek for much of the stretch between OUWUA and the Sacramento River.[6] Therefore transfers down Stony Creek are jeopardized by high losses. Potential transfers of OUWUA water may require involving exchanges with TC contractors.

If there is both dry-year surface water and conveyance ability the next question to answer is "is the transfer possible per the water code?" In general, groundwater substitution transfers have little trouble

[6] Personal conversations with Toccoy Dudley of DWR.

with a legal review. The legal 'transfer-ability' of source water available to the SCF partners, other than groundwater substitution water, is not as clear.

The components necessary to a groundwater substitution transfer are summarized in **Table 1-4.** The three components are 1) dry year water supply 2) groundwater pumping capacity and 3) conveyance. The OAWD is limited in their dry-year surface supply but possess the other two attributes. The OUWUA has limited groundwater pumping capacity but possess the other two components. GCID posses all three components. In addition, field investigations have confirmed the presence of a potentially high-producing confined aquifer, the Lower Tuscan formation: Hydrogeologic investigations underway by DWR-Northern District have documented the presence of this formation in the vicinity of the Project Area. Evaluation of well logs supported by recently developed wells support the notion that this groundwater source could potentially provide new supplies to the Partners.[7]

Table 1-4
Components of a Dry-year Groundwater Substitution Transfer

Partner	Groundwater Substitution Transfer Component		
	Dry Year Surface Supply	Groundwater Pumping Capacity	Conveyance of dry-year surface water
OAWD	Limited *(Junior CVP entitlement)*	Not limited	Not limited *(Forebear diversion into TC canal from Sacramento River)*
OUWUA	Not limited *(Adjudicated Pre-1914 storage and direct diversion rights)*	Limited	Limited *(Forbear diversions from Stony Creek – either travel down Stony Creek (high loss factor, or move water from South Canal to TC canal and ultimately Sac River at the drain).*
GCID	Not limited *(Base supply and supplemental CVP supply)*	Not Limited	Not limited *(Forbear diversions into the GCID from the Sacramento River)*

Summary of Physical Factors Influencing Alternatives Formulation

In summary, the field investigations and modeling analysis narrowed the set of alternative components. Initially the set of alternative components was believed to include variations of artificial direct recharge, in-lieu recharge, supply sources, extraction volumes, and yield destinations. However, as a result of the field investigations and subsequent modeling, artificial direct recharge was determined to offer less opportunity than originally thought. Furthermore, examination of historical water level data supported by modeling analysis indicates that the basin is more resilient than previously thought and is capable supporting additional production. In addition, greater understanding of the hydrogeology has revealed new sources of potential groundwater supplies. These findings combined have lead too more focused alternative formulation as discussed below.

Discussion of Institutional Factors Influencing Alternatives Formulation

An alternative that combines the resources of two or more partners is successful only if it provides each partner benefits that exceed those that each could achieve on their own. The most important implication

[7] It is noted that development of the Lower Tuscan formation as a source of new supply poses risks not yet fully identified or understood. For example, there remains limited understanding of the potential range of well's yields, the potential physical effects of long-term pumping, and the potential political ramifications of landowners predisposed to using private landowner wells rather than district-owned wells. These unquantified risks will be addressed through future efforts to compare and analyze SCF project alternatives.

this had to the alternatives formulation process was that each Partner needed to have a good sense of the individual water management options that they could pursue alone, so that they could weigh the benefits of collaboration versus individual actions. This resulted in organizing alternatives into two primary groupings, "Solo" Alternatives and Collaborative Alternatives, defined accordingly:

- *Solo Alternatives*: A solo alternative consists of individual action(s) identified for each Partner.
- *Collaborative Alternatives*: A collaborative alternative involves the joint operation of two or more district resources through either physical or institutional means, or both.

A series of focused meetings were held with each Partner individually to identify the water management options available to them, and to combine those options into a strategic plan of action. The individual strategic plans, or solo alternative, for each Partner serve the essential purpose of providing each Partner a means of judging the value of a collaborative approach relative to an individual (or solo) course. The approach to developing these two primary groups of alternatives is discussed further below under *Approach to Formulating the Project Baseline and Alternatives*.

[An expanded discussion will be added to address other institutional factors such as BMOs, air quality, SVWMP, CVPIA, etc]

APPROACH TO FORMULATING THE PROJECT BASELINE & ALTERNATIVES

Focused Alternatives Formulation Approach

The formulation process for developing conjunctive water management alternatives can involve a systematic identification and extensive evaluation of all potential sources of recharge water, all means and locations of groundwater recharge and production, and various combinations of these components. However, the fundamental implications stemming from the factors discussed above are that (1) Solo Alternatives are essential to the plan formulation process, and (2) the benefit of artificial recharge may be relatively small, effectively narrowing the field of potential collaborative alternatives. Thus, attention was concentrated on formulation of the Solo Alternatives and on identifying and formulating the types of collaborative alternatives most likely to succeed; i.e., those involving in-lieu recharge and offering opportunity to derive value or benefit from resources that otherwise would go unutilized.

Baseline Condition

As noted earlier, the Project Baseline is used as a reference condition for measuring the benefit or value of the various Solo and Collaborative alternatives. It is a hypothetical future condition that is assumed to exist if none of the alternatives was implemented; it is therefore sometimes also referred to as the "future without the project" or "without-project" condition.

The traditional standard for identifying possible future actions to include in a project baseline is the standard of "reasonably foreseeable", which is intended to exclude highly speculative actions. The Partners agreed that the project baseline should be comprised of non-speculative actions that clearly could be accomplished by each Partner. The parameters and actions ultimately included in the Project Baseline are described in Section 2.

"Solo" Alternatives

The purpose in developing the Solo Alternatives is to identify the combination of water management initiatives that each Partner would most likely pursue in the absence of participation in potentially more beneficial, collaborative alternatives. The Solo Alternatives serve as "yardsticks" for each Partner to gauge the advisability of entering into an alternative which involves some level of joint operation of

partner resources, as compared to an alternative which involves one partner proceeding alone. The approach used to identify each district's "Solo" Alternative is described below.

Collaborative Alternatives

Collaborative alternatives involve some degree of joint operation of district resources. This could involve the actual physical exchange of resources among the districts, and institutional mechanism that enables each district to modify their own resource utilization under a joint program, or a combination of the two. As noted previously, the realm of viable collaborative alternatives is narrowed as a result of the limited benefit of artificial recharge. In particular, it appears that the most fruitful opportunities for partnership are ones involving in-lieu recharge and where presently unutilized resources can be put to use.

Identification of "Solo" and Collaborative Alternatives

The project team worked closely with each district to define and refine their "Solo" Alternatives and to identify potential Collaborative Alternatives. The GW Model was used to evaluate the effect of each District's actions on the basin and the effect these actions would have if implemented together. An economic analysis was also conducted to compare the present value of project costs to the present value of project benefits, to determine economic feasibility. This analysis explored and improved the understanding of how each Partner's water supplies could best be managed in terms of quantity, distribution, and timing. The primary objective of developing this information was to educate the Partners and the Project Team so that the "Solo" Alternatives and Collaborative Alternatives could be refined as needed. The Project Team worked with each Partner to identify specific questions and/or planned actions.

SECTION 2. DESCRIPTION OF EXISTING AND BASELINE CONDITIONS

INTRODUCTION

This section describes the existing and baseline conditions in the Project Area. Both conditions are described in sections dedicated respectively to the Orland Unit (Subunit 1), Orland-Artois Water District (Subunit 2), Glenn-Colusa Irrigation District (Subunit 3) and the independent pumper areas (Subunits 4-7). The descriptions of existing conditions are based on observations and interpretations derived from the historical (1970 through 2000) water balances prepared for the various subunits (see **Map 1**)and in aggregate for the Project Area. The project baseline represents conditions that are predicted to occur in the future, if one of the project alternatives is not implemented. It is a hypothetical condition developed primarily to serve as a yardstick for measuring the relative merits of the various alternatives.

Discussion begins with examination of the assumptions that are common and applied uniformly to all three Partners to establish the project baseline. This is followed by sections describing each Partner's pertinent background information, water resources setting, and existing and individual baseline condition.

The information presented here is derived primarily from the prior tasks completed for the Feasibility Investigation:

- Initial Field Investigations (Task 3)
- Collect and Review Existing Data (Task 4)
- Characterize Existing and Future Hydrologic Conditions (Task 5)

COMMON BASELINE ASSUMPTIONS

The Baseline Condition is a hypothetical future condition that would exist if Solo or Collaborative project alternatives are not pursued. Development of Baseline conditions requires making certain assumptions about future conditions, some of which are unique to the individual Partners, and others of which are common among the Partners. This section describes the baseline assumptions that are common among the Partners.

Planning Horizon

The planning horizon refers to the point in time for which Baseline Conditions are developed. Factors that influence selection of the time horizon includes the presence of trends in historical land use and cropping, the time that would likely be required to implement the project alternatives, the horizons used for other related planning efforts, and other factors. Based upon review by, and discussion with, the SCF Partners a time horizon of 2025 was assumed for planning purposes. This is consistent with other planning efforts recently completed, such as the USBR water needs analysis completed for contract renewals, regional planning ongoing for CALFED, and the California State Water Plan Update (DWR Bulletin 160).

Hydrologic Conditions

The hydrologic period over which the alternatives are analyzed and evaluated must include enough variability to reveal how the alternatives would function under conditions of prolonged water shortages and surpluses. The historical water balances prepared for the Project Area cover the period of 1970 through 2000. This period probably includes sufficient hydrologic variability, but does not match the longer and even more variable period of 1922 through 1994, which is used by DWR, the USBR and

CALFED for planning purposes. Therefore, the historical hydrologic record spanning the period of 1922 to 1994 is used to develop Baseline Conditions, and for formulation and comparison of alternatives.

Future Land Use & Cropping Patterns

With minor exception, projections of future irrigated area and cropping patterns within each subunit were based on trends observed during recent years. The basic assumption is that recent trends are acceptable indicators of change that will occur between 2000 and 2025. The methodology described here was developed in consultation with staff of DWR's Northern District, to ensure comparable results with DWR land use projections. The first step was to assign the total land area within each subunit to the broad classifications of "cropped", "non-cropped" and "idle". The cropped area in 2025 was assumed to be the same as the maximum cropped area observed anytime between 1991 and 2000. (An exception was made for OAWD where land is still being developed for irrigation. In that case, 1,352 acres was added to the maximum observed cropped area, to account for land connected to the OAWD distribution system and paying assessments, but which has not yet been developed.) The non-cropped area in each subunit was then increased at a constant annual rate to account for urbanization, based on the growth in urban lands observed between 1993 and 1998 (the two years for which DWR land use data are available). Finally, lands not accounted for as cropped or non-cropped were assigned to an "idle" classification as a closure calculation.

Land within the cropped category was assigned to specific crops based on the percentage observed in 2000, plus the percentage change observed between 1996 and 2000, with a dampening factor allied to moderate the compounding effect.

The results of the cropping projections are presented in the appropriate following sections.

Irrigation Management Practices

Irrigation management practices, including irrigation methods and existing technologies, are assumed to be the same as those currently in place in the Project Area. The only exception to this assumption is for alternatives that may have as a key feature some change in the irrigation scheme within a district or districts.

ORLAND UNIT WATER USERS' ASSOCIATION (SUBUNIT 1)

Background

The Orland Unit Water Users' Association (OUWUA) is located in north central Glenn County (see **Map 1**). The OUWUA is a Non-Profit California Corporation. Founded in 1906, the Association petitioned the Secretary of the Interior to encourage the USBR (then the Untied States Reclamation Service) to develop an irrigation project near the town of Orland. As a result, the USBR began construction of the Orland Project in 1909. The facilities of the Orland Project deliver water from the Stony Creek watershed to the shareholders of the OUWUA.

There are 1,099 shareholders within the OUWUA. The average farm size in the OUWAU is relatively small, and some shareholders maintain hobby farms (33 percent of the shareholders having 5 acres or less). The average farm size is 18 acres. Approximately 25 percent of the farms are greater than 20 acres.

The OUWUA service area enjoys favorable growing conditions for agriculture. A thermal belt, with very few frosts, warms the Orland area. The soil is considered some of the richest and most productive in the nation (USBR). The textures of the soils in the OUWUA are predominately loam, gravelly loam and gravelly sandy loam. Average rainfall is 18 inches, most of which is measured between the first of November and the first of April.

The primary facilities of the Orland Project include East Park reservoir and Stony Gorge reservoir. The Project was constructed between 1909 and 1928. In 1954 the OUWAU took over operation and maintenance of the Project from the USBR. These reservoirs are upstream of the US Army Corps of Engineers (USACE) Black Butte Dam, constructed in 1962 for flood control.

Flows from Black Butte Reservoir are controlled by the USACE and are released to meet the total demands required by OUWUA. After calculating the total delivery demands for the day and adding 10 percent for losses, OUWUA calls the USACE at 7:00AM to give its daily order. At 1:00PM in the afternoon OUWUA has the opportunity to change their order if needed. Surface water is distributed in open channels to approximately 17,600 of the 20,200 acres of the OUWUA through 17 miles of canals; and 139 miles of laterals (CALFED 2003 [1]).

The project is divided into six geographic areas called 'beats'. Surface water deliveries are made to the six beats on a rotational basis. Regardless of the crop being grown, the soil texture, or the evapotranspiration rate, water is delivered every 12 days during the peak demand period from June through September and every 14 days at the beginning and end of the season when crop demand is lower. During the months of peak demand, it is not possible to shorten the rotation period because of capacity constraints mostly in the main laterals. Some growers augment surface water supplies with groundwater were the physical constraint of these rotational periods result in surface water delivery patterns that do not meet crop demands for producing maximum yield. Some growers use groundwater exclusively where surface water is not available. Of the 20,200 acres of the OUWUA, 17,600 are receiving surface water. Of the 2,600 acres that are not supplied surface water, approximately 500 acres are irrigated with groundwater and the rest are fallow.

Six fulltime ditchriders, one for each beat, control flows by manually adjusting turnout gates and checks. Irrigators are informed in advance of the time they will be provided water and it is their responsibility to open and close their farm turnout(s) at the right time. Water deliveries are not measured at farm turnouts, except for several piped turnouts with meters, but are typically estimated from experience and measurement at upstream flumes and weirs.

Due to the nature of the open channel distribution system an the limited use of meters within the OUWUA estimates of conveyance losses and operational spills are 20 percent of total diverted water.

The OUWUA has investigated modernizing its existing distribution system in order to enhance conservation (CALFED 2003 [1]). Three estimates of the volume of water that could be conserved were 40,100, acre-feet (AF) per year 25,400 AF per year and 14,400 AF per year depending on the size of the investment in infrastructure. The range of capital investments for the three alternatives are $221,640,000, $53,499,000 and 18,489,000, respectively. The OUWUA is currently deciding which, if any, of the conservation measures to adopt and is examining various financing scenarios. This topic is discussed in the section of this Technical Memorandum that describes SCF Partner Alternatives.

OUWUA employs a total of fifteen fulltime staff; six ditchriders, two dam-tenders, four maintenance workers, one foreman, one office manager and on manager. The current overall O&M cost for OUWUA is $869,000. Shareholders pay $29.50 per acre per year that entitles them to 3.0 AF per acre. For additional water, it costs $9.83 per AF for up to 2 AF and $10.90 per AF thereafter.

Water Resources Setting

Surface Water

With very little snow, winter runoff from the Stony Creek watershed occurs almost immediately after precipitation. The Stony Creek watershed had an average annual runoff of 410,000 AF for the period 1921 to 2001. The low of 17,000 AF occurred in 1977. The high of 1,435,000 AF occurred in 1983.

The reservoir capacity on the Stony Creek watershed is as follows: East Park Reservoir is 50,900 AF, Stony Gorge Reservoir is 50,000 AF and Black Butte Reservoir is 136,000AF (DWR). Approximately 90 percent of the time precipitation is sufficient to fill the OUWUA reservoirs, East Park and Stony Gorge. The total reservoir capacity in the upper watershed is not adequate to provide regular planned inter-annual carryover storage.

Black Butte Reservoir, while originally built for flood control was financially and operationally integrated with the CVP, authorizing use of conservation storage for irrigation and recreation.[8] Operations of the three reservoirs were coordinated under a 1964 agreement to increase the net benefits of the system.

The rights to water available to the Orland Project as summarized in **Table 2-1**. Many of the rights to the water delivered by the Orland Project's facilities were adjudicated in the terms of the Decree in the case of The United States of America vs. H. C. Angle, et al, 1930. Water rights from the Angle Decree provide for both storage of water and direct diversion of water. The Angle Decree provides a total of 85,050 af (not to exceed 279 cfs) of direct diversion rights for irrigation and reclamation. The Angle Decree provides rights for storing water in East Park Reservoir (51,000 af of Little Stony Creek water) and a maximum of 250 cfs of water on Big Stony Creek for irrigation and reclamation. In addition to the water rights adjudicated in the Angle Decree, the USBR holds 50,200 af of rights to storage of Stony Creek water. This storage water is contained in Stony Gorge Reservoir. [Need to comment on the USBR storage and diversion right of S006354.

Table 2-1
Summary of the Water Rights Available to the Lands of the Orland Project

Quantity	Type of Right	Date of Right	Time	Source
85,050 af not to exceed 279 cfs	Direct Diversion on Stony Creek	10//10/1906	Irrigation season as available	Angle Decree, Article VIII (1)
51,000 af	Storage of Little Stony Creek water	10/11/1906	Year round as available	Angle Decree, Article VIII (3)
250 cfs	Storage and conveyance of water from Big Stony Creek	3/25/1913	Year round as available	Angle Decree, Article VIII (4)
50,200 af	Storage, water of Stony Creek	Permit issued on 12/2/1925 License on 5/15/1944	November 1 to May 1	SWRCB Application number A002212 held by USBR for Orland Project

Groundwater

The lands of the Orland Project overlie the Stony Creek Fan (alluvium). Historically, surface water supplies are sufficient to meet irrigation demands, however some of the lands within the Project use groundwater for irrigation due to conveyance constraints of the Project. The quantity of ground water pumped in any year is estimated to average 3,000 af. A detailed description of the hydrogeology of the basin will be provided in TM 3.

Historical Water Demands & Supplies (1970 – 2000)

A water balance analysis was prepared for the Orland Unit for the period 1970 through 2000 as a means of understanding historical water demands and supplies, irrigation efficiency, and the relationship

[8] In addition to the USBR, USACE and OUWUA the City of Santa Clara operates a 6.2 MW hydroplant on Black Butte dam. The hydroplant is operated under a cooperative agreement between the City of Santa Clara, USACE and OUWUA.

between Unit operations and regional hydrology (see Technical Memorandum #3 for more information). The primary purpose in developing the historical water balances is to provide a factual basis for forecasting future cropping patterns and water demands under the Baseline Condition and project alternatives. Pertinent aspects of the water balance analysis are described below.

Cropping Patterns (Historical)

The total land area within the Orland Unit is 24,130 gross acres, of which approximately 15,000 to 17,000 acres were cropped and irrigated over the period of analysis. Exceptions to this were the critically dry years of 1977 and 1996, when water supply shortages resulted in reductions in irrigated area. The cropping pattern is dominated by pasture and forage, which accounts for roughly 60% to 70 % of the total cropped area. The dominance of pasture and forage is believed to be associated with the large number of small parcels in the Orland Unit that are not commercially farmed, and a rotational water delivery pattern that is conducive to forage production, and less so to production of other crops. Permanent crops, although a minor percentage of the total, have steadily expanded in acreage, from about 2,700 acres in 1970 to 3,500 acres in 2000. Field crops have at times been planted to more than 4,000 acres; however, field crops have seen a steady decline in recent years, falling to less than 2,000 acres in 2000. The maximum total irrigated area observed during the period of analysis was about 17,500 acres in 1982.

Water Diversions and Demands

The total measured historical water diversions in the Orland Project between 1970 and 2000 have ranged between 126,308 af/yr and 26,299 af/yr. The average diversion for that period has been 95,372 af/yr. Approximately 20 percent of that diversion is estimated to be conveyance losses (see **Figure 2-1**). The remainder of diversions after conveyance losses is available to meet applied water demand. Applied water demand is the sum of (ETaw) and the irrigation efficiency requirement. [9]

Figure 2-2 represents the various uses of surface water and groundwater to meet ETaw. The surface water diversions are categorized by conveyance losses, irrigation efficiency losses and ETaw. The average estimate of historical ETaw (given conveyance and irrigation efficiency losses) is 49,593 af/yr. On average, water demand is comprised 40% of ET of applied water, 40% on-farm losses and 20% system losses, indicating significant potential for demand reduction through reduction of losses. Private Pumping is negligible in most years, except in water-short years like 1976, 1977 and 1998. The maximum volume of private pumping ever to occur in the Orland Unit was about 13,000 af in 1976.

Baseline Condition (2025)

As noted earlier, the Project Baseline (or Baseline Condition) is used as a reference condition for measuring the benefit or value of the various Solo and partnership-based alternatives. It is a hypothetical future condition that is assumed to exist if none of the alternatives was implemented; it is therefore sometimes also referred to as the "future without the project" or "without-project" condition.

Assumptions

Common to all of the partner's baseline, or without project condition, is the assumption that the planning horizon looks out to 2020. Therefore estimates of future water demand and available water supply of the OUWUA were developed.

[9] To maintain the water balance, changes from year to year in water stored in the root zone must also be accounted for. A decrease in stored water across years is counted as a component of supply, while an increase in storage is represented as a component demand. The volumes of water associated with storage changes are generally small both year to year and cumulatively over the period of analysis, and can generally be neglected.

Cropping Patterns

The cropping pattern in the OUWUA is expected to shift slightly to more pasture and forage than what was historically grown, reflecting the expected increase in the already large number of small parcels that are not commercially farmed. Although the management of the OUWUA is anticipating that, either through the implementation of a solo alternative or a collaborative alternative, the existing rotational water delivery system can be replaced through system modernization it is not anticipated that the cropping patterns over the next 15 years will reflect this change

Water Supply and Demand

Water supply is not expected to change from historical. The OUWUA has relatively senior water rights (as discussed above) and the availability of water under those rights is not expected to change. The challenge before the OUWUA is to make certain that those rights are not reduced through environmental actions.

The demand for water in OUWUA is not expected to change significantly from historical. See **Figure 2-3** for a comparison of the historical and baseline demand. The average historical demand is 79,780 af. The average of the estimated baseline demand is 85,270 af. The difference of approximately 5,000 af per year represents the change to more water intensive pasture and forage crops.

ORLAND-ARTOIS WATER DISTRICT (SUBUNIT 2)

Background

The Orland-Artois Water District (Subunit 2) is located between the Orland Unit (Subunit 1) to the north and GCID (Subunit 3) to the south and east (**Map 1**) The District was formed in 1954 for the purpose of contracting with the United States (Bureau of Reclamation) for a supplemental surface water supply from the Central Valley Project (CVP). The parties originally entered into Contract No. 14-06-200-467-A on April 19, 1963; that contract was amended on September 15, 1964. The original contract, as amended, provided for supplemental surface water to be delivered to OAWD via the Tehama-Colusa Canal (TCC), a feature of the CVP construction of which had not yet begun when the contract was executed.

The original contract was superceded by Contract No. 14-06-200-8283A, entered into by the parties on February 26, 1976. The 1976 contract superceded the original contract with respect to provision of supplemental surface, and provided for the design, construction and repayment of a distribution system to deliver the contract water supply to District lands. According to the agreement, the Bureau provided design and construction management services. Since the expiration of the 1976 contract in 1995, the District has continued to receive Central Valley Project (CVP) water under a series of two-year interim contracts with the United States, each with the same maximum contract amount (53,000 acre-feet) as the 1976 contract. Along with other CVP water contractors, the District is currently negotiating long-term renewal of its water supply contract with the United States.

The District is comprised of 30,290[10] (gross[11]) acres of land interspersed with non-District lands in a checkerboard-like pattern. This pattern reflects the decisions made by individual landowners to join the District or not. The District's assessed area is 28,988 (gross) acres.

[10] According to District records, there are 30,290 gross acres within the District's boundaries. The area digitized to represent OAWD in the water balance analysis was comprised of 31,264 acres because it included some adjoining acreage as well as OAWD lands. This difference is not considered be significant for purposes of the Feasibility Investigation.

[11] Unless otherwise indicated, all references to irrigated areas are to net acreages actually planted to crops and receiving water for irrigation. In general, net acreages are about 6% less that assessed or gross acreages, and

Construction of the distribution system under the District's contract with the United States began in 197? and was completed in 198?. Delivery of CVP water began in 1976 and expanded gradually, year by year, as construction proceeded. The system consists of approximately 100 miles of buried asbestos-cement pipeline with diameters ranging from 8 to 96 inches (Figure ____) *(Note: OAWD distribution system map to be included in subsequent draft documen.)*. The combined delivery capacity through the 5 permanent and 3 temporary turnouts from the TCC is 427 cubic feet per second (cfs). The TCC bisects the District, running east to west across the northern portion of the District, then from north to south across the west side of the District. About 16,767 assessed acres lie down-gradient (generally south and east) of the TCC and are served by gravity, without the need for pumping. The remaining 12,221 assessed acres lie up-gradient (generally north and west) of the TCC and are served by canal side pumping plants that were constructed as components of the distribution system. The maximum elevation difference between the TCC and highest farm delivery is about ____ feet.

Water users are required to place water orders with the District, specifying the volume of water to be used at each turnout on each day. User's orders are compiled for each lateral pipeline system and associated TCC turnout, and submitted to the Bureau of Reclamation daily to enable coordinated operation of the TCC. The District pipelines are closed systems; they operate in response to grower demands, allowing growers to take delivery of their ordered volumes at the rates and durations that are most efficient or convenient for farm operations. There is no spillage from the system, and the District maintains a leak detection program to prevent appreciable leakage. Thus, system losses are negligible. Water deliveries are made to farms through individual farm turnouts with totalizing flow meters. District staff read meters monthly, with meter readings and water bills sent monthly to water users.

Water Resources Setting

Water demands within OAWD are satisfied by a combination of surface water and groundwater sources; both sources are described in the following sections.

Surface Water Sources

OAWD is traversed by several small, ephemeral creeks that originate in the foothills west of the District. The largest among these is Walker Creek, which at times poses a flood hazard. Some irrigation diversions are made from the creeks to District lands in the spring; however, these diversions are unrecorded and are generally believed to be insignificant from a District water supply perspective[12]. Thus, the District's main sources of surface water are imported, including CVP supplies provided under Contract No. 14-06-200-8283A (described above) and occasional, temporary (year to year) water transfers from other CVP water contractors. The maximum water quantity available under the District's CVP contract is 53,000 acre-feet annually (March 1 through February 28); however, this maximum is subject to limitation, depending on overall CVP water supply conditions and Bureau water allocation policy.

Because OAWD is generally water-short, each year the District seeks to augment its CVP contract supplies with short-term water transfers, primarily from CVP contractors that have temporary CVP contract surpluses. Throughout the mid- to late-1980s, due to favorable water supply conditions and prior to enactment of the Central Valley Project Improvement Act (CVPIA) in 1992, the District was successful in transferring significant quantities of water into the District. Since enactment of the CVPIA, and due to poor water supply conditions, water transfer opportunities have been limited.

---

therefore generally do not agree with acreage records maintained by Districts. The difference between net and gross acreage is the land area occupied by roads, farmsteads, canals, ditches, etc.

[12] Based on discussions with District staff, average annual diversions from local surface water sources were estimated to be 200 acre-feet annually, during March and April. For purposes of this Feasibility Investigation, this supply source is considered to be insignificant.

In addition to the surface supply source described above, OAWD filed an Application to Appropriate Water with the State Water Resources Control Board on May 15, 2002 (Application #31324). The State Board issued a Notice of Application on May 12, 2003, drawing protests from several interested parties; resolution of those protests is currently pending. If permitted as applied for, OAWD would be allowed to divert water from the Sacramento River at a rate of up to 400 cfs between the dates of October 1 and May 31, not to exceed 30,000 acre-feet for direct diversion for irrigation and frost control purposes, and not to exceed 80,000 acre-feet for diversion for underground storage. The total volume of direct diversion plus diversion to storage would not exceed 80,000 acre-feet during the permitted diversion period. At this time, it is uncertain whether a water right permit will be granted by the State Board or whether the application will be modified in response to protests or State Board concerns.

Groundwater Sources

While surface water is used in OAWD exclusively for agricultural purposes, groundwater serves both agricultural and rural domestic purposes. Groundwater production wells are owned and operated by individual landowners; OAWD does not own or operate any groundwater production wells. Customers having private wells use them to supplement their CVP water supply, particularly during drought conditions when deliveries are curtailed. It is not known how many privately owned and operated groundwater wells exist in OAWD, nor is amount of groundwater pumping known since wells are typically not metered. A description of the regional hydrogeology of the area is provided in Technical Memorandum No. 3 [*to be provided*].

Water Source Preferences

Because groundwater is generally available throughout the District, and because District surface water supplies are not sufficient to meet the total demands of each farm, most growers rely on a combination of surface water and groundwater to meet irrigation demands. The notable exception is certain locales on the west side of the District, where groundwater is not readily available in adequate quantities. In those areas, growers are strongly dependent on District surface water supplies. The District estimates that about 5,000 acre-feet of surface water is needed annually to serve lands that have limited groundwater.

The primary factors that growers consider in selecting water source are discussed below.

- Cost – Cost is widely regarded as the strongest single factor affecting water source decisions. In comparing costs between District surface water and private groundwater, most growers neglect capital recovery associated with private wells costs. Thus, private groundwater production tends to be favored whenever the variable costs of groundwater pumping (energy and pump O&M) are lower that the costs of purchasing surface water from the District. As noted above, however, there are areas on the District's west side where groundwater production is not feasible; in these areas, surface water is the only viable option.
  Moss/Algae – Due to a number of factors, District surface water at times contains high concentrations of moss and algae. Primary contributors are low velocities, long resident times and warm water temperatures in the TCC, which create conditions favorable for algae growth. Moss and algae do not significantly affect surface irrigation systems, but do pose serious problems to operation and maintenance of filtration systems used with drip and micro-spray systems. Thus, drip irrigators tend to favor groundwater as the preferred water source.
- Temperature – The temperature of District surface water varies seasonally, being cold in the winter and spring and warmer in the summer. In contrast, groundwater temperature is relatively stable year-round. Thus, compared to surface water, groundwater is very warm in the winter and warmer in the summer, depending on the depth from which groundwater is pumped. During the frost control season, growers definitely prefer to use groundwater, because it is more effective in preventing frost

damage to the crop. To the extent that groundwater is warmer in the summer, it is preferred by rice growers.

- Pathogens/Disease – Some crops are sensitive to water-born pathogens that may at times be present in surface water sources. Farmers concerned about such pathogens prefer to use groundwater.

Historical Water Demands and Supplies (1970 – 2000)

A water balance analysis was prepared for OAWD for the period 1970 through 2000 as a means of understanding historical water demands and supplies, irrigation efficiency, and the relationship between District operations and regional hydrology (see Technical Memorandum #3 for more information). The primary purpose in developing the historical water balances is to provide a factual basis for forecasting future cropping patterns and water demands under the Baseline Condition and project alternatives.

Cropping Patterns (Historical)

Prior to the start of surface water deliveries in 1976, roughly 10,000 acres within OAWD were identified as being irrigated with groundwater; the remaining District acreage was dry-farmed or idle. Since 1976, the irrigated area has expanded to between 22,000 and 23,000 acres (**Figure 2-4**). The dominant crop type initially was pasture and forage with relatively minor acreages of field crops and permanent trees and vines. It appears that there was no rice irrigated with groundwater prior to CVP deliveries. The area planted to field crops increased sharply in 1976 with the introduction of supplemental CVP water. This increase in field crop acreage, together with increases in rice and permanent crop acreage, resulted in a gradual increase in total irrigated area between 1976 and 1983, corresponding more or less to the period of construction of the distribution system. Since 1983, the areas planted to permanent crops and rice have continued to expand, while pasture and forage acreage have gradually declined. The maximum area irrigated was about 24,000 acres in 1997.

Water Demands and Supplies (Historical)

Irrigation demands in Orland-Artois are comprised of two components: (crop) ET of Applied Water and Farm Losses. Conveyance Losses from the pipe District distribution system are considered insignificant[13]. Irrigation demands have ranged from roughly 33 taf in 1975 before the introduction of surface water, to a high of 92 taf in 1988. The median demand is roughly 64 taf and occurred in 1991 **(Figure 2-5a; Table 2-2).** After the introduction of surface water, demand has consistently been comprised of 70% ET of Applied Water and 30% Farm Losses, reflecting a District-wide average on-farm efficiency of 70% since 1977.

Water supply sources include District Surface Water, including water received under the District's CVP water contract and occasional, one-year water purchases from other CVP contractors, and Private Pumping[14] (**Figure 2-5b**). The total utilized[15] supplies have met the demands described above, ranging from 33 taf to 92 taf with a median of 64 taf over the period of record. The supply source varies significantly from year to year depending on the availability of surface water under the District's CVP contract and through CVP water purchases. In 1992, during the drought, the water supply was comprised

[13] To maintain the water balance, change in storage across years is also accounted for. This results in a typically small, artificial component of demand in years when storage increases from year to year. This is called Storage Demand.

[14] To maintain the water balance, change in storage across years is also accounted for. This results in a typically small, artificial component of supply in years when storage decreases from year to year. This is called Storage Supply.

[15] The utilized supply is the quantity actually diverted from available sources to meet water demands; thus, the total utilized supply is equal to total demand. Additional water supplies may have been available, but were not used.

of only 23% District Surface Water and 77% Private Pumping while in 1988 the corresponding fractions were 93% District Surface Water and only 7% Private Pumping. On average, the water supply is comprised of 66% District Surface Water and 34% Private Pumping, reflecting a District-wide average efficiency of 66% over the 1970 to 2000 period.

Since the start of surface water deliveries in 1977, the District has transferred in an addition 6,400 af annually. However, over the period 1990 to 2000, transfers have amounted to less than 2,000 of annually, due to the effects of drought and CVPIA.

Table 2-2. Subunit 2 (OAWD) –Minimum, Maximum, and Average Values of Water Demand and Supply Components (1970-2000)

	Demand				Supply				
	ET of Applied Water	Farm Losses	Conveyance Losses	Storage Demand	District Surface Water	District Pumping	Private Pumping	Private Diversion	Storage Supply
Minimum	27,010	5,151	-	-	-	-	4,152	-	-
Maximum	54,030	42,687	-	3,016	84,127	-	54,361	-	2,828
Average	38,576	22,985	-	361	36,566	-	24,678	-	678

Regional Perspective

Prior to the import of surface water in 1976, activities on OAWD lands resulted in a positive net extraction of groundwater in all but one year (1973), meaning that groundwater pumping exceeded deep percolation from the combination of applied water and precipitation (**Figure 2-6**). Net extraction averaged about 15 taf during the 1970 to 1976 period. With the gradually increasing import of surface water between 1976 and 1983, the area transitioned from an area of net extraction to an area of net recharge. Even during years when CVP supplies were constrained and private pumping reached new highs (e.g., 1992 and 1994), net extraction was essentially zero, meaning that groundwater pumping was offset by an equal volume of groundwater recharge.

Baseline Condition (2025)

As previously described, the Partners agreed to use a modest forecast of Baseline Conditions featuring non-speculative assumptions and actions that clearly could be accomplished by each Partner. The assumptions used to shape the Baseline Condition for OAWD are discussed below, followed by discussion of the implication of the assumed conditions to future OAWD water demands and supplies.

Baseline Assumptions

The assumptions common to all Partners' baseline condition were discussed earlier. Following are the assumptions that are unique to OAWD's Baseline Condition.

1. **CVP Water Supplies:** OAWD's contract with the United States will be renewed at its current maximum amount of 53,000 afa. Pursuant to the Central Valley Project Improvement Act, tiered pricing provisions will be included that have the effect of making the top two 10-percent tiers unaffordable, thereby reducing the maximum useable quantity to 42,400 afa. Additionally, water availability will be constrained by federal water allocation policy and CVP water supply conditions. The assumed availability of water under OAWD's contract, by hydrologic year type, is tabulated below, reflecting the factors noted above as they would apply over long-term hydrologic cycles.
2. **CVP Water Cost:** Despite recent increases in CVP contract rates, it is assumed that the 80 percent of the contract supply not subject to tiered pricing will remain affordable to growers, including the District's operating charges. Thus, it is assumed that all water available under the District's CVP contract below the tiered pricing threshold would be purchased and used by OAWD growers.

Hydrologic Year Type	Assumed Contract Yield	
	(% of 53,000 af Contract max.)	TAF
W	80	42.4
AN	80	42.4
BN	50	26.5
D	25	13.3
CD	10	5.3

3. **Water Transfers:** Opportunities to supplement surface water supplies through short-term purchases will not exist, nor will OAWD sell water out of the District to generate revenues.
4. **Pending Water Rights Application:** It is highly speculative whether OAWD will be granted a permit to divert winter water from the Sacramento River and, if a permit is granted, whether the necessary arrangements can be made with the Bureau of Reclamation under a Warren Act contract for conveyance of the water from the Red Bluff Diversion Dam to the District. Thus, it is assumed that no water will be available to the District under the pending application.
5. **Participation in the Sacramento Valley Water Management Agreement (Phase 8):** Reflecting current OAWD Board policy, it is assumed that the District will not participate in this Agreement.

Cropping Patterns (Baseline)

By 2025, it is anticipated that the total (*net*) irrigated area within OAWD will be 25,312 acres (**Figure 2-7**). The major cropping difference compared to existing conditions would be a significant expansion of permanent crop acreage, reflecting continuation of the expansion in almond plantings observed in recent years. The expansion in permanent cropped area would be accompanied by minor expansions of rice and pasture/forage acreage and a modest reduction in field crop acreage. The non-cropped land area within the District would decrease to accommodate the overall growth in irrigated land area.

Water Demands & Supplies (Baseline)

Under the 2025 cropping pattern discussed above, and based on simulations using 1922 to 1994 hydrologic conditions (precipitation and runoff/water supply), the average on-farm ET of applied water (ETaw) demand would be 63 taf annually, ranging between 52 and 71 taf annually (**Figure 2-8**), depending on hydrologic conditions. The total applied water demand, based on 70% on-farm efficiency, would range between 75 and 101 taf annually, averaging 90 taf annually over the long term (**Figure 2-8**). Because water losses from the District distribution system are negligible, the total District water demand is the same as the applied water demand at the farm level, including on-farm losses.

Subject to the previously discussed assumptions, it is estimated that OAWD's CVP contract would yield an average of 27 taf annually, satisfying less than one-third of the long-term average applied water demand. The supply would range between 5 taf and 42 taf annually, depending on hydrologic conditions (**Figure 2-9**). Water demands in excess of available CVP supplies would be met entirely by groundwater supplies pumped by OAWD landowners. Average pumping would be 63 taf annually, ranging between 35 taf and 95 taf annually, as needed to fill shortages in surface water supplies (**Figure 2-10**). All pumping would be by private landowners, primarily from the Tehama Formation.

Discussion

Relative to existing conditions, the main consequence under the assumed Baseline Condition would be a significant increase in groundwater pumping needed to offset the anticipated reduction in CVP supplies and expansion of applied water demands. From a regional hydrology perspective, OAWD would change

from being a net groundwater recharge area under existing conditions to being a net groundwater discharge area under the Baseline Condition.

(Note: need a graph or table to illustrate this change.)

GLENN-COLUSA IRRIGATION DISTRICT (SUBUNIT 3)

Background

GCID is located in the central portion of the Sacramento Valley on the west side of the Sacramento River, as illustrated on **Map 1** (Glenn County portion only). The District's service area extends from northeastern Glenn County near Hamilton City to south of Williams in Colusa County. The east side of the District stretches toward the Coastal Range and Tehama-Colusa (TC) Canal. GCID's main facilities include a 3,000 cfs pumping plant and fish screen structure located on the Sacramento River at the northern end of the District, just north of Hamilton City, a 65-mile Main Canal, and approximately 900 miles of laterals and drains.

With 175,000 acres, GCID is the largest irrigation district in the Sacramento Valley. The soils within this area generally consist of clay-like and loam characteristics. The low infiltration rates of the tight soils within much of the District are conducive to furrow and border irrigation. To that end, rice is the predominant cultivated crop. Other crops include, but are not limited to, tomatoes, vine crops, sunflowers, prunes, almonds, and walnuts.

GCID uses an arranged schedule to deliver irrigation water to District customers. The main canal is situated along the west side of the District and supplies various laterals that supply individual farms and refuges. GCID does not supply municipal or industrial water.

In 1990 the District's Sacramento River diversion was identified as a significant impediment to the downstream migration of juvenile salmon. Following the state and federal listing of the winter-run Chinook salmon as endangered through the Endangered Species Act, pumping restrictions were imposed on GCID by a court-ordered injunction, preventing the District from diverting its full water entitlement. A long-term solution was developed to provide both safe fish passage past the GCID diversion facilities and to ensure a reliable water supply to GCID by allowing the District to divert their maximum capacity of 3,000 cfs. Key components of the solution included enlargement and improvement of the fish screen structure and the construction of a gradient facility in the main stem of the Sacramento River to stabilize the river channel. These facilities were complete in 2002.

In response to the reduced diversions described above, and three years in the last decade classified as "critically dry years," resulting in contract supplies being reduced to 75% of entitlement, the District developed a number of programs to supplement these reduced supplies, including an aggressive drainwater recapture program, an emergency water conservation program, a voluntary groundwater conjunctive water management program, and an in-basin water transfer program.

Water Resources Setting

Lands within GCID rely primarily on surface water and only a small fraction of landowners also pump groundwater. These sources are discussed further below.

Surface Water Sources

The Sacramento River serves as the principal water source for GCID. Its diversion is the largest surface water diversion on the river. The District holds both pre- and post-1914 appropriative water rights to divert water from the natural flow of the Sacramento. GCID also has adjudicated pre-1914 water rights under the Angle Decree, issued in 1930 by the Federal District Court, Northern District of California, to

divert water from the natural flow of Stony Creek. In addition, as the successor in interest to Central Canal and Irrigation Company, GCID has, under a May 9, 1906 Act of Congress the right to divert up to 900 cfs from the Sacramento River (Pub. L. No. 151, Ch. 2439).

GCID entered into a negotiated agreement with the USBR in 1964, quantifying the amount of water GCID could divert from the Sacramento River (Contract No. 14-06-200-0855A (Contract No. 0855A)). The resulting negotiated agreement recognized GCID's annual entitlement of a Base Supply of 720,000 ac-ft/yr of flows from the Sacramento River and also provided for a 105,000 ac-ft/yr allocation of Project Water, resulting in a total contract entitlement of 825,000 ac-ft/yr. The 825,000 ac-ft/yr entitlement recognized under contract for GCID is inclusive of their entitlement recognized under their Angle Decree rights, which, on average, yield about 15,000 to 18,000 ac-ft/yr. This negotiated agreement will remain in effect until March 31, 2004. Under the terms of a separate wheeling agreement with USBR, GCID can request to receive a portion of its entitlement water through the Tehama-Colusa Canal via two points on interconnections with the Tehama-Colusa Canal. The use of the Tehama-Colusa Canal for delivery of entitlement water is subject to available capacity as determined by USBR.

Contract No. 0855A does not limit GCID from diverting water for beneficial use during the months of November through March, to the extent authorized under California law. GCID has recently obtained a water right permit for non-contract period diversions in the amount of 182,900 ac-ft (up to 1,200 cfs). Although some pre-irrigation occurs within the District, non-contract period diversions are predominantly used for rice straw decomposition and waterfowl habitat. GCID also holds water rights to divert from a number of small tributaries to the Sacramento River, including Hunters Creek (2 cfs), an unnamed stream tributary to Funks Creek (2 cfs), Stone Corral Creek (11 cfs), and Colusa Basin Drain (134 cfs).

Reuse and Recirculation

As mentioned above, an aggressive drainwater recapture program, which includes both groundwater seepage and tailwater runoff from cultivated fields from within GCID's service area, is a part of GCID's overall water management program. GCID recaptures this water with both gravity and pump systems. Recaptured water is delivered to either laterals or the main canal for reuse by both in-District and out-of-District users. It is estimated that GCID currently recycles approximately 155,000 ac-ft annually.

Much of GCID's drainwater is captured for use by downstream districts such as the Provident Irrigation District (PID), Princeton-Codora-Glenn Irrigation District (PCGID), and Maxwell Irrigation District (MID). GCID is one of the irrigation districts that signed the Five Party agreement of June 2, 1956. This agreement represents a cooperative effort by GCID, PID, PCGID, MID, and two entities that have since dissolved (Compton-Delevan Irrigation District and Jaciento Irrigation District) to share operation and maintenance of the drains within their respective service areas and to share the right to recirculate the water in those drains. In addition, Colusa Basin Drain Mutual Water Company members (57,000 acres, gross) rely on tailwater from GCID and other upstream water users.

Groundwater

Approximately 200 privately owned wells are located within the District's boundaries. GCID operates one well with an approximate capacity of 10 cfs. Groundwater has been placed to greater use since Endangered Species Act (ESA) restrictions on GCID in the early 1990's. While historical records of groundwater pumping are not available district-wide, the California Department of Water Resources estimated that in 1993 approximately 4,200 acres were irrigated with 17,000 acre-feet of groundwater. This is believed to be representative of total independent private pumping throughout GCID in any given year aside from district-sponsored programs such as the voluntary groundwater conjunctive water management program discussed below. A description of the regional hydrogeology of the area is provided in Technical Memorandum #3 *(to be provided).*

In recent years, the District has supplemented its surface water supplies with groundwater from local production wells. It has accomplished this with a voluntary conjunctive water management program. This District-managed program involved more than 100 private landowners that were reimbursed by the District per acre-foot contributed to GCID's supply. The program has contributed up to an estimated 72,000 ac-ft in a single year (1992) in response to reductions in surface water supply.

Water Source Preferences

The circumstances associated with the Districts' Sacramento River entitlement, particularly the seniority and size of the water right, make it the preferred and primary source. Rather than developing and depending upon alternative supplemental sources, the District has emphasized the development of programs designed to make the best use of this source, programs such as those described previously.

Drainwater recovery and reuse is an important source of water to farmers within and outside GCID. Although not a new source of water, reuse of drainwater allows water users to manage the timing and quantity of water delivered, providing flexibility and maximizing water use efficiency in the area. The District has, and continues to, augment its drainage system to enable recovery of tailwater for reuse. In terms of relative costs, it tends to be the cheapest alternative to the Sacramento River entitlement. Continued expansion of drainwater recovery capabilities within the District may occur at the expense of impacting downstream users and must be carefully considered to avoid conflict. There is also a potential for salinity buildup on fields due to drainwater reuse, and the potential impacts on crop yields must be assessed.

The production of groundwater for local use by privately owned wells, either independent or in coordination with District operations, is the next most cost-effective option. Independently produced groundwater tends to be very small, less than 3% of total supply, and the pattern of this use has not changed significantly in recent years. The reasons for a farmer's preference to augment their surface water supply with groundwater vary. The most common reason is to accommodate crops susceptible to temperature and water quality changes. Supplies originating from the Sacramento River would tend to exhibit wider ranges seasonally as compared to groundwater. Groundwater produced as part of the District-managed conjunctive water management program has been a cost-effective tool in terms of offsetting reduced surface water supplies, as discussed previously. In more recent years the District-managed program has been used to help meet water needs outside of the District. The compensation for this water made to the District and its growers has enhanced the affordability and reliability of the District's supplies.

Water conservation measures such as canal lining, conveyance system automation, district-level water measurement, farm-level metering, precision farming techniques, and other irrigation technology improvements have been used effectively within GCID in last decade to improve water use efficiency and reduce diversions in times of shortage. Within the last decade, District diversions have been reduced as much as 25 percent (increased drainwater recovery and reuse also contributed to this savings). However, water conservation measures are typically the most expensive options and can be in conflict with the regional water management characteristics of the area. The hydrologic characteristics of the region GCID lies within, the Colusa Basin, can be described as a "flow-through" system, in that the vast majority of the water not consumptively used returns to drains and is rediverted by others, percolates into the ground and potentially pumped by others, or returns to the river and is reused downstream. Therefore, the actions of an upstream district such as GCID can have a considerable effect on downstream areas. Currently, GCID is participating, along with other Sacramento River Settlement Contractors and the U.S. Bureau of Reclamation, in a study to assess the potential for improved water measurement. The primary objective of this study is to identify the potential benefits of improved district-level and sub-basin-level water measurement and the potential issues and impacts that might arise.

Historical Water Demands and Supplies (1970 – 2000)

A water balance analysis was prepared for GCID for the period 1970 through 2000 as a means of understanding historical water demands and supplies, irrigation efficiency, and the relationship between District operations and regional hydrology (*Technical Memorandum #3 discusses the water balance in detail and will be provided later*). The primary purpose in developing the historical water balances is to provide a factual basis for forecasting future cropping patterns and water demands under the Baseline Condition and project alternatives. The water balance was developed for the Glenn County-portion of GCID only because of its close linkage to the proposed SCF Conjunctive Water Management Program area.

Cropping Pattern (Historical)

The total land area within GCID-Glenn County (Subunit 3) is 72,643 acres, with the cropped area ranging between roughly 32,000 acres and 60,000 acres over the 1970 to 2000 period (**Figure 2-11**). Rice is the predominant crop, accounting for approximately 85 percent of the District's irrigated acreage. Other important crops include tomatoes, orchards, vineseeds, cotton, alfalfa, and irrigated pasture.

Although the irrigated area varies considerably from year to year, there appears to have been an overall expansion in irrigated area over the period, with the irrigated area holding more or less constant at about 55,000 acres over recent years. The expansion in irrigated acreage is explained almost entirely by an increase in the dominance of rice, which increased in acreage from about 24,000 acres initially to 48,000 acres throughout most on the 1990s. Over the same period, the combined area of non-rice crops has remained essentially constant at 10,000 to 12,000 acres, while other non-cropped land uses declined in area by about 20,000 acres.

Water Demands and Supplies (Historical)

The GCID annual diversions are bimodal, a reflection of the cultural practices of growing rice. Near the beginning of the irrigation season when farmers are flooding their rice fields, beginning in the spring months, the District typically relies upon their entire allotted monthly contractual amounts. This need for water typically peaks during the hot, dry summer month of July, during which time maximum monthly diversions usually occur. This pattern is followed by a gradual decrease in diversions until later in the year when a much smaller peak occurs in the fall. This last peak is again a result of farmers flooding their rice fields, this time post-harvest for straw decomposition.

Historically, GCID has used all of its Base Supply and diverted a majority of their Project Supply. In 1981 and 1984, GCID purchased additional CVP water above the 105,000 ac-ft amount provided for in the contract. During the critical months, GCID diverted CVP water every year from 1964 to 1997, as shown on **Figure 2-12**.

The water demands were met primarily through District surface water with small supplemental amounts of private pumping (**Figure 2-13**). The water supplies are consistently composed of 97% District surface water and 3% private pumping throughout the period of record. Historical surface water supplies estimate for the Glenn County portion of GCID ranged from 292 taf to 507 taf per year, averaging 416 taf per year. Estimated private pumping ranged from 0 to 31 taf per year, with an average of 10 taf per year.

Regional Perspective

The water balance analysis indicates GCID is an area of recharge over the period of record from 1970 to 2000, meaning deep percolation from the combination of applied water and precipitation exceeded groundwater pumping. Net extractions ranged from roughly -111 taf to -277 taf per year and averaged roughly -188 taf or -2.6 AF/acre per year. Variability in net extractions can be mainly attributed to variability in annual rainfall (**Figure 2-14**). It is not surprising to see such large net recharge given the

large proportion of surface water supply available to the District. Even during critically dry years when the District surface water supply is reduced 25%, such a 1992, net recharge remains significant.

Baseline Condition (2025)

The assumptions used to shape the Baseline Condition for GCID are discussed below, followed by discussion of the implication of the assumed conditions to future GCID water demands and supplies.

Baseline Assumptions

1. Ongoing contract renewal efforts associated with GCID's Sacramento River supplies will likely result in similar contract entitlements. The renewed contract is also expected to include better provisions with regards to water transfers allowing for more flexibility. For the purposes of the feasibility investigation it is assumed that the renewed contract in its current form will be renegotiated and in place. For the purposes of defining GCID's baseline conditions, it is assumed GCID renews its settlement contract for 720,000 acre-feet of Base Supply and 105,000 acre-feet of Project Water Supply, totaling 825,000 acre-feet annually.

2. It is also assumed that GCID will continue to recover drainwater from district drains to generate supplies for local water supply reliability, especially in 75% supply years. Drainwater recapture is assumed to occur at levels similar to recent historical conditions. For the purposes of this investigation, the range of drainwater recapture is assumed to be between 25,000 acre-feet and 200,000 acre-feet per year.

3. Groundwater production for local use is expected to occur similar to recent historical conditions, and is assumed to meet all remaining unmet demands.

4. Outside of a potential SCF partnership, GCID will take measures to ensure local water supply reliability and to generate financial revenues to ensure affordability of surface water supplies to District water users, and to finance system modernization. The underlying strategy is to protect the District's water rights by maintaining a substantial base of surface water users. Groundwater substitution programs to support potential water transfers outside of the district are expected to continue and possibly expand in the future. This is the subject of further discussion under the Solo Alternatives section below.

5. GCID has one district-specific action that is included in the Baseline Condition. As part of the Sacramento Valley Water Management Agreement (i.e. Phase 8 settlement agreement) GCID has agreed to implement a groundwater substitution program. Environmental documentation and related efforts are underway to implement this and other related programs for other parties to the SWVMA. For this reason, the Baseline Condition for the SCF Feasibility Investigation assumes GCID's SVWMP project will be in place.

   As part of the SVWMP, GCID plans to transfer up to 30,000 acre-feet of water in below normal, dry, and critically dry years. The transfer water would be made available through the substitution of surface water, under the District's pre-1914 water right, for groundwater pumped within the District. It is assumed the transfer water would be regulated in and released from the Bureau of Reclamation's Shasta Lake, and would flow through the Sacramento River and then to the Delta. Transfer water reaching the Delta would be available for salinity and water quality control within the Delta, or for export to users within the SWP or CVP service areas.

   GCID will implement similar management and operational schemes used successfully in recent years to support similar groundwater substitution programs. For example, in June and July 2001, private well pumpers participated in producing 33,000 ac-ft of supply as part of the 2001 Water Forbearance Program executed between GCID, Bureau of Reclamation, and Westland's Water District. Facility

operations are assumed to include full utilization of the network of existing private landowner wells that have contracted with the District in past conjunctive use programs. The project components are summarized in **Table 2-3**.

Table 2-3: GCID Groundwater Substitution Program Components for 30,000 ac-ft SVWMP (Phase 8)

COMPONENT	DESCRIPTION/ASSUMPTION
Yield (ac-ft/yr)	30,000
Frequency	Below Normal, Dry and Critically Dry Year types (a)
Pumping Zone	Tehama Formation
Potential Recipients	Water users participating in DWR's Dry Year Water Purchase Program Environmental needs. CVP water users.
Surface Water Source	GCID's pre-1914 appropriative water rights on the Sacramento River.
Delivery Pattern	Irrigation pattern, June through October.
Pumping Location	Pumping will occur within the 175,000 acreage of GCID with approximately 80% in Glenn County and 20% in Colusa County. The precise location of wells would depend upon landowner participation. GCID estimates 100 to 115 wells would participate, approximately 85% diesel and 15% electric.
(a) Water year classification based on the Sacramento Valley Index.	

Cropping Pattern (Baseline)

By 2025, it is anticipated that the total (*net*) irrigated area within GCID (Subunit 3) will be 57,593 acres (**Figure 2-15**). Review of trends in recent historical crop acreage distributions in GCID suggest rice will continue to be the predominant crop in the future with small shifts towards higher value, more permanent crops and small reductions in lower valued crops, such as field and pasture crops. The non-cropped land area would remain virtually unchanged relative to recent observed conditions, suggesting negligible overall change in the total irrigated area within GCID (Subunit 3).

Water Demands & Supplies (Baseline)

For the feasibility investigation it is assumed that GCID's settlement contract will be renewed according to the conditions discussed above. For this reason it is not expected that the availability of GCID's Sacramento River water supply will change significantly.

Projected water demands for GCID are anticipated to remain relatively the same as current conditions (Sacramento River Basinwide Water Management Plan, Sep. 2002). The average historical demand for GCID-Glenn County based on the water balance analysis was estimated at 427 taf annually. The average of the estimated projected baseline demand is 450 taf over the same period of record. This is an estimated increase of approximately 5% on average. The difference is primarily attributable to a small assumed increase in rice and permanent crop acreage represented under the baseline condition as compared to recent historical conditions.

Discussion

Relative to existing conditions, the main change under the assumed Baseline Condition would be an increase in groundwater pumping in conjunction with the Phase 8 30 TAF per annum groundwater substitution program. From a regional hydrology perspective, under the Baseline Condition GCID's contribution as a net groundwater recharge area would be diminished as a result of this activity.

(Note: need a graph or table to illustrate this change.)

GROUNDWATER ONLY AREAS (SUBUNITS 4-7)

Background

[to be completed after review of this initial draft document]

Cropping Pattern (Historical)

The Ground Water only areas, Subunits 4-7 encompass 74,965 acres. The irrigated area has remained more or less constant from 1970 to 2000 ranging from 40,000 acres during the drought years of 1976 and 1977 to 55,000 acres with and average of 49,000 acres (**Figure 2-16**). A major trend displays steady increases in permanent crops offset by decreases in pasture and idle lands throughout the areas. Permanent crops have increased from 6,000 acres in 1970 to 20,000 acres in 2000. Pasture has decrease from 22,500 acres in 1970 to 13,000 acres in 2000. Other non-cropped land uses including idle lands have declined by roughly 5,000 acres. Field crop acreage has varied considerable from year to year ranging from 15,000 to 28,000 acres and averaging 20,000 acres; however there appears to be no increasing or decreasing trends. Rice acreages have remained relatively constant averaging roughly 900 acres.

Water Demands and Supplies (Historical)

The Ground Water only areas water demand components are (crop) ET of applied water and farm losses (**Figure 2-17a**). They have ranged from a low of 105 taf in 1998 to a high of 182 taf in 1994, the median year occurring in 1999 at 152 taf. The variation is directly related to variation in spring rain, 1998 had large quantities of spring rain while 1994 had relatively low quantities of spring rain. ET of Applied Water on average comprises approximately 70% of the water demand, while Farm Losses are 30% of the water demand. The only source of water supply is Private Pumping (**Figure 2-17b**).

Regional Perspective

The Groundwater only areas are net extractors averaging 49 taf or 0.62 AF per acre per year for the 1970 to 2000 period (**Figure 2-18**). Over this period there were four years (1973, 1983, 1995, and 1998) when these areas had net annual recharge to the Groundwater System cause by record high annual rainfalls leading to high levels of Deep Percolation of Precipitation.

Baseline Water Supplies and Demands (2025)

[to be completed after review of this initial draft document]

[see Figure 2-19 and 2-20]

SECTION 3. DESCRIPTION OF PROJECT ALTERNATIVES

INTRODUCTION

At the outset of this Feasibility Investigation, the expectation was that the project alternatives would involve some degree of actual sharing of physical resources between or among the Partners to implement the groundwater recharge and recovery cycles of a conjunctive water management program. However, as the hydrogeology of the Project Area became better defined, primarily by virtue of the efforts of the DWR Northern District, it became evident that the opportunities for conjunctive water management were more likely to involve independent actions pursued by each Partner and not actual, physical sharing of resources. The factors contributing to this outcome were discussed previously; briefly restated, the two primary contributing factors are:

The fact that groundwater system is essentially full, meaning that additional groundwater recharge is not needed or effective for implementing conjunctive water management *at this time.* The new source of water represented by the Lower Tuscan aquifer, which is believed to be substantial in quantity and developable at low cost, supplants the value of cooperative action, at least in the context of achieving local water supply reliability objectives.

In view of these conditions, primary emphasis was placed on developing a Solo Alternative comprised of the physical actions that the individual Partners were most likely to take to meet their respective objectives, but planned and conducted in a coordinated manner, with certain administrative and institutional functions served by the Partnership. Collaborative alternatives based on actual physical sharing of resources were also investigated. Both the Solo Alternative and the collaborative alternatives are described in the section.

SOLO ALTERNATIVE

As mentioned above, the Solo Alternative is comprised of the physical actions that each Partner would most likely take to pursue its individual objectives, combined with certain common administrative and institutional functions served by the Partnership. The physical actions that would be undertaken by each Partner represent the conjunctive water management program that best achieves that Partner's respective individual objectives with its available resources. Although the Partners would operate independently, the individual conjunctive water management programs comprising the Solo Alternative were formulated in a coordinated, integrated manner, particularly concerning potential effects on the groundwater system.

The administrative and institutional functions that would be performed by the Partnership include *monitoring* of groundwater conditions to ensure compliance with County BMO's and possibly other standards, *marketing* of water generated by the individual Partners and *environmental compliance*.

The individual conjunctive water management programs and the Partnership's administrative functions comprising the Solo Alternative are described below.

Orland Unit Water Users Association

Background

The goals of the OUWUA are to protect the Association's water rights by maintaining a substantial base of surface water users and to manage the water resource for local and state benefit. Maintaining a substantial base of surface water users could be achieved by transitioning from the Association's existing rotation delivery service to a more flexible, responsive water delivery service. Such an improvement in water delivery would allow the Association to better provide for the irrigation needs of its members,

particularly to those with relatively smaller parcels of land. A portion of the capital required for such an investment could be generated by contributing to the state's water shortages via voluntary transfers of water.

The SCF pursued two types of solo alternatives for the OUWUA. In addition to analyzing groundwater substitution transfers, as was done for the other two partners, the SCF investigation also analyzed the potential for the OUWUA to generate new yield via reservoir re-operation. Each of these two types of alternatives is discussed below in more detail.

Solo Alternative 1: Groundwater Substitution Transfers

The analysis of groundwater substitution transfers in OUWUA focused on two topics.

- Considerations for the production of the groundwater given the legal status of the Association as a California corporation.
- Conveyance of the forgone surface water down Stony Creek

Each of these two topics is discussed below in turn.

Production of Groundwater

Given the legal status of the OUWUA as a California corporation the ability of the Association to own wells and pump groundwater for distribution throughout its system should undergo a legal review. If the Association can legally own and operate wells for use in a groundwater substitution transfer then the Association needs to determine if it would choose to develop its own wells and/or whether it would rely on members to produce the groundwater.

If the Association is legally precluded from operating wells it owns for a groundwater substitution transfer then production of the groundwater falls to its members. In which case the volume of water available for transfer could depend on the existing capacity of pumping in the basin, and/or the incentives that could be offered members to construct new wells.

The water balance analysis described in the 'Baseline' section of this report estimates that the historical maximum amount of groundwater pumping in OUWUA is 13,000 acre-feet. Assuming this represents the existing groundwater pumping capacity, OUWUA could participate in annual groundwater substitution transfers of up to 13,000 acre feet annually. The capacity of a proposed program could be limited by two factors, namely:

- Not all growers who own the wells would choose to participate in the proposed program.
- Some of the existing pumps, used to produce the water, may not be allowed in the program if there are restrictions placed on the use of diesel pumps due to air quality constraints.

For purposes of evaluating this alternative it is assumed that 10,000 af could be transferred in any one year. The volume of a potential transfer will be more clearer understood during the development of the Groundwater Production Element Study.

The revenue generated by the proposed transfer would be used to compensate the members participating in the program that normally use surface water, for pumping groundwater. The remainder of the revenue, net of costs is, available for distribution to the Association and the members. The distribution of the net revenue would be based on a negotiation between participating members and the Association. **Table 3-1** shows per af net revenue available from a transfer. The transfer prices shown in **Table 3-1** reflect those used in the Sacramento Valley Water Management Plan, Short-Term Agreement. Pumping costs are an estimate, and could vary.

Table 3-1
Per Acre Foot Revenue and Costs of Groundwater Substitution by Year Type

Transfer Component	Year Type			
	Wet to Above Normal	Below Normal	Dry	Critical
Price	$50	$75	$100	$125
Pumping Cost	$20	$20	$20	$20
Net Revenue	$30	$55	$80	$105

Figure 3-1 shows the exceedance probability of the present value of the net revenue of a groundwater substitution transfer over 25 years. The figure shows the value of transferring 10,000 af in dry years and critical years and the value of transferring 10,000 af in below normal, dry and critical years. The dry year and critical year transfer has a 50 percent exceedance value of approximately $5.5 million. The average annual transfer volume over the 25 year project is 4,000 af. The transfer that occurs in above normal, dry and critical years has a 50 percent exceedance value of just over $9.0 million over 25 years. The average annual transfer volume when water is transferred in below normal, dry and critical years is 5,900 af.

Figure 3-2 shows the *annual* net revenue for the same information presented in **Figure 3-1**. The annual net revenue generated by a transfer is $550 thousand, $800 thousand and $1,050 thousand in below normal, dry and critical years, respectively. The frequency of the transfers is based on the Sacramento Valley River Year-type Index for the period from 1922 to 1994.

Facts to help generalize the information presented in **Figure 3-1** and **Figure 3-2**:

- The net revenue may not be available only to the Association. In the past some local districts that have participated in groundwater substitution transfers have paid members who pump between approximately 60 percent and 90 percent of the transfer price.
- The information presented in **Figure 3-1** and **Figure 3-2** is scalable, e.g. to estimate a transfer of 20,000 af in each specified year type multiple the estimates of net revenue and net present value times 2. To estimate the value to distributing the net revenue between the pumping-members and the Association multiple the estimates of net revenue by an appropriate factor.

Figure 3-3 provides a conceptual view of how to estimate the change in storage in the aquifer as a result of a groundwater substitution transfer of 10,000 af in dry and critical years. The natural recharge rate for the aquifer is not known with certainty. **Figure 3-3** shows three different estimates of the change in storage volume under three different estimates of natural recharge rates; 10,000 af per year, 7,500 af per year and 5,000 af per year. If the natural recharge rate were 5,000 af an the estimated change is storage over the hydrologic trace ranges from negative 70,000 acre feet to positive 15,000 acre feet. Likewise, the change in storage when recharge rates are estimated to be 7,500 af per year and 10,000 af per year show similar reductions in storage and relatively higher increases. In all likelihood the increases in storage volume represented by the conceptual drawing would not be as high as they are shown because at some storage level the basin rejects recharge because it is full when the transfers began. **Figure 3-3** is intended to provide an intuitive understanding of how modest groundwater substitution transfers that occur in only the two most dry year types can have minimal impact on the storage of the basin.

Conveyance of Transfer Water

The last issue to be discussed under this alternative is the potential challenge faced by conveying transferred water down Stony Creek. Recent work by the DWR suggests that Stony Creek is a loosing stream for most of the area between OUWUA Eastern boundary and the Sacramento River. The rate of loss may be a factor in a transfer if the potential buyer of the water believes that the loss rate is too high. One possible solution to this challenge would be to adjust the price (or quantity) of the transfer to reflect the loss. Another possible solution to the challenge that is more advantageous, is to time the transfer to occur when there is already water in Stony Creek. Thus, avoiding or reducing the loss. There may be a

limit to how much timing can be used to avoid the challenge based on the potential buyers needs. The solution would have to be found once more particulars of a potential transfer were know.

Solo Alternative 2: Reservoir Re-operation

The combined storage of East Park and Stony Gorge reservoirs is approximately 100,000 af. To the extent that the reservoirs could be re-operated to put new water in the system OUWUA may have the opportunity to transfer that water. In order to prove-up the availability of new water under a re-operation alternative OUWUA would have to show that it can lower the end of year storage of the reservoirs below the historical levels. Using this method to 'prove-up' the existence of new yield would prove to the potential buyer and participating agencies that the re-operation is 'pushing' water out of the reservoir, essentially spilling water, that would not have otherwise been there but for the transfer.

The steps to proving-up this sort of transfer start by analyzing the historical end of season storage to see if the current operations of the reservoir creates a predictable end of season storage that is nearly always the same. **Figure 3-4** shows the end of month storage for the sum of East Park and Stony Gorge Reservoirs over the hydrologic trace from 1956 through 2003. What can be seen by examining **Figure 3-4** is that there is a wide variance in end of season storage. This variance may prove an obstacle to prove-up that a change in the end of season storage, that would result from a transfer, would not have occurred anyway. It may still be possible to affect a re-operation transfer however much more work would have to go into understanding how the end of season storage for the reservoirs is planned. Since the Stony Creek Fan was an investigation of conjunctive use and how best to utilize the groundwater aquifer, further work on re-operation alternative was determine to be outside the current scope of work. However, OUWUA may benefit from continued investigation of a re-operation.

Solo Alternative 3: Reservoir Reoperation Combined with Conservation

As part of a CALFED study OUWUA examined the possibility of providing new water by investing in system modernization. One of the alternatives of the report entitled, *OUWUA Distribution System Modernization and Water Conservation Project* proposed an investment of $53,499,000 in 'Canal Rehabilitation' thereby conserving 25,400 af annually. One of the stated purposes in the study was examine the ability of OUWUA to transfer this conserved water.

California Water Code §1011 authorizes the transfer of water made available because of "water conservation efforts". However, the State Water Resources Control Board (SWRCB) has clarified the State's position in its 1999 Order WR 99-012 on the petition by Natomas Mutual Water Company to transfer conserved water. The Order states:

> *The SWRCB concludes that, pursuant to Water Code section 1725, Natomas may transfer the right to use the amount of water that Natomas would have consumptively used but for Natomas's conservation efforts. A reduction in diversions that does not reduce consumptive use cannot be transferred pursuant to section 1725.*

For this reason the SCF Investigation feasibility study team recommends that OUWUA does not pursue a transfer of conserved water.

At the same time as the aforementioned report was being completed there was an additionally, CALFED investigated underway that investigated the possibility of increasing yield to the Tehama Colusa Canal via water use efficiency. The document entitled *OUWUA and TCCA Regional Water Use Efficiency Project* describes the findings. The document suggests that re-operating the existing reservoirs on Stony Creek in conjunction with a well field new yield may be available to the region. The document was intended to examine the physical nature of a program and not the legal aspects of water rights.

The SCF study team followed the direction of the CALFED study by examining the potential for OUWUA to create new yield by combining conservation efforts with re-operation. So that rather than

transferring conserved water the OUWUA would be offering to change the pattern of water deliveries to a potential buyer through re-operation. This alternative would face the same challenges in a potential transfer as the challenges faced in Solo Alternative 2, none the less the study team attempted to estimate the volume of water that could be made available by combining conservation with re-operation.

A CALSIM model of the Stony Creek system was obtained from the Bureau and estimates where made of changes to end of year storage from a 25,400 af reduction in irrigation demand. **Table 3-2** shows the results of this modeling effort. The estimated change in end of September storage for the three reservoirs is 15,600 af. The range of changes is from a maximum of 47,200 af to a negative 14,300. The extent to which that OUWUA can transfer any or all of this water is met with the same challenges as described in Solo Alternative 2. It may still be possible to affect a transfer under Solo Alternative 3 however much more work would have to go into understanding how the end of season storage for the reservoirs is planned and how the revenue necessary to generate the conservation could be raised.

Table 3-2
Change in End of September Storage Statistics

	East Park	Stony Gorge	Black Butte	Total
Average	4.9	4.1	6.7	15.6
Maximum	17.6	11.1	18.5	47.2
Minimum	-5.5	-3.0	-5.9	-14.3

In summary, it appears that the OUWUA has multiple alternatives available to them both for re-operation and groundwater substitution transfers. The conclusion of this analysis is that the alternative that presents the fewest challenges for 'proving-up' a transfer, and the least cost is the groundwater substitution transfer.

General Issues for OUWUA Alternatives

As a nonprofit corporation OUWUA is limited in the amount of revenue that can be generated from other than their specified non-profit purpose. For example, if a nonprofit corporation engages in profit-making activities unrelated to its recognized nonprofit purpose, it must set up a separate corporation to engage in that activity or risk losing its nonprofit, or tax exempt, status, or pay tax on the revenue. The OUWUA is limited to only earn 15% of total revenue from activities such as water transfers without facing taxation. The OUWUA may want to consider what legal structure serve, it best under future operations.

Orland-Artois Water District

Under Baseline Conditions, it was shown that OAWD's 2025-level water demands would increase relative to existing demands, while the availability of surface water supplies under its CVP contract and through short-term water would decrease. The effect would be that OAWD landowners would need to pump substantially more groundwater from the Tehama Formation than has ever been pumped historically, which may not be sustainable. These conditions compel the District to take positive measures to fulfill its fundamental mission of providing reliable, affordable water supplies to its landowners. These measures, discussed below, comprise the District's Solo Alternative.

- District Development of Lower Tuscan Groundwater – District-sponsored development of groundwater drawn from the Lower Tuscan Formation. The Lower Tuscan is generally regarded as being separate from the overlying Tehama and Stony Creek formations, thus representing a new, essentially undeveloped water supply source. The District's plan would be to develop sufficient

capacity from the Lower Tuscan so that, combined with available surface water supplies, the resulting magnitude of private pumping from the Tehama Formation would be sustainable.

- Pricing Incentives – Provision of pricing incentives that encourage growers to use District CVP surface water supplies and District-produced groundwater in favor of privately produced groundwater. This means that the blended cost of District water supplies (CVP surface water and District-produced groundwater) must be maintained below the cost of private groundwater production. With this incentive, landowners would use District water supplies to exhaustion before relying on their own wells, thereby limiting extractions from the Tehama to sustainable levels.
- Strategic Marketing of CVP Supplies – Marketing of modest portions of the District's CVP contract supply, when market conditions are favorable, to generate revenues as needed to implement the pricing incentives described above.

District Development of Lower Tuscan Groundwater

As described under the Baseline Condition, the expected long-term yield of the District's CVP supply is about 27 taf annually. In addition, based on historical observations and experience, the District believes that the safe yield from the Tehama formation, the source of most private pumping, is about 30 taf annually. Thus, currently available supplies total to just 57 taf annually on average, or about 33 taf short of OAWD's projected long-term average water demand of 90 taf. To fill this shortage, the District has embarked on a program to develop additional groundwater supplies from the Lower Tuscan Formation.

The District completed a 1,520-foot test hole into the Lower Tuscan in late 2003. The e-log results were promising, so the District is proceeding with construction of a 1,320-foot production well, which reportedly will be the deepest groundwater well yet to be constructed in the Sacramento Valley. Interpretation of the e-log by DWR Northern District staff indicates that the well should produce at the rate of approximately 3,000 gpm (6.7 cfs). The well will be located strategically to tie into the existing Lateral 35.2 at a point where relatively large downstream demands will allow maximum production opportunity each year. Additionally, the selected site has electrical power available nearby, so the pump can be electrically driven. (Cost estimates reveal that at current rates diesel is marginally less expensive than electricity for powering groundwater wells, neglecting powerline extension costs. However, concerns about emerging air quality regulations that could apply to diesel engines lead to an overall preference for electrical energy.) Operations studies conducted by the District indicate that the well should be able to produce up to 3,300 af annually, depending on the magnitude and distribution of demand.

The cost of the Lower Tuscan well is estimated to be $230,000 *(need to confirm this with OAWD staff)*, complete with pump, motor, controls, inter-tie to the existing distribution system, and SCADA improvements to enable automatic operation and remote monitoring and control override. The annual cost of the well is estimated to be $48,000, including $13,600 in capital recovery, $3,300 in annual O&M and $31,100 in annual energy charges. Thus, the cost of water produced by the well will be about $15/af, which is lower than the cost of the District's CVP supply and privately-produced groundwater. The District is planning to monitor groundwater conditions as the first well is operated, and to construct additional wells to the extent that the Lower Tuscan system can accommodate additional development. Ultimately, the District would install about 10 wells to achieve the targeted 33 taf of annual production capacity. Studies conducted by the District indicate that the unit water cost should not change appreciably as additional wells are constructed and production capacity is scaled up.

The quality of the Lower Tuscan water is reportedly very good. Coming from deep aquifers, it is anticipated to have a year-round temperature of 70 to 74 degrees F. This relatively high temperature will provide benefits to rice farmers and growers who apply water for frost control purposes.

Pricing Incentives

To achieve sustainable conjunctive water management, OAWD needs to ensure that use of available District surface water and groundwater supplies is maximized, so that GW extractions from the Tehama Formation by landowners are minimized. (This strategy also benefits other pumpers drawing from the Tehama Formation, which includes nearly all neighboring independent pumpers.) However, this priority of use will not occur naturally, because District supplies are generally more costly than privately-produced groundwater. To achieve the desired use priority, the District intends to use pricing incentives. Neglecting intangible factors that influence landowners' water source preference, the blended per acre-foot cost of surface water and groundwater delivered by the District must be less than the per acre-foot cost of privately produced groundwater. Under projected average water supplies and present pricing conditions, the total subsidy would be $282,000 on average, or $4.70 per acre-foot for the 30,000 acre-feet pumped by landowners on long-term average (Table ___) *(table not yet developed)*. This amount would vary between $66,000 and $402,000 annually, depending on the amount of CVP water available each year. Because CVP is the most expensive of the three available sources, the maximum subsidy would be needed in full CVP water supply years and the minimum in years of zero CVP supply.

The effect of the subsidy would be to maintain the effective price of District water equal to the price of groundwater, or about $16 per af under existing conditions. In practice, the subsidy would require occasional "tuning" to achieve the intended result, because of changes in relative water costs and to account for intangible factors that are also reflected in landowners water source preferences. In particular, the subsidy would have to be increased if CVP water costs increase as expected.

The revenues needed to implement the price subsidies would be derived from the sale of modest proportions of available District CVP water supplies, as described in the following section.

Strategic Marketing of CVP Supplies

As a water-short district, the District Board is philosophically opposed to transfers of water out of the basin before in-basin needs are first satisfied. However, the Board has taken the position that marketing a portion of its CVP supply is justified if it enables a net expansion or ensures affordability of its total water supply. In this context, the District plans to market CVP water in selected years, when water prices are high and significant revenue can be generated from the sale of modest volumes of water. The anticipated sales of CVP water would be conducted pursuant to the water transfer provisions of the CVPIA. Key provisions of the CVPIA as they relate to the planned transfer/sale of CVP contract supplies by OAWD are listed below.

1. Transfers are effectively limited to other CVP contractors, because water transferred to non-CVP contractors must be repaid at the greater of the full cost or cost of service rates.
2. The water available for transfer is limited to the water that would have been consumptively used or irretrievably lost to beneficial use during the year or years of the transfer (*unless* the transfer is to another CVP contractor located within the county or area of origin, in which case the full unused volume may be transferred).

Considering these factors, and given the objective to seek out high prices, logical transfer partners north of the Delta would be the federal wildlife refuges and south would be water-short CVP contractors, such as Westlands, San Benito County and Santa Clara County Water Districts.

A number of water marketing strategies were tested using a monthly operations model developed specifically for OAWD. The model operates with the long-term demands presented earlier, and allows the user to input certain parameters, priorities and constraints. The following parameters were input for a series of runs aimed at testing various market strategies:

1. The District's CVP contract would yield the annual percentages discussed previously under the Baseline Condition.
2. The District must reserve a minimum of 5,300 af annually of its CVP supply to meet water demands an lands that do not have access to groundwater, located primarily on the west side of the District.
3. The District's groundwater pumping capacity from the Lower Tuscan Formation is 33 taf annually.

The water marketing strategies tested are distinguished primarily by the different percentages of CVP contract supply that would be marketed in different year types, ranging from marketing modest amounts of water in dry years only to marketing appreciable amounts of water in D, BN and AN years. This progression generally maintains the highest possible price per acre-foot of water sold as the marketed volume increases (**Table 3-3**). Despite the fact that the highest price occurs in CD years, OAWD does not contemplate marketing water in those years, to ensure that the small amount of CVP water available under contract to the District is available to landowners in areas without groundwater.

Table 3-3. OAWD Water Marketing Scenarios

Scenario	Volume Marketed (AF)			Remaining CVP Water Available (AF)	Revenue Generated ($)	
	Min	Max	Average		Average Total	Average $/AF)
Base Case (No Marketing)	0	0	0	26,863	$0	$0
1: (25%D)	0	3,313	726	26,137	$72,603	$100
2:(50%D)	0	6,625	1,452	25,411	$145,205	$100
3: (20%D; 20%BN)	0	5,300	1,597	25,266	$134,315	$84
4: (50%D; 50%BN)	0	13,250	3,993	22,870	$335,788	$84
5: (50%D; 50%BN; 50%AN)	0	21,200	6,897	19,966	$480,993	$70

Scenario 1 looks at marketing 25% of available CVP supplies in D years only. The volume marketed in any particular year would range between 0 and 3,313 af, averaging 726 afy and preserving 26,137 afy of CVP supply for in-District uses. All water would be sold at the assumed D year price of $100 per af, generating revenues of about $73,000.

Scenario 2 is identical to Scenario 1, except that the D year percentage is increased from 25% to 50%, doubling the maximum and average marketed volumes as well as the average transfer revenue. The amount of CVP water retained for in-District uses would decrease slightly to 25,411 afy.

Scenario 3 involves marketing 20% of available CVP supplies in D and BN years. The volume marketed in any particular year would range between 0 and 5,300 afy, averaging 1,597 afy. The volume of CVP water remaining available for in-District uses would be 25,266 afy on average. The average price received for marketed water would be $84 per af.

Scenario 4 is identical to Scenario 3, except that the D and BN year percentages are increased from 20% to 50%, increasing the maximum year marketed volume to 13,250 af and the average marketed volume to

nearly 4,000 afy. The average market revenue increases to nearly $336,000, while the price per af remains at $84. The average volume of CVP supply retained for in-District uses falls to 22,870 afy.

Scenario 5 is the most aggressive strategy evaluated; it looks at marketing 50% in D, BN and AN years. The maximum marketed volume would be 21,200 afy in AN year types, and the average marketed volume would be nearly 6,900 afy. The average price received would be $70 per af, earning the District an average of just over $480,000. About 20,000 afy would be retained for in-District uses.

A summary of these results is shown in **Figure 3-5**, which shows a plot of market revenues in relation to market volume. It can be seen that the District would need to market roughly 3,200 afy on average to generate the $282,000 of revenue needed to subsidize District water supplies. The average price received at this level of market participation, subject to the strategies laid out above, would be roughly $88 per af. It should be noted that this analysis neglects water transfer transaction costs, such as would be needed for environmental documentation, monitoring and meeting other possible requirements.

Glenn-Colusa Irrigation District

Outside of a potential SCF partnership, GCID will take measures to ensure local water supply reliability and to generate financial revenues to ensure affordability of surface water supplies to District water users, and to finance system modernization. As an example of the measures being taken to support this strategy, GCID is developing a water transfer project in support of the Sacramento Valley Water Management Program (SVWMP). (This measure is include in GCID's Baseline Condition and is described above.) GCID may also pursue strategic water transfers above those dedicated to the SVWMP. These additional transfers are what define GCID's Solo Alternative. The features of GCID's Solo Alternative are summarized below, and discussed in the following sections.

Solo Alternative: Groundwater Substitution Transfers

As described under the Plan Formulation, a greater understanding of the physical behavior of the basin indicates that the basin is more resilient than originally thought and that direct recharge through artificial spreading facilities does not significantly enhance basin yield. In consideration of these findings, GCID's Solo Alternative is designed to explore the District's ability to implement transfers of Base Supply water made available through groundwater substitution.

The groundwater substitution-based strategies initially tested for the GCID Solo Alternative were distinguished by the frequency of the annual water transfer, and by the groundwater production scheme. Each of these topics is discussed below.

Source and Frequency of Transfer Water

The source of the transfer water made available under the groundwater substitution program would be GCID's pre-1914 appropriative water rights on the Sacramento River, referred to as Base Supply under GCID's Sacramento River Settlement Contract with the United States Bureau of Reclamation (Reclamation) (Contract No. 14-06-200-855A). The transfer water would be delivered on a pattern similar to that which GCID would have required for irrigation. The water will stay in the river for export to potential customers downstream. For the purposes of this analysis it is assumed that upstream reservoirs (i.e. Oroville or Shasta) will account for this transfer water and will manage these reservoirs to assure releases occur at times when exports south of the Delta could be made.

The transfer water will be made available in below normal (BN), Dry (D), and critically dry (CD) year types. For purposes of exploring the differences, economically and hydrologically, of reducing the frequency of the water transfer, a variation of the groundwater substitution program is to make transfer water available in D and CD years only.

Production of Groundwater

As described in the Existing and Baseline Condition discussions, GCID has pumped groundwater in conjunction with groundwater substitution-based programs with no long-term changes to the groundwater basin. For the purposes of developing GCID's Solo Alternative, similar management and operational schemes used successfully in recent years are also assumed for this evaluation.

Based on review of past pumping programs, GCID's Solo Alternative assumes that 90,000 af could be produced in a given water transfer year. The initial analysis assumes that the entire 90,000 af will be produced by private well pumpers. The location of groundwater wells is assumed to be the 200 approximate privately owned wells, of which roughly 80% are located in Glenn County and 20% are located in Colusa County. The degree of certainty to which these well owners would all participate is unknown. In addition, analysis of past programs indicates that average production of participating wells is approximately 500 af per year per well; 200 wells would produce, then, 100,000 af/yr which is 20,000 af/yr short of the assumed 90,000 af/yr (Solo Alternative) plus 30,000 af/yr (GCID SVWMP included in the Baseline Condition). For the feasibility investigation, it is assumed that 240 privately-owned wells would participate. The level of actual participation and potential production capacity per well will be the subject of detailed examination as part of the Groundwater Production Element investigation. During this investigation emerging air quality regulations that could apply to diesel engines used to drive agricultural wells will also be given additional consideration, given that approximately 85% of the privately owned wells within GCID are diesel driven.

Recognizing the above concerns and in light of the developments regarding the potential viability of utilizing the Lower Tuscan Formation as a "new" supply source, a variation of the GCID Solo Alternative is to utilize District-developed wells in this formation. Recent explorations of this formation by others in the region, including OAWD, indicate the cost of water produced by wells tapping this resource can be as low as $15/af (see OAWD Solo Alternative discussion). Selecting sites strategically to tie into existing conveyance facilities is critical to allow for proper distribution of water produced. Furthermore, sites located where electric power is nearby could provide advantages in terms of emerging air quality regulations mentioned previously. However, stand-by charges associated with PG&E power supplies can also be cost-prohibitive. These issues will be further addressed as part of the subsequent alternatives evaluation (to be completed following review of this document) and also as part of the Groundwater Production Element investigation.

Groundwater Substitution Transfer Scenarios

The groundwater substitution scenarios considered for GCID are summarized in **Table 3-4**, and described briefly below.

Scenario 1 considers transferring 90,000 af/yr in BN, D, and CD years. Groundwater pumped in substitution of this transfer would occur from existing private owned wells. **Scenario 2** is identical to Scenario 1, except that transfers only occur in D and CD years. **Scenario 3** is identical to Scenario 1, except that groundwater pumped in substitution of the transfer water would occur from new District-owned wells developed in the Lower Tuscan formation. **Scenario 4** is identical to Scenario 1, except that half of the groundwater pumped in substitution of the transfer water would occur from existing private owned wells and half from new District-owned wells developed in the Lower Tuscan formation.

Table 3-4:
GCID Groundwater Substitution Program Components for Solo Alternative

COMPONENT	DESCRIPTION/ASSUMPTION			
	Scenario 1	Scenario 2	Scenario 3	Scenario 4
Yield (ac-ft/yr) (a)	90,000	90,000	90,000	90,000
Frequency (b)	BN/D/CD	D/CD	BN/D/CD	BN/D/CD
Pumping Zone	Tehama	Tehama	Lower Tuscan	Tehama and Lower Tuscan
Private or District Owned Wells	Private	Private	District	Both
Well Locations	Depends upon landowner participation. Assume uniform distribution similar to the 200+ wells known to exist.		Adjacent to the Main Canal AND where the Lower Tuscan is present.	Combination of uniform distribution of known wells and District wells along Main Canal.
No. of Wells	240 (c)		40 (d)	120 Private and 20 District
Potential Recipients	• Water users participating in DWR's Dry Year Water Purchase Program • Environmental needs. • CVP water users.			
Surface Water Source	GCID's pre-1914 appropriative water rights on the Sacramento River.			
Delivery Pattern	Irrigation pattern, June through October.			

a) The yield shown for each scenario is the amount above the Phase 8 30,000 ac-ft already include in the GCID Baseline Condition. For each scenario it is assumed the Phase 8 yield is produced in the same manner (same Frequency, Pumping Zone, Wells, etc.) as the 90,000 ac-ft, unless otherwise specified.
b) Water year classification based on the Sacramento Valley Index (Year-type abbreviations: BN=Below Normal; D=Dry; CD=Critically Dry).
c) Assumes 500 AF/Y per privately owned well, based on analysis of past pumping programs which have averaged as high as 581 AF/Y per well (1994). Thus, total capacity of 240 wells equals 120,000 ac-ft.
d) Assumes 3000 AF/Y per District-owned well, based on operations studies conducted by OAWD. Thus, total capacity of 40 wells equals 120,000 ac-ft.

Groundwater modeling analysis (using the GW Model) was conducted to evaluate the effect of the additional groundwater pumping as a result of the 90,000 af/yr transfer program. Locations throughout the study area were identified for review of simulated groundwater levels under Baseline Conditions and the Solo Alternative. Review of simulated well hydrographs indicate the following:

- Under Scenario 1, groundwater levels in and adjacent to the groundwater pumping region within GCID consistently showed declines in groundwater levels relative to Baseline Conditions of between 5 and 10 feet, with a maximum difference of approximately 18 feet in the middle of the pumping area. Simulated groundwater levels showed no long-term decline in groundwater storage.
- Under Scenario 2, groundwater levels responded favorably to the pumping in only D and CD years. Simulated groundwater levels were between 3 and 5 feet less than those under Scenarios 1. Also of particular note is that in areas adjacent to the pumping region, simulated groundwater levels under Scenario 2 returned to near Baseline Condition levels following periods of wetter than normal conditions, before declining below Baseline Condition levels in subsequent D and CD year combinations. This is indicative of a basin that is being replenished by natural recharge under the circumstances.

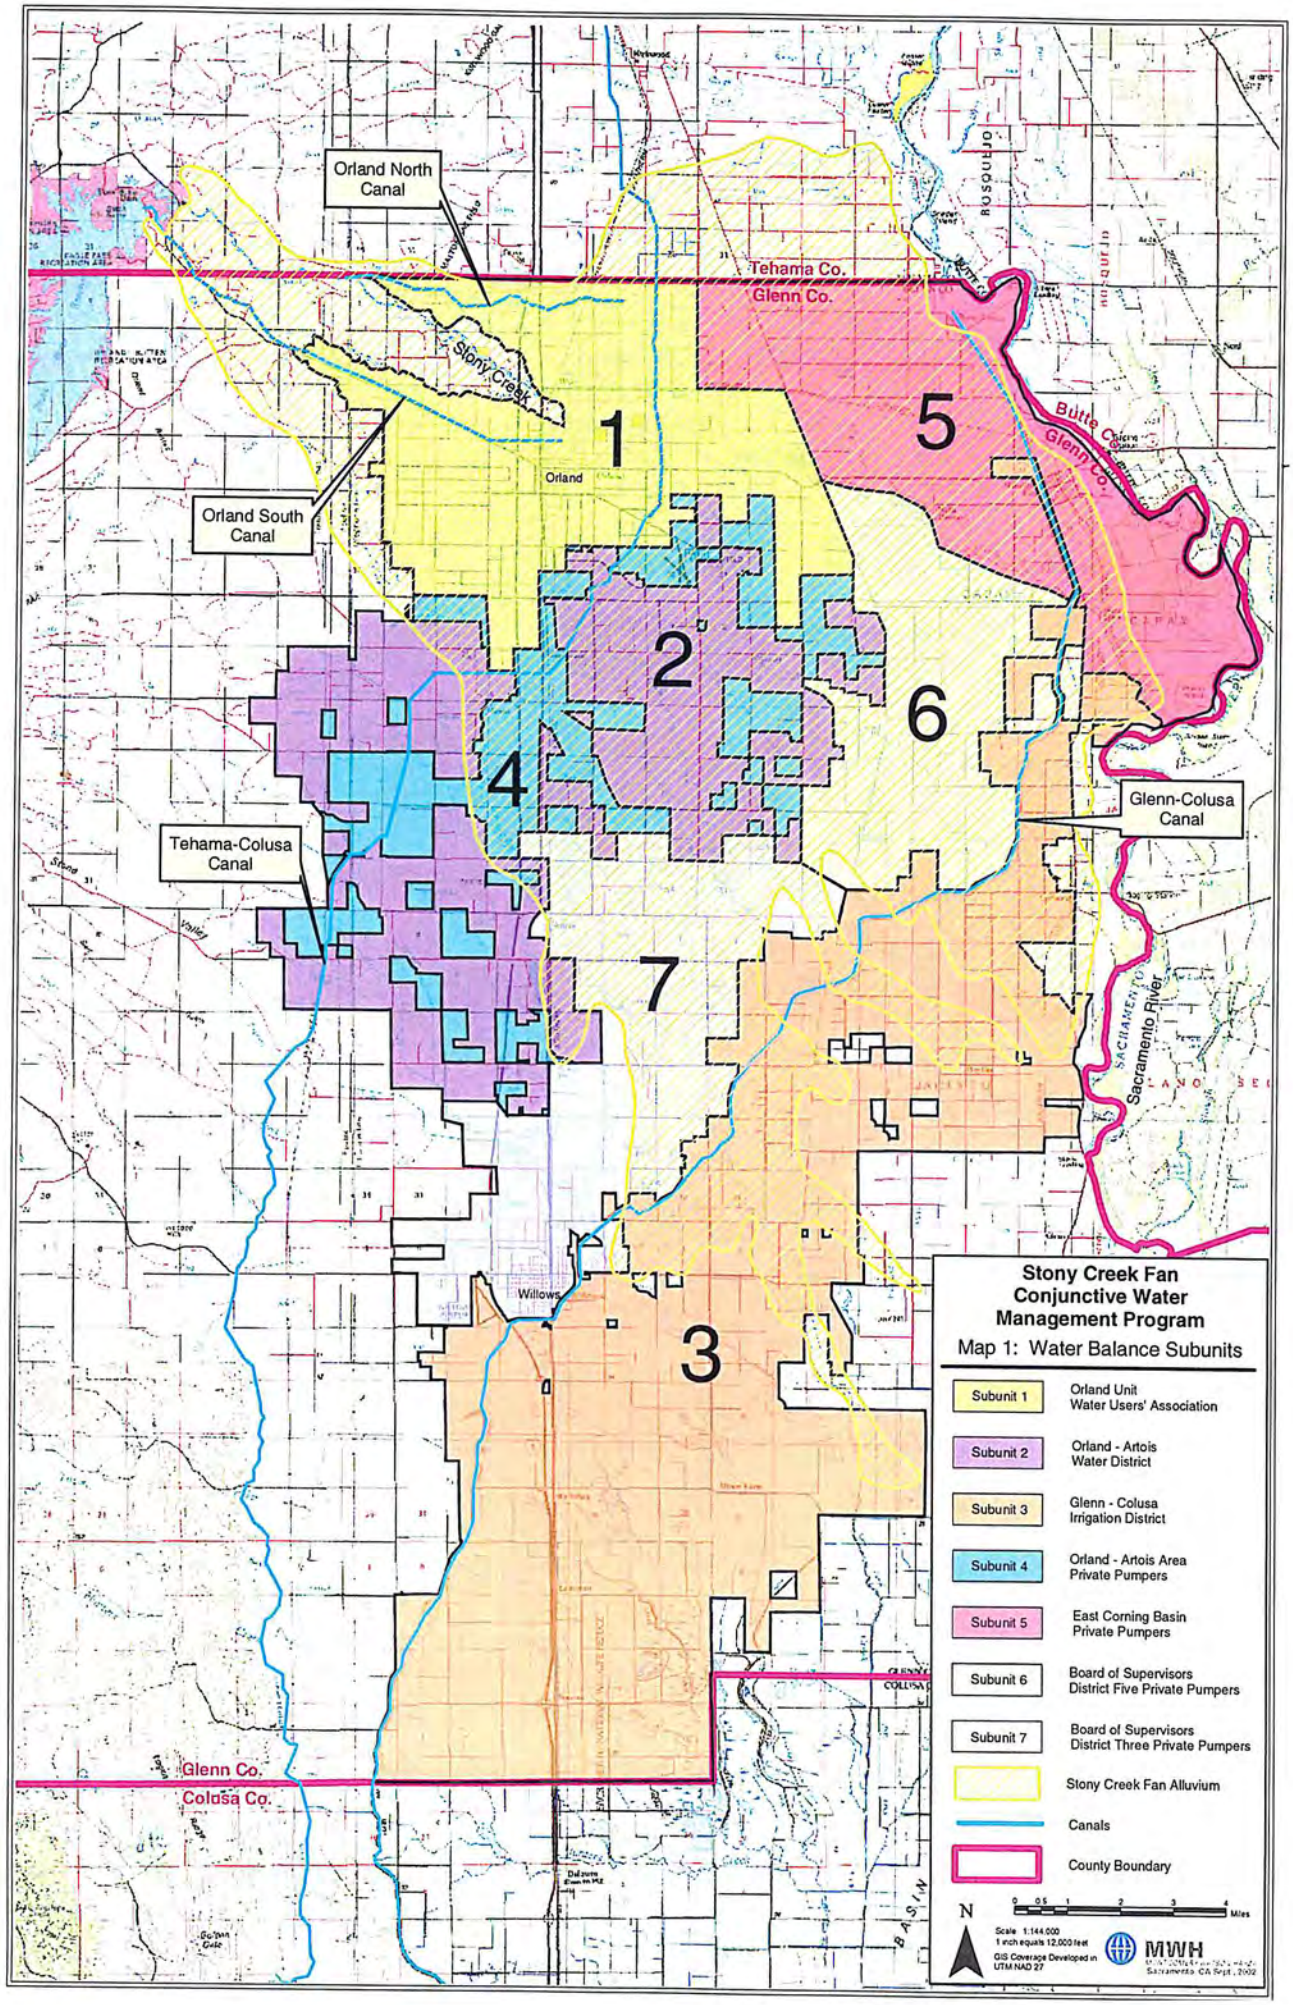
- Under Scenario 3 and 4, groundwater modeling results were somewhat inconclusive because of the poor hydrogeologic understanding of the Lower Tuscan formation, particularly the understanding of its influence on the groundwater aquifer layers, that compromised the GW Models ability to accurately simulate these conditions. It is expected, however, that groundwater levels in the Tehama formation would decline very little, if at all, because of the information suggesting that the Lower Tuscan formation which is relatively isolated from the Tehama formation due to the presence of the overlying confining layer known as the Upper Tuscan formation.

It should be noted that details of this hydrologic analysis will be presented as part of documentation summarizing the groundwater modeling efforts *(to be provided following review of this document)*. In addition, further economic and financial analysis of GCID's Solo Alternative will be completed for the purposes of completing the alternative evaluation effort for the feasibility investigation final report.

COLLABORATIVE ALTERNATIVES

[to be completed]

Overview of this section



- *Review the partner's objectives. Describe the need to examine how to use available resources more effectively.*
- *Summarize the partner resources, surface water and groundwater supplies and potential relationships.*
- *Describe how various collaborative alternatives were screened.*
- *Introduce the collaborative alternatives and describe them below.*

Alternative C1

- *Collaborative Alternatives that examine using OUWUA dry-year supplies with OAWD's conveyance system.*

Alternative C2

- *Collaborative Alternatives that examine using GCID Unused Base Supplies for In-lieu Recharge in OAWD*

SECTION 1 INTRODUCTION

The purpose of this report is to present the conceptual model developed for the Stony Creek Fan Integrated Groundwater and Surface water Model (SCFIGSM).

The purpose of developing a conceptual model is to simplify the modeling problem and organize the relevant field data and information so that the hydrogeologic system can be analyzed (Anderson and Woessner, 1992). The actual hydrogeologic system is too complicated to model; therefore, it needs to be simplified as much as possible. However, a conceptual model should retain enough complexity and level of detail in the representation of the actual field conditions so that the numerical model can reproduce the physical system responses with reasonable accuracy. It has been found that the long-term regional groundwater response projections require the following:

1. assessment of the hydrologic components of the physical system being modeled;
2. delineation of hydrogeology;
3. specification of associated land and water use processes that affect groundwater levels;
4. description of boundary conditions; and
5. definition of horizontal and vertical flow regimes within the system.

Development of a sound conceptual model is essential to understanding how the groundwater basins in a study area may respond to different water management strategies. The conceptual model serves as the basis for the development of a numerical simulation model.

PROJECT BACKGROUND

The Stony Creek Fan is a geologic feature located in Glenn and Tehama counties, near Orland. The coarse grained nature of the Stony Creek alluvial fan provides potential opportunities for direct recharge of the surface water during years of excess surface water supply. However, additional exploration and studies are needed to help determine the optimum approach to conjunctive use operations and methods of groundwater recharge (direct and in-lieu) and recovery of stored groundwater. In addition, studies are needed to assure compliance with the local groundwater management plans, ordinances, and Basin Management Objectives (BMO).

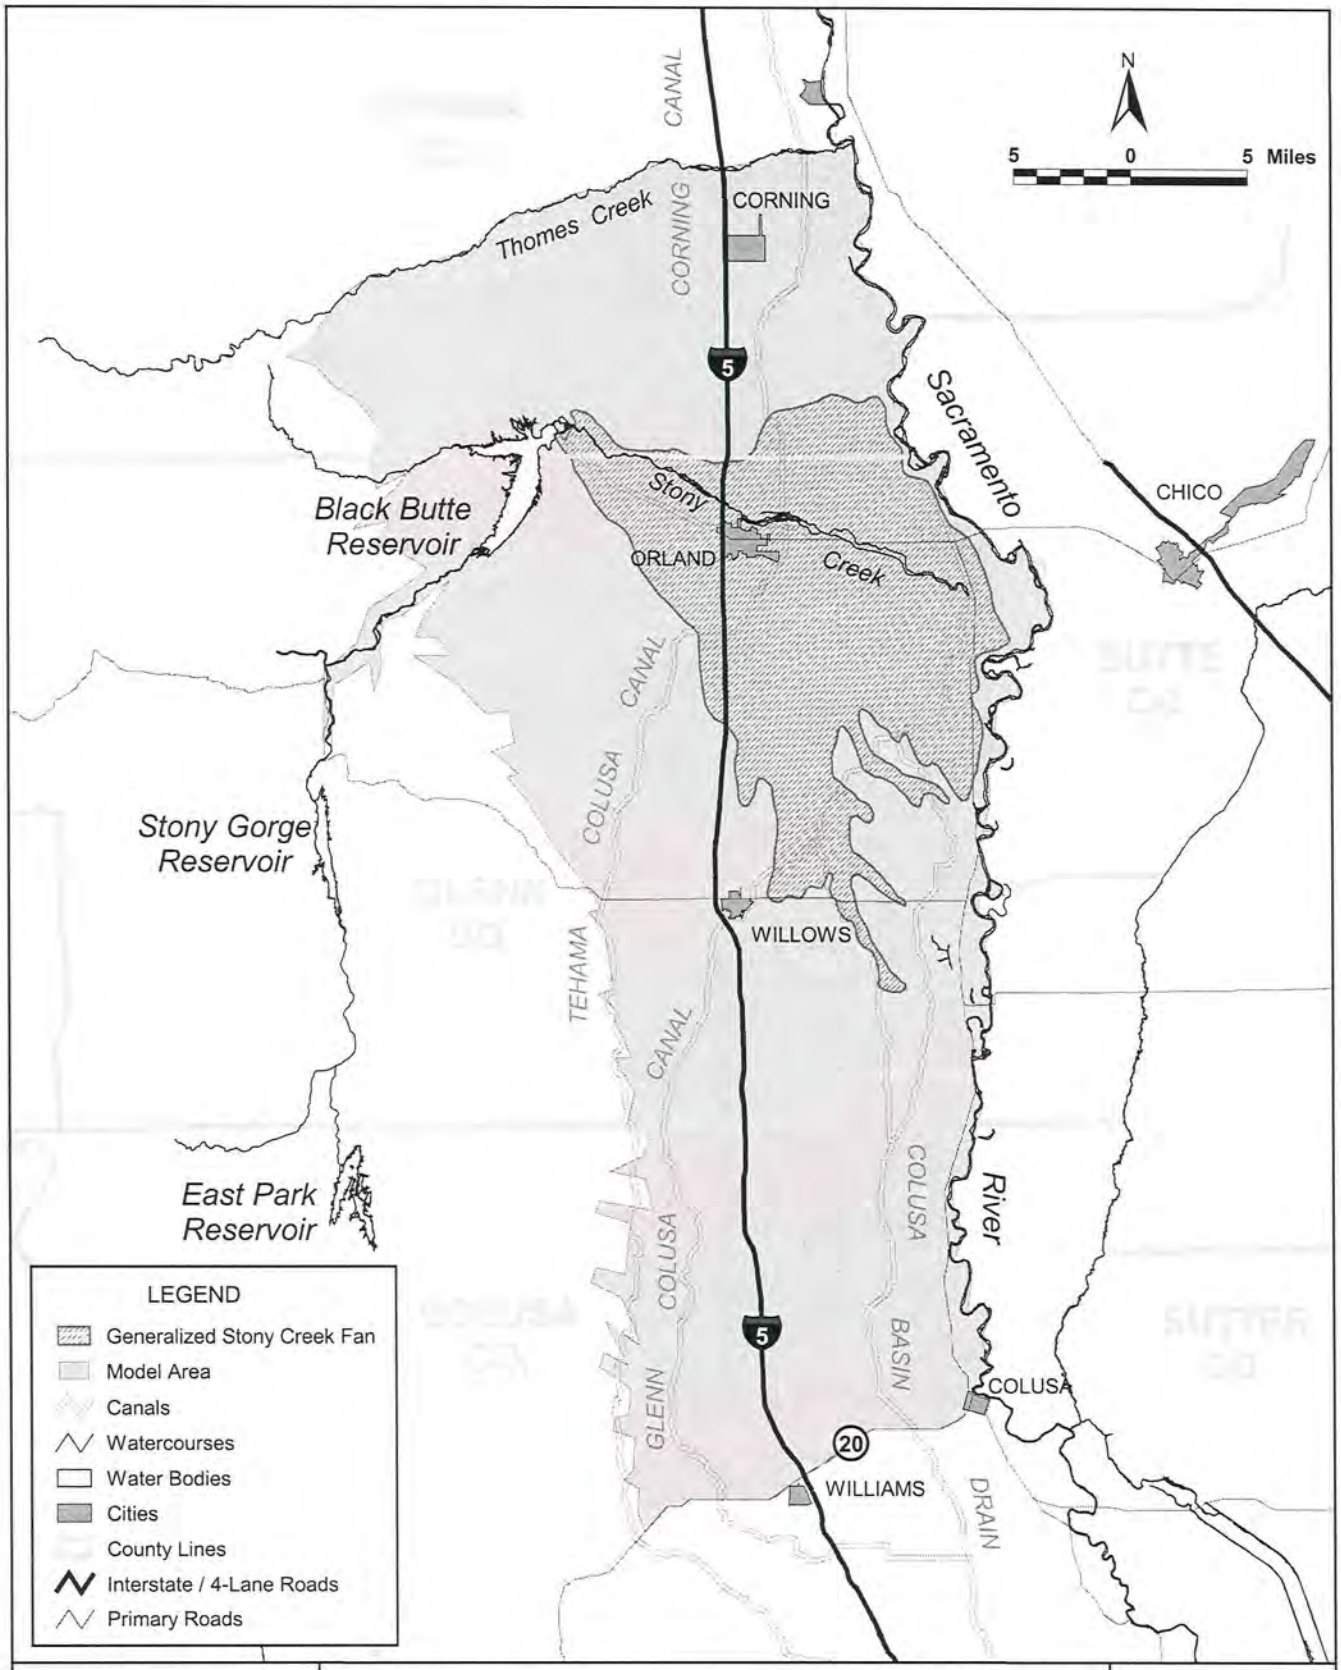
Three Sacramento Valley water purveyors, Orland-Artois Water District (OAWD), Orland Unit Water Users' Association (OUWUA), and Glenn-Colusa Irrigation District (GCID), hereinafter

referred to as "Program Sponsors", agreed through a Memorandum of Understanding (MOU) earlier this year to cooperatively pursue development of the Stony Creek Fan Conjunctive Water Management Program (Program).

The SCFIGSM is being developed in coordination with the California Department of Water Resources (DWR) and the three Project Sponsors to serve as an analytical tool that can provide quantitative information on a comparative basis to help answer different questions on the groundwater and surface water system characteristics and to evaluate alternative conjunctive water management strategies.

STUDY AREA

The general study area, shown in Figure 1.1, extends about 30 miles from west to east and about 70 miles from north to south. The study area includes three reservoirs (the East Park Reservoir, the Stony Gorge Reservoir, and the Black Butte Lake), three major streams (the Thomes Creek, the Stony Creek, and the Sacramento River), five major water distribution canals (the Tehama-Colusa Canal, the Glenn-Colusa Canal, the Colusa Basin Drain, the Orland North Canal, and the Orland South Canal), and several small creeks.



The Stony Creek Fan, shown as a hatched area in Figure 1.1, is a highly permeable near surface formation that extends southeast from the Black Butte Reservoir in the Glenn County. The study area for this project includes the Stony Creek Fan and the areas surrounding the Fan that are included in the model.

The SCFIGSM model area is smaller than the general study area because it follows the hydrogeologic boundaries and features of the underlying groundwater aquifer that is being modeled. The model area is bounded on the north by Thomes Creek and on the south by Highway 20. The model area extends east from the geologic contact with the Coast Ranges Foothills to the Sacramento River.

ORGANIZATION OF THE TECHNICAL MEMORANDUM

The SCFIGSM Conceptual Model Technical Memorandum is organized into the following sections:

- **Section 1: Introduction** describes the purpose, project background, study area and organization of this technical memorandum.
- **Section 2: Hydrogeology** describes the hydrogeology of the Stony Creek Fan Model Area.

WRIME Water Resources & Information Management Engineering, Inc.

STONY CREEK FAN CONJUNCTIVE WATER MANAGEMENT PROGRAM

Model Study Area

FIGURE 1.1

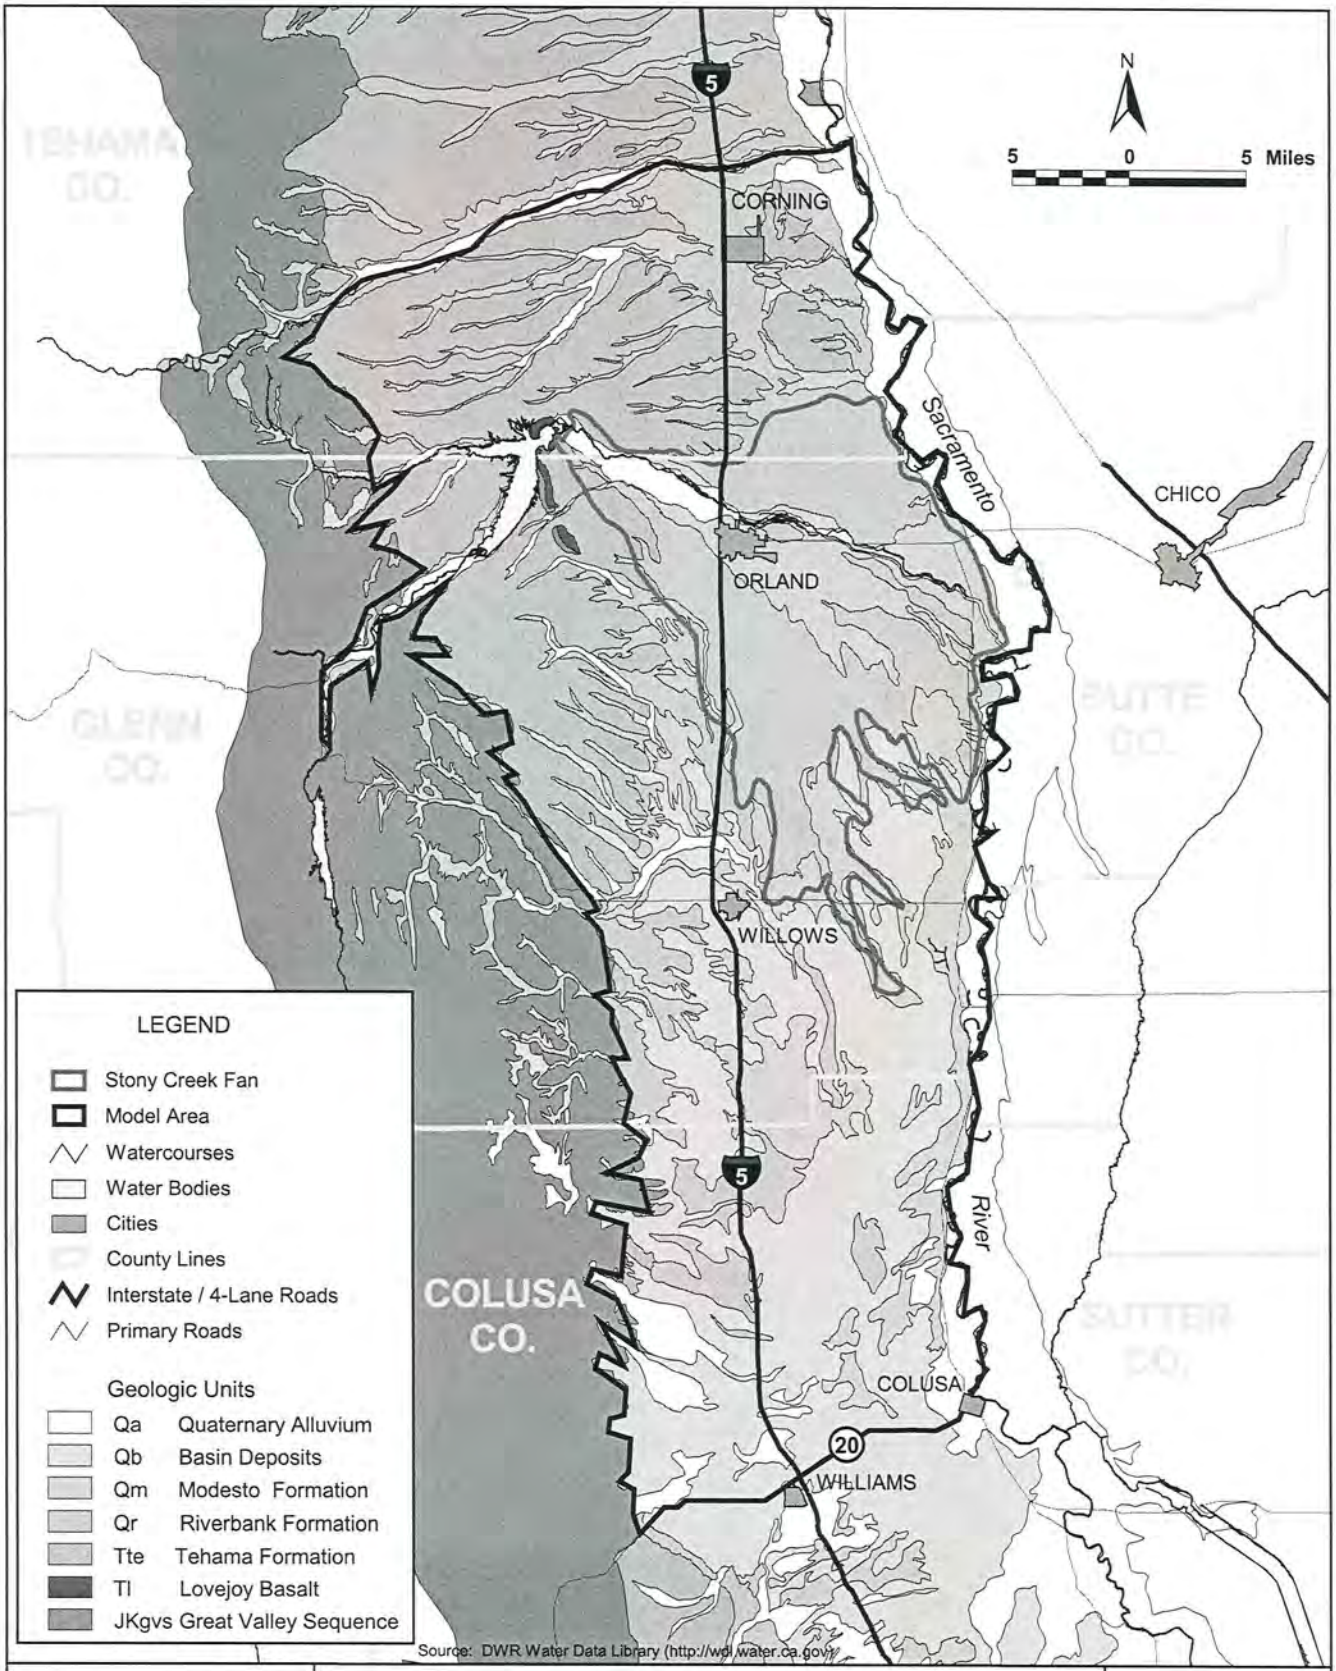
- **Section 3: Hydrology** describes the general hydrology of the study area.
- **Section 4: Modeling Goals and Objective** describes the goals and objectives of the modeling, which guides the model formulation and development
- **Section 5: Conceptual Model** describes the conceptual model for the study area.
- **Section 6: Summary** presents a summary of conceptual model development and potential model uses.

DRAFT

SECTION 2 HYDROGEOLOGY

The description of the study area geology provided in this technical memorandum builds on DWR's recent geologic mapping of the area, well log data analysis, and previous investigations by various agencies and authors.

The DWR Northern District is currently in the process of completing comprehensive geologic mapping of the Stony Creek Fan. Several geologic cross sections were developed based on analysis and interpretation of recent and E-logs, and oil and gas logs. These geologic cross-sections are not yet published but were provided as preliminary data to the project study team solely for the purpose of use in the development of conceptual model for SCFIGSM.



This geologic mapping effort of DWR has resulted in the redefinition of the hydrogeologic setting of Sacramento Valley north of the Sutter Buttes. Until recently, it was believed that the northern Sacramento Valley alluvial aquifer system consisted primarily of a thick layer of interbedded sands and clays. The recent aquifer mapping by the DWR Northern District provides more detailed information about the different aquifer layers that are present in the northern Sacramento Valley.

Monitoring and production well logs for the Counties of Glenn, Tehama, and Colusa are also available as hardcopy data at the DWR Northern District office in Red Bluff. About 400–500 driller's logs were reviewed and screened for the geographic coverage and the level of detail reported in the well log. About 154 driller's logs were further analyzed, interpreted, and used to supplement the existing geologic cross-section data to develop an understanding of the hydrogeology.

DEPOSITIONAL ENVIRONMENT

The geology of the Stony Creek Fan area consists of both marine deposits and continental deposits. The older marine deposits contain saline water and underlie the younger continental deposits. The freshwater bearing continental deposits are the geologic units of interest in the Stony Creek Fan Conjunctive Water Management Program. The geologic units present in the study area are shown in Figure 2.1 and a brief description of the characteristics of these units is provided in Table 2.1.

During the Cretaceous Period to early Miocene Epoch, the present Sacramento Valley trough was inundated by an inland sea, which deposited thousands of feet of marine sediments above the pre-Cretaceous granitic basement rocks. After withdrawal of the marine waters in the

FIGURE 2.1

Table 2.1
Description of Geologic Units in Study Area

System and Series		Geologic Unit	Lithologic Character	Maximum Thickness[1] (ft)	Water-bearing Character
QUATERNARY	Holocene	Alluvium Qa	Unconsolidated unweathered gravel, sand, silt, and clay[1].	80	Deposits are moderately to highly permeable with high permeability gravelly zones yielding large quantities to shallow wells[2]. Although deposits along Stony, Chico, and Thomes Creeks are important recharge areas[2], extensive water bearing capacity is restricted by thickness and areal extent[1].
		Basin Deposits Qb	Unconsolidated[5] fine-grained silts and clays, locally interbedded with stream and channel deposits along the Sacramento River[1].	150	Deposits are typically saturated nearly to the ground surface[2]. The low to moderate permeability results in yields of small quantity and poor groundwater quality to domestic wells[1,2].
	Pleistocene	Modesto Formation Qm	Poorly sorted[5] unconsolidated weathered and unweathered gravel, sand, silt, and clay[3].	200	Moderately to highly permeable[1].
		Riverbank Deposits Qr	Poorly sorted[5] unconsolidated to semi-consolidated[3] pebble and small cobble gravels interlensed with reddish clay, sand, and silt[1].	200	Water-bearing capability is limited by thickness. These poorly to highly permeable deposits supply moderate groundwater amounts to domestic and shallow irrigation wells. Deeper irrigation wells may be supplied if the wells contain multiple perforation zones[1].
TERTIARY AND QUATERNARY	Pliocene and Pleistocene	Tehama Formation Tte	Fluviatile moderately consolidated pale green, gray, and tan sandstone and siltstone enclosing lenses of sand and gravel; silt and gravel; and cemented conglomerate derived from the Coast Ranges[1,3].	2,000	Local high permeability zones within this characteristically low to moderate permeability unit, widespread distribution, and deep thickness cause this formation to be the principle water bearing unit in the area. Deep well yields are typically moderate, but are highly variable[2].
TERTIARY	Pliocene	Tuscan Formation Tt	This series of volcanic flows, consolidated tuff breccia, tuffaceous sandstone, and volcanic ash derived from the Cascade Range interfingers with the Tehama Formation as it westerly grades into volcanic sands, gravels, and clays[1,2]. The formation is divided by layers of thin tuff or ash units into four lithologically similar units A-D[1].	1,500	Within this formation, moderately to highly permeable volcanic sediments are hyraulically confined by layers of tuff breccias and clays[2]. Units A and B are the primary water-bearing zones and are composed of volcanic conglomerate, sandstone, and siltstone layers interbedded with lahars. Stragraphically higher, the massive lahar deposits of unit C confine groundwater in the permeable beds of units A and B[1].
		Nomlaki Tuff Member	Tuff breccias and white tuffs of dacitic composition. This member of the Tehama and Tuscan Formations serves as an important stratagraphical marker bed in northern Sacramento Valley[5].	60[5]	Poorly permeable.
	Miocene	Neroly Formation Tn	Marine to non-marine tuffaceous andesitic sandstone interbedded with tuffaceous shales and tuff layers. Contains local conglomerate lenses[4].	500	This formation of variable permeability contains interstitial fresh water under confined conditions[4], however, deposits of the Neroly Formation are typically located below the base of fresh water.
		Lovejoy Basalt Tl	Black, dense, hard microcystalline basalt[3].	65	Largely non-water bearing.
	Miocene and Oligocene	Upper Princeton Valley Fill Tupg	Non-marine sandstone containing mudstone, conglomerate, and sandstone conglomerate interbeds[3].	1,400	Largely non-water bearing or contains saline water.
	Eocene	Lower Princeton Submarine Valley Fill Tlpg	Marine conglomerate and sandstone interbedded with silty shale[3].	2,400	Largely non-water bearing or contains saline water.
CRETACEOUS		Great Valley Sequence JKgvs	Marine siltstone, shale, sandstone, and conglomerate[3].	15,000	Largely non-water bearing or contains saline water[2].
PRE-CRETACEOUS		Basement Complex pTb	Metamorphic and igneous rocks.	n/a	May contain groundwater, mainly saline, in fractures and joints.

Miocene Epoch, there was a period of erosion dominated by the deposition of continental deposits.

During the Pliocene Epoch, the northern Coast Range uplift was initiated and the Sacramento Valley began to assume its current form. Coast Range uplift and related erosion of the uplifted block resulted in deposition of the Tehama Formation onto the heavily eroded, subsiding valley floor. In late Pliocene period, volcanic activity on the southern Cascade Range caused the widespread deposition of the Nomlaki tuff across the northern Sacramento Valley. This extensive ash layer is found near basal deposits of the Tehama and Tuscan Formations. Continuous volcanism in the southern Cascade Range produced consecutive mudflows of basaltic and andesitic composition. These igneous deposits were reworked coincident with volcanic activity resulting in the Tuscan Formation on the east side of the Sacramento Valley.

The deposition of the Tehama and Tuscan Formations occurred simultaneously during the Pliocene Epoch. These thick, widespread deposits overwhelmed the previous topography, creating a relatively flat plain that was repeatedly dissected by meandering and braided streams.

Fluviatile sedimentation of the Tehama Formation was continuous on the west side of the Sacramento Valley throughout the Pliocene and possibly into the Pleistocene period. During the middle part of the Pleistocene period, mountain-building activity brought the Coast Ranges to their current structure and shape. The Tehama Formation deposits, along with older deposits, were involved in this folding and faulting event, and formed low hills and dissected uplands. Intense erosion concurrent and following this orogenic activity reworked the Tehama Formation and redeposited the sediments near the center of the Valley. Much of these sediments were carried away by the Sacramento River.

Quaternary sedimentation is represented in the deposition of broad alluvial fans and flood plains. In the vicinity of the Stony Creek Fan, the newly eroded surface of the Tehama Formation was covered with poorly sorted gravel deposits of the Pleistocene Modesto and Riverbank Formations. Gravels of these terrace deposits were partially supplied by continued erosion of the Coast Ranges. The northwest Sacramento Valley cycle of valley deposition continues to the present day.

The low hills and dissected uplands appear between the Coast Ranges and the alluvial fans of the valley. An abrupt increase in the land slope marks the transition between the alluvial fans and the uplands. These hills are topographic expressions of subsurface folding and faulting of the Tehama Formation and older underlying sediments.

As streams draining east from the Coast Ranges leave the low hills and dissected uplands, they flow out into the relatively flat valley floor. This change in slope causes them to deposit their bed load, forming broad alluvial fans. Alluvial fan deposits are an intricate system of buried channels formed by a dynamic fluviatile depositional environment. An example of an alluvial fan is the Stony Creek Fan (Figure 1.1 in Section 1), the focus of the current study. This fan is the largest and most complex alluvial fan in the northwest portion of the Sacramento Valley and was deposited by Stony Creek. The apex of the Stony Creek Fan is approximately five miles northwest of the town of Orland, where Stony Creek flows out of the low hills. The Stony Creek Fan extends east to the Sacramento River flood plain, and south to the Colusa basin deposits near the town of Willows. The surface of the fan is not smooth, but rather cut by many abandoned channels. Smaller and less impressive fans have been deposited by intermittent streams south of the Stony Creek Fan. In general, these deposits are much finer grained than the deposits of the Stony Creek Fan.

In flat, low-lying basins between the alluvial fans and the Sacramento River, distal alluvial fan sediments merge with the fine-grained basin deposits. During flooding events along the Sacramento River, water spills over the natural river levee and accumulates in these basins. The trapped water creates temporary lakes, and the quiescent environment allows for deposition of fine-grained suspended material. The Colusa Basin, which extends 60 miles south of the Stony Creek Fan, is an example of this depositional phenomenon.

The Sacramento River and Stony Creek have deposited a large quantity of coarse material in the northwest Sacramento Valley over thousands of years. These deposits form the alluvial aquifer in the study area. The Sacramento River and Stony Creek are also the primary sources of surface water to the study area.

GEOLOGIC FAULTS

The Sacramento Valley is an asymmetrical northward-trending syncline partially filled with sedimentary deposits. Several faulting, folding, and uplift events tilted the Sierra Nevada block relative to the Coast Ranges. Latter orogenic events are expressed in folding and faulting of Pre-Middle Pleistocene basal deposits. Faults related to this geologic activity include the Paskenta, Willows, Corning, and Black Butte Faults.

WATER BEARING FORMATIONS

The key characteristics of the water-bearing geologic formations of the study area are summarized in Table 2.1, presented previously. These units include the Pliocene Tuscan

Formation; Pliocene and Pleistocene Tehama Formation; Pleistocene Modesto and Riverbank Formations; and the Holocene alluvial, basin, and flood plain deposits.

Marine sediments in the study area include the Miocene Neroly Formation, the Miocene and Oligocene Upper Princeton Valley Fill, the Eocene Lower Princeton Submarine Valley Fill, and the Cretaceous Great Valley Sequence. These deposits define the subsurface freshwater aquifer boundary. In general, these largely non–water bearing deposits occur below the base of fresh water; thus they may contain small amounts of saline water.

Pliocene Tuscan Formation

Tuscan deposits are characterized by their Cascade Range origin and volcanic signature. This extensive series of basaltic and andesitic volcanic flows, consolidated tuff breccia, tuffaceous sandstone, and volcanic ash is primarily located on the northeastern portion of the Sacramento Valley. The Tuscan Formation underlies much of the Valley floor and extends from the Cascades to the center of the Valley where it grades into volcanic sands, gravels, clays, and interfingers with the Tehama Formation. Thin tuff or ash units separate the Tuscan Formation into four distinct, yet lithologically similar Units A, B, C, and D (D being the youngest). Only A, B, and C are found in the project study area. Unit C is composed of massive lahar (mudflow) deposits with volcanic sandstone and conglomerate interbeds. Tuscan Formation Unit C is referred to as the Upper Tuscan Formation. Tuscan Units A and B are largely composed of layered, inter-bedded lahars, siltstone, and volcanic sandstone and conglomerate; they are referred to as the Lower Tuscan Formation. Unit A is distinguished from Unit B by the presence of metamorphic rock fragments in siltstone layers. This formation contains fresh water.

Pliocene-to-Pleistocene Tehama Formation

Deposits of the Tehama Formation are characterized by their fluviatile nature and origin from the Klamath Mountains and Coast Ranges. This assemblage of moderately consolidated sandstone and siltstone with local coarse lenses is located in the northwest portion of the Sacramento Valley. These yellowish to greenish grey deposits are separated from the underlying Eocene Epoch and Cretaceous Period marine sediments by an unconformity. The Tehama Formation was deposited under floodplain conditions by rivers and streams flowing from nearby mountains in a subsiding, low relief valley. Several properties of the Tehama Formation indicate a western and northwestern origin. Mineral composition and rock type of Tehama deposits are identical to those in the Coast Ranges and Klamath Mountains. Additionally, the grain size of Tehama Formation sediments decreases to the south and east, suggesting a western and northwestern origin. This formation contains fresh water.

PLIOCENE NOMLAKI MEMBER

This deposit is recognized as a member of both the Tehama and Tuscan Formations indicating simultaneous deposition. The Nomlaki Member is composed of coarse tuff breccias and white tuffs of dacitic composition and has an eastern source. This widespread deposit serves as an important stratigraphical marker in the northern part of Sacramento Valley. This formation contains fresh water.

PLEISTOCENE DEPOSITS

Terrace deposits of the Pleistocene Modesto and Riverbank Formations are composed of poorly sorted clay, silt, sand, and gravel, and form a thin veneer at the ground surface. The Riverbank Formation is distinguished from the Modesto deposits by interbedded clay layers. In the Stony Creek Fan area, these terraces are well defined, but they are absent or poorly defined along other minor streams in the study area. This formation contains fresh water.

HOLOCENE DEPOSITS

Quaternary alluvium, the most recent deposit, is found along major rivers and is composed of unconsolidated unweathered clay, silt, sand, and gravel. Fine-grained flood plain deposits include silt with minor amounts of sand. The basin deposits are composed of fine-grained sediments and are found in flood basins and near streams. The coarse-grained sediments of the alluvial fan include sand and gravel. This formation contains fresh water.

HYDROGEOLOGY

The Stony Creek Fan deposits include Pleistocene and Holocene upper, unconfined aquifer deposits. As Stony Creek meandered across the fan, channels were created, abandoned, and then buried, creating a complex system of coarse- and fine-grained sediments. The variable nature of this fluviatile, depositional environment causes difficulty in defining groundwater aquifers within the fan.

The Stony Creek alluvial fan sediments form a thin veneer over the Tehama Formation. During the Pleistocene, the surface of the Tehama Formation was intensely eroded, then backfilled with both coarse- and fine-grained deposits of the Stony Creek Fan. The resulting uneven contact between the geologic units makes it difficult to determine the contact between the Stony Creek Fan deposits and the underlying Tehama Formation. The nature and extent of groundwater interaction between these deposits is uncertain due to the channelized nature of both formations.

Typical Tuscan deposits are coarser than those of the Tehama Formation. Simultaneous deposition of these extensive formations onto a broad valley surface resulted in the interfingering of Tuscan and Tehama sediments near the center of the valley. In general, the grain size of the Tehama Formation becomes finer to the east, and the Tuscan Formation grades into volcanic gravels, sands, and clays where the deposits overlap. The nature of groundwater interaction where these formations merge is uncertain.

The aquifer system of the Stony Creek Fan Area includes a freshwater aquifer overlying a saline aquifer. The freshwater alluvial aquifer system in the study area is composed of late Tertiary to Quaternary continental deposits. The aquifer system includes an upper unconfined alluvial aquifer consisting of Quaternary deposits overlying a confined aquifer system composed of Quaternary and Tertiary continental deposits of fluvial and volcanic origin. The saline aquifer system composed primarily of Tertiary and older marine deposits.

FRESHWATER AQUIFER SYSTEM

The freshwater aquifer system is composed of an unconfined aquifer overlying a confined aquifer as described below.

Unconfined Aquifer

The upper unconfined aquifer consists of Quaternary deposits, including Holocene alluvium, flood plain, alluvial fan, and basin deposits, and the Pleistocene Riverbank and Modesto Formations. The unconfined aquifer system is important to local groundwater users, but the potential for significant groundwater storage is limited due to insufficient thickness.

Recharge Areas

The unconsolidated, highly permeable Quaternary alluvium deposits are important recharge areas. These deposits are generally located along major rivers and facilitate groundwater recharge from rivers. Highly permeable alluvial fan deposits, specifically of the Stony Creek Fan, are also important recharge areas. The moderately permeable basin deposits and floodplain deposits are less important recharge areas.

In addition to the Holocene deposits, the highly permeable terrace deposits of the Pleistocene Modesto and Riverbank Formations are significant recharge areas. Water bearing capabilities of these formations are limited by their thickness.

Confined Aquifer

The confined aquifer is composed of Tertiary Deposits, including the Pliocene and Pleistocene Tehama Formation and the Pliocene Tuscan Formation. These widespread and thick formations are important in aquifer storage and well water supply.

Tehama Formation

The Tehama Formation is the primary water source of the study area. Groundwater in this formation occurs under semi-confined to confined conditions. The widespread occurrence and relatively higher thickness allow this formation to supply water to most of the wells in the study area. Moderately compacted, thickly bedded sandstone and siltstone layers derived from the Coast Ranges result in characteristically low to moderate permeability. However, thinner lenses of sand and gravel result in local, high permeability zones.

Potential for groundwater recharge and storage is limited by the geographic irregularity of these permeable lenses. Well yields are typically moderate for deeper wells. However, well yields vary from high to low due to variable permeability zones. Generally, wells located near the Stony Creek Fan have higher yields than those located to the south. The Tehama Formation has a higher concentration of more permeable coarse material in the vicinity of the alluvial fan deposits. Variations in well yields indicate the north to south decrease in grain size.

Tuscan Formation

The Tuscan Formation serves as the primary source of groundwater on the east side of the Sacramento River. In the study area, these deposits occur at depths in excess of the depths of the most of the existing domestic and irrigation wells.

Moderately permeable to highly permeable volcanic sediments are hydraulically confined by layers of tuff breccias and clays within the Tuscan formation. The low permeability lahar deposits of Unit C serve as confining beds for the underlying older Tuscan Units A and B. Although Unit C contains permeable volcanic sandstone and conglomerate interbeds, this unit is characterized by an overall low yield of water to wells. Units A and B are much more coarse-grained than the overlying Unit C, causing them to be the primary water-bearing zones of eastern Sacramento Valley.

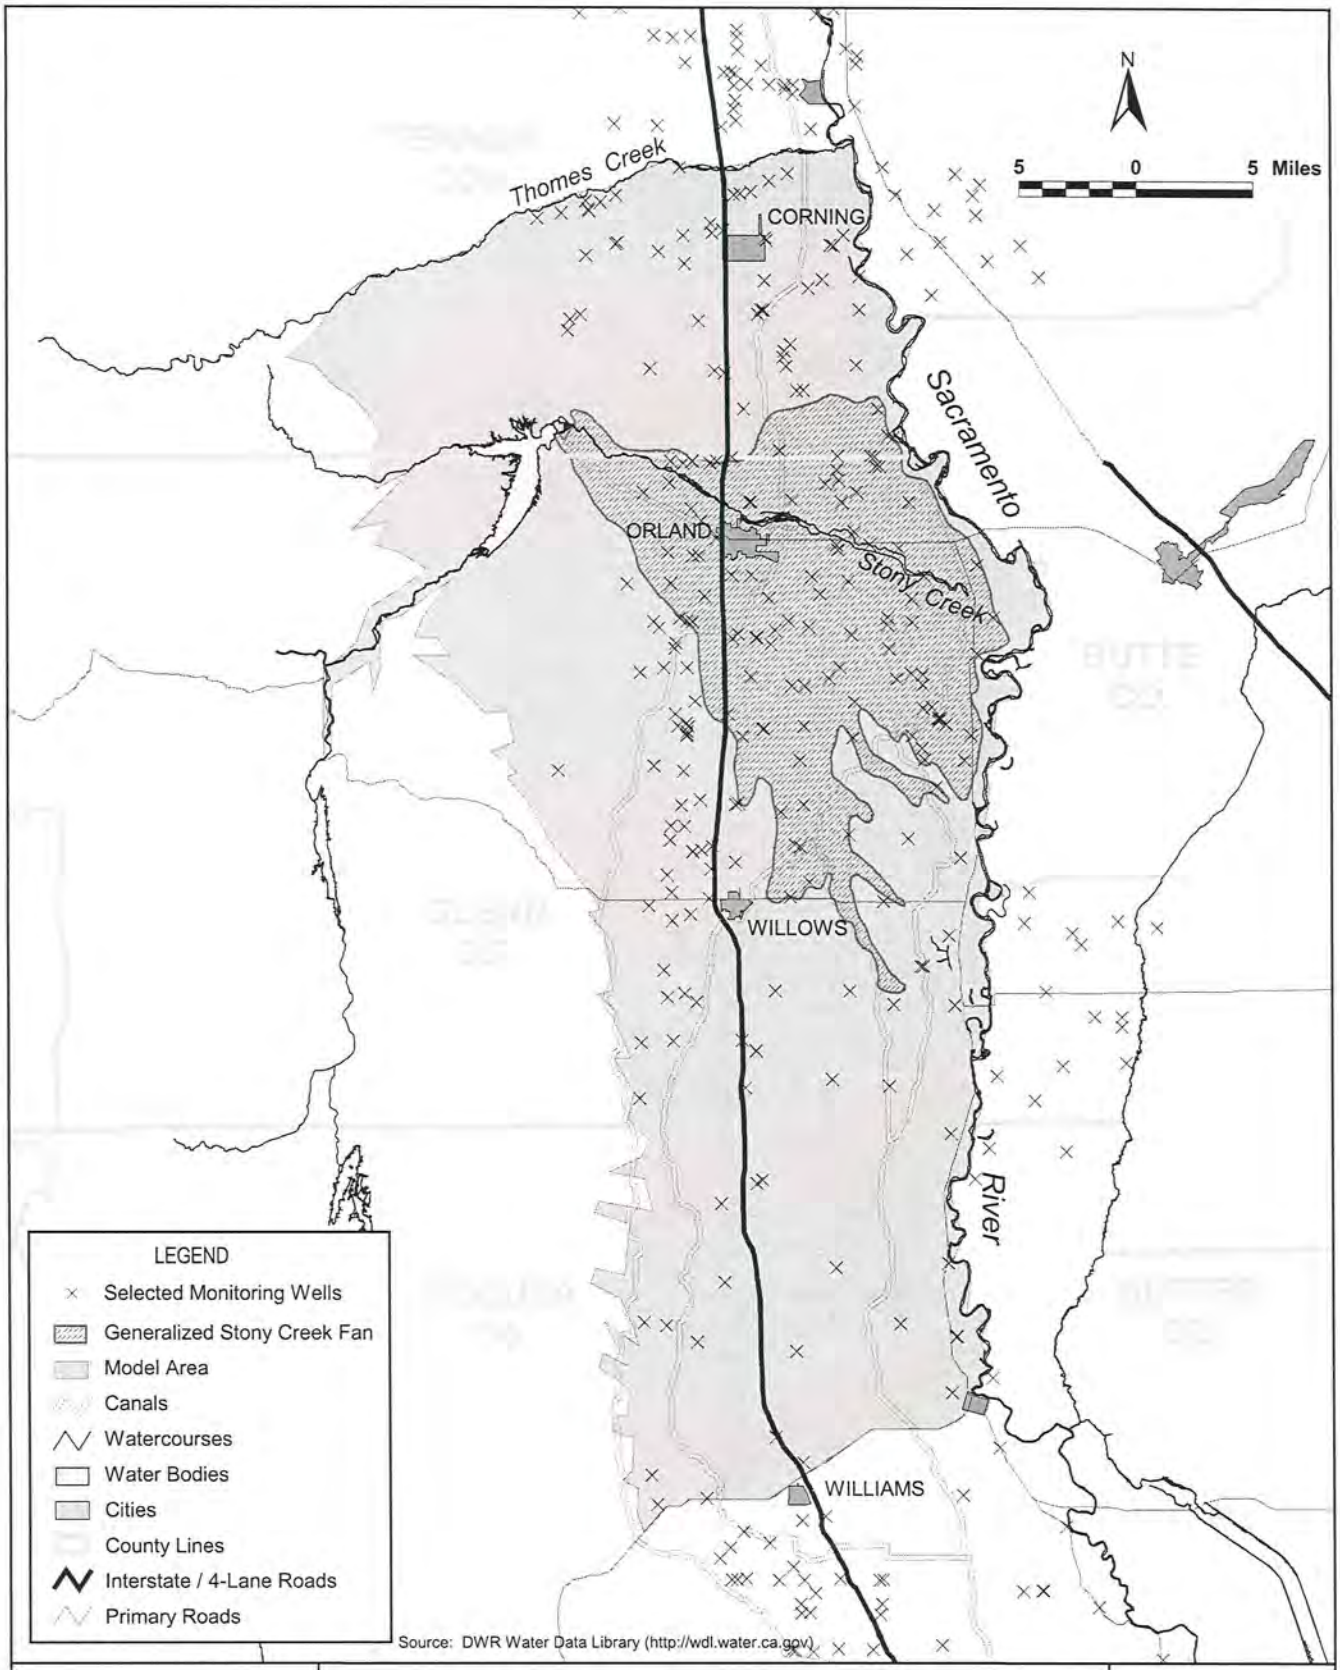
Saline Aquifer System

The saline aquifer system lies beneath the fresh water aquifer. The base of the fresh water aquifer is defined by the contact between continental deposits and pre-Pliocene marine

deposits. The marine deposits present in the study area subsurface include the Miocene Neroly Formation, the Miocene and Oligocene Upper Princeton Valley Fill, the Eocene Lower Princeton Submarine Valley Fill, and the Cretaceous Great Valley Sequence.

HISTORIC GROUNDWATER CONDITIONS

DWR Bulletin 118-6 provided historic water level contours for 1912 and 1961 in the Sacramento Valley. The 1912 pre-development conditions water level in the study area varied from 80 feet to 300 feet above mean sea level. The direction of groundwater flow was generally in southeast direction. Bulletin 118-6 also provided a water level difference map between the years 1961 and 1912, which showed no difference in almost the entire study area except a 10 feet rise in groundwater level near the town of Orland.



DWR has been collecting water level data at different monitoring wells in the study area for a number of years. The locations of selected past and current monitoring wells in the study area are shown in Figure 2.2. There are about 191 wells (18N–22N) in the Glenn County, 40 wells (15N–18N) in the Colusa County, and 203 wells (23N–25N) in the Tehama County that are monitored intermittently. The period of record spans from 1921 to current. Table 2.2 shows the frequency of water level measurements at wells for the 3 counties in the study area. This data is used to develop historic groundwater level contours for different periods and are presented in Figures 2.3 to 2.12. It should be noted that there are few monitored wells in the area northwest of Willows.

The fall of 1969 water surface elevation is shown in Figure 2.3. The recorded data for October 1969 were used to develop this contour map. During the month of October, the water surface elevations are at their lowest following high groundwater pumping in summer months and prior to aquifer recharge during rainy winter months.

The contour map for March 1974 (Figure 2.4) shows water level conditions prior to 1976-77 drought and prior to Tehama-Colusa Canal deliveries. In general, there is little change from the October 1969 groundwater levels, except small decreases in groundwater levels in some areas.

The contour map for March 1977 (Figure 2.5) map shows water level conditions during a historical dry period. Water levels show a decrease in elevations across the study area in response to the drought conditions. The October 1977 water level contour map (Figure 2.6) shows the impact of dry conditions compounded by increased groundwater pumping during the summer months.

Following the 1976 to 1977 drought conditions, additional surface water was delivered to the model area via the Tehama-Colusa Canal. This, along with a historical wet period, enabled

Spring 2000 Groundwater Elevation Contour Map

DRAFT

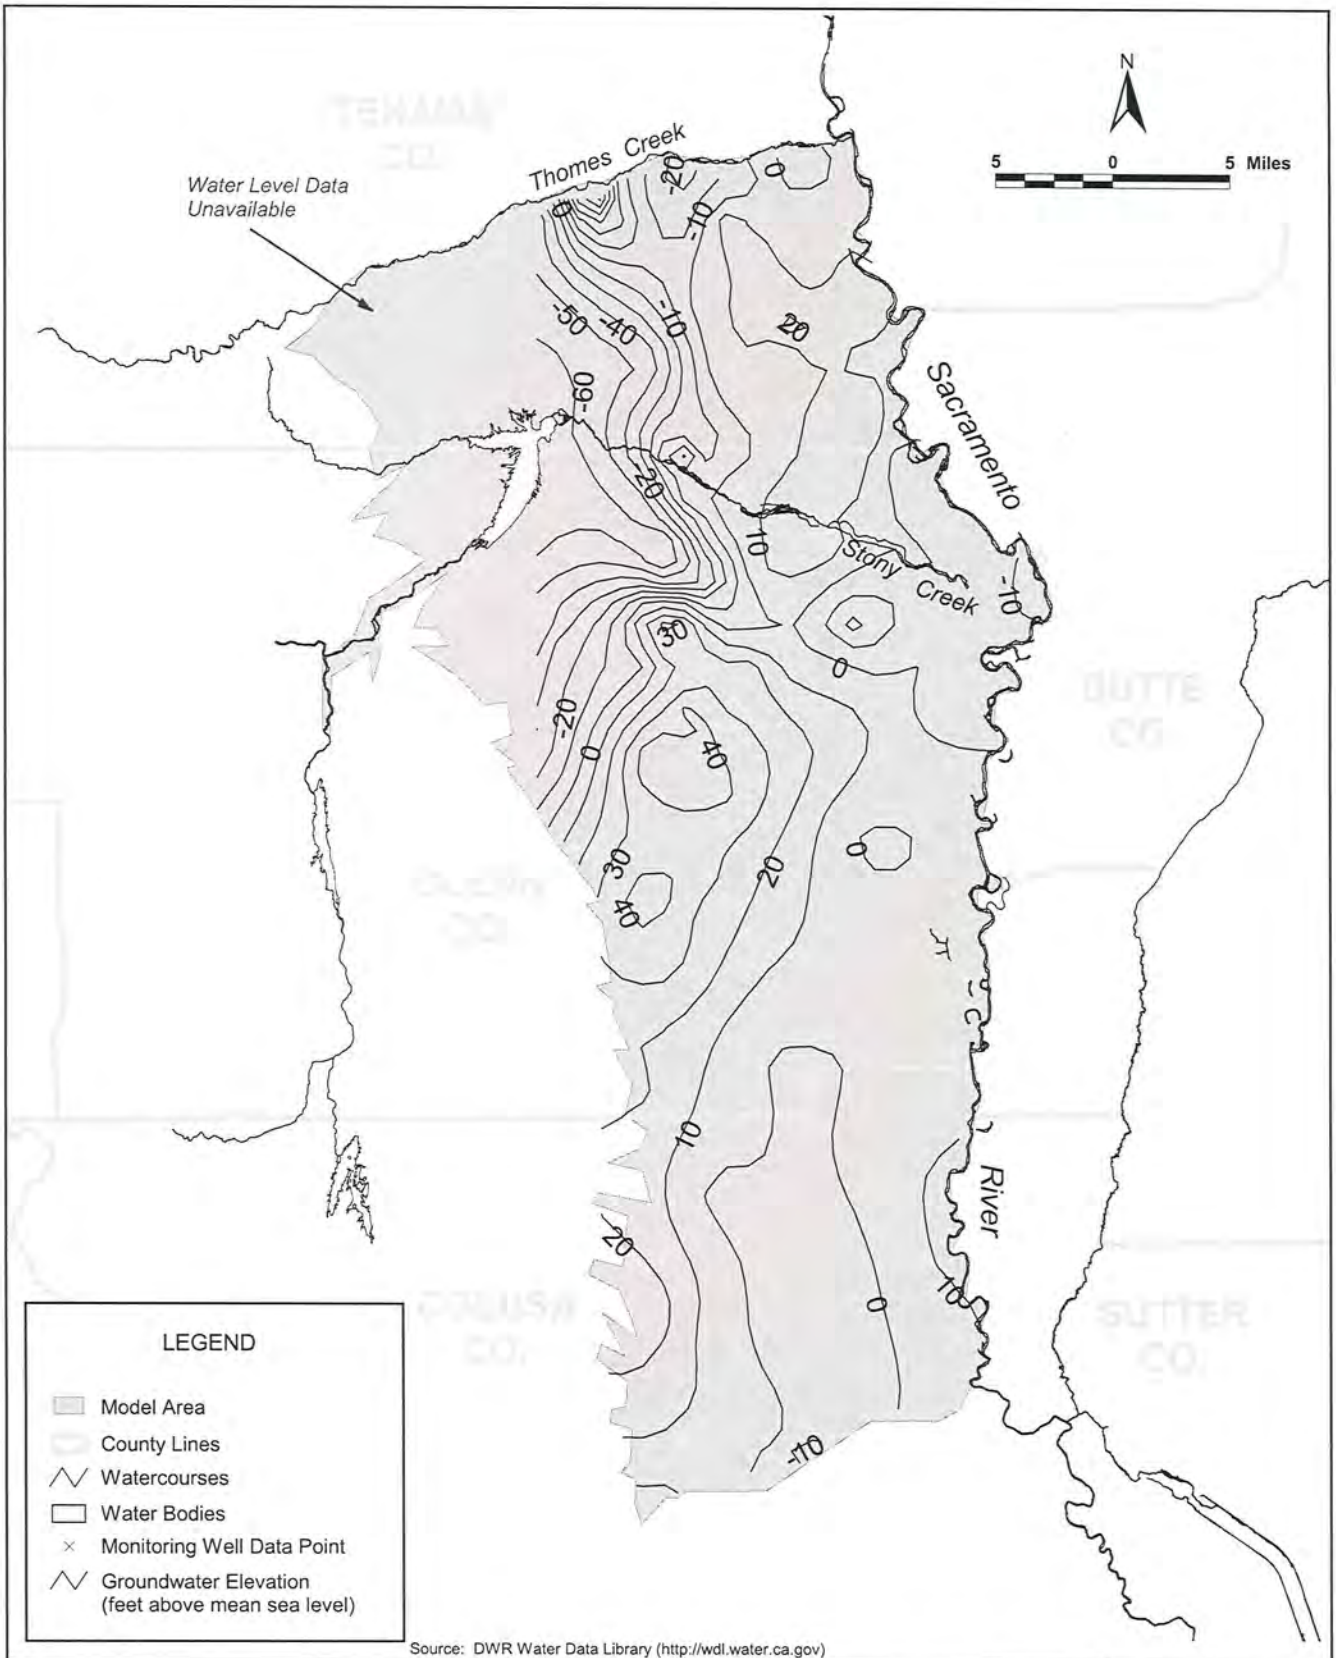
MARCH 2003

FIGURE 2.12

groundwater surface elevations to increase substantially. The March 1983 water level contour map (Figure 2.7) shows significant increases in elevations as compared to the 1977 maps. The 1983 map also shows increases in elevations as compared to the October 1969 contour map indicating full recovery of the aquifer to pre-drought conditions.

The March 1986 water level contour map (Figure 2.8) shows a slight decrease from the 1983 conditions. This map was constructed to evaluate water level conditions previous to the 1987-1992 drought.

The March 1992 water level contour map (Figure 2.9) shows water level conditions at the end of the 1987-1992 drought. Groundwater surface elevations decreased in response to the drought conditions. The October 1992 water level contour map (Figure 2.10) shows additional decreases resulting from increased summer groundwater pumping.



The March 1994 water level contour map (Figure 2.11) shows recovery of the aquifer with increasing groundwater surface elevations.

The March 2000 water level contour map (Figure 2.12) shows current groundwater surface elevation conditions. This map shows a slight increase in elevations compared to the March 1994 conditions.

The overall trend of the groundwater conditions is relatively stable. Although the groundwater surface elevation maps show declines in response to drought conditions, the contour maps demonstrate full aquifer recovery. This general trend is demonstrated by the groundwater surface elevation difference contour map (Figure 2.13) showing the change in elevations from the October 1969 conditions to the March 2000 conditions. In many of the areas of the basin, there is little or no change, while other portions, specifically in the area of the Stony Creek fan, groundwater levels increased by as much as 30 feet. This trend also holds true when comparing the 1969 map with the March 2000 map.

Well Hydrograph Analysis

In addition to evaluating contour maps, individual well hydrographs were analyzed for groundwater level trends. Specific well information was obtained from the Department of Water Resources, Northern District, Sacramento Valley Groundwater Basin groundwater level monitoring program. Historical water surface elevations are available in published county reports and DWR website postings. Data contained in this database is current through water level measurements made in the Fall of 2002. Six wells, as shown in Figure 2.14, are chosen to illustrate historical groundwater level trends in the model area. These trends are discussed in the following section.

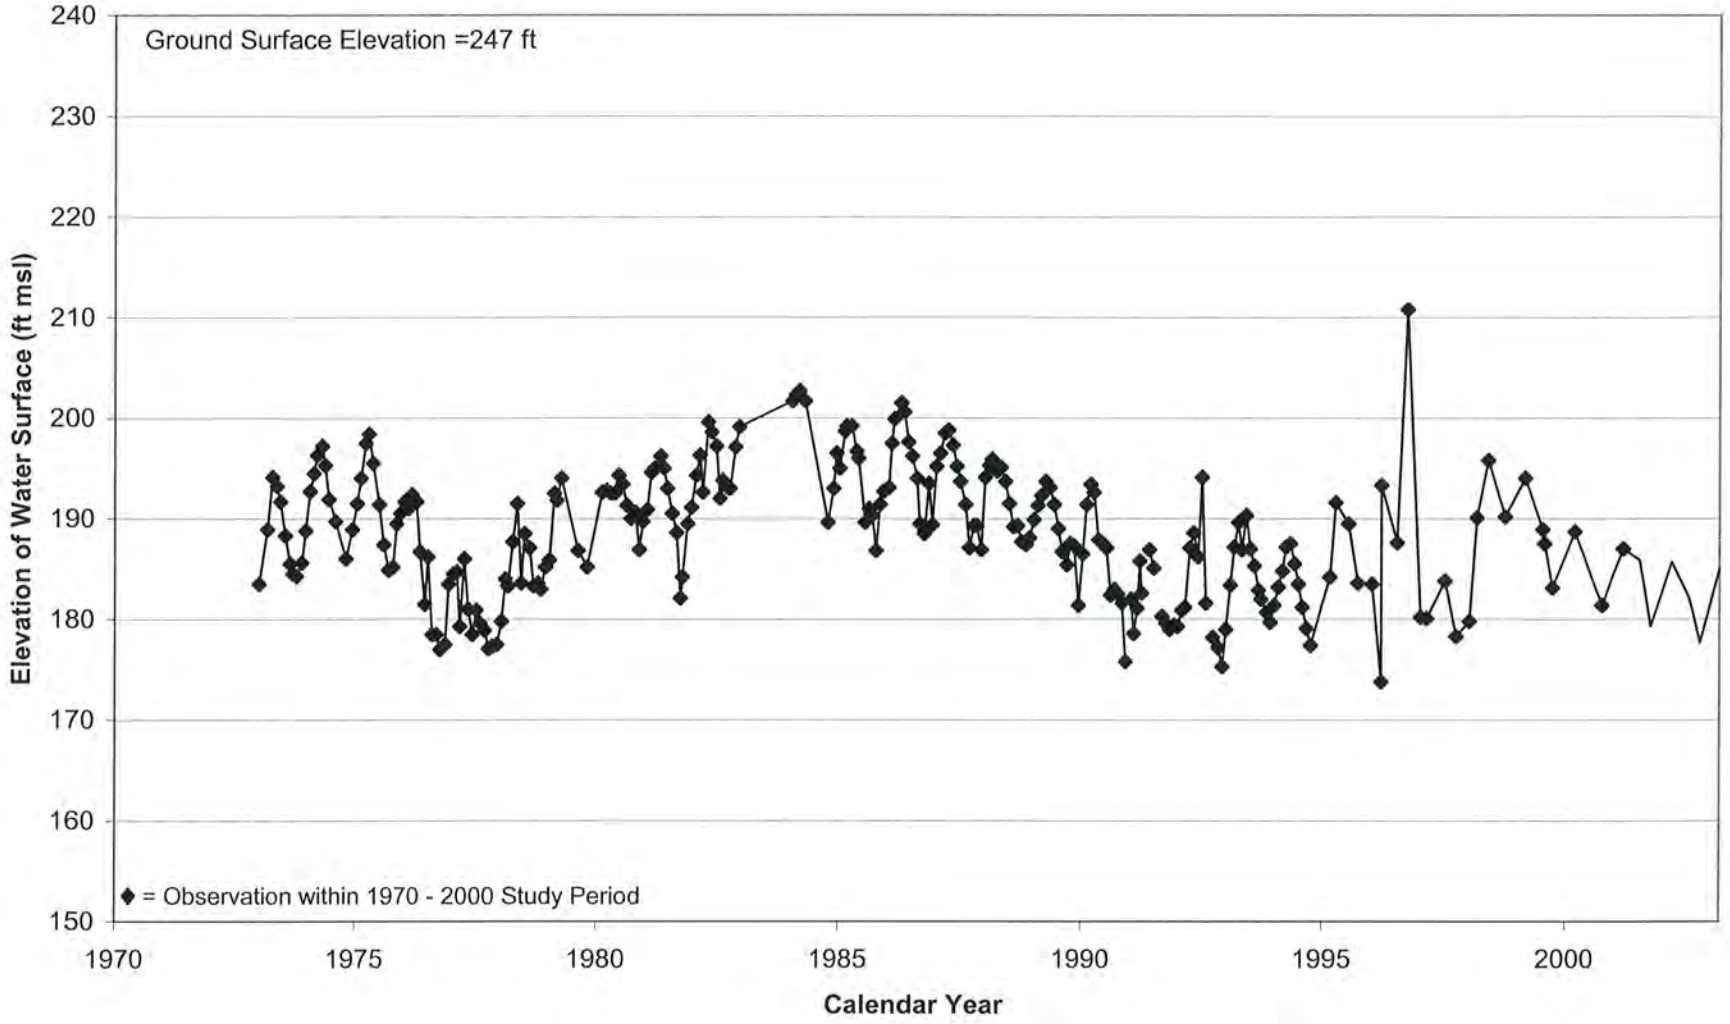
Tehama County

DWR and USBR have been collecting groundwater level data on 138 wells beginning in the late 1920's through the Tehama groundwater monitoring program. The information collected previous to 1993 is summarized in *Groundwater Levels in the Sacramento Groundwater Basin, Tehama County*. Of the 138 wells in the Tehama County monitoring program, 43 wells are located within the model area

In general, the historical groundwater level in Tehama County is constant. This is depicted in hydrographs for wells 23N03W12L01M and 24N03W26K01M, shown respectively in Figure 2.15 and Figure 2.16. Some wells in the area may show groundwater level declines reflecting the 1976-77 and 1987-92 drought periods. However, all water levels in Tehama County recovered from these droughts.

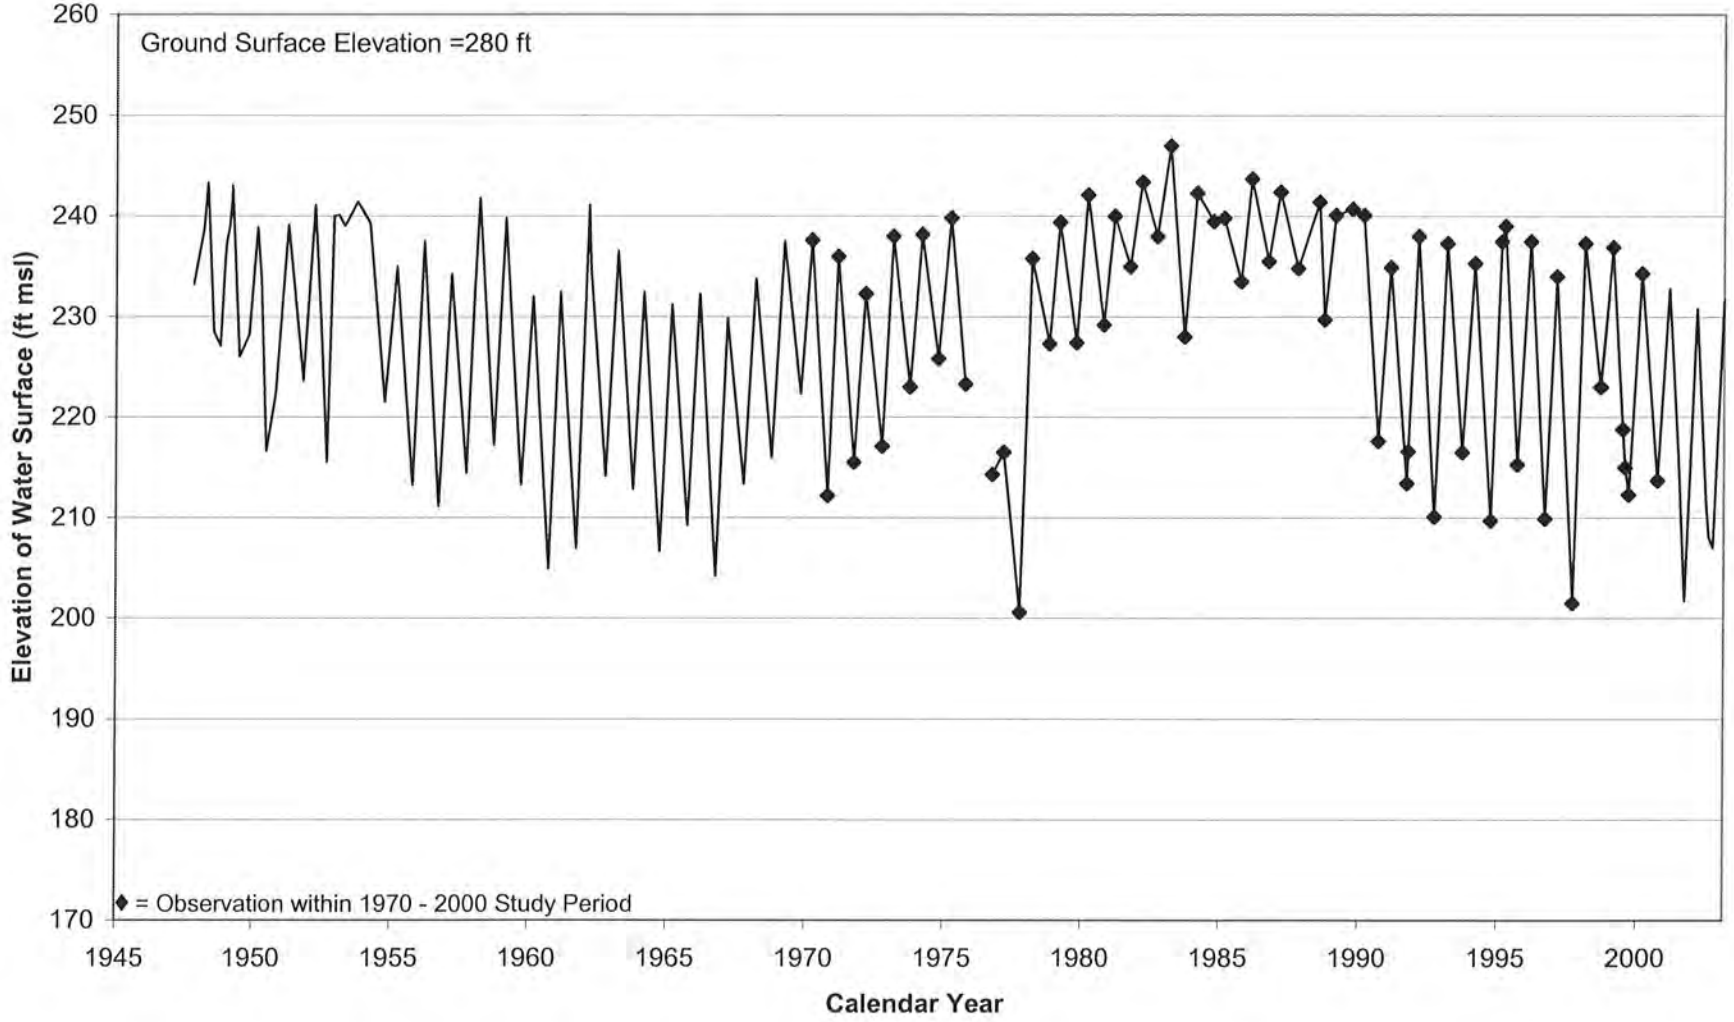
Glenn County



There are two groundwater monitoring programs in Glenn County. The first is similar to the groundwater monitoring program in Tehama County. Under this program, groundwater levels in Glenn County have been collected by DWR and USBR since the mid 1920's and continuing to 1997 and are summarized in *Groundwater Levels in the Sacramento Valley Groundwater Basin, Glenn County*. This study monitors 174 wells in Glenn County. The second groundwater monitoring program is the Basin Management Objective program. The information collected in this study is summarized in *Basin Management Objective (BMO) For Groundwater Surface Elevations in Glenn County, California*. There are 50 wells in this program, 42 monitored by DWR and 8 monitored by independent water districts.

In general, the current groundwater level for Glenn County is unchanged from historical groundwater levels, depicted in the well hydrograph for 19N02W29Q01M shown in Figure 2.17. The 1976-777 and 1987-92 droughts are reflected in many hydrographs in the area, both droughts followed by a recovery of the aquifer to pre-drought conditions. Surface water supplied by the Tehama-Colusa Canal was introduced to many parts of Glenn County near the end of the 1976-77 drought. This reduced the need for groundwater pumping as reflected in the rise in groundwater level around this time at well 21N03W31R02M (Figure 2-18).

Colusa County



The report *Groundwater Levels in the Sacramento Valley Groundwater Basin, Colusa County*, summarizes the data collected by DWR and USBR in Colusa County from the late 1920's to

Figure 2.15

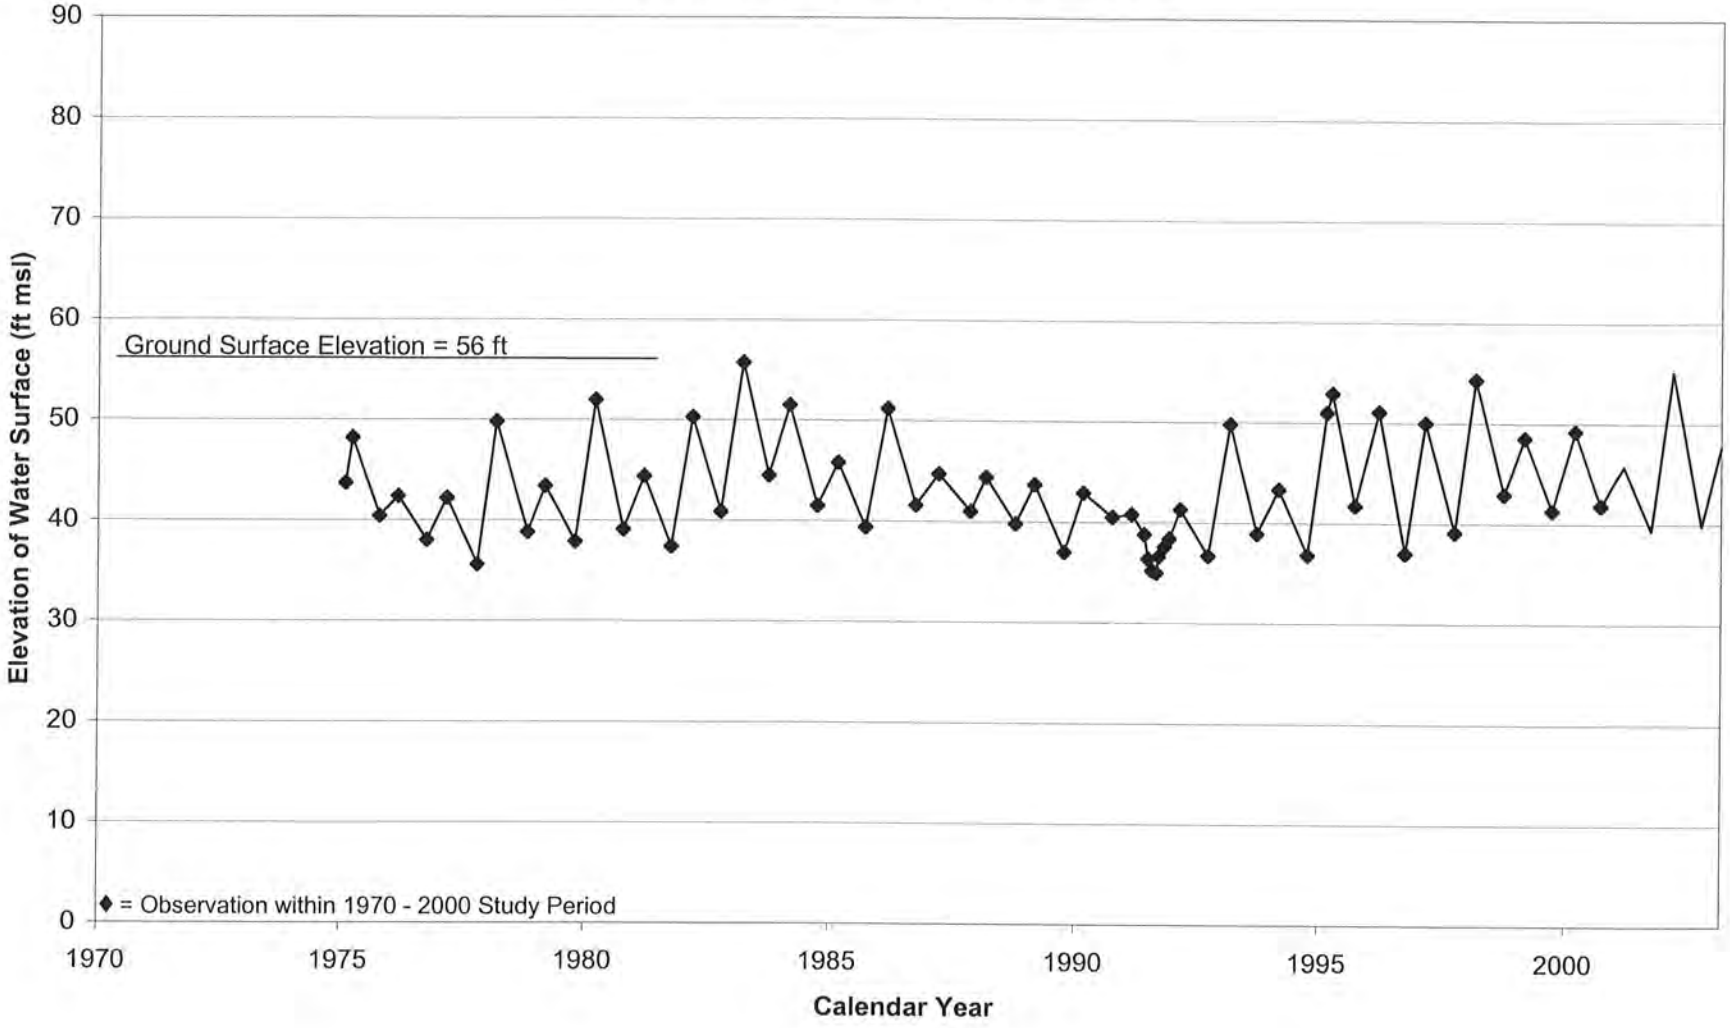
1995. There are 114 wells in this groundwater monitoring program, 23 of which are located within the model area.

The historical groundwater level trend in Colusa County is constant, as depicted in the hydrographs for wells 16N02W12J02M and 16N03W07Q01M, shown respectively in Figure 2.19 and Figure 2.20. Some wells in the county may reflect the 1976-77 and 1987-92 drought periods demonstrated by declines in water level, followed by full recovery.

SOILS

The processes that control the percolation of precipitation, runoff, and applied water are tied to soil properties. Published soil surveys for Glenn County, Colusa County, and Tehama County by the NRCS were reviewed for the Stony Creek Fan model area. The information contained in these surveys provides data necessary to classify the model elements based on hydrologic soil type. Inclusion of this information into the SCFIGSM enables the model to capture the influence of the ground surface and the soil horizon on aquifer recharge.

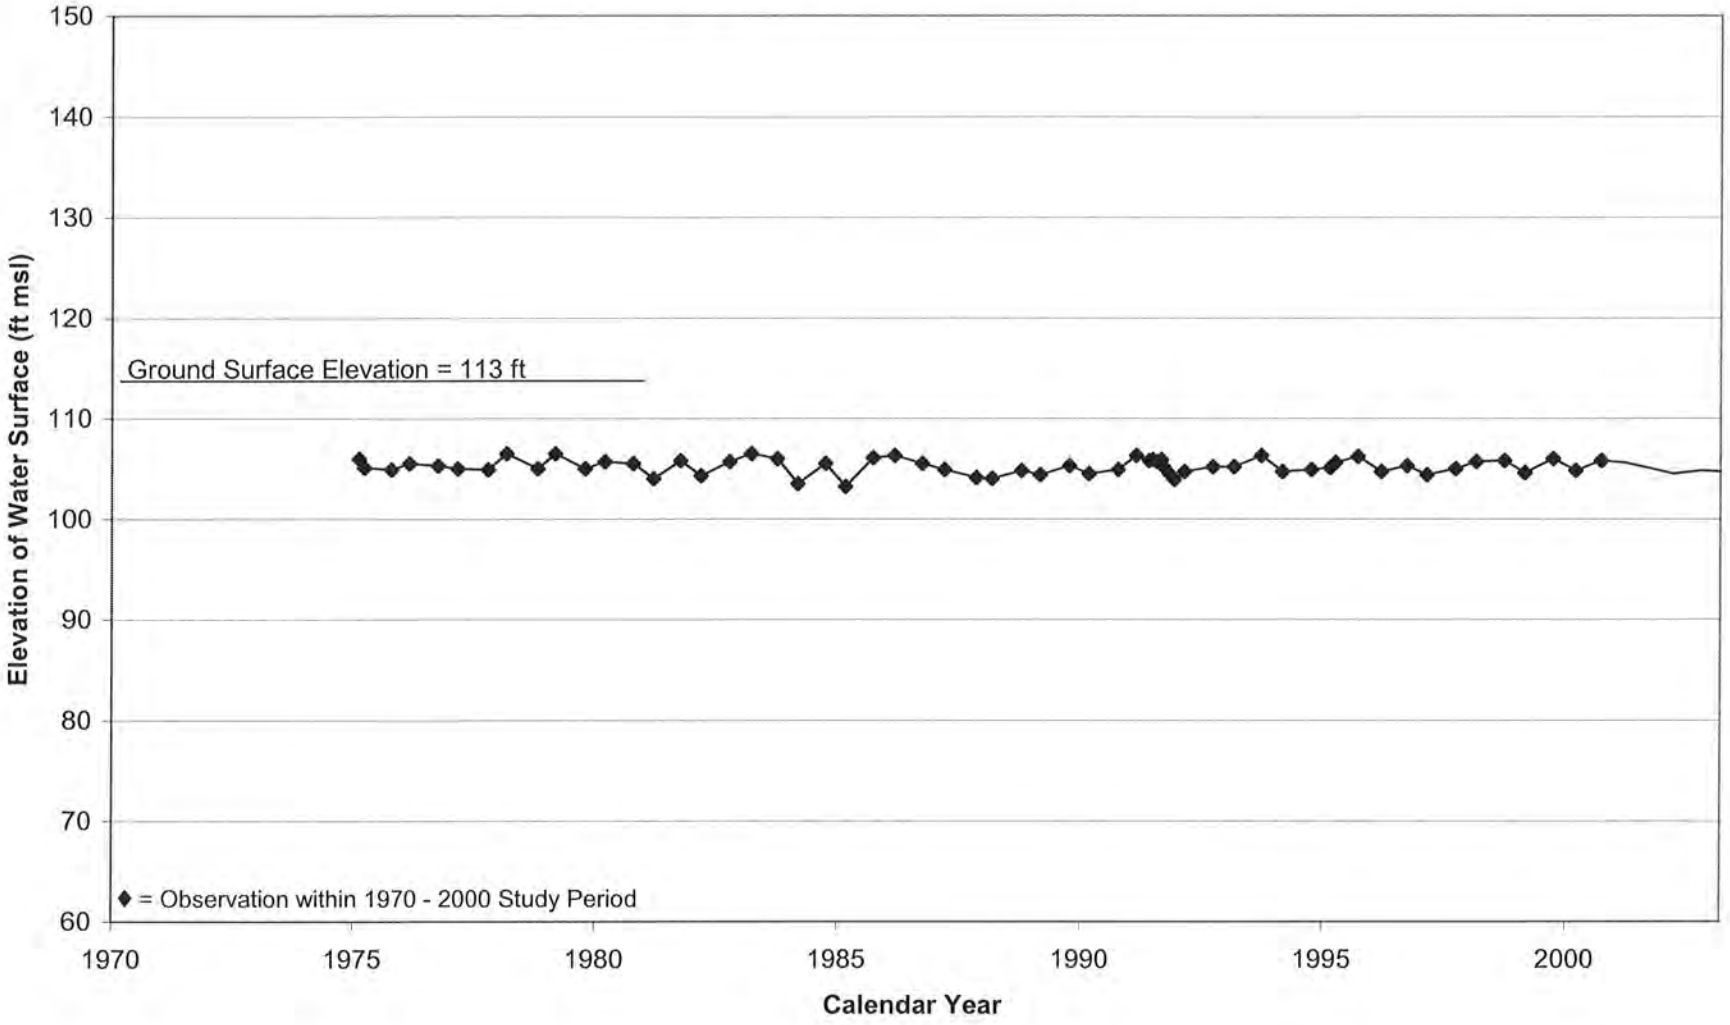
The National Resource Conservation Service (NRCS), formerly the Soil Conservation Service, has published three soil surveys in the study area for Colusa County (1907), Glenn County (1965), and Tehama County (1967). These soil surveys are compilations of a series of aerial photographs containing soil type boundaries, and tables and text detailing the soil types.



The NRCS is developing a Soil Survey Geographic Database (SSURGO) containing digital copies of original soils survey maps. The SSURGO mapping scales generally range from 1:12,000 to 1:63,000. A SSURGO database for Colusa County is available. Tehama County and Glenn County do not have a SSURGO database at this time.

HYDROLOGIC SOIL GROUPS

For the purposes of hydrologic analysis, soil types can be classified into four hydrologic soil groups, Groups A-D. This categorization system is based on estimates of runoff potential, infiltration rates, water intake, and water transmission of a saturated soil profile, with Group A having the lowest runoff potential and D having the highest.



Predominant soil group and geomorphic feature associations of the study area are summarized in Table 2.3 along with the corresponding hydrologic soil groups. Typical hydrologic soil groups are discussed for the following geomorphic features: foothills, low terraces and older alluvial fans, more recent alluvial fans and flood plains, and basin deposits. These associations are demonstrated in Figure 2.21, which shows the hydrologic soil type distribution by element.

STONY CREEK FAN CONJUNCTIVE WATER MANAGEMENT PROGRAM

Hydrologic Soil Types

DRAFT

MARCH 2003

FIGURE 2.21

Soil groups C and D are the predominant soil groups of the study area and are associated with foothills, low terraces and basin deposits. More permeable soil groups A and B are associated with major hydrologic features such as the Sacramento River and the more recent alluvial fans and flood plains, such as the area of the Stony Creek alluvial fan deposits.

DRAFT

This section summarizes the general hydrology of the Stony Creek Fan study area based on the information compiled during the Data Collection and Assessment Task of this project. The hydrology of a groundwater basin is the primary driving force for groundwater flow and quality. Therefore, it is essential to understand the hydrologic characteristics of the model area in order to develop a sound conceptual model.

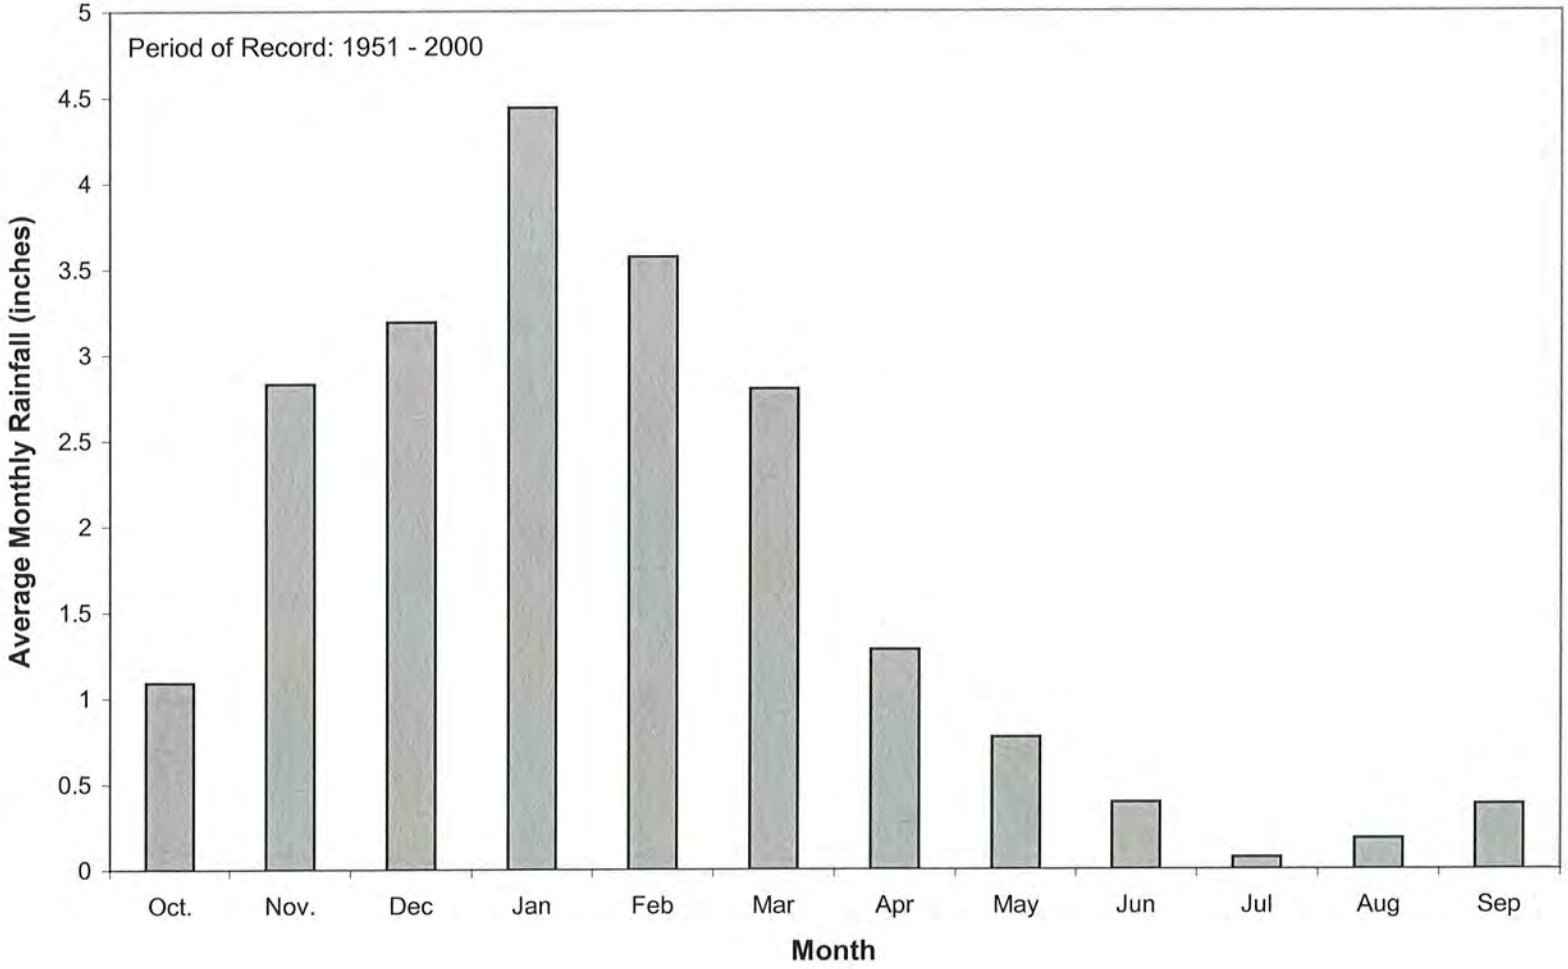
SURFACE WATER SUPPLIES

RAINFALL

The hydrology of the Stony Creek Fan model area is typical of a California inland basin characterized by dry summers and moist winters. Annually, the area receives an average of 24 inches of rainfall. The typical rainfall pattern is that of little to no rainfall in the summers with most of the precipitation occurring during the winter months. Figure 3.1 shows the monthly distribution of rainfall at a gaging station near the town of Orland. Figure 3.2 shows the accumulative departure from the mean precipitation for the same gauging station. This graph represents the climatic trends in the study area for the period from 1951 to 2000.

The long-term annual average rainfall distribution in the study areas is presented in Figure 3.3. This isohyetal map is developed by DWR using one hundred years of precipitation data from various raingages in the study area.

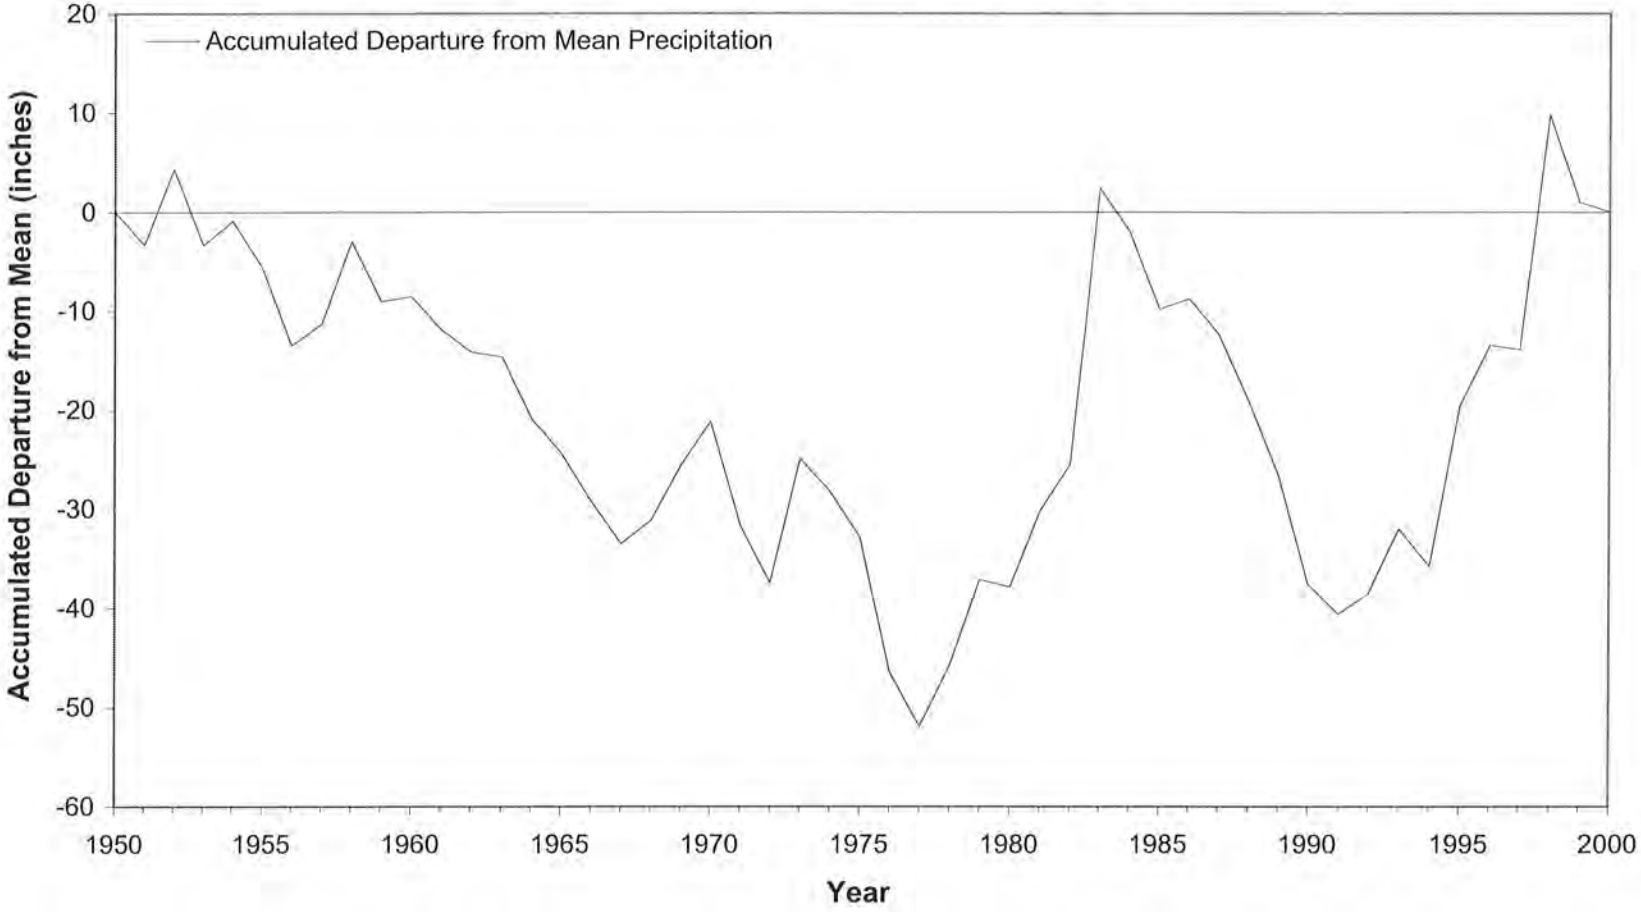
STREAMFLOWS



There are three major streams in the model area:

- **Thomes Creek** that coincides with the northern boundary of the model area
- **The Sacramento River** that coincides with the eastern boundary of the model area, and
- **Stony Creek** that is located within the model area.

The average annual inflows from these streams are presented in Figure 3.4 to 3.6.



There are other tributaries of the Sacramento River on the east; these eastside streams are outside the model area, but they contribute inflows at the model boundary.

Monitored by USGS (gage 11383730) from 1945 - 1978
Monitored by DWR (gage A02700) from 1978 - 2001
Partial missing data from 1983-1989 was estimated using the daily flow correlation between the Sacramento River at Vina gage and the Sacramento River at Old Ferry gage (USGS 11383730).

Figure 3.6
Stream Inflow to SCFIGSM from Stony Creek

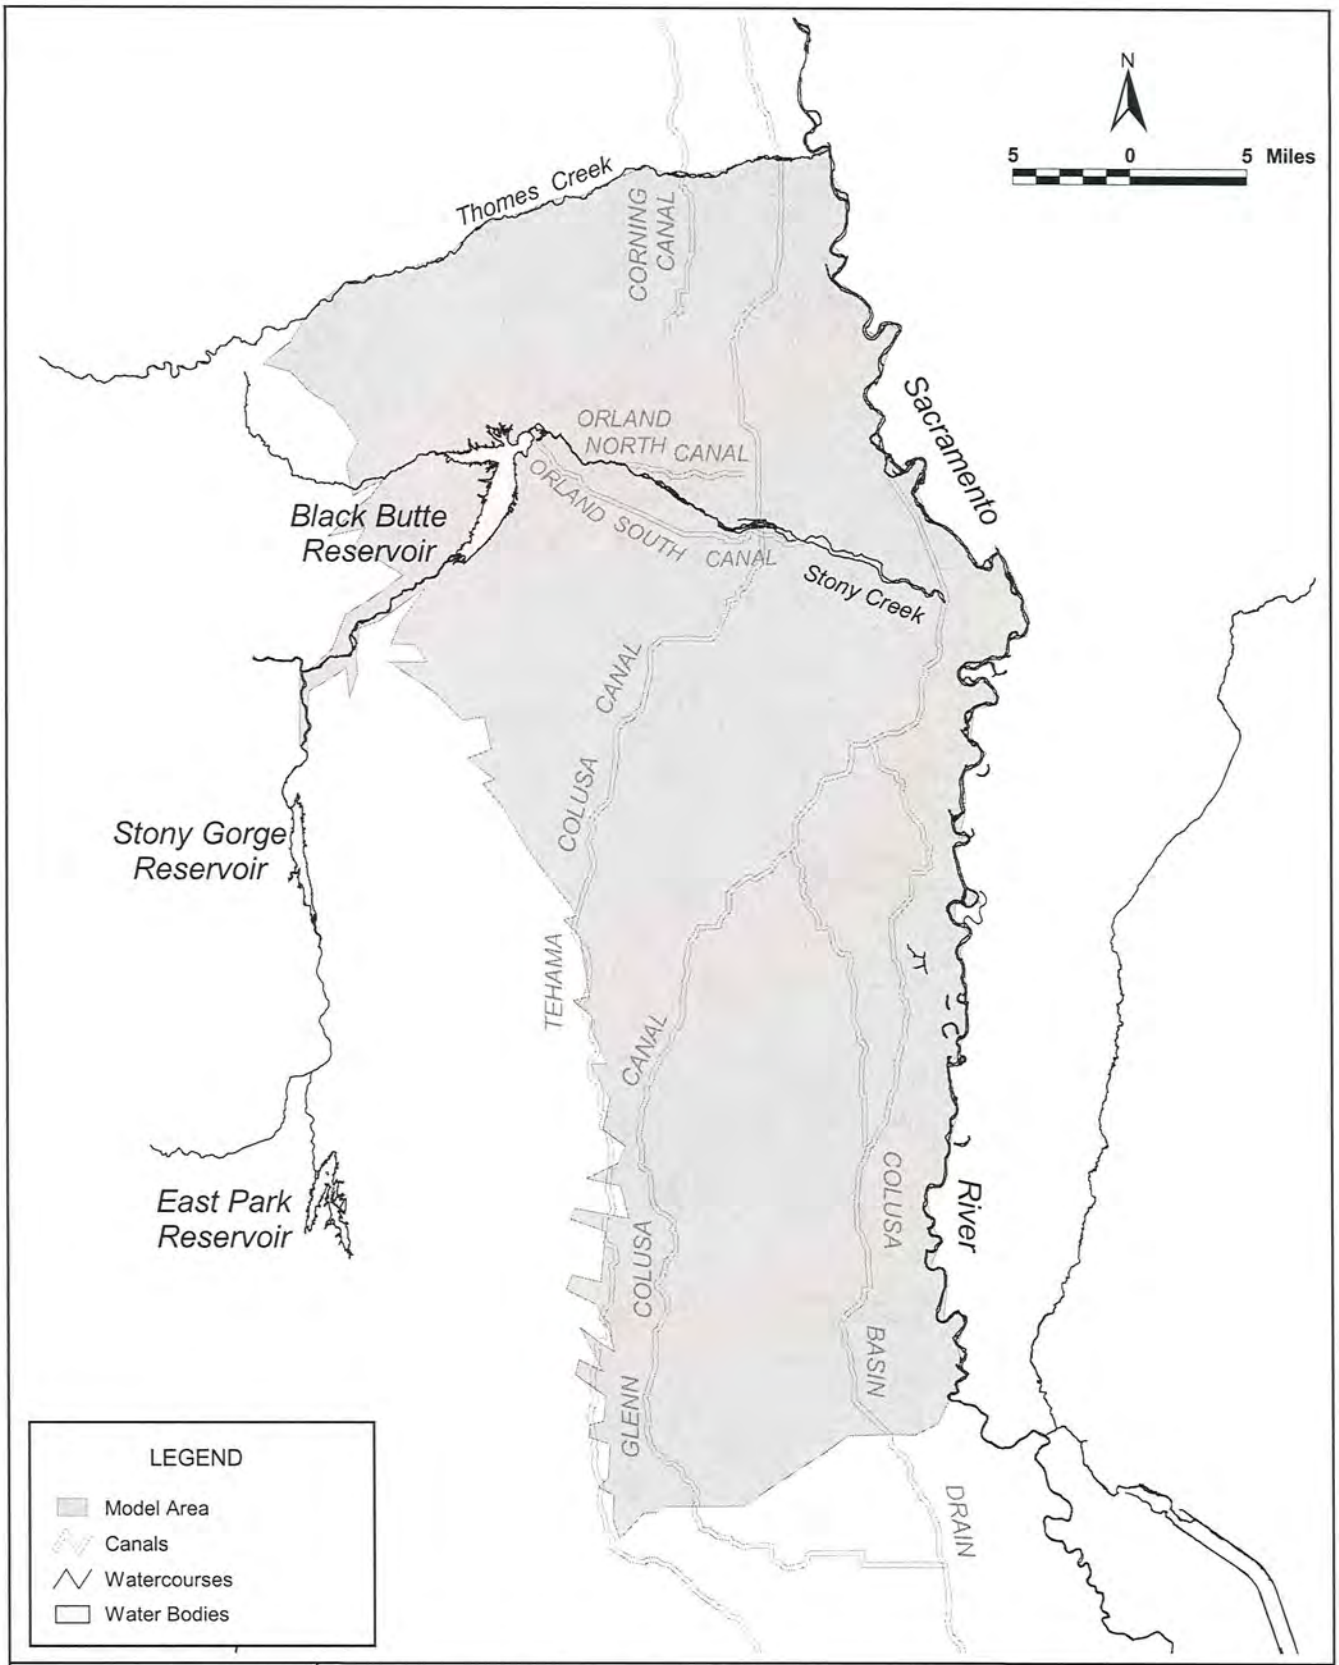
Source: Stony Creek at Black Butte Reservoir (Operations Data)
Monitored by US Corps of Engineers from 1963 - 2001 (Water Control Data System Report, US Corps of Engineers, www.spk/wc.usace.army.mil)

Two primary sources of stream flow data are the USGS and the DWR. The USGS data is obtained from the web site (http://water.usgs.gov/usa/nwis/sw) and the DWR data is obtained from the Northern District. There are several stream gauging stations in the study area, some of which are now discontinued.

Small Watersheds

There are several small ungauged intermittent streams along the western boundary of the model area. Flow along these streams are not significant to be modeled as streams; however, the surface run off associated with these streams is a source of aquifer recharge. Estimation of inflow along these streams can be conducted by specifying the small watershed drainage areas and precipitation rates. Inflows can be set as an input to the groundwater node at which the streams enter the model area.

Surface Water Diversions and Delivery



The agricultural land in the model area is irrigated by surface water from adjacent rivers and reservoirs and by groundwater pumping.

The Stony Creek system includes East Park, Stony Gorge, and Black Butte Reservoirs. Water is primarily supplied from Black Butte Reservoirs to Orland Unit Water Users Association (OUWUA). During spring, some water is diverted from Stony Creek to the Glenn-Colusa Canal.

The Sacramento River does not include any storage facilities within the model area. There are five major diversion locations along the river. These diversion locations are for the following water districts:

- Glenn-Colusa Irrigation District,
- Provident Irrigation District,
- M&T Chico Ranch, (outside model area)
- Princeton-Corado-Glenn Irrigation District, and
- Maxwell Irrigation District.

The irrigation water is brought into the model area using a network of lined and unlined canals and pipelines. There are six major canals and drains within the model area; these are shown in Figure 3.7 and listed below:

WRIME Water Resources & Information Management Engineering, Inc.	STONY CREEK FAN CONJUNCTIVE WATER MANAGEMENT PROGRAM	MARCH 2003
	Locations of Major Canals and Drains	FIGURE 3.7
	DRAFT	

- **Corning Canal** - the southern extent of this canal extends about 5 miles into the northern boundary of the model area.
- **Orland North and South Canals** are entirely within model area; they deliver water from Black Butte reservoir to Orland Unit Water User Association (OUWUA).
- **Tehama Colusa Canal** is a concrete lined canal that traverses the model area from north to south along the western edge; it diverts water from Sacramento river outside of the model area .
- **Glenn-Colusa Irrigation District Main Canal** is an unlined canal, which diverts water from Sacramento river inside the model area.
- **Colusa Basin Drain** is an unlined canal that is used as a major irrigation drain in the Glenn Colusa Irrigation District.

The Corning Canal provides water to districts within the Tehama County. There are two water districts within the model boundary that receive water from the Corning Canal. These districts are Thomes Creek Water District and Corning Water District.

The Tehama-Colusa Canal provides water to over fifteen districts within Tehama, Glenn, and Colusa counties. Within in the model area, the Glenn-Colusa Irrigation District is largest recipient of water supplied by the Tehama-Colusa Canal.

The Glenn-Colusa Canal provides water to the Glenn-Colusa Irrigation District. It should be noted that the national wildlife refuges located in the GCID also receive water from the Glenn-Colusa Canal.

Water in the Colusa Basin Drain consists of return flow from GCID and other water districts that divert directly from the Sacramento River. GCID and Colusa Basin Water Users Association divert water from the Colusa Basin Drain.

The surface water diversion data is obtained from three different sources: DWR Northern District (*Sacramento Valley Westside Data*, 1970-1992), USBR, and GCID.

Table 3.1 shows the average annual surface water diversions from these sources into the model area.

Table 3.1
Summary of 1970 to 2000 Average Annual Diversions

District	Total Diversion by District	Diversion Amount Applied within SCFIGSM
North Canal		
1 - Orland Unit Water Users Association deliveries from Black Butte Reservoir via North Canal	32100[1,2]	32,100

[4] Davids Engineering Water Balance Model

[5] Estimated based on data provided by Source 3 and following equation:

Diversion from Sacramento River + Tehama-Colusa Canal Delivery - GCID (Supply to Glenn County) - GCID (Delivery to outside model area) = GCID (Deliveries to Colusa County within model area

GROUNDWATER

SOURCES OF RECHARGE

Groundwater elevation in the Stony Creek Fan area are directly affected by the volumes of water that recharges the underlying groundwater basin. Recharge of the model area consists of the following hydrologic components:

- Deep percolation of precipitation and applied water
- Stormflow recharge
- Recharge from unlined agricultural drains
- Recharge from ponded rice fields
- Steam aquifer interactions
- Subsurface inflow from adjacent groundwater basins;

Estimates of these hydrologic components will be developed using the SCFIGSM.

GROUNDWATER OUTFLOW

Groundwater pumping data in the study area is not generally recorded except for special pumping program undertaken by a water purveyor. Annual pumping data from 1994 to 1999 and 2001 were collected from GCID for 107 wells. These wells are located in the areas between the Glenn-Colusa Canal and the Sacramento River. No other records of historic groundwater pumping could be found. It appears that historic groundwater pumping will need to be estimated using applied water demand, surface water deliveries and irrigation efficiencies. Groundwater pumping has varied over time due to variations in climate, land use, and the availability of alternative sources of water.

Urban water supplies in the study area are entirely from the groundwater source. A water duty of 2 acre-feet per acre is used to estimate the groundwater pumping for urban use. This amounts to an average of 19,000 ac-ft. This amount of pumping is insignificant when compared to the groundwater pumping for agricultural use. Agricultural pumping can be estimated as the difference between agricultural water demand and surface water supply. The surface water supply data are measured data. The agricultural water demand is estimated using Consumptive Use of Applied Water (CUAW) methodology. This methodology uses antecedent soil moisture conditions, crop evapotranspiration requirements, rooting depths, crop acreages,

and irrigation efficiency. Preliminary estimates of groundwater pumping using this land-use based methodology and areally averaged rainfall show that the groundwater pumping in the model area are in the vicinity of 400,000 ac-ft to 500,000 ac-ft. These preliminary estimates will be revised as more data analysis is conducted during model development process

The historic knowledge of the groundwater conditions in the study area indicates that there are two groundwater divides (no flow boundary) in the study area: one in the north along Thomes Creek and one in the south along Highway 20. This knowledge has resulted in choosing the model boundary to be Thomes Creek and Highway 20. On the west, the geologic contact provides a no flow boundary. On the east of the model area, it is thought that groundwater flows into the model area from the east.

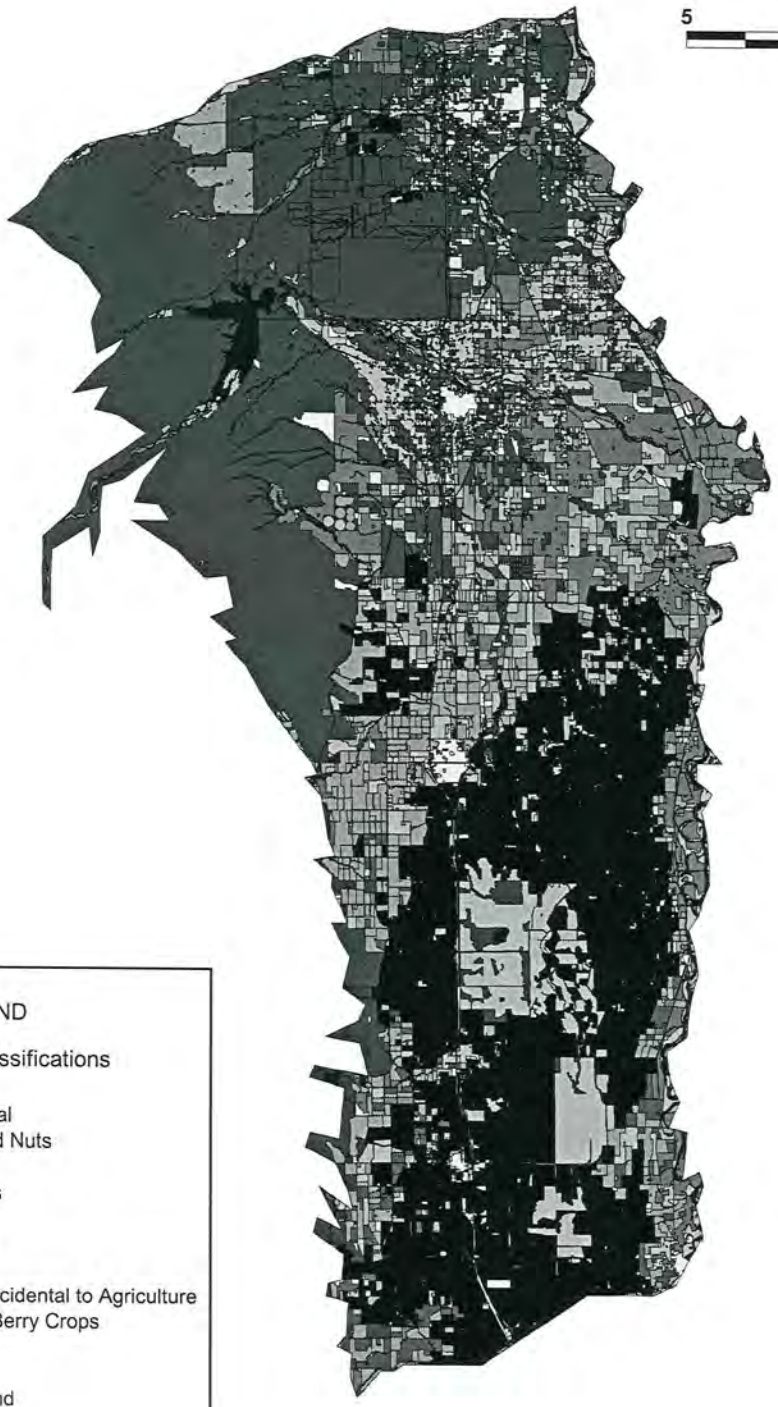
LAND AND WATER USE

LAND USE

Land use data for Glenn, Tehama, and Colusa counties were obtained from DWR in two formats: (a) electronic Arc View shape files for recent years; and (b) hardcopy summary tables by USGS quad sheet. The survey years for each county differ from one another. A composite map of the most recent land use patterns in the study area is developed using the most recent land use surveys and is presented in Figure 3.8.

IRRIGATED CROP ACREAGE DATA

Irrigated crop acreage data for the Glenn, Tehama, and Colusa counties are obtained from several sources, as listed below:



1. U.S. Bureau of Reclamation – CVP Contractors Crop Report;
2. Agricultural Commissioner – Countywide data reported annually;
3. Web Site http://www.nass.usda.gov/ca/bul/agcom/indexcac.htm for Glenn County

The historic land use trends for agricultural, urban, and rice acreage is shown in Figure 3.9.

WATER USE

The primary water use in the model area is for agriculture. Surface water comprises the major source of agricultural water supply. Groundwater is used to (a) supplement additional needs for water; and (b) to irrigate lands that do not receive surface water.

A preliminary data analysis indicates that the total amount of surface water use in the model is in the vicinity of about 1,000,000 ac-ft. It should be noted that these numbers are preliminary and provides general idea about the water use to be utilized in the development of the conceptual model.

SECTION 4 MODELING GOALS AND OBJECTIVES

It is important to consider the modeling goals and objectives during the development of the conceptual model. The choice of the features and capabilities of a model and the level of detail depends on the goals and objectives of the development of the numerical simulation model. In addition, modeling goals and objectives guides the decision regarding the inclusion, exclusion, and simplification of hydrologic processes to be considered in the conceptual model.

MODELING GOALS

The Program Sponsors have identified both common and specific goals for the Stony Creek Fan Conjunctive Water Management Program.

COMMON GOALS OF THE SPONSORS

1. Protect local surface water and groundwater resources consistent with Glenn County ordinances, specifically the Glenn County Groundwater Management Plan BMOs, and State and Federal laws;
2. Pursue opportunities to maximize Program benefits through strategic, synergistic linkages with other regional water management activities and authorities;
3. Secure water supply reliability locally and provide opportunities for improved water supply reliability for water users' elsewhere in the state; and
4. Seek ways to achieve environmental benefits that are compatible with Program operations.

INDIVIDUAL GOALS OF THE SPONSORS

Individual Goals – Orland Unit Water Users' Association

- Enhanced management of surface water resources; and
- Infrastructure improvements

Individual Goals – Orland-Artois Water District

- Secure affordable water supply reliability in all years.

Individual Goals – Glenn-Colusa Irrigation District

- Improved reliability and increased flexibility through integration of basin surface water and groundwater resources.

MODELING OBJECTIVES

In order to meet the above Program goals, it is necessary to develop a thorough understanding of:

- the groundwater basin behavior in the Program area;
- the surface water systems behavior and its interaction with underlying aquifers; and
- the interrelationships among the various operational parameters of the river/reservoir/aquifer systems.

An integrated groundwater and surface water model can be used as an analytical tool to meet the above-mentioned needs. It can also be used to determine the optimal combination of physical and operational parameters that best meet the goals of the Program Sponsors. The model will also be used to assess potential environmental and third party impacts resulting from the proposed conjunctive use Program.

In order to ensure the success of the modeling efforts in meeting the Program goals, it was decided to establish modeling objectives through discussion with key technical and managerial people involved with the Program. Several interviews and meetings were conducted in that regard and objectives, issues, concerns, and questions related to modeling were identified.

The project team members selected three modeling objectives for the Stony Creek Fan Conjunctive Water Management Program. These are:

- To develop for the Stony Creek Fan and the surrounding Glenn County area an analytical tool that can represent the groundwater and surface water flow systems and their interactions.
- To develop a planning level analytical tool that can provide quantitative information on a comparative basis to help answer different questions on the groundwater and surface water system characteristics and to evaluate alternative conjunctive water management strategies.
- To develop a tool that can be used in assessing management strategies consistent with the Program goals and objectives.

The process of selection of these objectives included interviews with the Program sponsors, assessment of the modeling needs through careful analysis of the Program goals and objectives, evaluation of the criteria for meeting the Program goals, and technical sessions among the project team members.

An effort was also made to prioritize the model capabilities and features. However, it was found that almost all of the identified model capabilities and features are needed for the evaluation and analysis of the Program. As a result, no priorities were assigned to any particular model feature.

On the basis of the required model features, Integrated Groundwater Surface water Model (IGSM) was selected as the model to be used for the Stony Creek Conjunctive Water Management Program. Several criteria were used in the model selection process, as listed below:

- A model that can meet the three modeling objectives identified by the Program Sponsors;
- An integrated hydrologic model that can simulate both the surface water and groundwater systems and their interactions;
- A model that has reservoir operations simulation capabilities;
- A model that has the built-in capability to evaluate conjunctive water management programs without development of additional elaborate program modules;
- A model that has most of the required features identified by the Program Sponsors;
- A model that can be easily modified to accommodate relevant features that may be needed for a Conjunctive Water Management Program;
- A non-proprietary model;
- A model that has a history of successful applications in California;
- A model that has the capability to share/exchange data with the regional groundwater model of the Central Valley (e.g. CVGSM - Central Valley Groundwater Surface Water Model) for boundary conditions generation;
- A model that has the capability to share/exchange data with the regional/statewide reservoir operations model, such as CALSIM, DWRSIM, and PROSIM; and

- A model that can be developed for the Program in a timely and cost effective manner.

The IGSM meets all of the above selection criteria. In addition, both the DWR staff and the project team members are familiar with the IGSM, which will ensure successful model application in a timely and cost effective manner.

DRAFT

SECTION 5 CONCEPTUAL MODEL

The purpose of building a conceptual model is to simplify the modeling problem and organize the relevant field data and information so that the hydrogeologic system can be analyzed (Anderson and Woessner, 1992).

There are three key steps in developing a conceptual model, such as:

- Conceptual description of modeling of hydrologic processes;
- Delineation of hydrostratigraphic units and model grid; and
- Definition of flow systems and boundary conditions.

The conceptual model for the Stony Creek Fan Integrated Groundwater Surface water Model (SCFIGSM) is described below.

CONCEPTUAL DESCRIPTION OF MODELING OF HYDROLOGIC PROCESSES

In IGSM, the hydrologic system is divided into four major subsystems as shown in Figure 5.1. These are:

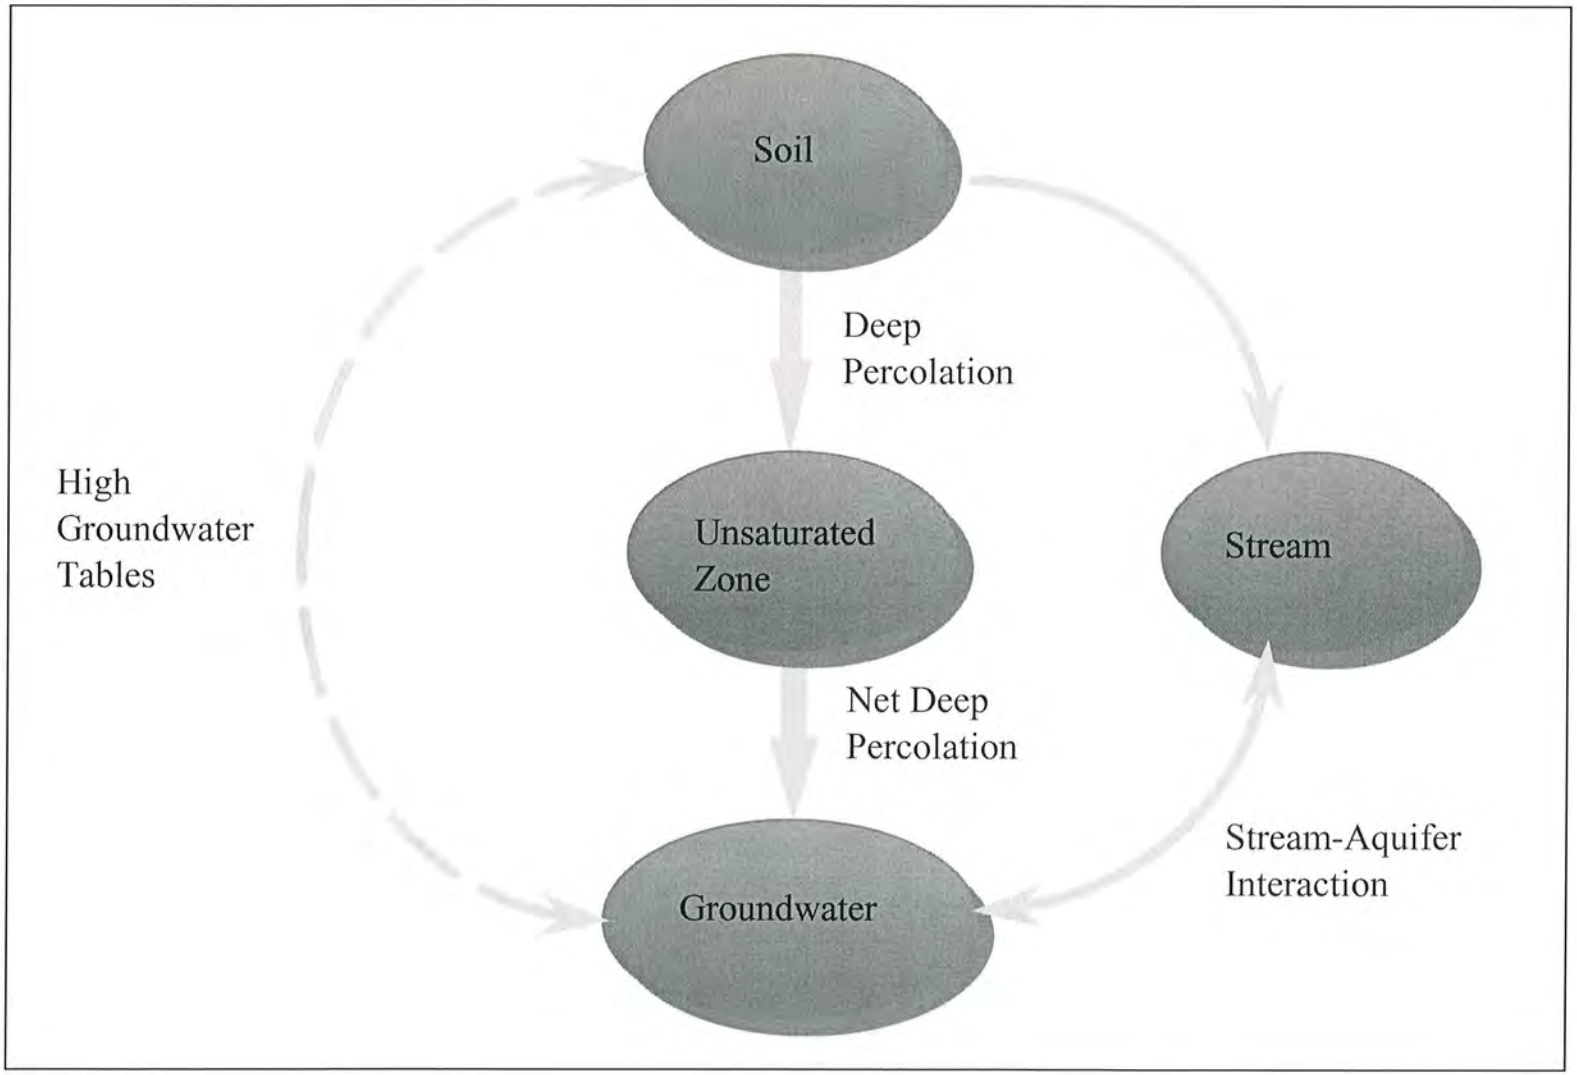
- Soil Zone;
- Stream System
- Unsaturated Zone;
- Groundwater Zone.

The hydrologic components of these physical subsystems that are considered in IGSM are shown in Figure 5.2.

SOIL ZONE

The SCFIGSM will simulate soil zone processes including evapotranspiration, direct runoff, infiltration, and deep percolation from rainfall and applied water. The computations will be performed at a finer geographical scale represented by finite element discretization. Evapotranspiration from the soil surface is computed on the basis of crop consumptive use requirement and available soil moisture. Direct runoff from rainfall and applied water is computed by using a modified Soil Conservation Service (SCS) runoff curve number method.

Figure 5.1
Hydrologic System Interactions



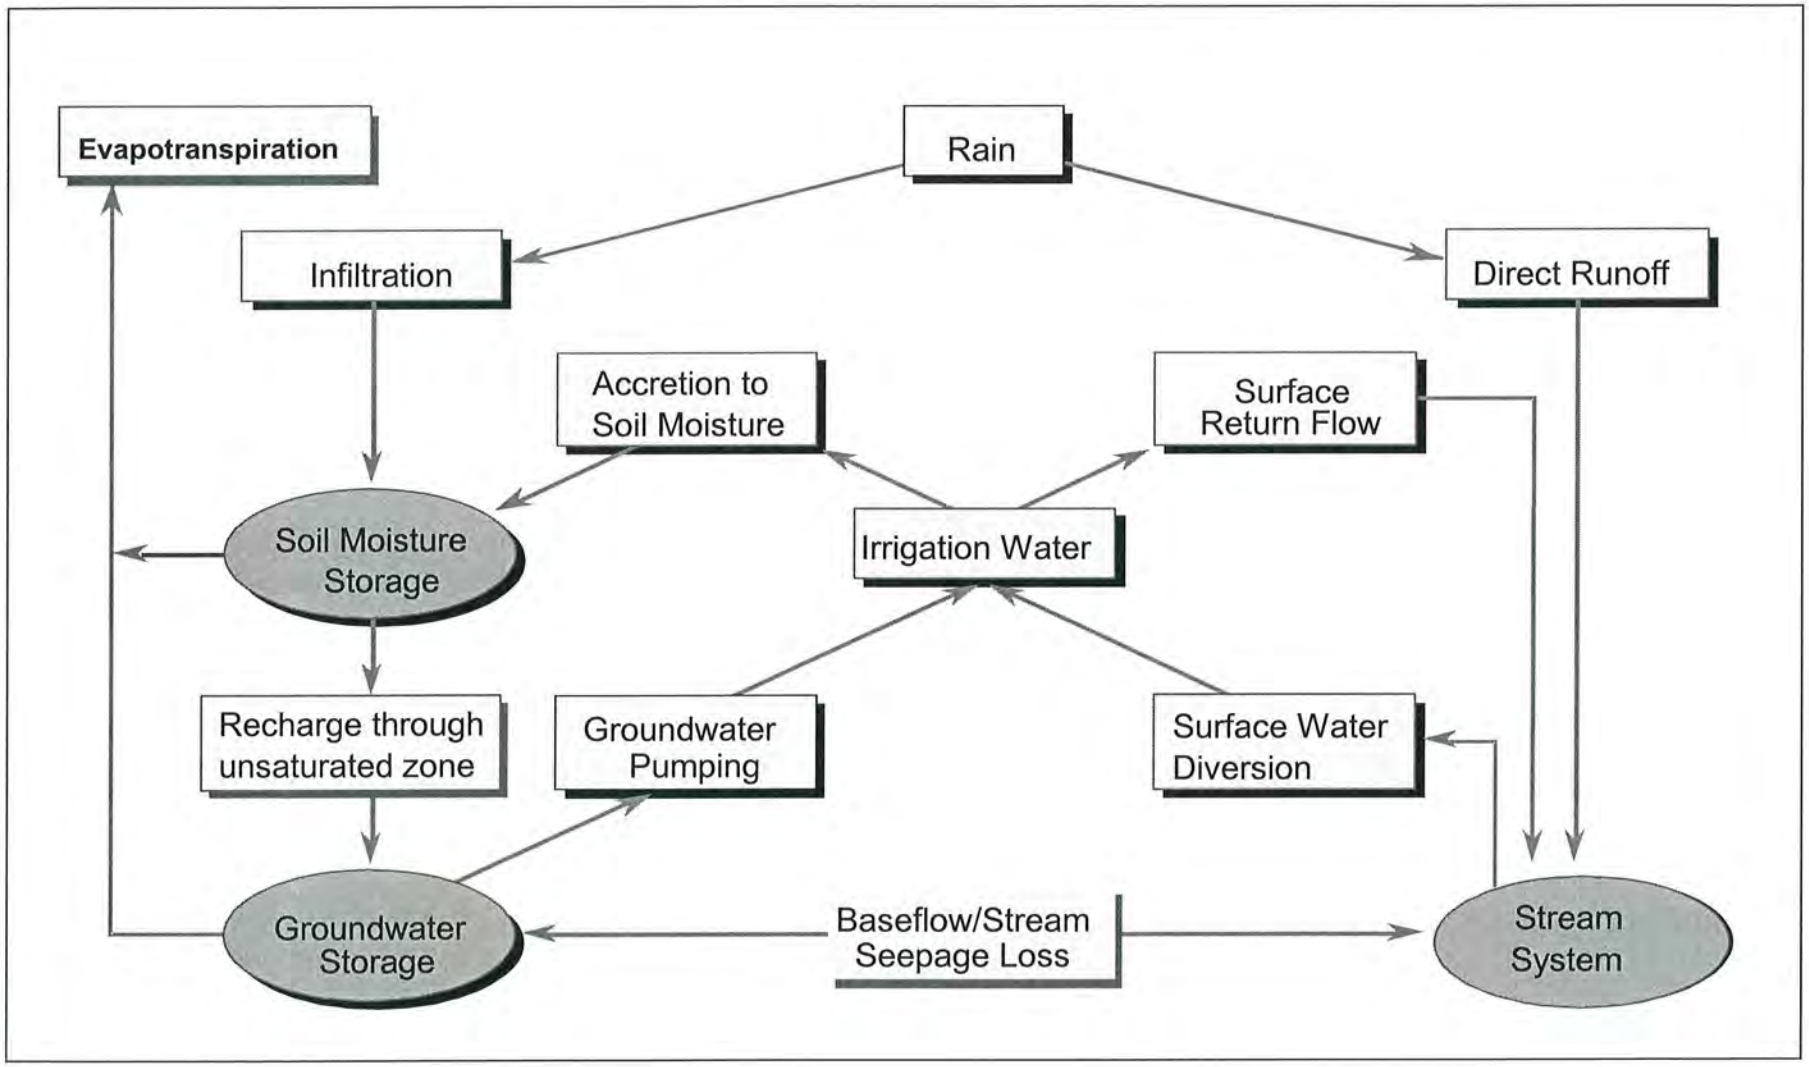


Figure 5.2
Hydrologic Components

The computed runoff from each finite element is routed to the appropriate stream node. Percolation of precipitation and applied water is added to the unsaturated zone that underlies the soil zone.

Input data for soil zone simulation includes initial soil moisture; rainfall; land use history; SCS hydrologic soil group and; minimum soil moisture requirements for:

- crop growth;
- crop consumptive use;
- root zone depth for each crop;
- surface drainage pattern; etc.

Parameter data for this submodel includes:

- SCS curve number;
- field capacity; and
- soil infiltration rate.

STREAM SYSTEM

The water balance equation is solved for each stream element to simulate streamflow in SCFIGSM. The stream elements are a series of 1-dimensional line elements that are used to describe the stream system within the model area. Each stream element is defined by two consecutive stream nodes that are coincident with the aquifer nodes. Components of water balance in a stream element of SCFIGSM are:

- inflow at upstream node of the stream element;
- direct runoff (lateral inflow);
- surface water diversions;
- wastewater discharge;
- agricultural return flow; and
- gain or loss due to interaction with the underlying aquifer.

The gain or loss due to stream aquifer interaction is computed by using mathematical equations that are based on water levels in the stream and underlying aquifer. The depth of water in the

stream is computed using stage-discharge relationships at the corresponding stream node. The solution of the water balance equation in this manner provides the downstream outflow for a stream element. This outflow is used as the upstream inflow for the stream element that is downstream of the current stream element.

The input data for the stream system simulation includes:

- stream configuration;
- stream node elevation;
- cross-section;
- stage-discharge relationship;
- stream inflows at boundary;
- tributary inflows;
- wastewater discharges to streams; and
- streamflow diversions.

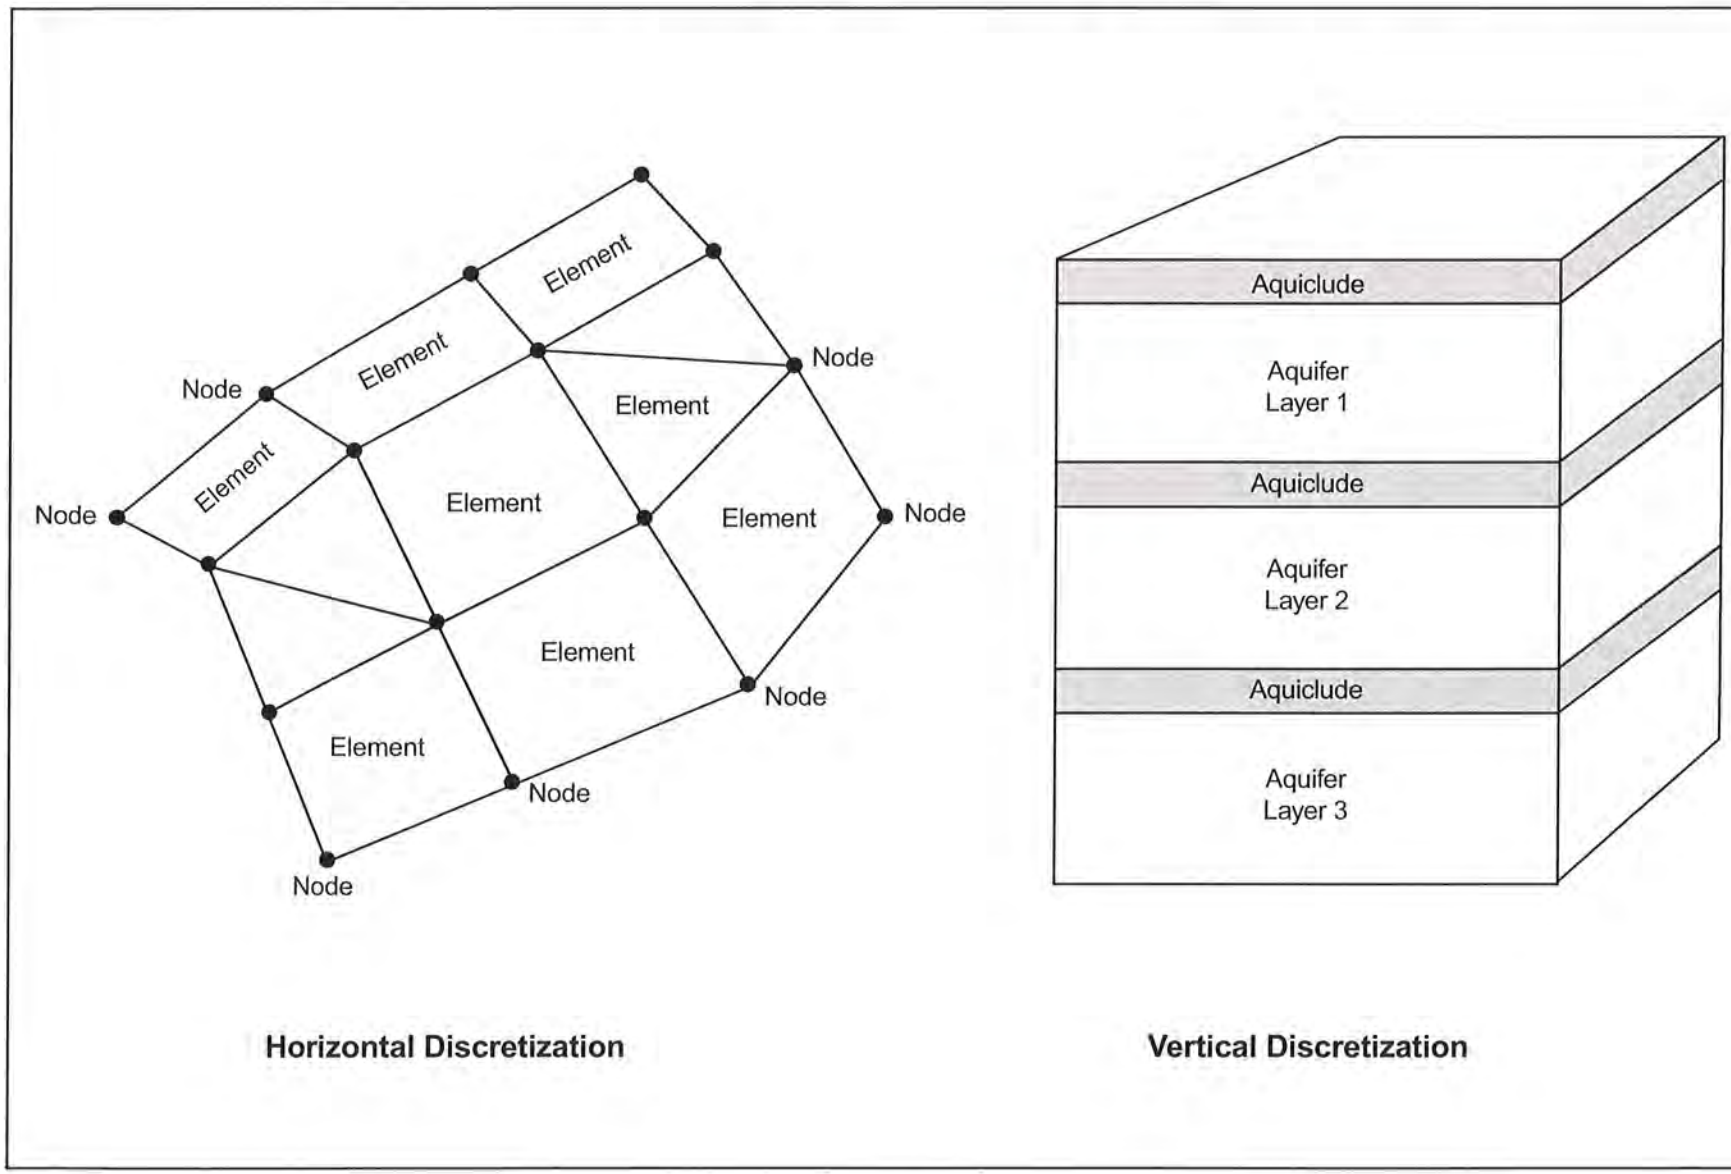
The parameter data for this submodel includes hydraulic conductivity and thickness of the streambed.

VADOSE ZONE SIMULATION

Water that percolates down from the soil zone travels through the vadose zone as unsaturated flow and eventually reaches the saturated groundwater zone. The mathematical equation of unsaturated flow is solved numerically at every time step. The vadose zone is divided into a number of discrete layers of specified thickness. The one-dimensional vertical flow equation is solved layer by layer on a nodal basis. The number of vadose zone layers at any node at any time is determined by the depth to groundwater at the corresponding node. The deep percolation of applied water and precipitation that passes through the soil zone becomes the inflow to the uppermost vadose zone layer. Outflow from the overlying layer becomes inflow to the layer beneath, and so on. The outflow from the last vadose zone layer becomes inflow to the saturated groundwater zone. The effect of the rise and fall of the water table is incorporated into this submodel by keeping track of depth to groundwater and vadose zone moisture content. SCFIGSM vadose zone simulation is capable of simulating perched water table conditions resulting from the presence of low permeability zones.

The input data for vadose zone simulation includes thickness of vadose zone layers, vertical hydraulic conductivity and effective porosity.

GROUNDWATER ZONE



Saturated groundwater flow is simulated in SCFIGSM by solving the governing groundwater flow equation by the Galerkin finite element technique. The model flow domain has been broken down horizontally into a collection of small polygonal areas. These areas are called finite elements and they can be either three-sided or four-sided polygons. The vertices of these elements are called nodes. The network of finite elements and nodes is called a model grid. The groundwater flow domain has been broken down vertically into three discrete layers that represent the underlying groundwater aquifers. These aquifers are separated by aquicludes. A conceptual representation of horizontal and vertical discretization of the flow domain is presented in Figure 5.3.

Aquicludes limit the vertical movement of water, and are generally composed of low hydraulic conductivity materials such as silt and clay; or interbedded sequences where the hydraulic conductivity is governed by silt and clay. The aquifers are primarily composed of materials with relatively high conductivity. The predominant flow paths in groundwater aquifers are horizontal. The horizontal flow system is simulated by solving a two-dimensional groundwater flow equation. The governing differential equation is converted into a set of algebraic equations defined at the finite element nodes. This set of algebraic equations is then solved by using a matrix iterative technique until a specified convergence criterion is satisfied. The vertical flow system is simulated by solving a leakage equation based on the groundwater elevations in two adjacent aquifers.

The input data for groundwater flow simulation includes:

- well location;
- well diameter and perforation interval of wells;
- monthly pumping;
- boundary conditions at boundary nodes;
- initial groundwater elevations;
- aquifer and aquiclude thickness at each node;
- hydraulic conductivity of aquifer and aquiclude material;
- specific yield;

Figure 5.3
Horizontal and Vertical Discretization of Groundwater Flow

- specific storage; and
- leakance.

HYDROLOGIC WATER BALANCE

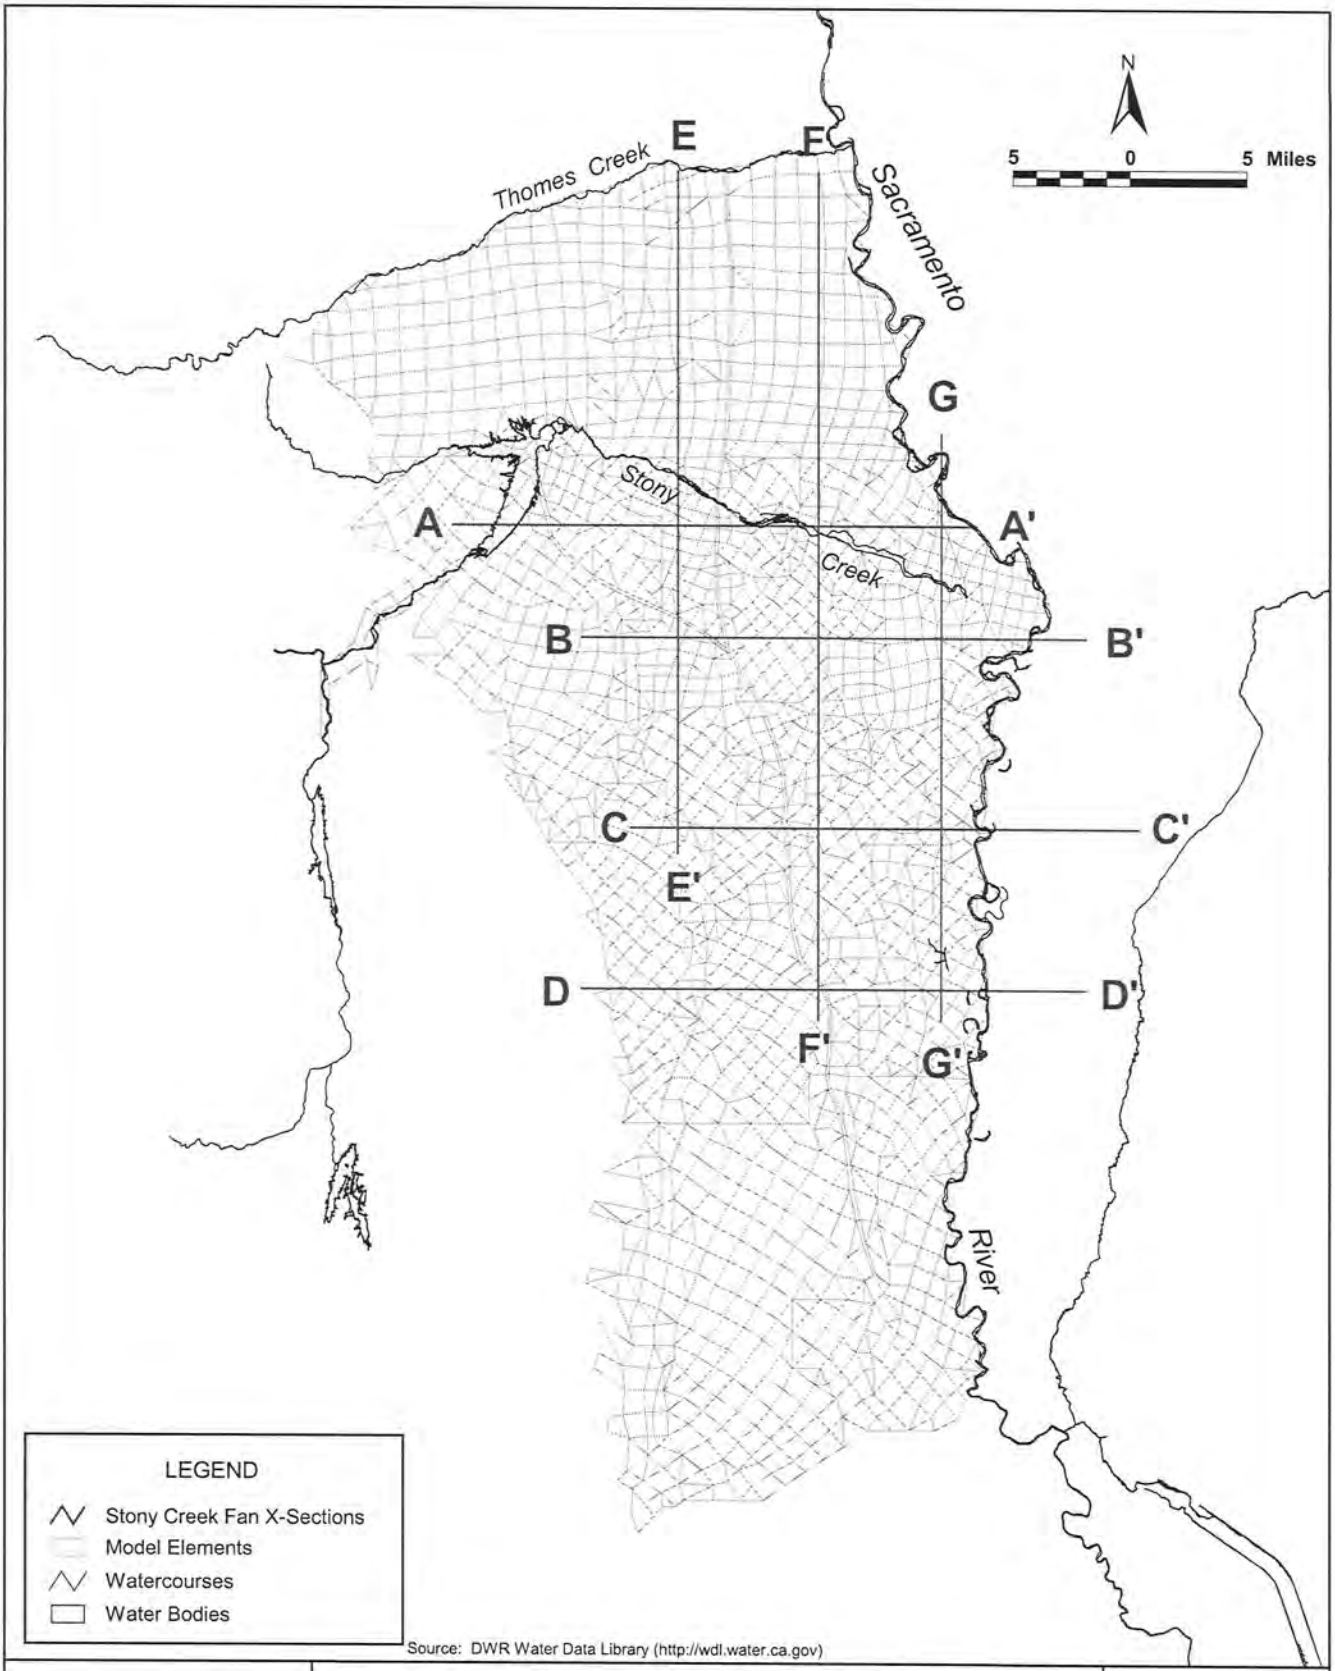
The primary purpose of all hydrologic modeling is to solve the water balance equation of the selected model area or watershed. The model area can be hydrologically defined, such as a watershed or drainage basin; it can also be politically or arbitrarily defined, such as water district, county, or a plot of land. Regardless of the geographic scale or time period of simulation, water balance equation should be developed as the first step of modeling to identify the appropriate components of the hydrologic cycle for a specific model area. The defining criterion for a model's reliability is how well it incorporates water balance equation for the modeled hydrologic subsystem. A model that does not explicitly generate output showing water budget at appropriate temporal and spatial scale should be used with extreme caution.

The IGSM is a unique hydrologic model that places significant emphasis on hydrologic water balance. An estimate of the net inflow of the Stony Creek Fan IGSM area can be made by summing up the appropriate hydrologic components of the physical system being modeled. This estimate is intended to ensure that the model is properly representing the key hydrologic components of the groundwater basin. As discussed above, SCFIGSM tracks the movement of all of the primary sources of water coming into and leaving the basin, including rainfall, streamflows, applied water, consumptive use, and subsurface inflows and outflows.

The model outputs are reviewed and refined during the model calibration to ensure that the primary sources of inflows and outflows in the different physical subsystems (e.g. soil zone, groundwater subsystem, stream subsystem) of the model are represented properly. This includes annual and monthly water budgets for groundwater, streamflow, soil moisture, and land and water use for the entire model area and for selected model subareas. The key components for each of these water budgets are listed in the Table 5.1 below.

Table 5.1 Water Budget Components

Budget	Components					
Groundwater	Deep Percolation	Stream Recharge	Boundary Flows	Pumping	Overdraft	
Streamflow	Upstream Flow	Rainfall Runoff	Gain from Groundwater	Diversions	Return Flows	Downstream Flow
Soil Moisture	Rainfall	Irrigation	Evapo-transpiration	Direct Runoff	Percolation	Return Flow
Water Use	Agricultural Use	Urban Use	Pumping	Diversions	Imports	Shortages



Model Simulation Period

The study period for the SCFIGSM is the 31-year period representing water years 1970 to 2000 (October 1969 to September 2000). This recent period was chosen in part because there is a relatively good set of land and water use data as well as hydrologic data such as rainfall, streamflow, and groundwater levels. This period also includes two historic drought events, 1976-1977 and 1989-1992, and two historic flood events, 1983 and 1986. This time period also includes the introduction of significant quantities of surface water to the area. This simulation period is assumed to be adequate for developing and calibrating a hydrologic model like IGSM.

The SCFIGSM will analyze the hydrologic water balance on an annual basis for this 31 years of model simulation period.

DELINEATION OF HYDROSTRATIGRAPHY

The geologic information described in Section 2 was used in conjunction with the recent geologic mapping by the DWR and well construction logs to define the hydrostratigraphic units of the SCFIGSM. Hydrostratigraphic units comprise geologic units of similar hydrogeologic characteristics and properties. Several geologic formations may be combined into one hydrostratigraphic unit or a geologic formation may be subdivided into aquifer and confining units. Seven hydrostratigraphic cross-sections from the DWR's unpublished recent geologic mapping effort were used as anchor points for developing the detail stratigraphic definition of the entire model area. These sections are shown in Figure 5.4. The number and location of these sections were selected based on the location of lithologic and geophysical data, and for stratigraphic coverage of the entire model area.

STONY CREEK FAN CONJUNCTIVE WATER MANAGEMENT PROGRAM

DWR Geologic Cross Sections Used in Stratigraphic Analysis

DRAFT

MARCH 2003

FIGURE 5.4

In developing hydrostratigraphic sections, ground surface elevations were obtained from the U.S. Geologic Survey Digital Elevation Model (DEM) database. The base of the aquifer system is considered to be the base of the freshwater-bearing deposits obtained from recent geologic mapping by the DWR and the past reports published by USGS.

The conceptual model is developed with four hydrostratigraphic units as presented in Figure 5.5, and summarized on Table 5.2.

SCFIGSM Layer 1

The conceptual model for SCFIGSM Layer 1 includes Pleistocene and Holocene deposits consisting of Holocene alluvium, alluvial fan, flood plain, and basin deposits, and the Pleistocene Modesto and Riverbank Formations. The highly permeable sands and gravels of Pleistocene Modesto and Riverbank Formations are only present on the Stony Creek Fan. Where Layer 1 is present throughout the model area it is exposed at the ground surface, and represents the unconfined groundwater system. Wells perforated in this layer are likely used for domestic and some agricultural water supplies.

The highly permeable sands and gravels are 50 to 80 feet thick within the Stony Creek Fan. They are not present outside the Stony Creek Fan. On the Fan, some of the highly permeable deposits are underlain by up to 50 feet of finer-grained alluvial or basin deposits. Outside the Fan, alluvial and basin deposits can reach a total thickness of 200 feet. The conceptual model stratigraphy was developed to reflect the significant difference in the characteristics of the Fan material and the other alluvial deposits present within the model area.

Inside the Fan Area

Inside the Stony Creek Fan Area, SCFIGSM Layer 1 represents the 50 to 80 foot thick highly permeable sand and gravel deposits. Any alluvial or basin deposits that may be present beneath the sands and gravels are included in Layer 2.

Outside the Fan Area

Outside the Stony Creek Fan Area, SCFIGSM Layer 1 represents the upper 80-foot thickness of the basin and alluvial deposits. Any remaining basin or alluvial deposits are considered part of SCFIGSM Layer 2.

Figure 5.5
Conceptual Model Stratigraphy

Layer 2		greater than 80 feet 2	2 ●		
Layer 3				3 ●	
Layer 4					4 ●

■ Designates the composition of each layer in the current model using Layer 1 = 50-80 feet thick where Layer 1 is defined by the hydrogeologic properties of the material.

● Designates the composition of each layer in the alternate model which would follow the geologic cross sections exactly and classifly Layer 1 as all Quaternary alluvial deposits.

SCFIGSM Layer 2

The conceptual model for SCFIGSM Layer 2 consists primarily of the Tehama Formation (described in Section 3). The widespread distribution and thickness allow this formation to supply water to many of the agricultural wells in the study area. The Tehama Formation is present throughout the model area ranging in thickness from about 200 feet to over 2,000 feet. Model Layer 2 thickens from west to east about halfway across the model area. Model Layer 2 thins rapidly where Model Layer 3 is present (Table 5.2). As mentioned above, for modeling purposes, Layer 2 does include some basin and alluvial deposits.

Model Layer 2 generally represents groundwater systems ranging from semi-confined to confined conditions. Confinement generally increases with depth, but the actual level of confinement may vary locally due to other conditions, such as continuously perforated wells connecting different aquifer layers. Model Layer 2 is exposed at the ground surface in the northwestern portion of the model area.

SCFIGSM Layer 3

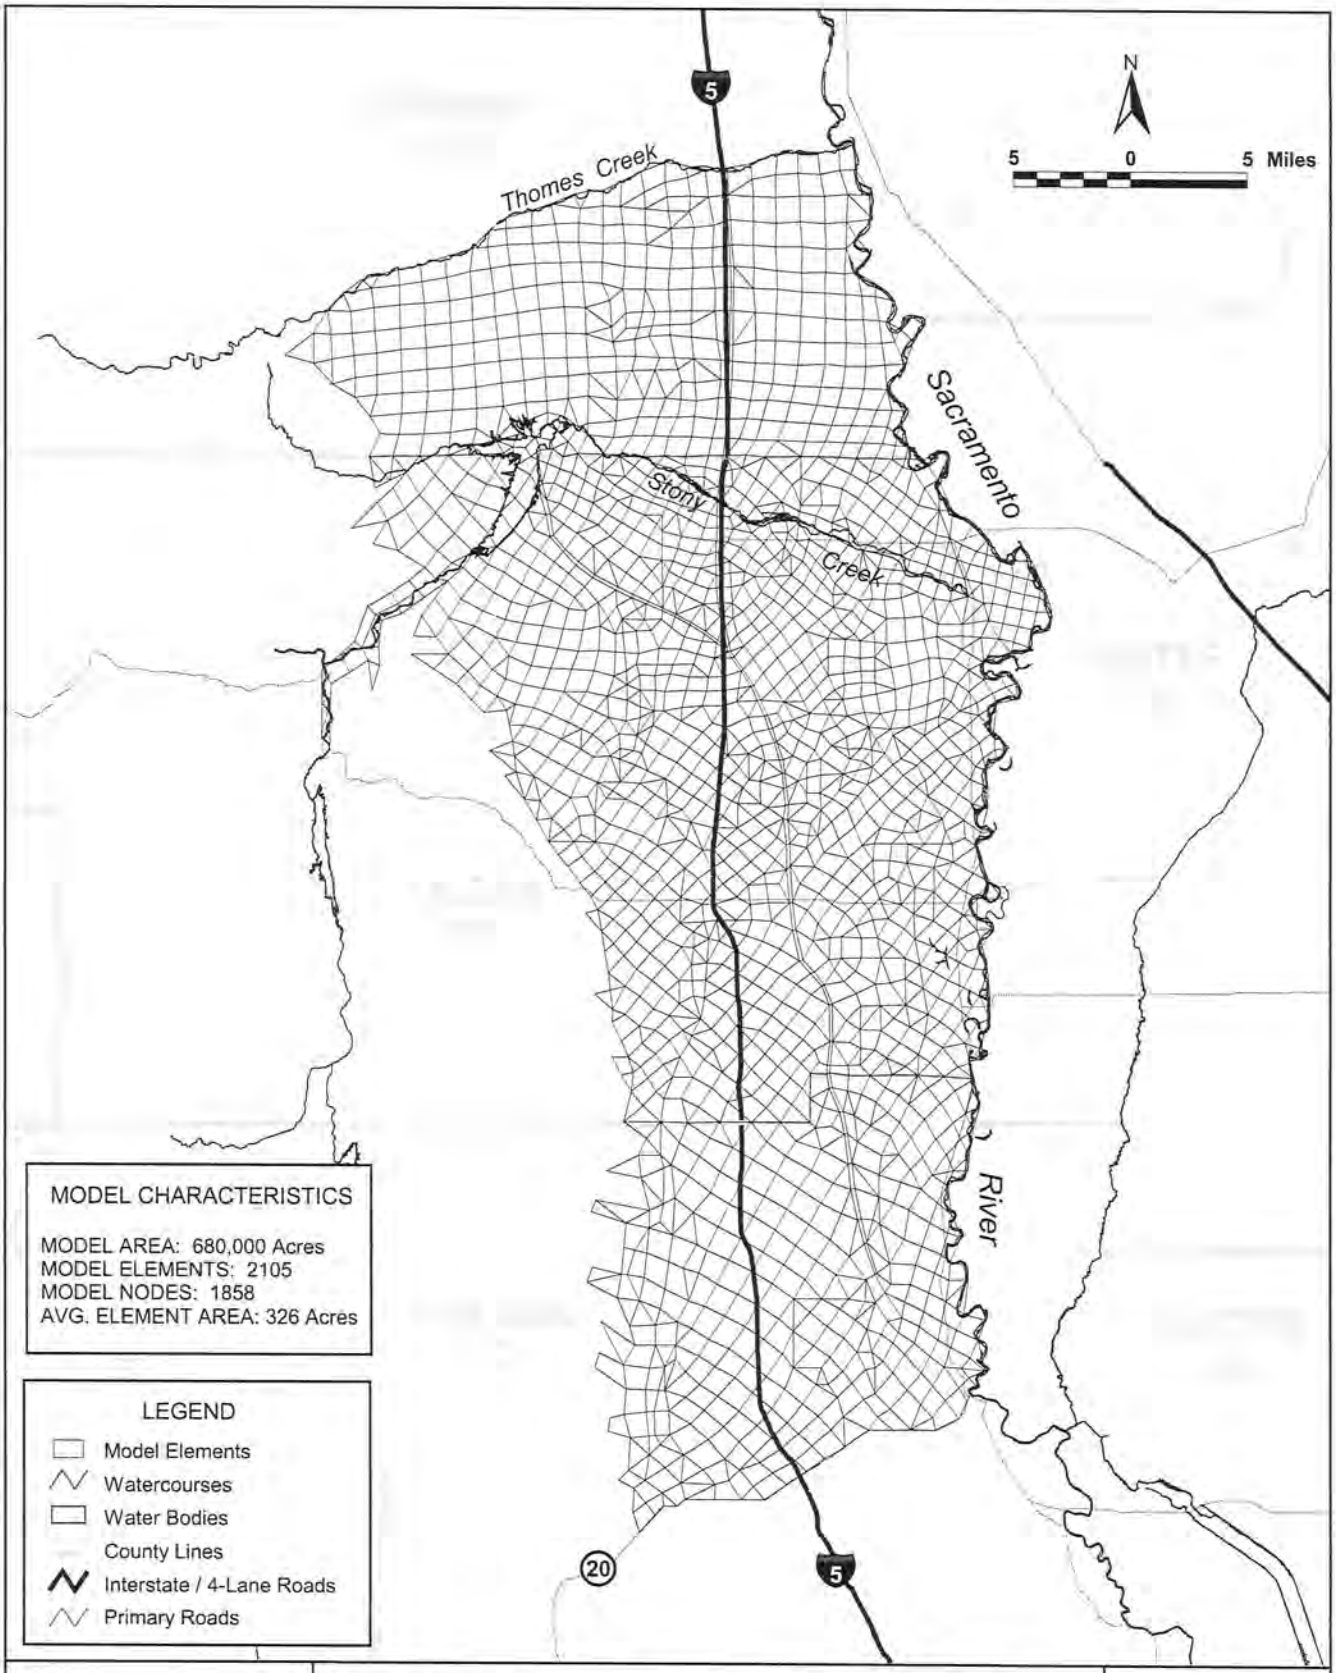
The conceptual model for SCFIGSM Layer 3 consists of the Upper Tuscan Formation (described in Section 3). Model Layer 3 is present throughout the eastern portion of the model area (Figure 5.5). Although this layer contains coarse grained sandstone and conglomerate lenses within the study area, this layer predominantly consists of fine-grained lahar deposits, so groundwater within Layer 3 represents confined aquifer conditions. Because of its overall low permeability, few wells in the model area rely on Layer 3 for groundwater supply.

SCFIGSM Layer 4

The conceptual model for SCGIGSM Layer 4 consists of the Lower Tuscan (described in Section 3). Model Layer 4 is present throughout the eastern portion of the model area (Figure 5.5). In contrast to Layer 3, it is composed of more permeable volcanic conglomerate, sandstone, and siltstone layers interbedded with lahars. It is overlain by the Upper Tuscan Formation (Layer 3), which acts as a confining layer; as a result, groundwater within Layer 4 represents confined aquifer conditions. At this time, few production wells in the model area reach Layer 4, so it currently has little groundwater production and water level data.

BASE OF THE AQUIFER SYSTEM

The base of the aquifer system is considered to be the base of the freshwater-bearing deposits (Figure 5.5). The base of the aquifer system is represented by the base of Model Layer 2 (base of the Tehama Formation) in the western half of the model area. The base of the aquifer system is represented by the base of Model Layer 4 (base of the Lower Tuscan Formation) in the eastern half of the model area.



The base of freshwater is mapped in the model area on the basis of available electronic log data. In some locations the base of freshwater is identified to exist within the lower portions of the Tehama Formation or Tuscan Formation (Figure 5.5**Error! Bookmark not defined.**). The base of freshwater is not considered as a boundary between model layers because it is not a fixed location (such as the base of a formation).

SCFIGSM GRID

A two-dimensional finite element grid network was developed to model the groundwater flow in the Stony Creek Fan Area. The entire model area consists of about 1,060 square miles. The SCFIGSM model grid (shown in Figure 5.6) was divided into 2,105 elements and 1,858 model nodes. The average size of single element is about one-half square mile (316 acres). Notable features of the model grid are:

- Model boundary matches the hydrologic and hydrogeologic boundaries of the Stony Creek Fan Area;
- Grid orientation follows the regional groundwater streamlines;
- Elements are smaller in the vicinity of steep groundwater gradients; and
- Thin strips of elements are used to incorporate the discontinuities in the groundwater levels across major geologic faults and barriers.

The model grid is defined by Universal Transverse Mercator (UTM) coordinates at each model node and be the list of connecting nodes for each model element. The x-y coordinates for each model node were obtained from Geographic Information System (GIS) coverage of the model area in UTM Zone 10.5. The list of connecting nodes for each element was developed after numbering the model nodes and model elements. Two independent sets of sequential numbers were used for nodes and elements. These node and element numbers are used in specifying model input data.

STONY CREEK FAN CONJUNCTIVE WATER MANAGEMENT PROGRAM

Model Grid

DRAFT

MARCH 2003

FIGURE 5.6

The SCFIGSM grid was developed to reflect local conditions including:

- Geologic and Hydrogeologic Considerations,
- Hydrologic Considerations, and
- Potential Water Management Project Areas.

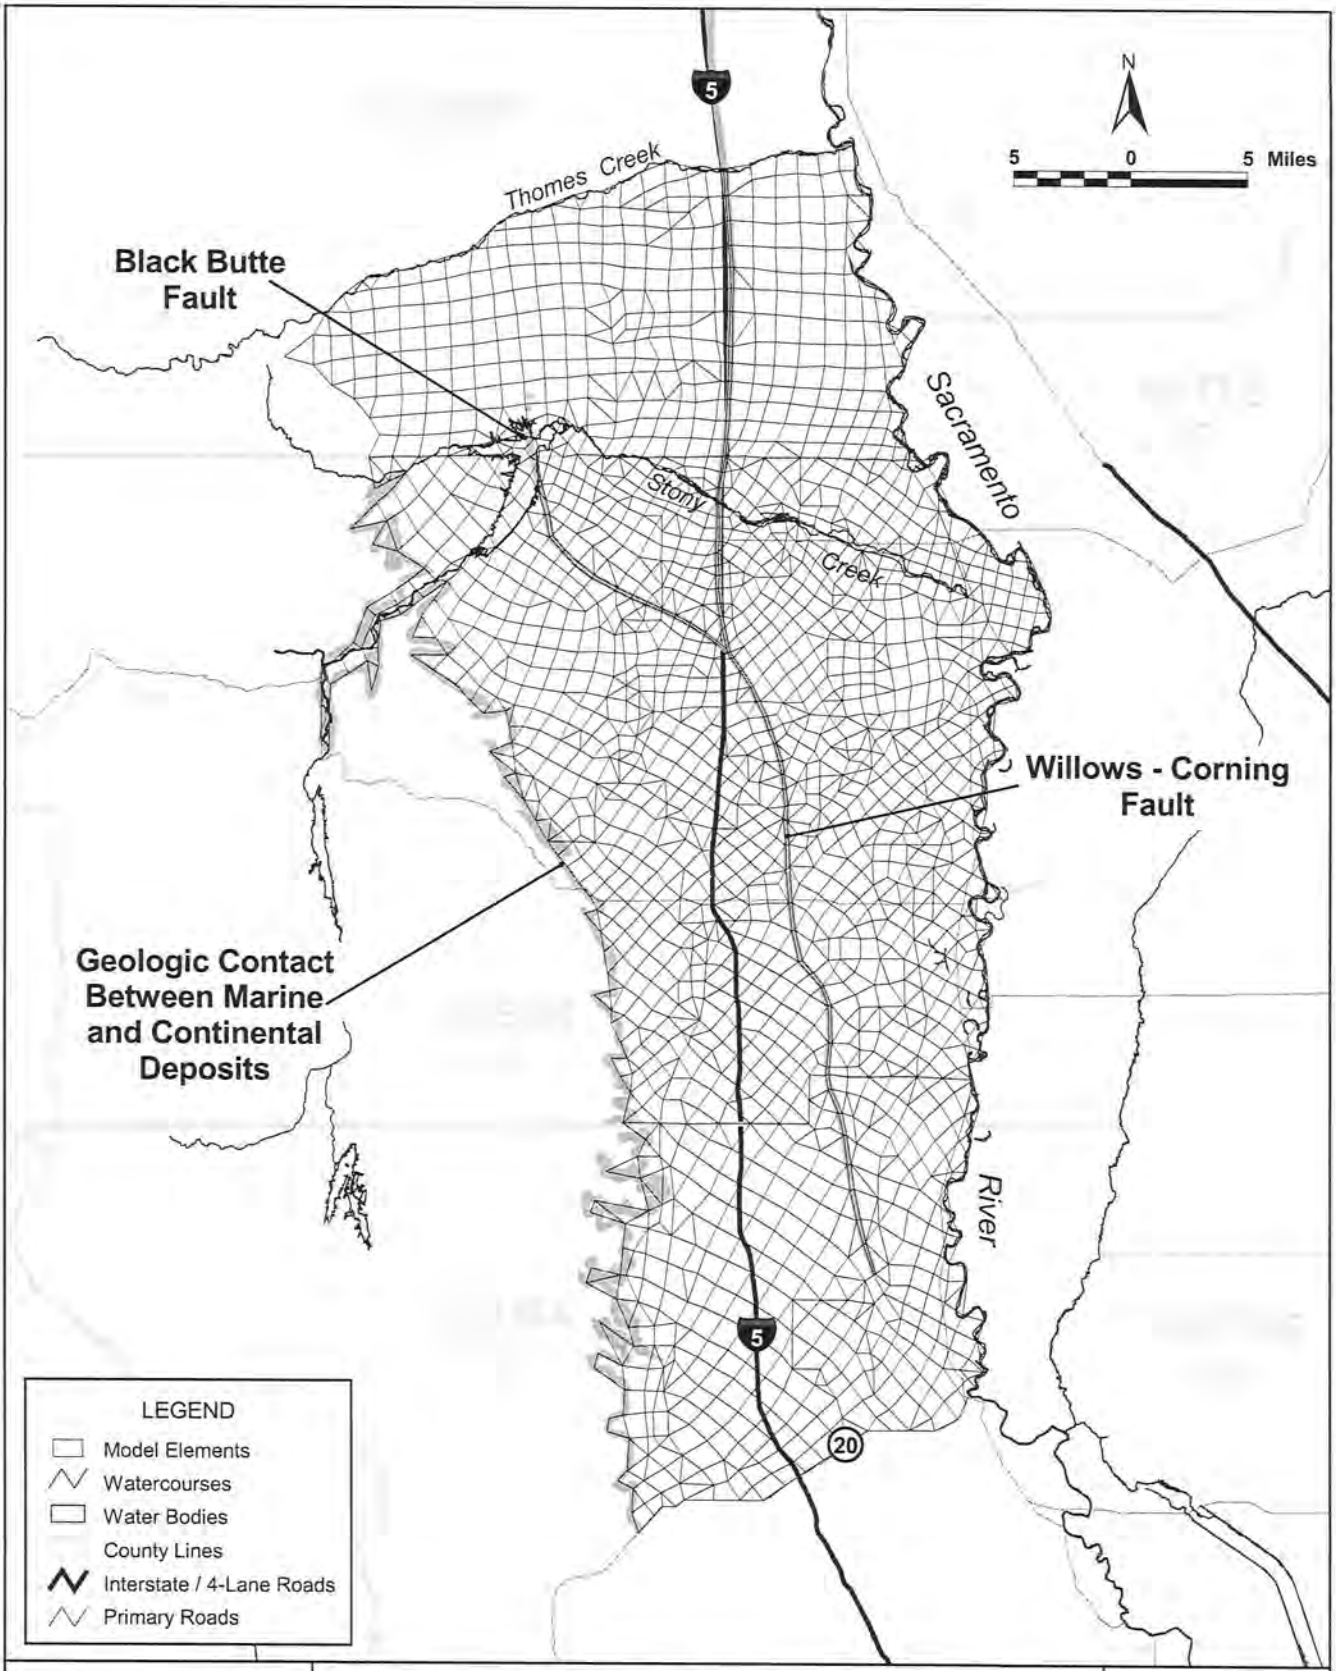
Each of these considerations is described below.

GEOLOGIC AND HYDROGEOLOGIC CONSIDERATIONS

The geologic and hydrogeologic information presented in Section 3 was considered during the SCFIGSM model grid development. These include:

- Geologic Contacts,
- Faults, and
- Groundwater Flow Direction.

Geologic Contacts



The western boundary of the SCFIGSM grid was defined as the contact between the marine basement rocks of the Coast Range and the continental and alluvial deposits of the Central Valley.

Faults

The SCFIGSM model grid was developed to reflect those faults that either may affect the flow of groundwater, or result in an abrupt change in the aquifer thickness. The SCFIGSM model grid reflects existence of faults by a narrow band of elements along the trace of the fault. After several discussions with DWR, the two faults incorporated into the model grid include the Black Butte Fault and the Willows-Corning Fault. The locations of these faults are shown in Figure 5.7.

Groundwater Flow Direction

The long-term regional groundwater flow directions were considered in the SCFIGSM grid development. Near the Stony Creek Fan, the regional groundwater flow direction is from the fan's apex to the distal portions of the fan generally in the northwest to southeast direction.

STONY CREEK FAN CONJUNCTIVE WATER MANAGEMENT PROGRAM

Geologic and Hydrogeologic Considerations

DRAFT

MARCH 2003

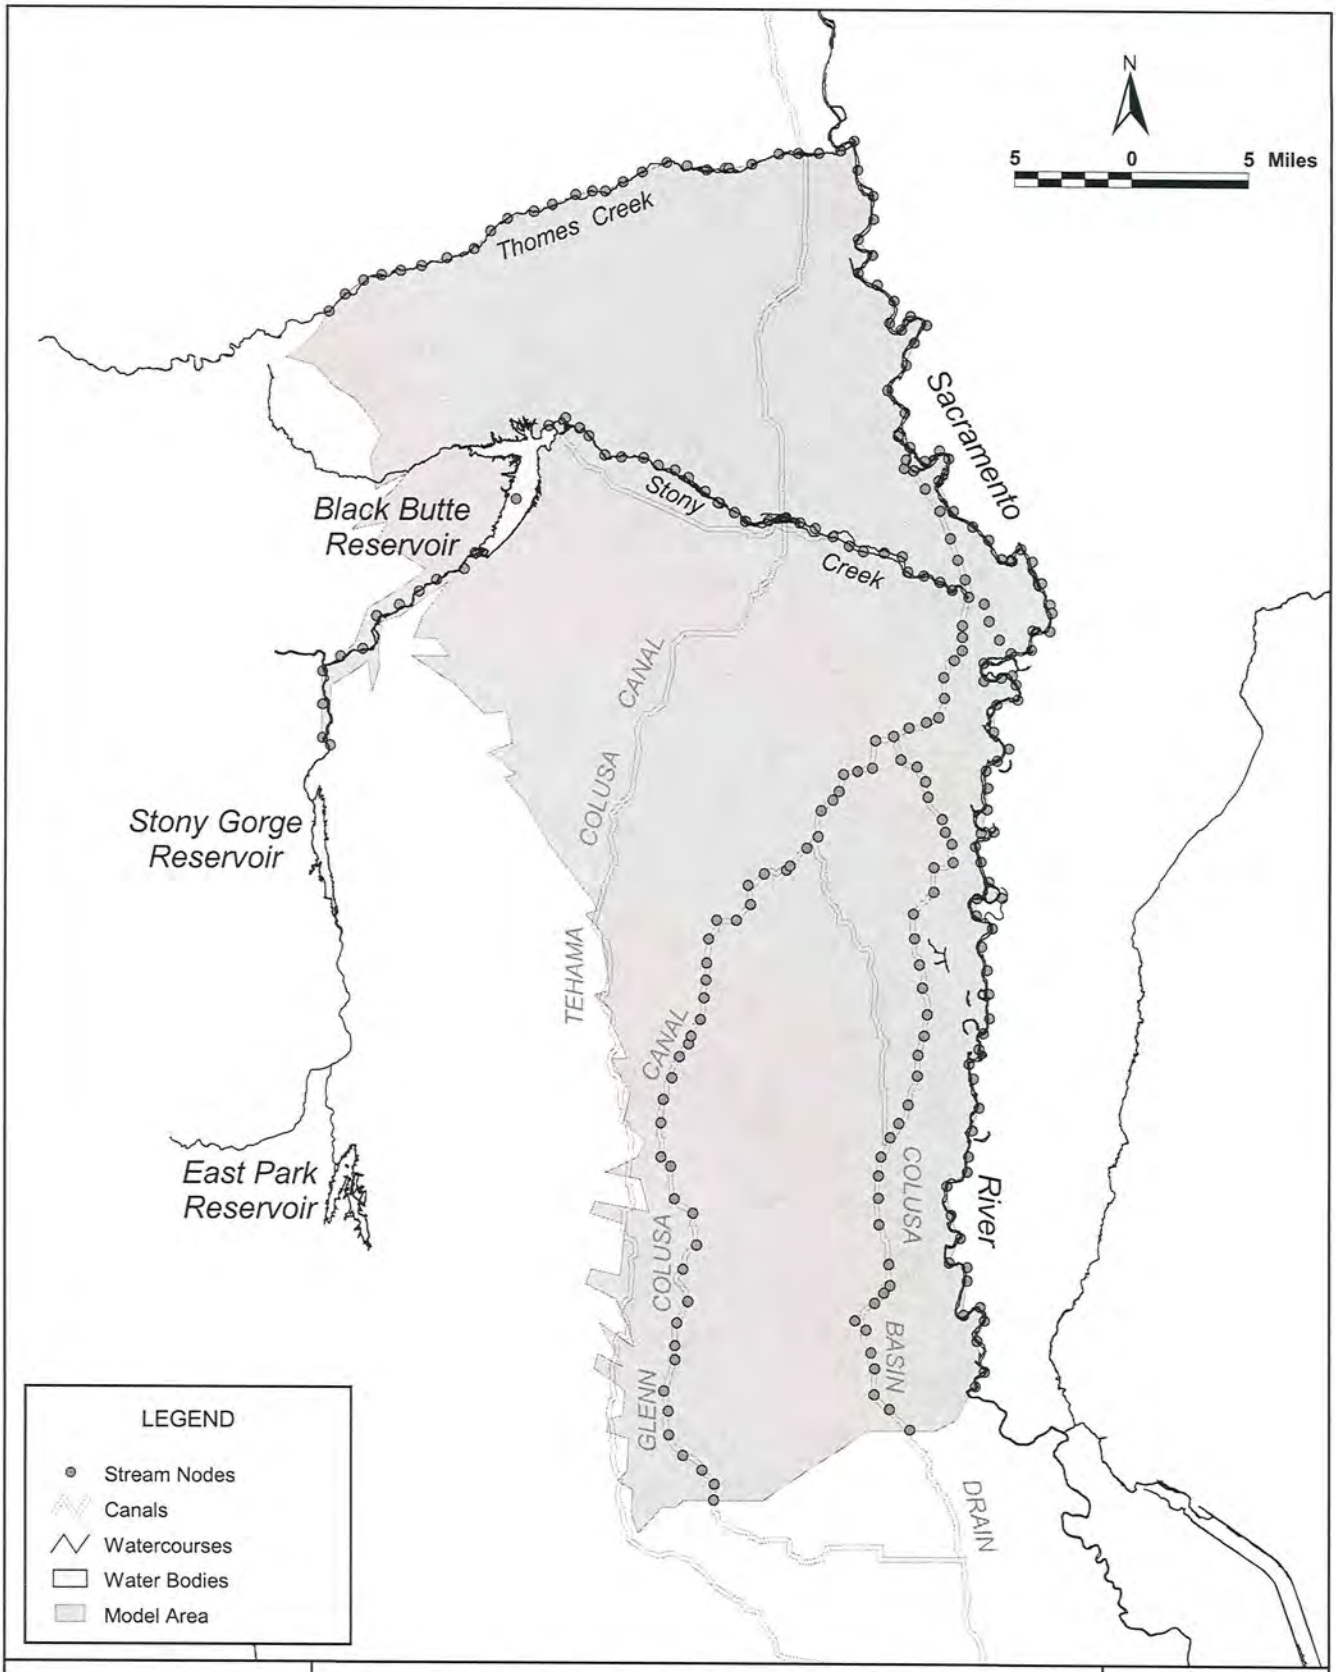
FIGURE 5.7

North and South of the Stony Creek Fan groundwater generally flows from the upland areas in the west towards the Sacramento River near the center of the Valley.

HYDROLOGIC CONSIDERATIONS

The surface water flow system is modeled by using 1-dimensional line elements along the stream courses. These line elements are defined by stream nodes that are coincident with the aquifer nodes. An independent numbering system is used to number the stream nodes. There are 266 stream nodes representing the surface water flow system in the SCFIGSM. This includes rivers, creeks, and lakes as well as major leaky water delivery canals and drains. Figure 5.8**Error! Bookmark not defined.** shows the locations of the hydrologic features simulated in the SCFIGSM model area, such as:

- Rivers and Creeks,
- Lakes, and
- Canals and Drains.



Rivers and Creeks

There are three rivers and creeks simulated in the SCFIGSM: Thomes Creek, Sacramento River, and Stony Creek.

- **Thomes Creek** coincides with the northern boundary of the SCFIGSM, and is simulated along the stream nodes shown in Figure 5.8**Error! Bookmark not defined.**.
- **The Sacramento River** coincides with the eastern boundary of the SCFIGSM, and is simulated along the stream nodes shown in Figure 5.8.
- **Stony Creek** is located within the SCFIGSM model area. It is simulated both above and below Black Butte Reservoir along the stream nodes shown in Figure 5.8.

Lakes

Black Butte Lake is located entirely within the SCFIGSM model area. The model grid was developed to represent the maximum inundation area of Black Butte Lake. The extent of the Black Butte Lake is shown in Figure 5.8.

STONY CREEK FAN CONJUNCTIVE WATER MANAGEMENT PROGRAM

Location of Hydrologic Features

DRAFT

MARCH 2003

FIGURE 5.8

Canals and Drains

There are two ways to model canals and drains in SCFIGSM: (1) by explicitly defining canals and drains as 1-dimensional stream elements, similar to river and streams; and (2) by specifying a series of recharge elements along the canal which recharges a portion of diverted water to the aquifer during conveyance of irrigation. The explicit definition of canals and drains require specification of canal cross section data and flow-stage rating curve at every stream node.

Two major canals and drains are modeled in the SCFIGSM by using 1-dimensional line elements; these are:

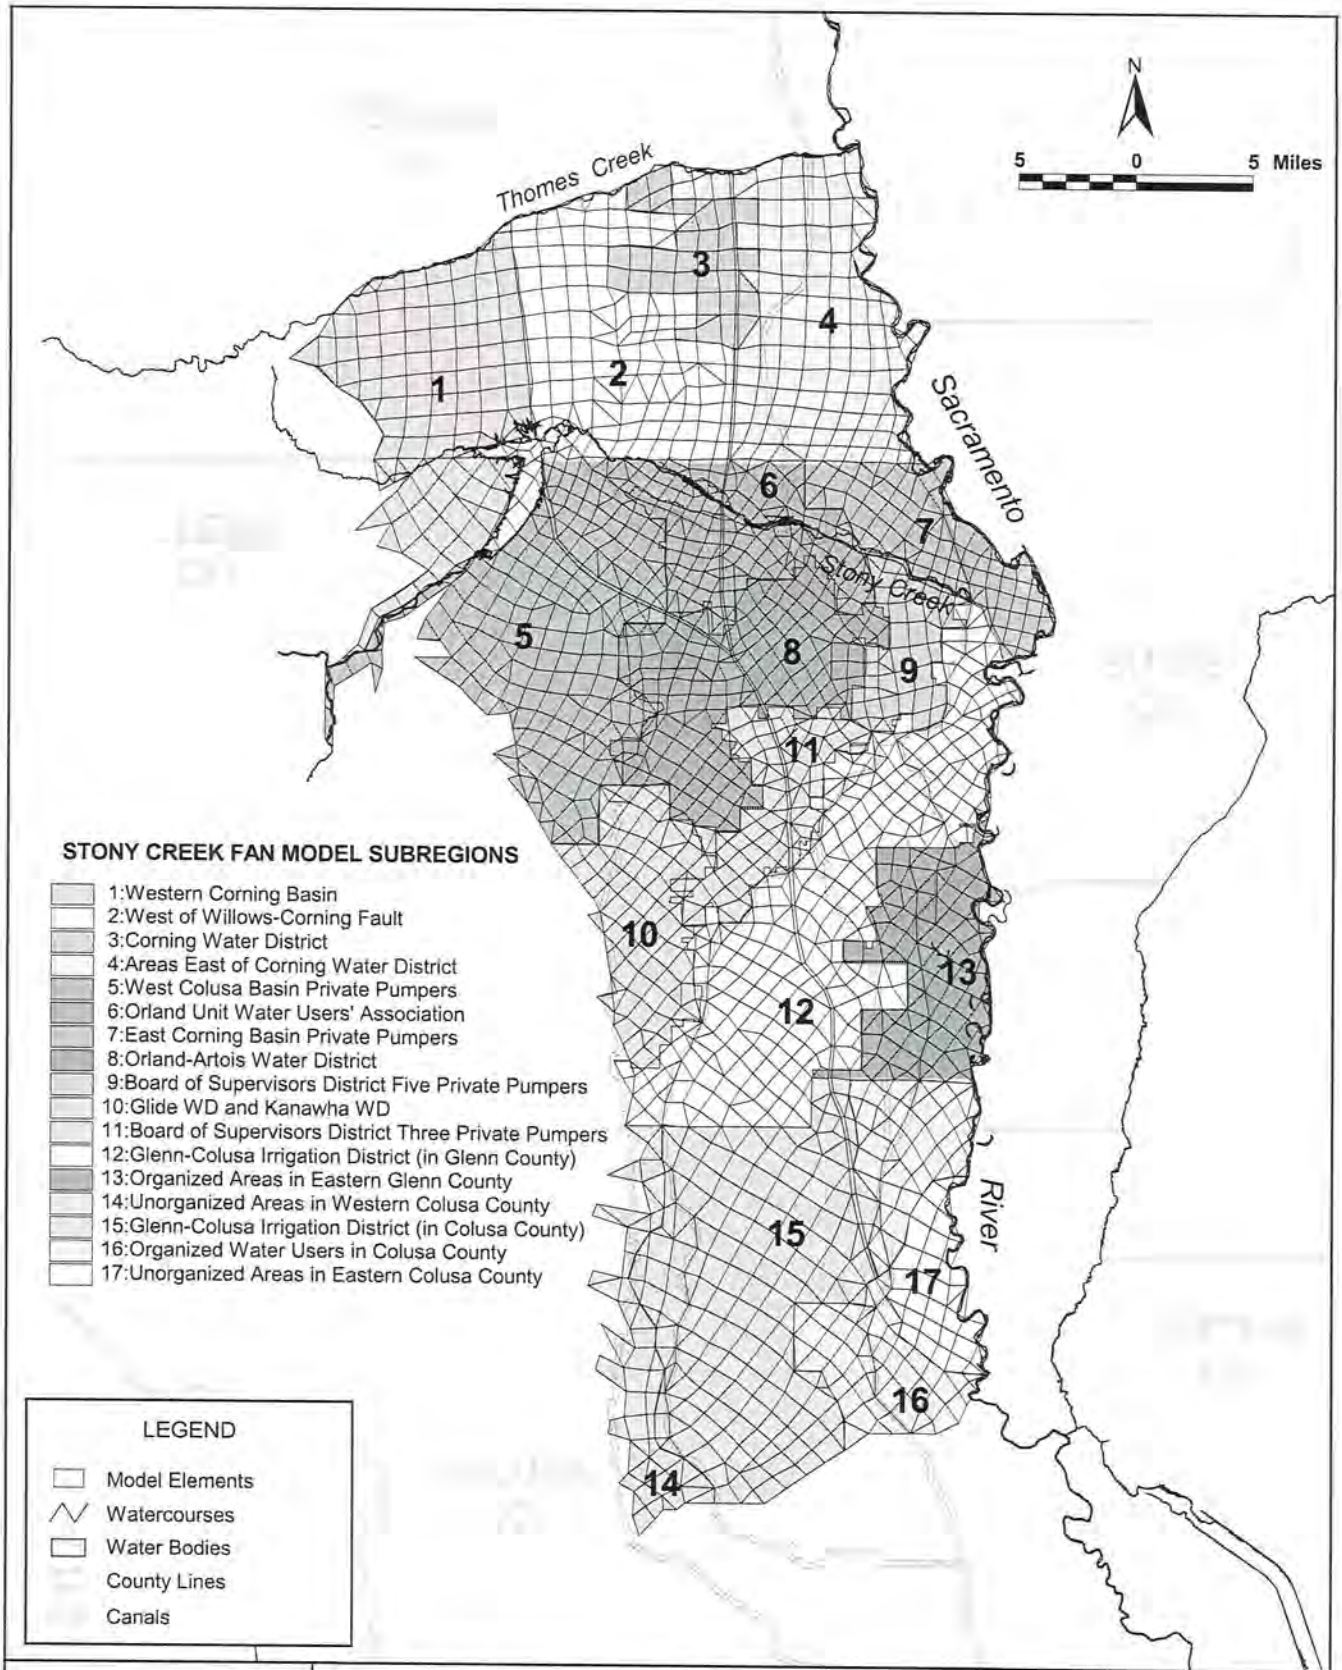
- The **Glenn-Colusa Irrigation District Main Canal** is unlined. It is simulated in the SCFIGSM along the stream nodes shown on Figure 5.8.
- The **Colusa Basin Drain** is unlined. It is simulated in the SCFIGSM along the stream nodes shown on Figure 5.8.

These canals are considered to be major water conveyance facilities that interact with the groundwater aquifer.

There are other leaky irrigation canals in the model area; such as Orland North and South Canals and Corning Canal. They will be simulated by specifying recharge elements along the canal.

The Tehama Colusa canal is concrete lined and leaks only a small amount of water. It can also be modeled by specifying recharge elements if canal seepage is determined to be of importance during the model calibration.

Potential Water Management Project Areas



Water and land use management in the model area is represented in the SCFIGSM by subdividing the model area into 17 management areas called subregions. The criteria for the subregion delineation is described below and presented in Table 5.2. The SCFIGSM model subregions are shown on Figure 5.9.

Stony Creek Feasibility Study Subunits

Model subregions were developed to provide geographic coverage similar to the water balance subunits used in the Stony Creek Fan Feasibility Study. This criterion was utilized to define six subregions on or adjacent to the Stony Creek Fan as presented in Table 5.2 and shown in Figure 5.9. SCFIGSM Subregions 6, 7, 8, 9, 11, and 12 were defined based on this criterion.

Table 5.2
SCFIGSM Model Subregions

Stony Creek Fan Conjunctive Use Project		*Primary Criteria*	*Optional Criteria*	
Subregion Number	**Model Subregion Name**	**Stony Creek Fan Feasibility Study Water Balance Subunits**	**Glenn County BMO Basin Management Sub-Area**	**Comments**
1	Western Corning Basin	NA	1 (West Corning Basin Private Pumpers)	Includes unorganized areas in western Tehama County.

STONY CREEK FAN CONJUNCTIVE WATER MANAGEMENT PROGRAM

Model Subregions

DRAFT

MARCH 2003

FIGURE 5.9

Glenn County Basin Management Objectives Basin Management Sub-Areas

Additional model subregions were developed to provide geographic coverage similar to the basin management subareas used in the Glenn County Basin Management Objectives. This criterion was utilized to define four subregions within the model area in Glenn County as presented in Table 5.2 and shown in Figure 5.9**Error! Bookmark not defined.**. SCFIGSM Subregions 1 (portion in Glenn County), 5, 10, and 13 were defined based on this criterion.

Tehama County

Four subregions were defined in Tehama County based on the hydrogeologic conditions and water supply source (access to surface water). Subregions 1 (portion in Tehama County), 2, 3, and 4 were defined based on this criterion.

Colusa County

Four subregions were defined in Colusa County, primarily based on the water supply source (access to surface water). Subregions 14, 15, 16, and 17 were defined based on this criterion.

DESCRIPTION OF FLOW SYSTEMS AND BOUNDARY CONDITIONS

The groundwater flow system in the SCFIGSM area is part of the larger Central Valley groundwater basin of California. The Central Valley groundwater basin encompasses about 20,000 square miles of area. It is an almost flat alluvial plain extending more than 400 miles from near Redding in the north to near Bakersfield in the south. The width of the valley ranges from 20 to 70 miles with an average of 50 miles in most places. The Central Valley is a closed groundwater basin with an outlet into the Sacramento-San Francisco Delta where two major rivers of the Valley, the Sacramento River and the San Joaquin River, drain their outflows. The Valley is surrounded by the Klamath mountains on the north, by a volcanic plateau of the Cascade Range on the northeast, by the Coastal Ranges on the west, by the Sierra Nevada on the east, and by the Coast Ranges and the Tehachapi mountains on the south. The SCFIGSM groundwater basin is part of this larger Central Valley groundwater basin.

The underlying groundwater aquifer in the SCFIGSM model area is replenished by precipitation recharge, streams/canal seepage, and recharge of applied water over vast lands of irrigated acreage. Recent geologic investigations indicate that the SCFIGSM model area also receives groundwater from areas east of Sacramento River through relatively transmissive lower Tuscan formation which has surface outcrops in Butte County, east of the Sacramento

River. The underlying aquifer is also pumped to meet irrigation demands that cannot be met by surface water supplies. Almost all of the urban water demands in the area is also met by groundwater pumping.

The groundwater flow system in SCFIGSM model area can be defined by specifying the boundaries of the model area. IGSM requires specification of boundary conditions such as groundwater elevation or flux along the boundary of the model. The types of boundary conditions that can be handled by the SCFIGSM include:

- Prescribed flux
- Specified head
- Mixed head (rating table between heads and flows)
- General head
- Small watershed inflow

The small watershed inflow boundary condition accounts for groundwater baseflow or streamflow generated from the watershed areas adjacent to the model area. The model can simulate subsurface or surface outflows from these areas and route them as groundwater recharge or to nearby streams within the model area.

The specific boundary conditions of SCFIGSM are described below.

EXTERNAL BOUNDARIES

North Boundary

The model area is bounded on the north by the Thomes Creek. A no flux boundary condition is assumed along that boundary because of historical evidence of water level measurements and groundwater contour maps;

East Boundary

The model area is bounded on the east by the Sacramento River. A specified flux boundary condition is assumed along this boundary because of anectdotal evidence of water flowing underneath the Sacramento River through the lower Tuscan Formation. The amount of specified flux will be determined during model calibration.

South Boundary

The model area is bounded on the south by the Highway 20, which acts as a groundwater divide on the basis of historical evidence of water level measurements and groundwater contour maps.

West Boundary

The model area is bounded on the west by the geologic contact. A no flux boundary condition is assumed along this boundary.

INTERNAL BOUNDARIES

The internal boundaries are the geologic faults within the model area; they are:

A. Willows Corning Fault; and

B. Black Butte Fault.

Provisions for these internal boundaries require that the model be constructed such that barrier effects and rapid groundwater level changes across faults can be simulated. In order to simulate these internal boundaries, the model grid are kept finer spacing along these boundaries and then allowed to gradually transition to a coarser spacing away from the boundaries. These boundaries may not be vertically continuous.

SECTION 6 SUMMARY

A conceptual model for the Stony Creek Fan Integrated Groundwater and Surfacewater Model (SCFIGSMM) was presented in this report. The conceptual model was developed on the basis of hydrogeology of the model area, hydrology, land use, water use, and other relevant information and data as well as goals and objectives of the modeling.

This conceptual model will guide the development of the numerical simulation model for the Stony Creek Fan. The following section provides additional information on the potential uses and limitations of the numerical model.

MODEL USES AND LIMITATIONS

The primary intent of the Project Sponsor is to use the SCFIGSM in the formulation and development conjunctive water management strategies in the study area. This is generally a three-step process:

1. development of an calibrated model;
2. development of a baseline model; and
3. use of model in the alternatives analysis.

The definition of these model types is provided below:

Calibrated (or Historic) Model: A model that simulates the historic conditions (generally 20 to 30 years period) and is calibrated with recorded observations of groundwater levels (or other relevant variables of interest); the process of calibration (or history matching) ensures that the model is representative of the physical system being modeled.

Baseline Model: This is a revised version of the Calibrated Model with the following changes in input data: (a) the future land and water use conditions (such as 2030 build out conditions) replace the historic land and water use data; and (b) the surrogate for the future hydrology is a long sequence of historic observed hydrology. This baseline model provides the reference frame for comparison of all alternatives.

Alternatives Models: These are the versions of Baseline model with different alternative scenarios of land and water use conditions and/or conjunctive water management programs. The results of these models are used to determine the comparative impacts of different alternatives with reference to the Baseline Model results.

USE OF MODELS FOR DEVELOPMENT AND/OR REFINEMENT OF BMOS

Basin Management Objectives (BMO) are basin operational criteria developed on the basis of historic measurements of well water levels, understanding and observations of groundwater basin behavior, and other field observations. A baseline model (with existing or 2030 conditions and historic hydrologic sequence as a surrogate for future hydrology) cannot be used to evaluate/ revise/implement BMOs, because the purpose of a baseline model is to give reference frame for analyses of alternative management plans, while BMOs are real-time operational guidelines. Furthermore, a model cannot tell whether BMOs are met or not met; the compliance with BMOs can be evaluated only through monitoring of the water levels in the area. Therefore, model should not be used for implementing the Glenn County Groundwater Management Ordinance.

However, a calibrated model can be used to (a) possibly re-examine the assumptions made during the development of the BMOs; (b) enhance the information background of an existing decision or a revised decision related to the Groundwater Management Ordinance or BMOs; (c) identify sensitive areas where additional monitoring may be required to check compliance with BMOs; (d) develop general response characteristics and/or sensitivity ranges among different physical and operational elements; and (e) enhance understanding of the groundwater system behaviors, characteristics, and constraints.

The use of the calibrated model for the above purposes is contingent upon how well the model matches the historical groundwater level observations and how well the model represents physical systems to provide insights (not exact answer) into the groundwater basin response characteristics and into the inter-relationships among different physical and operational elements

USES AND LIMITATIONS OF MODELS IN MEETING THE COMMON GOALS OF THE PROGRAM SPONSORS

One of the common goals of the Program Sponsors is to pursue opportunities to maximize Program benefits through strategic, synergistic linkages with other regional water management activities and authorities. The model can help identify some opportunities or give some quantitative information to help formulate, understand, evaluate, and rank opportunities that can be specified in terms of model input data.

Another common goal of the Program Sponsors is to secure water supply reliability locally and provide opportunities for improved water supply reliability for water users' elsewhere in the state; the model can be used in a statistical mode to develop probabilistic measures of water supply reliability in the face of hydrologic uncertainties and different demand levels.

Another common goal is to seek ways to achieve environmental benefits that are compatible with project operations. A groundwater and surface water model cannot seek ways to achieve environmental benefits; also, a hydrologic model cannot determine whether environmental benefits are achieved or not. But the model can provide information on the water levels and stream flows that can be used as an indicator or measure for evaluating environmental benefits of different alternative plans.

Uses and Limitations of Models in Meeting the Individual Goals of the Program Sponsors

The Orland Unit Water Users' Association has two individual goals: (1) enhanced management of surface water resources; and (2) infrastructure improvements. A model will be able to assess on a comparative basis different alternative ways to manage surface water resources (e.g. reservoir reoperations, conjunctive use, water exchanges etc.). In addition, a calibrated model can provide general estimates of canal seepage loss ranges and help compare different alternatives of canal lining; a calibrated model also can help screen pumping well field sites or recharge sites on a preliminary basis. Both model input data and output data will be helpful in this regard.

The Orland-Artois Water District's individual goal is to secure affordable water supply reliability in all years. The hydrologic model database will have the historic water needs and water supply data and it can be used in a statistical mode to help evaluate the water supply reliability, once the quantitative measure for affordable water supply reliability is determined by the district through its planning process.

The Glenn-Colusa Irrigation District's individual goal is to improve reliability and increase flexibility through integration of basin surface and groundwater resources. As mentioned before, a calibrated model can be used in the statistical mode to help evaluate the water supply reliability, once a quantitative measure of reliability in terms of hydrology is established by the district through its planning process. In addition, an integrated surface water and groundwater model will provide insights into the interrelationships among surface water and groundwater resources to help evaluate management strategies consistent with this individual goal.

General Limitations of a Model

"Models are simplified mathematical representations of physical processes. Constructing a model that accounts for all the finest details of a process is not possible, nor is it useful or necessary." (Saquib Najmus, Water Resources Planning, AWWA Manual M50, AWWA, 2001, p.144). Thus no hydrologic model is an exact representation of the physical world. Therefore, the simulated or predicted groundwater levels from a groundwater model should never be

taken as absolute numbers to be compared against field measurements. Rather, the results of a calibrated groundwater model should be viewed as reasonable approximations of groundwater levels subject to the error ranges of history matching during calibration and also subject to the model assumptions, model set-up, and input data deficiencies.

However, it should be noted that a well-calibrated model could be used effectively in a comparative analysis mode to evaluate the relative impacts of different alternative scenarios.

Specific Limitations of the Model for the Stony Creek Fan Conjunctive Water Management Program

The specific limitations of the model for the Stony Creek Fan Conjunctive Water Management program cannot be determined a priori because they depend on (a) the model selection; (b) the conceptual model for the Stony Creek Fan; (c) the input data quality, level of accuracy, and deficiency; (c) necessary model assumptions; (d) necessary simplifications of physical system; (e) the specific performance of the calibration (history matching) for the Stony Creek Fan model application and the level of calibration, etc.

As part of the model development and documentation process the specific limitations of the Stony Creek Fan model will be evaluated and reported to help the Project Sponsors understand the modeling process as well as the model results and findings. It should also be noted that some potential uses of the model other than the specific purposes for which the model is developed, may require modifications of the Stony Creek Fan model application. However, those potential uses of the model may or may not be desirable or deemed appropriate by the Program Sponsors or stakeholders, regardless of the technical feasibility.

CONCLUSIONS

The conceptual model for SCFIGSM, described above, will serve as the foundation for the development and calibration of the numerical simulation model for Stony Creek Fan model area. The conceptual model will also guide the determination of the level of detail of model input/output data and calibration targets. It should be noted that clarification and refinements of the SCFIGSM conceptual model may be necessary during the model development and calibration process as a better understanding of the physical system is developed through more detailed data collection and analysis.

PROJECT SUMMARY

November 2, 2017

ORLAND-ARTOIS WATER DISTRICT
GROUNDWATER RECHARGE INVESTIGATION
USING 215 CONTRACT WATER

SPRING 2017 TEST

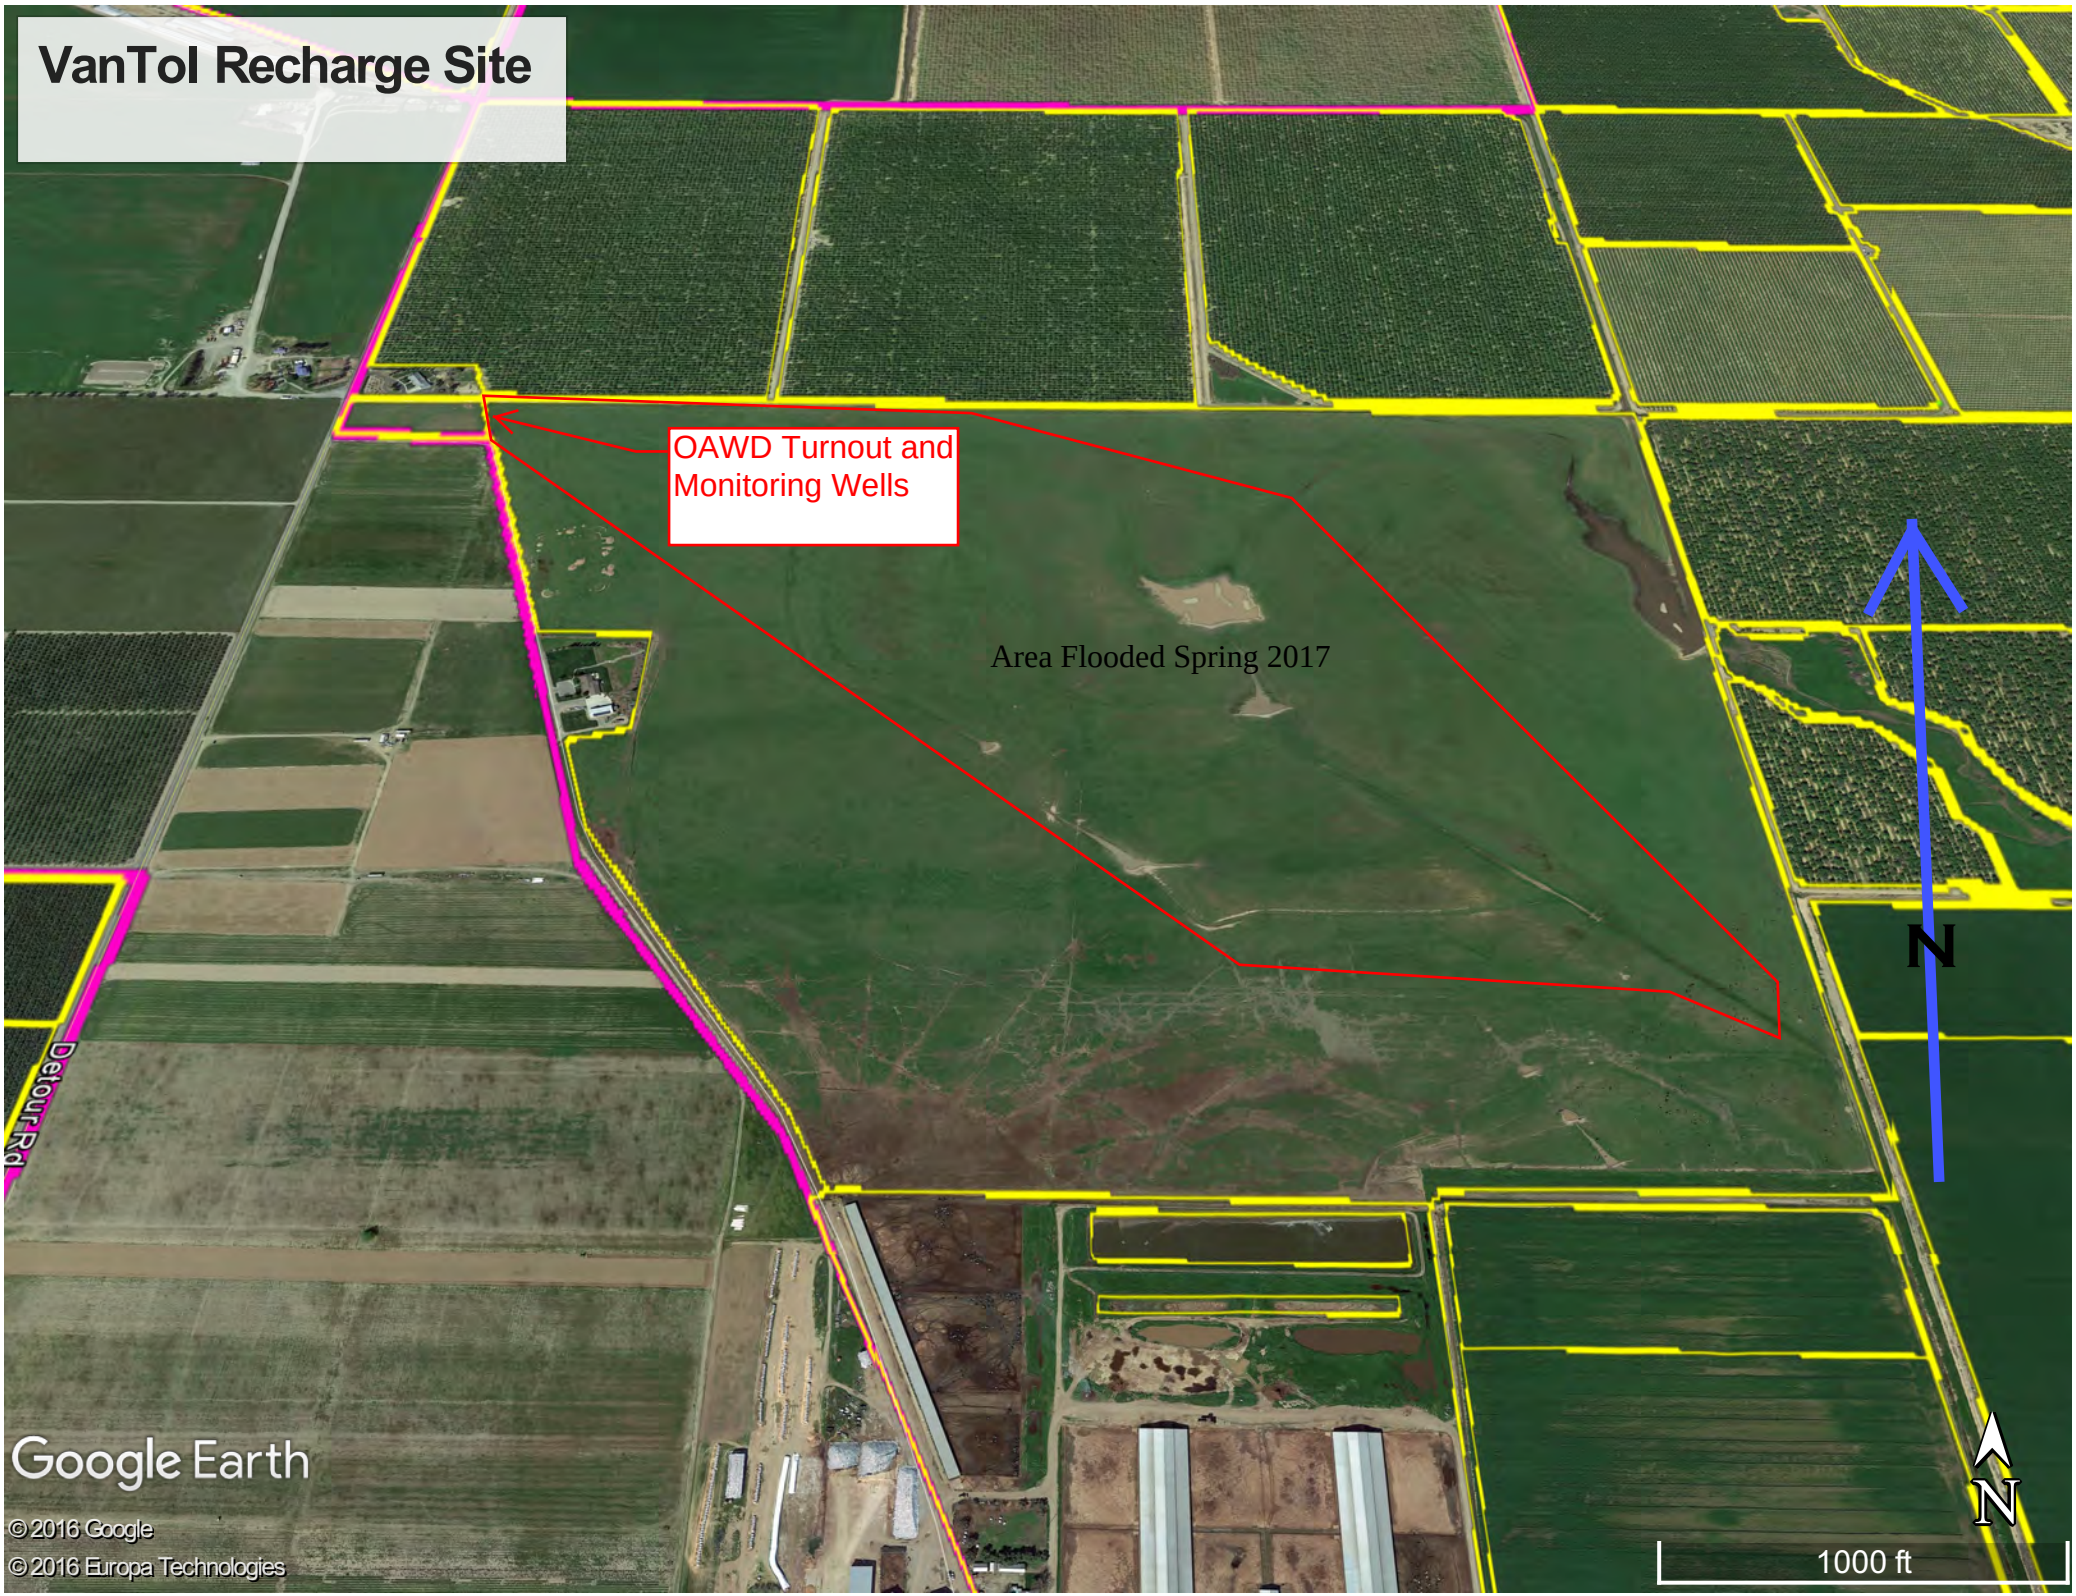
Orland-Artois Water District (OAWD) has been interested in groundwater recharge and the conjunctive use of surface and groundwater for some time. In 2002, along with the Glenn-Colusa Irrigation District and the Orland Unit Water Users Association, the Stony Creek Fan Partnership was formed to investigate the recharge capabilities of the Stony Creek Fan in Glenn County. Several dedicated monitoring wells were constructed to test the recharge of surface water in different areas of the Stony Creek Fan. Later the partnership constructed several deep wells into the Tuscan Aquifer and performed an aquifer performance test. Today most of the monitoring wells are still in use collecting data for DWR including the VanTol site in OAWD. The VanTol site is located on the Westside of County Road M about 3/4s of a mile North of Road 30. All of the monitoring wells are still there including 3 80' to 90' wells and 1 triple completion well to 420'.

In recent years there has been a move towards permanent crops on district as well as non-district lands. These crops are almonds, walnuts, pistachios, and olives which are irrigated with drip and micro-sprinkler systems. The non-district lands are using ground water and many of the district lands are also using groundwater because of the ease of filtering. The expanded use of groundwater, the recent drought years, and the replacement of rice and field crops that utilized flood irrigation with surface water have all contributed to the decline of the local aquifers. More acres are in production and even in fields using surface water the efficient irrigation systems do not allow for recharge. Even with the recent wet year, aquifer levels are considerably lower than they were in 2002. DWR has identified a depression west of Artois that is a concern to water users in that area. In 2002 the Stony Creek Fan Project revealed that the recharged water was moving to the Southeast. Today DWR and the County of Glenn are thinking that the Artois depression is drawing water from East to West towards the depression.

In 2017 OAWD acquired a Section 215 Temporary Water Contract from Reclamation. The 215 water has a lower cost than other water but is available only during times when there are high flows in the rivers and streams. The OAWD Directors felt that a recharge test using 215 Water in the old VanTol Stoney Creek Fan site would give us some new data on the recharge capabilities in the area and be cost effective. If we can recharge water in the gravels at and around the VanTol site and it moves west towards the Artois depression it would be significant. We could recharge much more water in the gravels than the heavy ground in the area of the depression. There are some areas around the depression which may be valuable for recharge but the VanTol site is already set up for a recharge test and the wells there are about 30 feet lower than in 2002.

OAWD staff started flooding the Southeast section of the VanTol property on April 20th and turned off the water on May 2nd. 102 acre-feet of water was used and the site was monitored and the wells measured. We have continued measuring the wells to date. The results show a slight rise in the wells at the end of flooding and when compared to other wells we measure in the area, the VanTol wells started dropping 2-3 weeks later. We felt this was a positive outcome for the test and hope to continue in the coming winter and spring. In the coming months the District will be working with a Chico State grad student who will be running the recharge site as part of his thesis. It will be an expanded test using a test basin and utilizing nearby drains to test their effect on recharge. We are also hoping to show the direction of flow of recharged water.

Emil Cavagnolo



Orland-Artois Water District General Manager

Nice to have an audience.

TECHNICAL MEMORANDUM

DRAFT

Stony Creek Fan Conjunctive Water Management Program

SCFIGSM Hydrogeology and Model Stratigraphy

To:	Eric Hong, DWR	**CC:**	Sue King Rick Massa Van Tenney Toccoy Dudley Derrick Louie Ron Milligan Roger Putty Grant Davids
From:	Saquib Najmus Mike Cornelius	**Date:**	January 20, 2003
Subject:	**Stony Creek Fan Integrated Groundwater and Surface Water Model (SCFIGSM) Hydrogeology and Model Stratigraphy**		
Project Reference:	Contract No.: 4600000734 Task Order: WRIME-Glenn-0901-001		

DRAFT

SECTION 1 INTRODUCTION

PURPOSE

The purpose of this memorandum is to document the methodology used to develop the stratigraphy data for the Stony Creek Fan Integrated Groundwater and Surface Water Model (SCFIGSM). The SCFIGSM will be used in the Stony Creek Fan Conjunctive Water Management Program (Program) to evaluate the impacts of water management scenarios on groundwater aquifer underlying the Stony Creek Fan.

The SCFIGSM is being developed in coordination with the California Department of Water Resources (DWR) and the three Project Sponsors – the Orland Artois Water District (OAWD), the Orland Unit Water User Association (OUWUA) and Glenn Colusa Irrigation District (GCID).

DWR Northern District has recently mapped the hydrogeology of the northern Sacramento Valley in great detail; this effort has resulted in the redefinition of the hydrogeologic setting of Sacramento Valley north of the Sutter Buttes. Until recently, it was believed that the northern Sacramento Valley alluvial aquifer system consisted primarily of a thick layer of interbedded sands and clays. The recent aquifer mapping by the DWR Northern District provides more detailed information about the different aquifer layers that are present in the northern Sacramento Valley. The SCFIGSM model incorporated the recent information about the northern Sacramento Valley aquifer.

The primary goals of this Technical Memorandum are to:

- Identify and summarize the available sources of geologic and hydrogeologic data in the SCFIGSM area.
- Establish the hydrogeologic setting and describe how it is used to develop the conceptual model stratigraphy.
- Discuss the SCFIGSM finite element grid.
- Document the development of the SCFIGSM stratigraphy data.

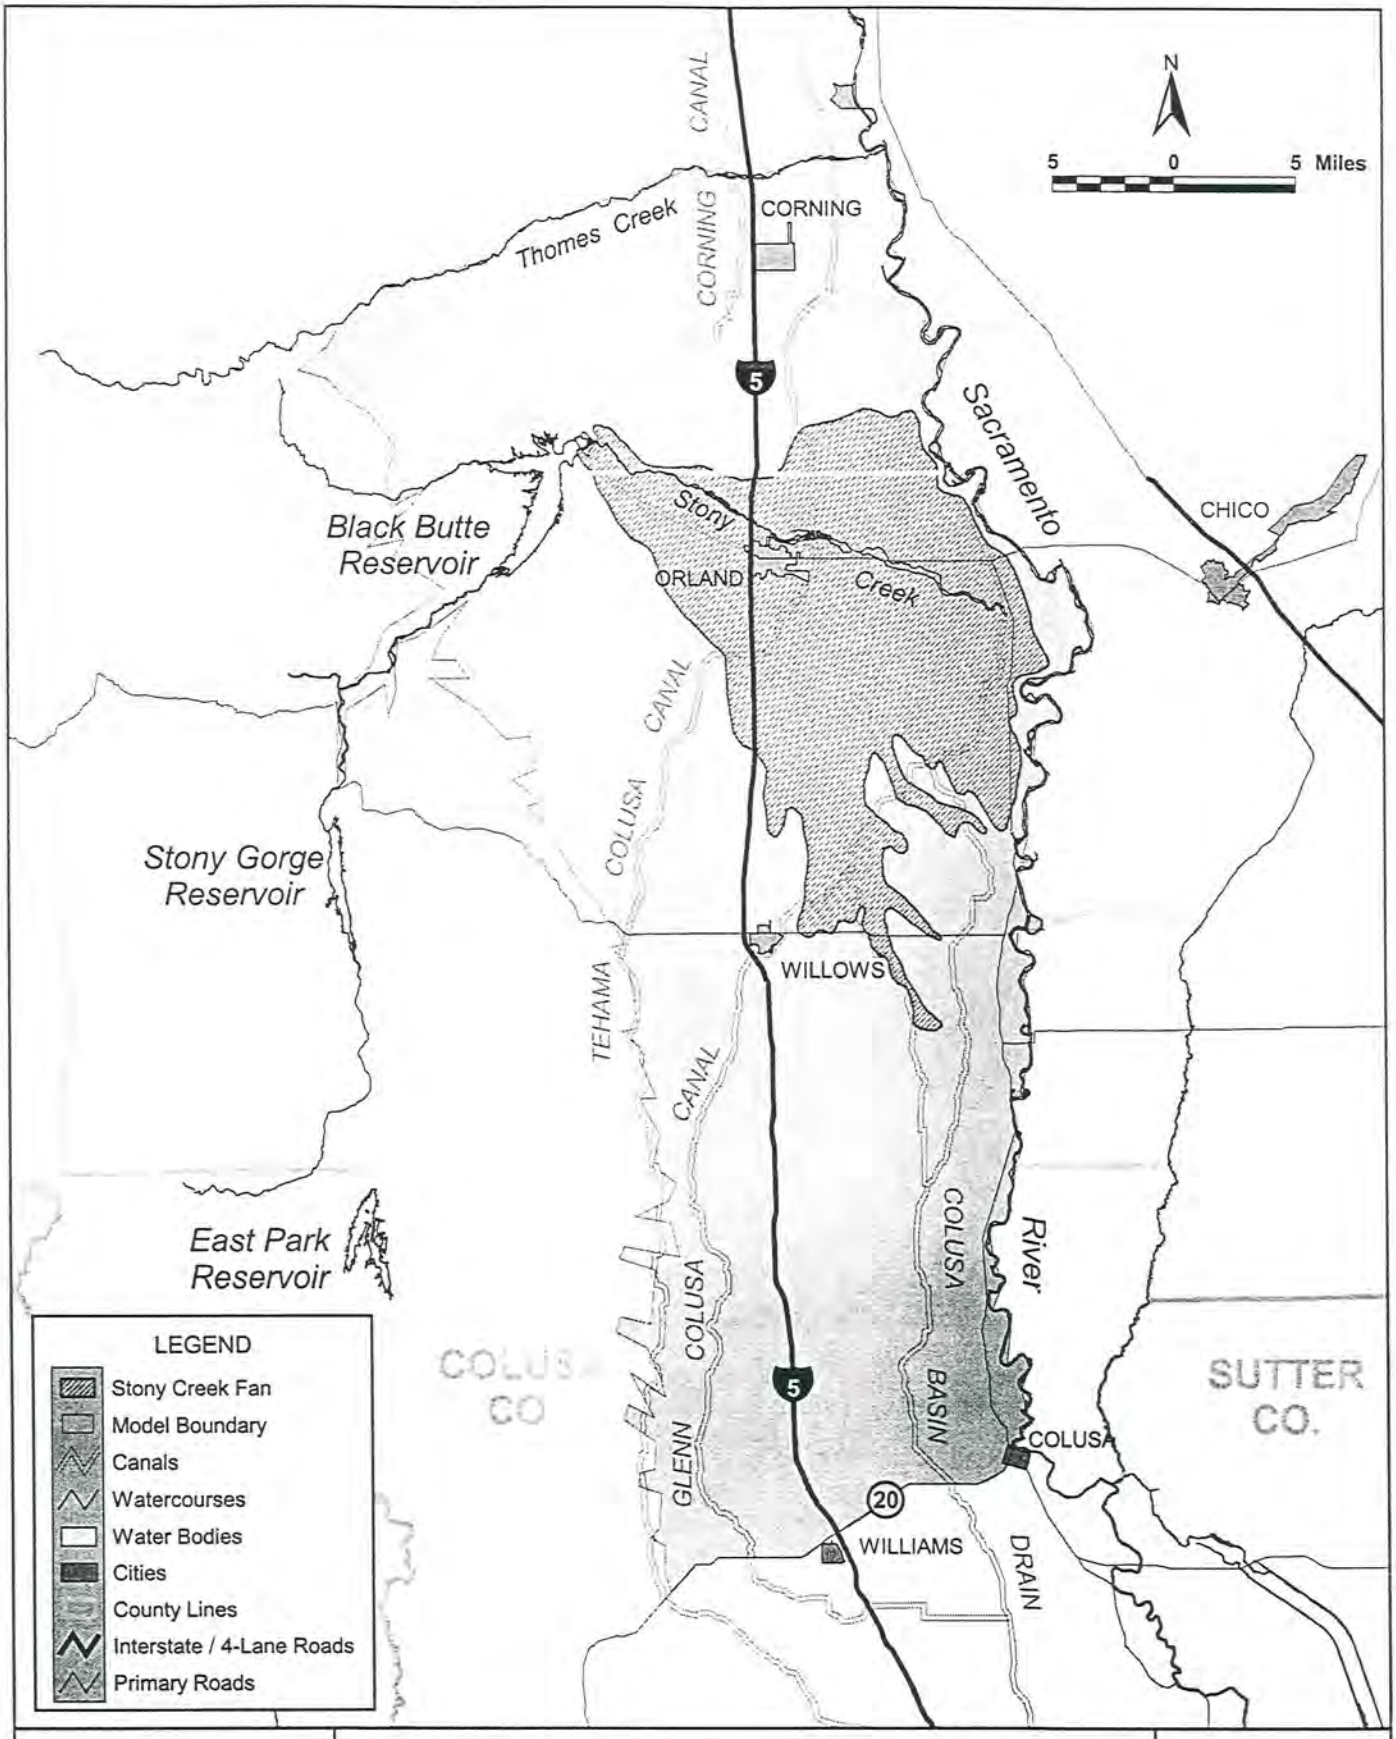
DRAFT

STUDY AREA

Stony Creek Fan Conjunctive Water Management Program Study Area

The Stony Creek Fan, as shown in Figure 1.1, is a highly permeable geologic formation that extends southeast from the Black Butte Reservoir in the Glenn County. The study area for this project includes the Stony Creek Fan and the areas surrounding the Fan that may be included in the SCFIGSM (including the Counties of Tehama, Glenn, and Colusa).

The general study area, shown in Figure 1.1, extends about 30 miles from west to east and about 70 miles from north to south. The study area includes three reservoirs (the East Park Reservoir, the Stony Gorge Reservoir, and the Black Butte Lake), three major streams (the Thomes Creek, the Stony Creek, and the Sacramento River), five major water distribution canals (the Tehama-Colusa Canal, the Glenn-Colusa Canal, the Colusa Basin Drain, the Orland North Canal, and the Orland South Canal), and several small creeks.



The SCFIGSM model area (model area) is smaller than the general study area because it follows the hydrogeologic boundaries and features of the underlying groundwater aquifer. The model area is bounded on the north by Thomes Creek and on the south by Highway 20. The model area extends east from the geologic contact with the Coast Ranges Foothills to the Sacramento River.

DRAFT

TECHNICAL MEMORANDUM OUTLINE

The SCFIGSM Hydrogeology and Model Stratigraphy Technical Memorandum is organized into the following sections:

- **Section 1: Introduction** identifies the purpose and outline of this technical memorandum.
- **Section 2: Collection and Review of Available Data** lists the available geologic and hydrogeologic data used in this analysis.
- **Section 3: Geologic and Hydrogeologic Setting of Model Area** summarizes the available data.
- **Section 4: Conceptual Model Stratigraphy for SCFIGSM** presents the conceptual model stratigraphy for the SCFIGSM.
- **Section 5: SCFIGSM Model Grid** describes the development of the SCFIGSM grid.

SECTION 2 COLLECTION AND REVIEW OF AVAILABLE DATA

This section describes the available geologic and hydrogeologic data that were collected and reviewed during the development of the stratigraphy data for the SCFIGSM.

The available data and information for the Program was summarized in two previous project reports:

- Integrated Groundwater and Surface Water Model (IGSM) Data Collection and Assessment Report for the Stony Creek Fan Conjunctive Water Management Program, (WRIME, Inc., August 2002), and
- Existing Data Report, Technical Memorandum 1, Stony Creek Fan Conjunctive Water Management Program (MWH/Davids Engineering, December 2002).

Other sources of information utilized to develop the SCFIGSM stratigraphy data are described below.

DRAFT

PUBLISHED STUDIES AND REPORTS

The geology and hydrogeology of the Sacramento Valley has been investigated since the 1920s. The following list of reports provided regional information on the geology, hydrogeology, aquifer characteristics, and storage capacity of the aquifer system in the study area.

- Evaluation of Groundwater Resources; Sacramento Valley, Bulletin 118-6, DWR, 1978.
- Groundwater Levels in the Sacramento Valley Groundwater Basin, DWR, 1997.
- Geologic Features and Groundwater Storage Capacity of the Sacramento Valley, California, U.S. Geological Survey Paper 1497, 1961.
- Water Quality and Supply on Cortina Rancheria, Colusa County, California, USGS Water Resources Investigation 89-4004, 1989.
- Glenn-Colusa Irrigation District; Reconnaissance Evaluation of Groundwater Resources, CH2M HILL, 1978.
- Geochemistry of Groundwater in the Sacramento Valley California, Laurence C. Hull, USGS Professional Paper 1401-B, 1984.
- Base and Thickness of Post-Eocene Continental Deposits in the Sacramento Valley, California, R.W. Page in cooperation with DWR, USGS Water Resources Investigation 45-73, 1974.

- Progress Report of Groundwater Development Studies, North Sacramento Valley, DWR, 1976

RECENT/UNPUBLISHED STUDIES AND REPORTS

Some of the most recent work completed by DWR is not published yet. Two of these efforts are:

- Sacramento River Basin–Wide Water Management Plan Groundwater Hydrology Technical Memorandum, DWR Northern District, Bulletin 118-7 (Draft, unpublished, January 2000).
- California's Groundwater, Bulletin 118, Update 2002.

Sacramento River Basin–Wide Water Management Plan Groundwater Hydrology Technical Memorandum, DWR Northern District, Bulletin 118-7

The Sacramento River Basin–Wide Water Management Plan presents the results of a groundwater resource assessment for selected areas within the Sacramento Valley and Redding groundwater basins. This report emphasized areas associated with the Sacramento River Settlement Contractors, who are participating in Reclamation's development of a Basin-Wide Water Management Plan (BWMP).

As part of this project, the DWR Northern District is currently in the process of completing comprehensive geologic mapping of the Stony Creek Fan. Several geologic cross sections were developed based on analysis and interpretation of recent and E-logs, and oil and gas logs. These geologic cross-sections are not yet published but were provided as preliminary data to the project study team solely for the purpose of use in the model development.

DRAFT

California's Groundwater, Bulletin 118, Update 2002

Bulletin 118–Update 2002 identifies and describes the two groundwater basins, Corning and Colusa, in the study area. Bulletin 118 briefly describes the hydrogeologic conditions of the underlying aquifers, which were taken into consideration during the development of the conceptual model hydrogeology for the SCFIGSM. This information is currently available at the Bulletin 118 website, listed below:

(http://www.waterplan.water.ca.gov/groundwater/updatemain.htm).

OTHER DATA SOURCES

Well log and construction data, and water level data are both available from DWR. This information was used to supplement the available geologic and hydrogeologic data used in developing the stratigraphic data for the SCFIGSM. Each of these data sources is briefly described below.

Well Log and Construction Data

Monitoring and production well logs for the Counties of Glenn, Tehama, and Colusa are available as hardcopy data at the DWR Northern District office in Red Bluff. About 400–500 driller's logs available at the Northern District office were reviewed and screened for geographic coverage and level of detail reported in the well log. About 154 driller's logs distributed throughout the proposed model area were selected for use in the model data development. These well log data were analyzed, interpreted, and used to supplement the existing geologic cross-section data to develop the model stratigraphy.

Historic Groundwater Levels

Historic groundwater level data for 191 wells (18N–22N) in the Glenn County, 40 wells (15N–18N) in the Colusa County, and 203 wells (23N–25N) in the Tehama County were downloaded from DWR Web site (http://www.wdl.ca.gov). A preliminary assessment of the groundwater level data shows that there are adequate data for developing the initial condition of the SCFIGSM as well as for model calibration.

DRAFT

SECTION 3 GEOLOGIC AND HYDROGEOLOGIC SETTING OF MODEL AREA

The geologic and hydrogeologic setting for the model area is presented in this section to document the available information and provide the background information needed to develop the conceptual model stratigraphy (presented in Section 4), model grid (presented in Section 5), and the SCFIGSM stratigraphy data (presented in Section 6).

This section focuses on the geologic and hydrogeologic conditions of the model area; it includes discussion of the following:

- Geologic History
- Geomorphic Features
- Geologic Setting
- Hydrogeologic Setting

DRAFT

GEOLOGIC HISTORY

This section presents the geologic history of the model area as it relates to the deposition of marine deposits and continental deposits. In general, the older marine deposits contain saline water and underlie the younger continental deposits which contain fresh water. The freshwater bearing continental deposits are the geologic units of interest in the Stony Creek Conjunctive Water Management Program. The geologic units and a brief description of their characteristics are presented on Table 3-1.

During the Cretaceous Period to early Miocene Epoch, the present Sacramento Valley trough was inundated by an inland sea, which deposited thousands of feet of marine sediments upon the pre-Cretaceous granitic basement rocks. After withdrawal of the marine waters occurred in the Miocene Epoch, there was a period of erosion during which time there was deposition of continental deposits.

Table 3.1
Stony Creek Fan IGSM
Geologic Units in Study Area

System and Series		Geologic Unit	Lithologic Character	Maximum Thickness[1] (ft)	Water-bearing Character
QUATERNARY	Holocene	Alluvium Qa	Unconsolidated unweathered gravel, sand, silt, and clay[1].	80	Deposits are moderately to highly permeable with high permeability gravelly zones yielding large quantities to shallow wells[2]. Although deposits along Stony, Chico, and Thomes Creeks are important recharge areas[2], extensive water bearing capacity is restricted by thickness and areal extent[1].
		Basin Deposits Qb	Unconsolidated[5] fine-grained silts and clays, locally interbedded with stream and channel deposits along the Sacramento River[1].	150	Deposits are typically saturated nearly to the ground surface[2]. The low to moderate permeability results in yields of small quantity and poor groundwater quality to domestic wells[1,2].
	Pleistocene	Modesto Formation Qm	Poorly sorted[5] unconsolidated weathered and unweathered gravel, sand, silt, and clay[3].	200	Moderately to highly permeable[1].
		Riverbank Deposits Qr	Poorly sorted[5] unconsolidated to semi-consolidated[3] pebble and small cobble gravels interlensed with reddish clay, sand, and silt[1].	200	Water-bearing capability is limited by thickness. These poorly to highly permeable deposits supply moderate groundwater amounts to domestic and shallow irrigation wells. Deeper irrigation wells may be supplied if the wells contain multiple perforation zones[1].
TERTIARY AND QUATERNARY	Pliocene and Pleistocene	Tehama Formation Tte	Fluviatile moderately consolidated pale green, gray, and tan sandstone and siltstone enclosing lenses of sand and gravel; silt and gravel; and cemented conglomerate derived from the Coast Ranges[1,3].	2,000	Local high permeability zones within this characteristically low to moderate permeability unit, widespread distribution, and deep thickness cause this formation to be the principle water bearing unit in the area. Deep well yields are typically moderate, but are highly variable[2].
TERTIARY	Pliocene	Tuscan Formation Tt	This series of volcanic flows, consolidated tuff breccia, tuffaceous sandstone, and volcanic ash derived from the Cascade Range interfingers with the Tehama Formation as it westerly grades into volcanic sands, gravels, and clays[1,2]. The formation is divided by layers of thin tuff or ash units into four lithologically similar units A-D[1].	1,500	Within this formation, moderately to highly permeable volcanic sediments are hyraulically confined by layers of tuff breccias and clays[2]. Units A and B are the primary water-bearing zones and are composed of volcanic conglomerate, sandstone, and siltstone layers interbedded with lahars. Stragraphically higher, the massive lahar deposits of unit C confine groundwater in the permeable beds of units A and B[1].
		Nomlaki Tuff Member	Tuff breccias and white tuffs of dacitic composition. This member of the Tehama and Tuscan Formations serves as an important stratagraphical marker bed in northern Sacramento Valley[5].	60[5]	Poorly permeable.
	Miocene	Neroly Formation Tn	Marine to non-marine tuffaceous andesitic sandstone interbedded with tuffaceous shales and tuff layers. Contains local conglomerate lenses[3].	500	This formation of variable permeability contains interstitial fresh water under confined conditions[4], however, deposits of the Neroly Formation are typically located below the base of fresh water.
		Lovejoy Basalt Tl	Black, dense, hard microcystalline basalt[3].	65	Largely non-water bearing.
	Miocene and Oligocene	Upper Princeton Valley Fill Tupg	Non-marine sandstone containing mudstone, conglomerate, and sandstone conglomerate interbeds[3].	1,400	Largely non-water bearing or contains saline water.
	Eocene	Lower Princeton Submarine Valley Fill Tlpg	Marine conglomerate and sandstone interbedded with silty shale[3].	2,400	Largely non-water bearing or contains saline water.
CRETACEOUS		Great Valley Sequence JKgvs	Marine siltstone, shale, sandstone, and conglomerate[3].	15,000	Largely non-water bearing or contains saline water[2].
PRE-CRETACEOUS		Basement Complex pTb	Metamorphic and igneous rocks.	n/a	May contain groundwater, mainly saline, in fractures and joints.

In the Pliocene Epoch, the northern Coast Range uplift was initiated which is associated with this mountain-building episode, the Sacramento Valley began to assume its current form. Coast Range uplift and related erosion of the uplifted block resulted in deposition of the Tehama Formation onto the heavily eroded, subsiding Sacramento Valley floor. In late Pliocene time, volcanic activity on the southern Cascade Range caused the widespread deposition of the Nomlaki tuff across the northern Sacramento Valley. This extensive ash layer is found near basal deposits of the Tehama and Tuscan Formations. Continuous volcanism in the southern Cascade Range produced consecutive mudflows of basaltic and andesitic composition. These igneous deposits were reworked coincident with volcanic activity resulting in the Tuscan Formation on the east side of the Sacramento Valley.

During the Pliocene Epoch, deposition of the Tehama and Tuscan Formations occurred simultaneously. These thick, widespread deposits overwhelmed the previous topography, creating a relatively flat plain that was repeatedly dissected by meandering and braided streams.

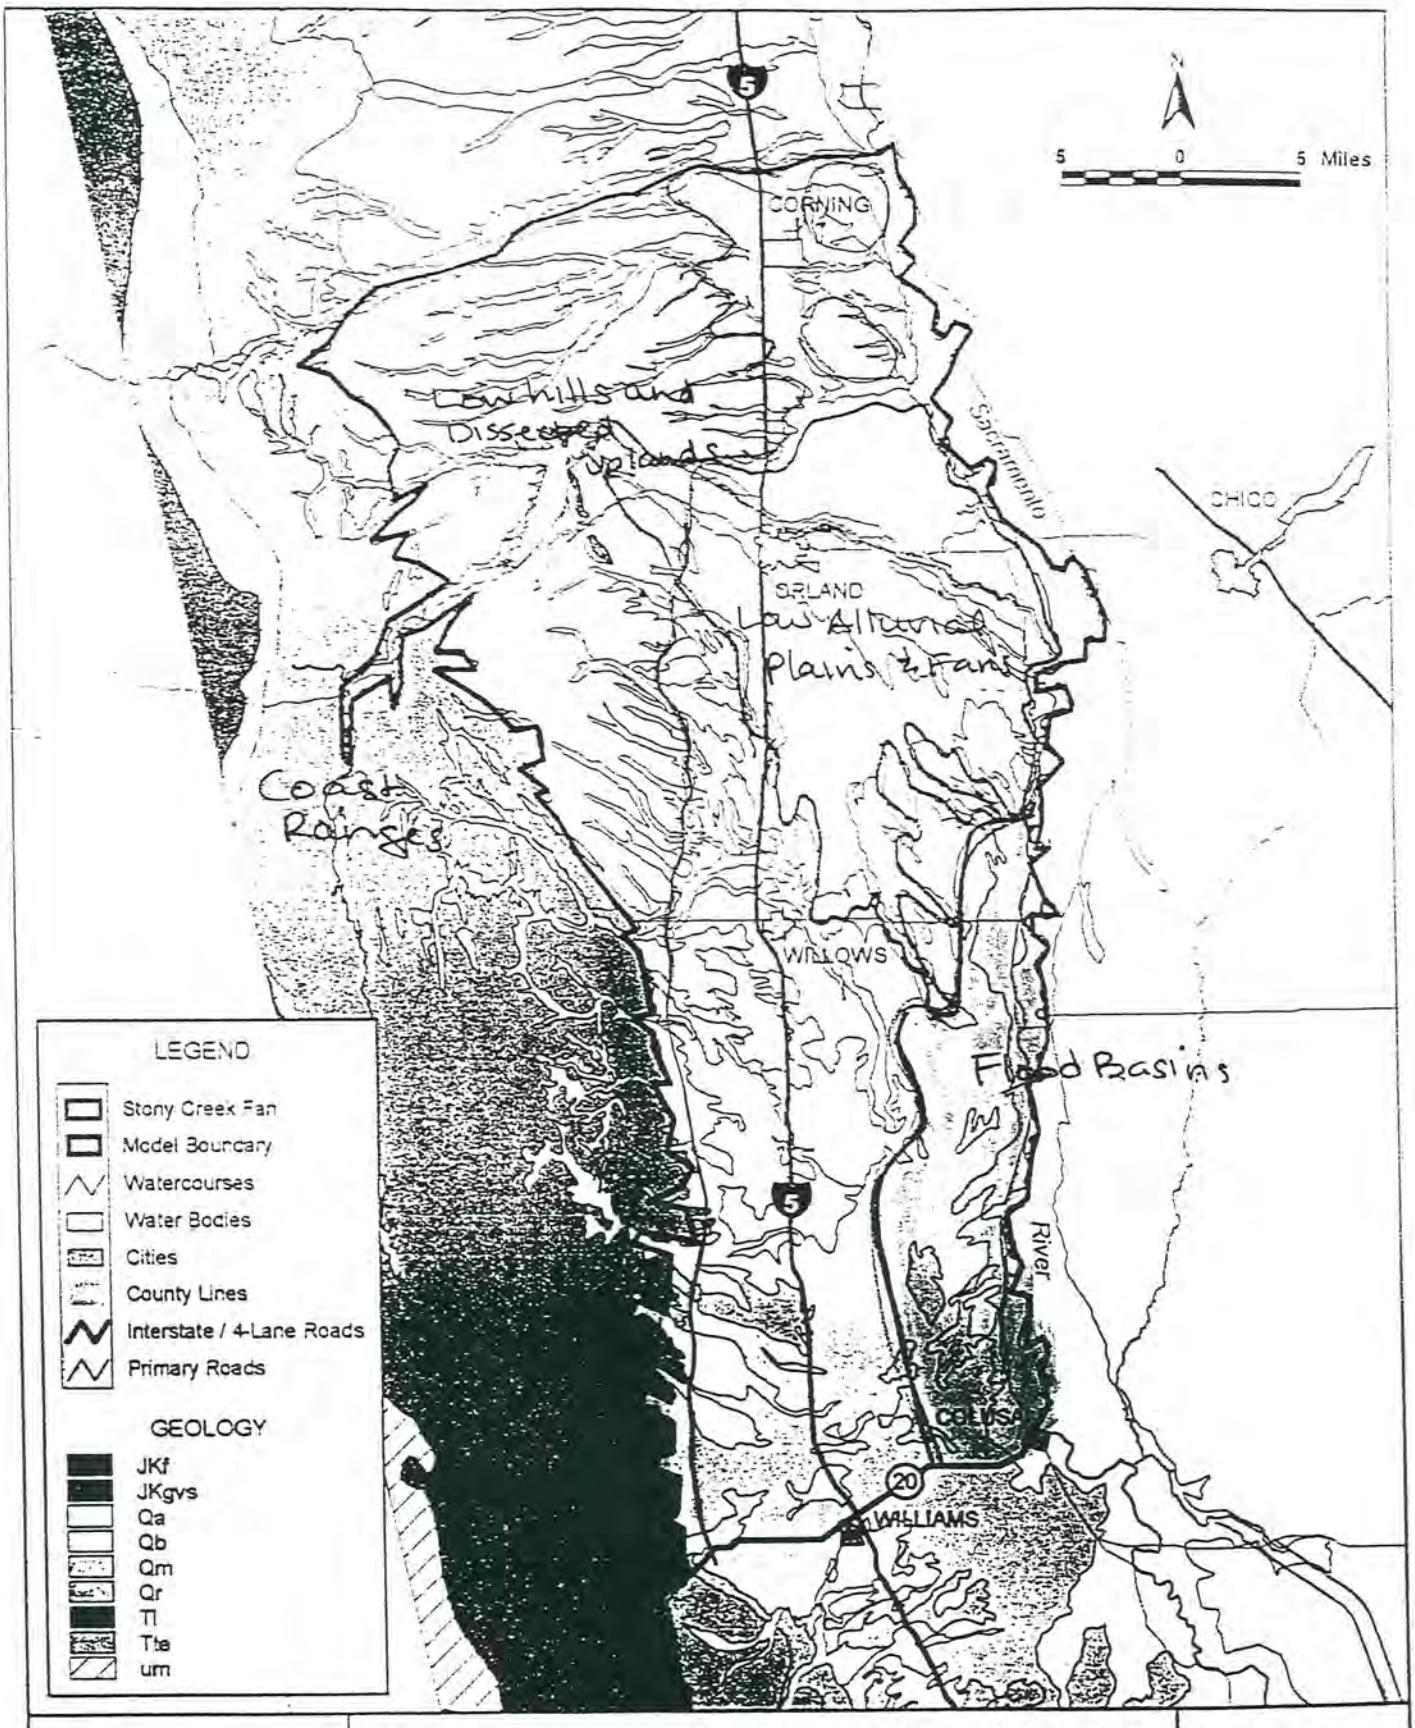
Fluviatile sedimentation of the Tehama Formation was continuous on the west side of the Sacramento Valley throughout the Pliocene and possibly into the Pleistocene. During the middle part of the Pleistocene, mountain-building activity brought the Coast Ranges to their current structure and shape. The Tehama Formation deposits, along with older deposits, were involved in this folding and faulting event, and formed low hills and dissected uplands. Intense erosion concurrent and following this orogenic activity reworked the Tehama Formation and redeposited the sediments near the center of the Valley. Much of these sediments were carried away by the Sacramento River.

Quaternary sedimentation is represented in the deposition of broad alluvial fans and flood plains. In the vicinity of the Stony Creek Fan, the newly eroded surface of the Tehama Formation was covered with poorly sorted gravel deposits of the Pleistocene Modesto and Riverbank Formations. Gravels of these terrace deposits were partially supplied by glaciers in the Coast Ranges and Klamath Mountains and partially by continued erosion of the Coast

DRAFT

Ranges. The northwest Sacramento Valley cycle of valley deposition resulting from continuous erosion in the Coast Ranges and low foothills continues to present day.

GEOMORPHIC FEATURES



Geomorphic features of the study area include the Coast Ranges, low hills and dissected uplands, alluvial fans, and flood plains (Figure 3.1). The Sacramento River and Stony Creek have significant hydrological influence on the study area.

The Coast Ranges represent the western border of the study area and extend south from the Klamath Mountains to the Cuyama River near San Luis Obispo. These north-south trending mountain ranges are predominantly composed of sedimentary deposits with minor volcanic intrusions. The sedimentary fault blocks within the ranges are complexly folded. In general, the Coast Ranges reach no higher than 6,560 feet above mean sea level.

The low hills and dissected uplands are located between the Coast Ranges and the alluvial fans of the valley. An abrupt increase in slope marks the transition between the alluvial fans and the uplands. These hills are topographic expressions of subsurface folding and faulting of the Tehama Formation and older underlying sediments.

As streams draining the Coast Ranges leave the low hills and dissected uplands, they flow out into the relatively flat valley floor. This change in slope causes them to deposit their bedload, forming broad alluvial fans. Alluvial fan deposits are an intricate system of buried channels formed by a dynamic fluviatile depositional environment. An example of an alluvial fan is the Stony Creek Fan (Figure 1.1), the focus of the current hydrogeologic investigation. This fan is the largest and most complex alluvial fan in the northwest portion of the Sacramento Valley and was deposited by Stony Creek. The apex of the Stony Creek Fan is approximately five miles northwest of the town of Orland, where Stony Creek flows out of the low hills. The Stony Creek Fan extends east to the Sacramento River flood plain, and south to the Colusa basin deposits near the town of Willows. The surface of the fan is not smooth, but rather cut by many abandoned channels. Smaller and less impressive fans

GEOMORPHIC FEATURES MAP

DRAFT

JANUARY 2003

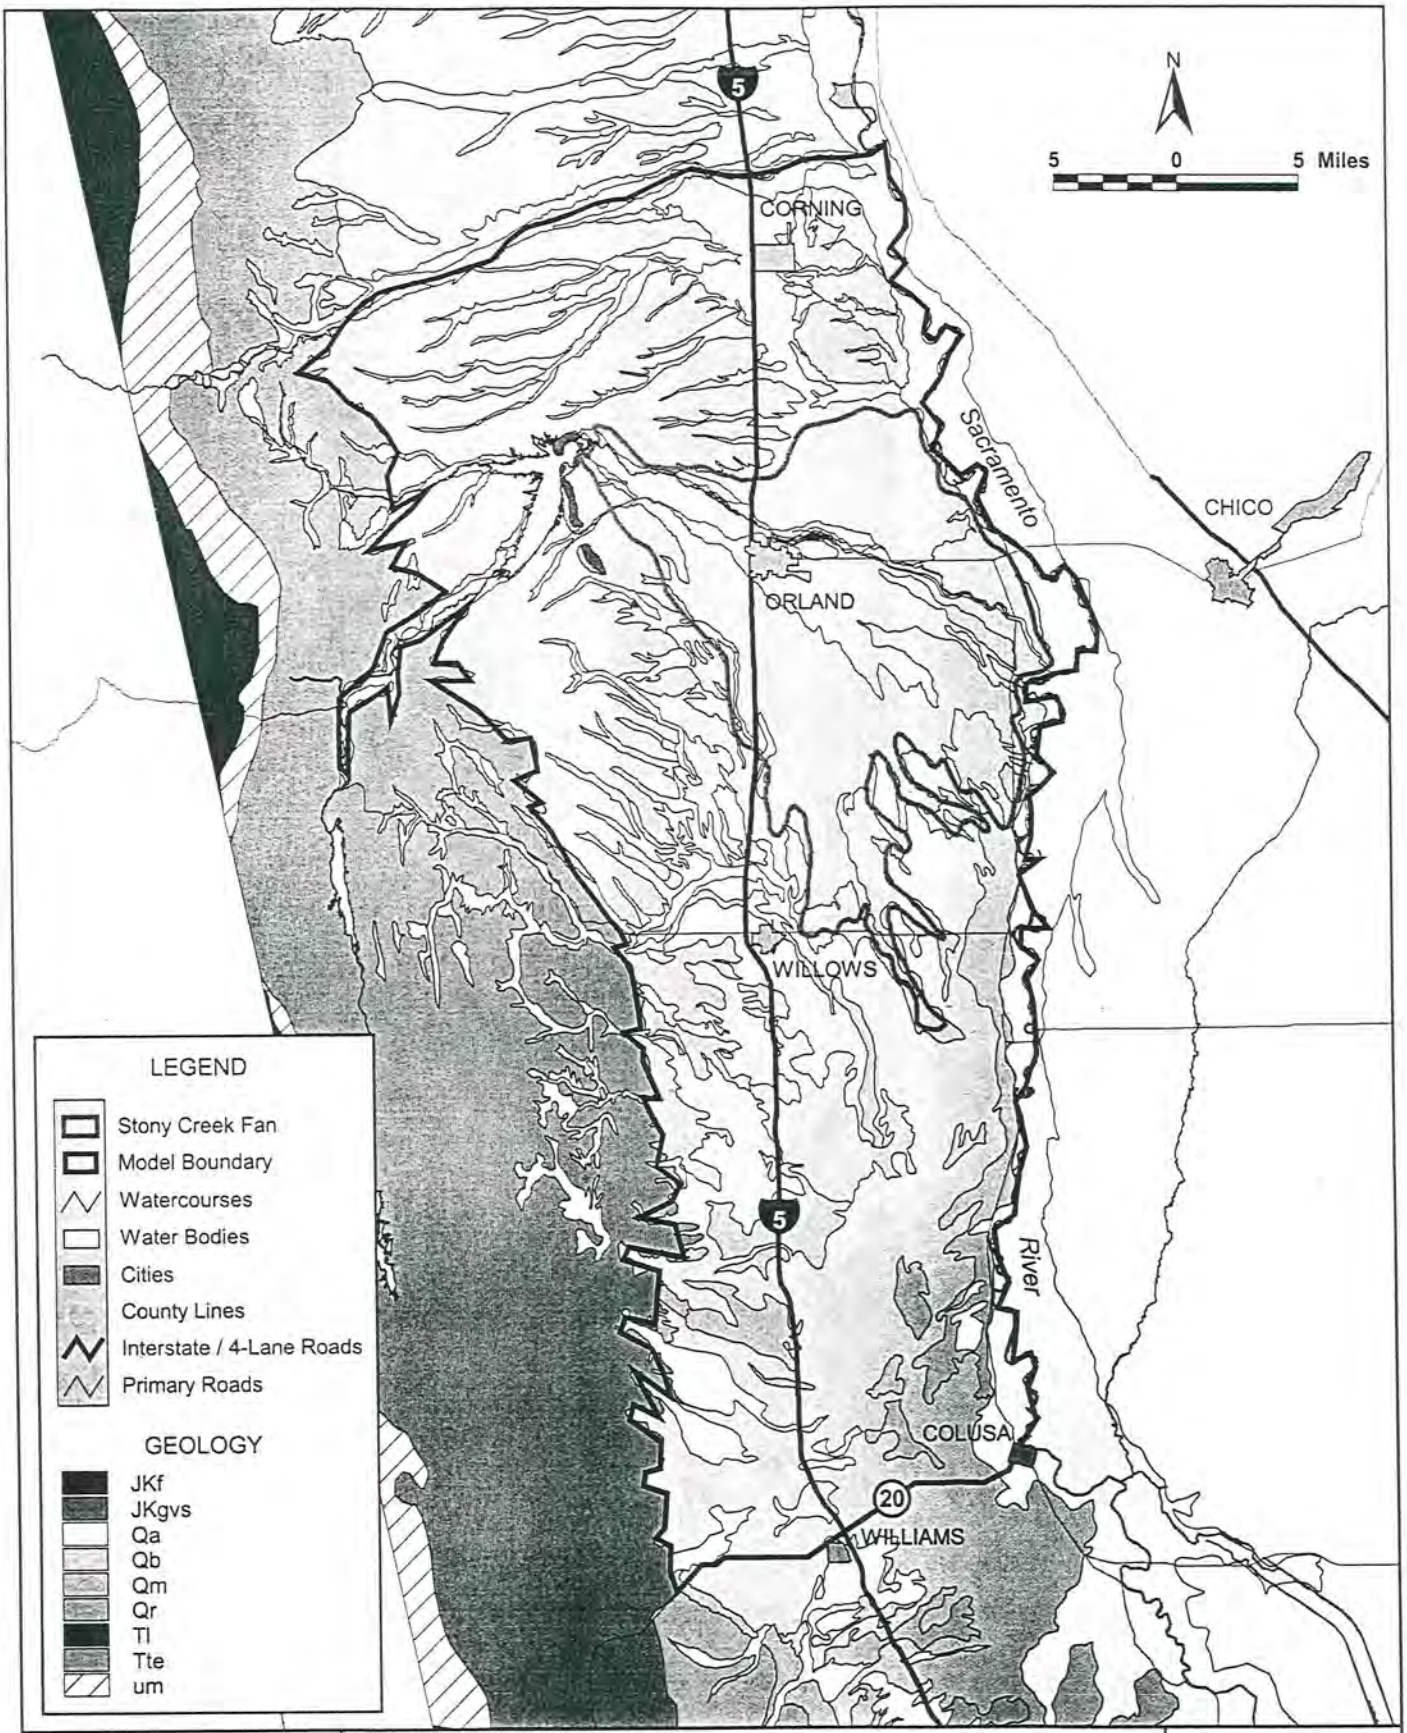
FIGURE ~~X~~ 3.1

have been deposited by intermittent streams south of the Stony Creek Fan. In general, these deposits are much finer grained than the deposits of the Stony Creek Fan.

In flat, low-lying basins between the alluvial fans and the Sacramento River, distal alluvial fan sediments merge with the fine-grained flood plain and basin deposits. During flooding events along the Sacramento River, water spills over the natural river levee and accumulates in these basins. The trapped water creates temporary lakes, and the quiescent environment allows for deposition of fine-grained suspended material. The Colusa Basin is an example of this phenomenon, and extends 60 miles south of the Stony Creek Fan.

The Sacramento River and Stony Creek are responsible for depositing a large quantity of coarse material in the northwest Sacramento Valley over thousands of years. These deposits constitute the alluvial aquifer in the study area. The Sacramento River and Stony Creek are important sources of surface water to the study area.

DRAFT



GEOLOGIC SETTING

Structure

The Sacramento Valley is an asymmetrical northward-trending syncline partially filled with sedimentary deposits. Several faulting, folding, and uplift events tilted the Sierra Nevada block relative to the Coast Ranges forming this structural basin. Latter orogenic events are expressed in folding and faulting of Pre-Middle Pleistocene basal deposits. Faults related to this activity include the Paskenta, Willows, Corning, and Black Butte Faults.

Geologic Units

This summary of the geologic units in the study area focuses on the Pliocene and younger sediments of the alluvial groundwater aquifer. These sediments include the Pliocene Tuscan Formation; Pliocene and Pleistocene Tehama Formation; Pleistocene Modesto and Riverbank Formations; and the Holocene alluvial, basin, and flood plain deposits (Figure 3.2 and Table 3.1). Little detail is given to the underlying older marine sediments.

RIME Water Resources & Information Management Engineering, Inc

STONY CREEK FAN CONJUNCTIVE WATER MANAGEMENT PROGRAM

Geologic Map

DRAFT

JANUARY 2003

FIGURE 3.2

Pre-Pliocene Marine Deposits

Marine sediments in the study area include the Miocene Neroly Formation, the Miocene and Oligocene Upper Princeton Gorge Formation, the Eocene Lower Princeton Gorge Formation, and the Cretaceous Great Valley Sequence. These deposits define the subsurface freshwater aquifer boundary. In general, these largely non–water bearing deposits occur below the base of fresh water; thus they may contain small amounts of saline water. The Neroly Formation is composed of marine to nonmarine tuffaceous andesitic sandstone interbedded with tuffaceous shales and tuff layers with local conglomerate lenses. This formation generally contains saline water; however, it may contain small amounts of freshwater. The nonmarine deposits of the Upper Princeton Gorge Formation consist predominantly of sandstone containing mudstone, conglomerate, and conglomerate sandstone interbeds. Although these are continental deposits, they occur below the base of freshwater and contain saline groundwater; thus, the Upper Princeton Gorge sediments are grouped with the marine deposits. The Lower Princeton Gorge Formation is characterized by marine sandstone and conglomerate with silty shale interbeds. Sedimentary marine clastic rocks constituting the Great Valley Sequence include siltstone, shale, sandstone, and conglomerate.

DRAFT

Pliocene Tuscan Formation

Tuscan deposits are characterized by their Cascade Range origin and volcanic signature. This extensive series of basaltic and andesitic volcanic flows, consolidated tuff breccia, tuffaceous sandstone, and volcanic ash is primarily located on the northeastern portion of the Sacramento Valley. The Tuscan Formation underlies much of the Valley floor and extends from the Cascades to the west side of the Valley where it grades into volcanic sands, gravels, clays, and interfingers with the Tehama Formation. Thin tuff or ash units separate the Tuscan Formation into four distinct, yet lithologically similar Units A, B, C, and D (D being the youngest). Of these units, only A, B, and C are found in the study area. Unit C is composed of massive lahar (mudflow) deposits with volcanic sandstone and conglomerate interbeds. Tuscan Formation Unit C is referred to as the Upper Tuscan Formation. Both Units A and B are largely composed of layered, interbedded lahars, siltstone, and volcanic sandstone and conglomerate. Tuscan Formation Units A and B are referred to as the Lower

Tuscan Formation. Unit A is distinguished from Unit B by the presence of metamorphic rock fragments in siltstone layers.

Pliocene-to-Pleistocene Tehama Formation

Deposits of the Tehama Formation are characterized by their fluviatile nature and origin from the Klamath Mountains and Coast Ranges. This assemblage of moderately compacted sandstone and siltstone with local coarse lenses is located in the northwest portion of the Sacramento Valley. These yellowish to greenish grey deposits are separated from the underlying Eocene Epoch and Cretaceous Period marine sediments by an unconformity. The Tehama Formation was deposited under floodplain conditions by rivers and streams flowing from nearby mountains in a subsiding, low relief valley. Several properties of the Tehama Formation indicate a western and northwestern origin. Mineral composition and rock type of Tehama deposits are identical to those in the Coast Ranges and Klamath Mountains. Additionally, the grain size of Tehama Formation sediments decreases to the south and east, suggesting a western and northwestern origin.

DRAFT

Pliocene Nomlaki Member

This deposit is recognized as a member of both the Tehama and Tuscan Formations indicating simultaneous deposition. The Nomlaki Member is composed of coarse tuff breccias and white tuffs of dacitic composition and has an eastern source. This widespread deposit serves as an important stratigraphical marker in the northern part of Sacramento Valley.

Pleistocene Deposits

Terrace deposits of the Pleistocene Modesto and Riverbank Formations are composed of poorly sorted clay, silt, sand, and gravel, and form a thin veneer at the ground surface. The Riverbank Formation is distinguished from the Modesto deposits by interbedded clay layers. In the Stony Creek Fan area, these terraces are well-defined, but they are absent or poorly defined along other minor streams in the study area.

Holocene Deposits

Quaternary alluvium, the most recent deposit, is found along major rivers and is composed of unconsolidated unweathered clay, silt, sand, and gravel. Fine-grained flood plain deposits include silt with minor amounts of sand. The basin deposits are composed of fine-grained sediments and are found in flood basins and near streams. The coarse-grained sediments of the alluvial fan include sand and gravel.

Geologic Relationships

This section identifies the relationship between the geologic units in the model area. There are two specific areas of interest because of their potential affect on the groundwater in the aquifer system.

- Alluvial sediments of the Stony Creek Fan and the underlying Tehama Formation
- Tehama Formation and the Tuscan Formation

Each of these is described below.

Stony Creek Fan Area

The Stony Creek Fan deposits include Pleistocene and Holocene upper, unconfined aquifer deposits. As Stony Creek meandered across the fan, channels were created, abandoned, then buried, creating a complex system of coarse- and fine-grained sediments. The variable nature of this fluviatile, depositional environment causes difficulty in defining groundwater aquifers within the fan.

The Stony Creek alluvial fan sediments form a thin veneer over the Tehama Formation. During the Pleistocene, the surface of the Tehama Formation was intensely eroded, then backfilled with both coarse- and fine-grained deposits of the Stony Creek Fan. The resulting uneven contact between the geologic units makes it difficult to determine the contact between the Stony Creek Fan deposits and the underlying Tehama Formation. In addition, the similar lithology, variable grain size, and the channelized nature of both deposits result in questionable boundary lines.

DRAFT

Tuscan and Tehama Formations Relationship

Typical Tuscan deposits are coarser than those of the Tehama Formation. Simultaneous deposition of these extensive formations onto a broad valley surface resulted in the interfingering of Tuscan and Tehama sediments near the center of the valley. In general, the grain size of the Tehama Formation becomes finer to the east, and the Tuscan Formation grades into volcanic gravels, sands, and clays where the deposits overlap. The nature of groundwater interaction where these formations merge is uncertain.

HYDROGEOLOGIC SETTING

The aquifer system of the Stony Creek Fan Area includes a freshwater aquifer overlying a saline aquifer. The freshwater alluvial aquifer system in the study area is composed of late Tertiary to Quaternary continental deposits. The aquifer system includes an upper unconfined alluvial aquifer consisting of Quaternary deposits overlying a confined aquifer system composed of Quaternary and Tertiary continental deposits of fluvial and volcanic origin. The saline aquifer system composed primarily of Tertiary and older marine deposits.

DRAFT

Freshwater Aquifer System

The freshwater aquifer system is composed of an unconfined aquifer overlying a confined aquifer as described below.

Unconfined Aquifer

The upper unconfined aquifer consists of Quaternary deposits, including Holocene alluvium, flood plain, alluvial fan, and basin deposits, and the Pleistocene Riverbank and Modesto Formations. The unconfined aquifer system is important to local groundwater users, but the potential for significant groundwater storage is limited due to insufficient thickness.

Holocene Deposits

The unconsolidated, highly permeable Quaternary alluvium deposits are important recharge areas. These deposits are generally located along major rivers and facilitate groundwater recharge from rivers. Highly permeable alluvial fan deposits, specifically of the Stony Creek

Fan, are also important recharge areas. The moderately permeable basin deposits and floodplain deposits are less important recharge areas.

Pleistocene Deposits

In addition to the Holocene deposits, the highly permeable terrace deposits of the Pleistocene Modesto and Riverbank Formations are significant recharge areas. However, low permeability clay beds of the Riverbank Formation limit the water-bearing capabilities of this deposit.

Confined Aquifer

The confined aquifer is composed of Tertiary Deposits, including the Pliocene and Pleistocene Tehama Formation and the Pliocene Tuscan Formation. These widespread and thick formations are important in aquifer storage and well water supply.

Tehama Formation

The Tehama Formation is the primary water source of the study area. Groundwater in this formation occurs under semi-confined and confined conditions. The widespread distribution and high thickness allow this formation to supply water to most of the wells in the study area. Moderately compacted, thickly bedded sandstone and siltstone layers derived from the Coast Ranges result in characteristically low to moderate permeability. However, thinner lenses of sand and gravel result in local, high permeability zones.

Potential for groundwater recharge and storage is limited by the geographic irregularity of these permeable lenses. Well yields are typically moderate for deeper wells. However, well yields vary from high to low due to variable permeability zones. Generally, wells located near the Stony Creek Fan have higher yields than those located to the south. The Tehama Formation has a higher concentration of more permeable coarse material in the vicinity of the alluvial fan deposits. Variations in well yields indicate the north to south decrease in grain size.

DRAFT

Tuscan Formation

The Tuscan Formation serves as the primary source of groundwater on the east side of the Sacramento River. In the study area, these deposits occur at depths inaccessible to most domestic and irrigation wells. Of the four Tuscan Units, only A, B, and C are found in the study area.

Within this formation, moderately to highly permeable volcanic sediments are hydraulically confined by layers of tuff breccias and clays. The low permeability lahar deposits of Unit C serve as confining beds for the underlying older Tuscan Units A and B. Although Unit C contains permeable volcanic sandstone and conglomerate interbeds, this unit is characterized by an overall low yield of water to wells. Units A and B are much more coarse-grained than the overlying Unit C, causing them to be the primary water-bearing zones of eastern Sacramento Valley.

DRAFT

Saline Aquifer System

The saline aquifer system lies beneath the fresh water aquifer. The base of the fresh water aquifer is defined by the contact between continental deposits and pre-Pliocene marine deposits. The marine deposits present in the study area subsurface include the Miocene Neroly Formation, the Miocene and Oligocene Upper Princeton Gorge Formation, the Eocene Lower Princeton Gorge Formation, and the Cretaceous Great Valley Sequence.

SECTION 4 CONCEPTUAL MODEL STRATIGRAPHY FOR SCFIGSM

This section presents the conceptual model stratigraphy for the SCFIGSM. The conceptual model stratigraphy was presented to the Stony Creek Fan Technical Team at the August 8, 2002, Technical Team Meeting. The conceptual model stratigraphy was developed based on the hydrogeologic properties of the geologic units described in Section 3. A schematic of the four-layer conceptual SCFIGSM stratigraphy is presented in Figure 4.1, and summarized on Table 4.1.

DRAFT

SCFIGSM LAYER 1

The conceptual model for SCFIGSM Layer 1 includes Pleistocene and Holocene deposits consisting of Holocene alluvium, alluvial fan, flood plain, and basin deposits, and the Pleistocene Modesto and Riverbank Formations. The highly permeable sands and gravels of Pleistocene Modesto and Riverbank Formations are only present on the Stony Creek Fan. Where Layer 1 is present throughout the model area it is exposed at the ground surface, and represents the unconfined groundwater system. Wells perforated in this layer are likely used for domestic and some agricultural water supplies.

The highly permeable sands and gravels are 50 to 80 feet thick within the Stony Creek Fan. They are not present outside the Stony Creek Fan. On the Fan, some of the highly permeable deposits are underlain by up to 50 feet of finer-grained alluvial or basin deposits. Outside the Fan, alluvial and basin deposits can reach a total thickness of 200 feet. The conceptual model stratigraphy was developed to reflect the significant difference in the characteristics of the Fan material and the other alluvial deposits present within the model area.

Inside the Fan Area

Inside the Stony Creek Fan Area, SCFIGSM Layer 1 represents the 50 to 80 foot thick highly permeable sand and gravel deposits. Any alluvial or basin deposits that may be present beneath the sands and gravels are included in Layer 2.

Figure 4.1
Stony Creek Fan IGSM
Conceptual Model Stratigraphy

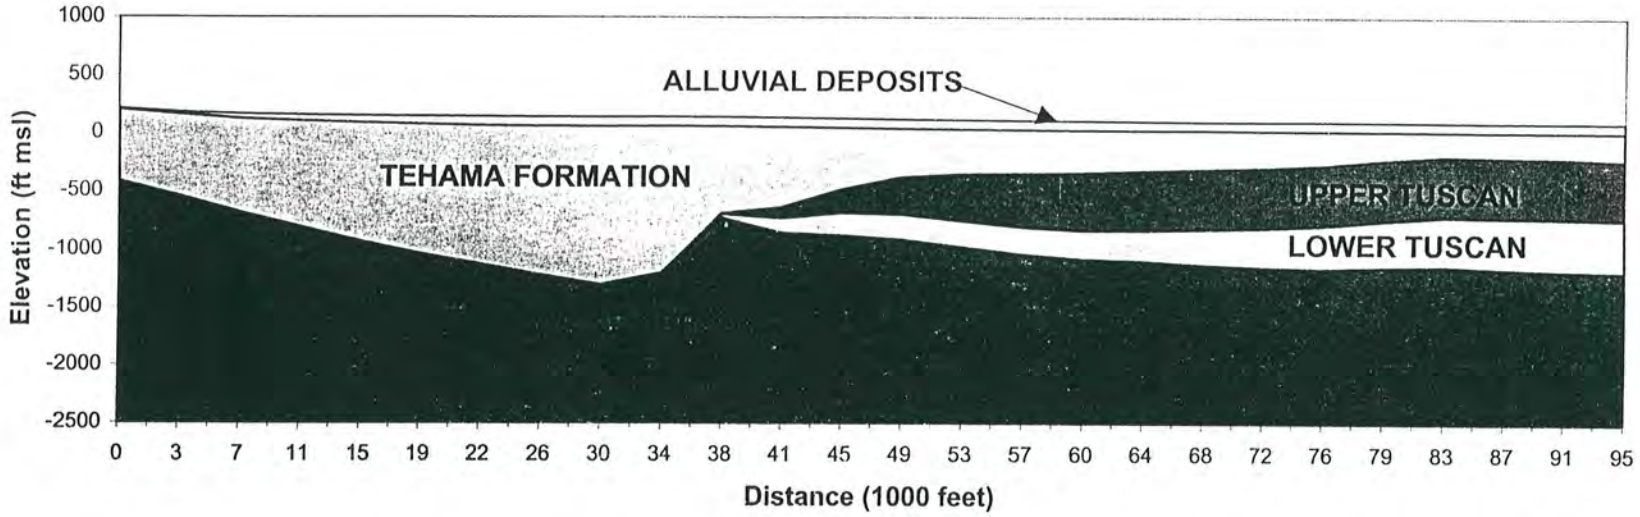


Table 4.1
SCFIGSM Stratigraphy
Definition of Layers

Location within Model	Fan Material	Alluviam, Basin and Flood Plain Deposits	Tehama Formation	Upper Tuscan Formation	Lower Tuscan Formation
	Predominantly gravel and sand with minor amounts of silt and clay.	Characterized by fine-grained silts and clays.	Moderately compacted sandstone and siltstone enclosing lenses of sand and gravel; silt and gravel; and cemented conglomerate.	Characterized by massive lahar deposits.	Composed of volcanic conglomerate, sandstone, and siltstone layers interbedded with lahars.
Inside Fan Area					
Layer 1	1 ●	1			
Layer 2		2	2 ●		
Layer 3				3 ●	
Layer 4					4 ●
Outside Fan Area					
Layer 1	Not Present	up to 80 feet 1 ●			
Layer 2		greater than 80 feet 2	2 ●		
Layer 3				3 ●	
Layer 4					4 ●

■ Designates the composition of each layer in the current model using Layer 1 = 50-80 feet thick where Layer 1 is defined by the hydrogeologic properties of the material.

● Designates the composition of each layer in the alternate model which would follow the geologic cross sections exactly and classifly Layer 1 as all Quaternary alluvial deposits.

Outside the Fan Area

Outside the Stony Creek Fan Area, SCFIGSM Layer 1 represents the upper 80-foot thickness of the basin and alluvial deposits. Any remaining basin or alluvial deposits are considered part of SCFIGSM Layer 2.

SCFIGSM LAYER 2

The conceptual model for SCFIGSM Layer 2 consists primarily of the Tehama Formation (described in Section 3). The widespread distribution and thickness allow this formation to supply water to many of the agricultural wells in the study area. The Tehama Formation is present throughout the model area ranging in thickness from about 200 feet to over 2,000 feet. Model Layer 2 thickens from west to east about halfway across the model area. Model Layer 2 thins rapidly where Model Layer 3 is present (Table 4.1). As mentioned above, for modeling purposes, Layer 2 does include some basin and alluvial deposits.

DRAFT

Model Layer 2 generally represents groundwater systems ranging from semi-confined to confined conditions. Confinement generally increases with depth, but the actual level of confinement may vary locally due to other conditions, such as continuously perforated wells connecting different aquifer layers. Model Layer 2 is exposed at the ground surface in the northwestern portion of the model area.

SCFIGSM LAYER 3

The conceptual model for SCFIGSM Layer 3 consists of the Upper Tuscan Formation (described in Section 3). Model Layer 3 is present throughout the eastern portion of the model area (Figure 4.1). It consists of fine-grained lahar deposits, so groundwater within Layer 3 represents confined aquifer conditions. Because of its low permeability, few wells in the model area rely on Layer 3 for groundwater supply.

SCFIGSM LAYER 4

The conceptual model for SCGIGSM Layer 4 consists of the Lower Tuscan (described in Section 3). Model Layer 4 is present throughout the eastern portion of the model area (Figure 4.1). In contrast to Layer 3, it is composed of more permeable volcanic

conglomerate, sandstone, and siltstone layers interbedded with lahars. It is overlain by the Upper Tuscan Formation (Layer 3), which acts as a confining layer; as a result, groundwater within Layer 4 represents confined aquifer conditions. At this time, few production wells in the model area reach Layer 4, so it currently has little groundwater production and water level data.

BASE OF THE AQUIFER SYSTEM

The base of the aquifer system is considered to be the base of the freshwater-bearing deposits (Figure 4.1). The base of the aquifer system is represented by the base of Model Layer 2 (base of the Tehama Formation) in the western half of the model area,. The base of the aquifer system is represented by the base of Model Layer 4 (base of the Lower Tuscan Formation) in the eastern half of the model area,.

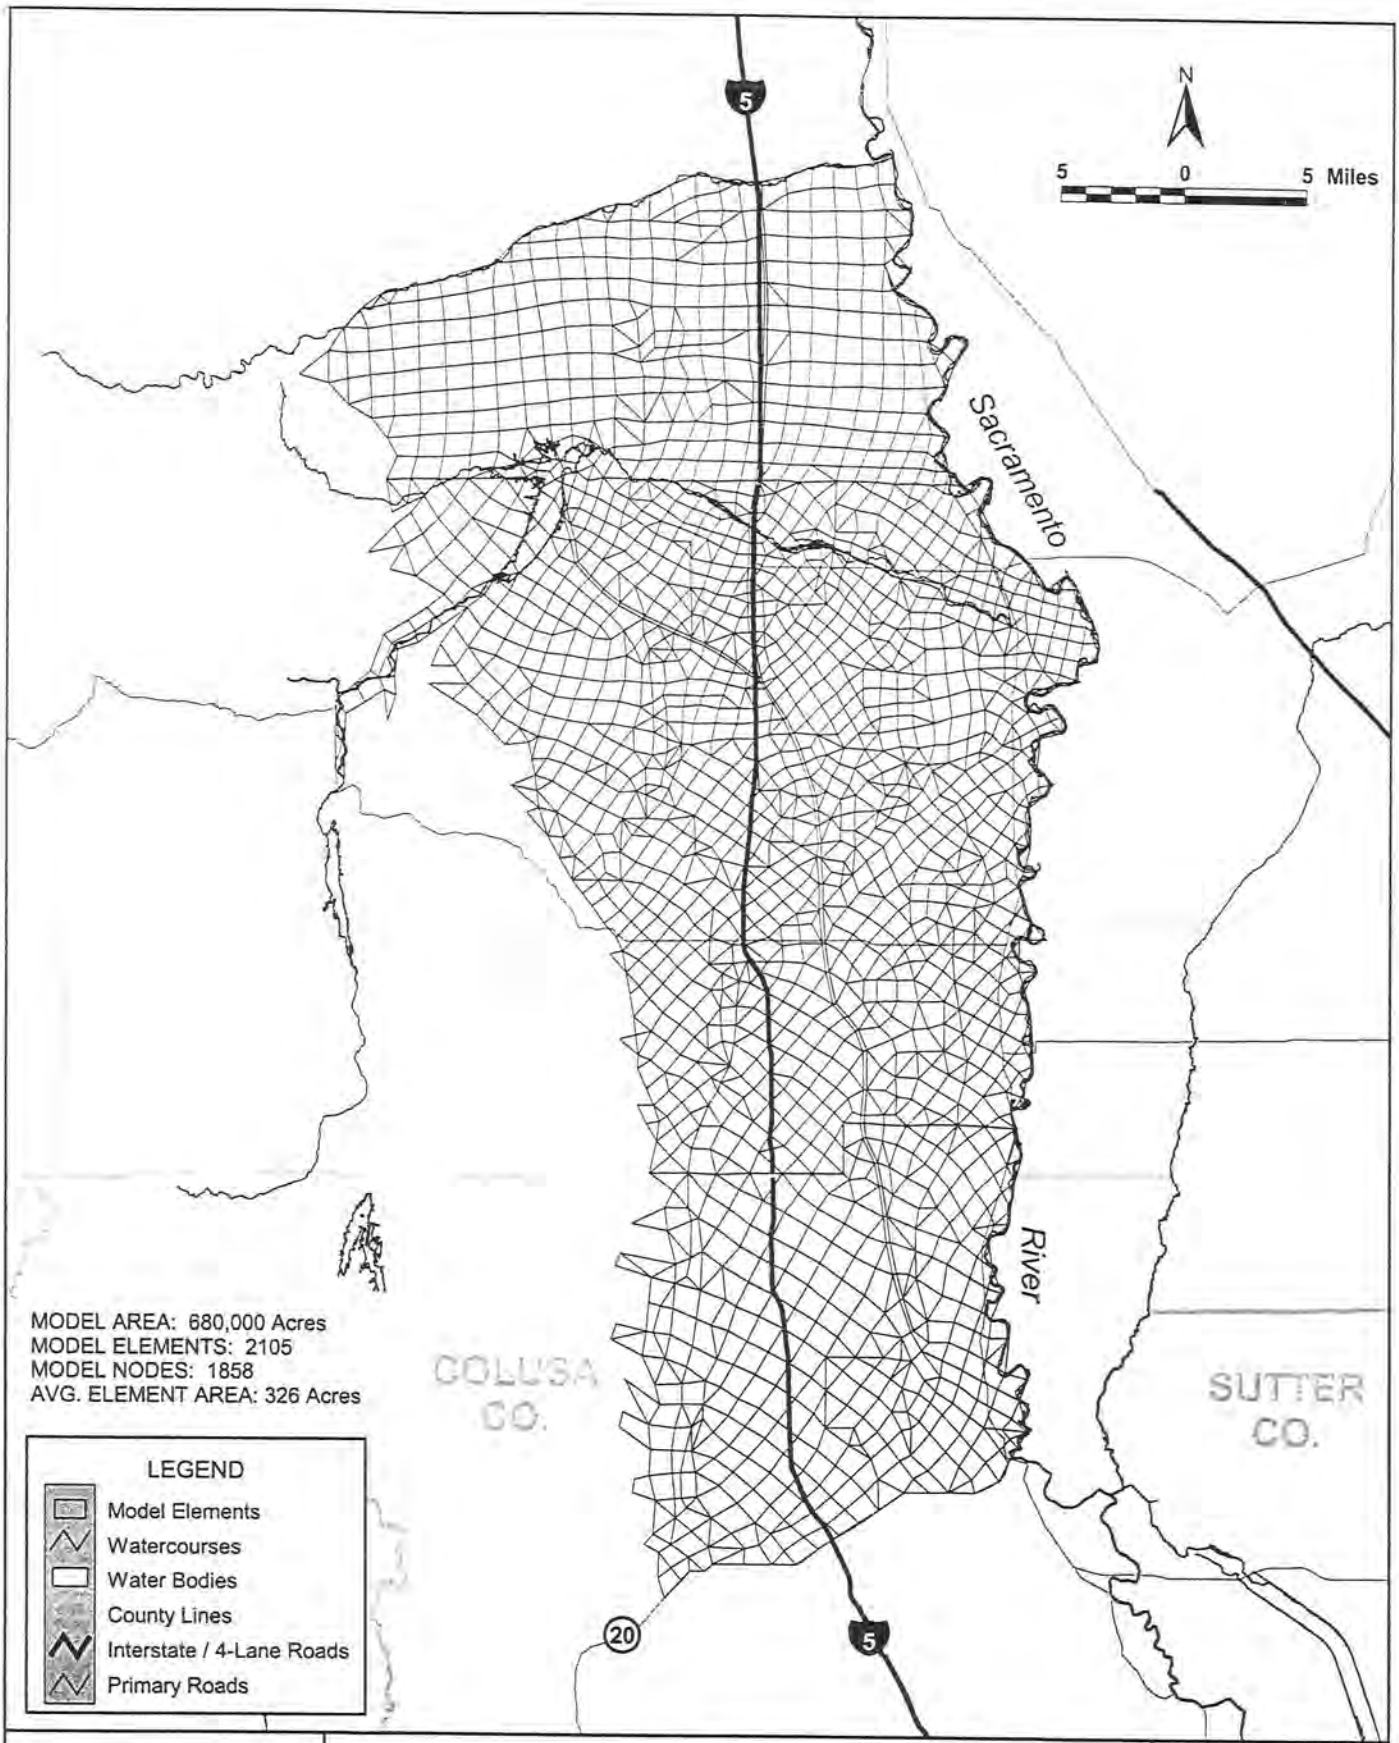
The base of freshwater is mapped in the model area on the basis of available electronic log data. In some locations the base of freshwater is identified to exist within the lower portions of the Tehama Formation or Tuscan Formation (Figure 4.1). The base of freshwater is not considered as a boundary between model layers because it is not a fixed location (such as the base of a formation). Also, it is unlikely to significantly interact with the water supply projects because it is located at the bottom of the aquifer system.

DRAFT

SECTION 5 SCFIGSM GRID

The purpose of this section is to document the methodology used to develop the SCFIGSM grid. A two-dimensional finite element grid network was developed to model the groundwater flow in the Stony Creek Fan Area. The entire model area consists of about 1,060 square miles. The SCFIGSM model grid (shown in Figure 5.1) was divided into 2,148 elements and 1,853 model nodes. The average size of single element is about one-half square mile (316 acres). Notable features of the model grid are:

- Model boundary matches the hydrologic and hydrogeologic boundaries of the Stony Creek Fan Area;
- Grid orientation follows the regional groundwater streamlines;
- Elements are smaller in the vicinity of steep groundwater gradients; and
- Thin strips of elements are used to incorporate the discontinuities in the groundwater levels across major geologic faults and barriers.



The model grid is defined by Universal Transverse Mercator (UTM) coordinates at each model node and be the list of connecting nodes for each model element. The x-y coordinates for each model node were obtained from Geographic Information System (GIS) coverage of the model area in UTM Zone 10.5. The list of connecting nodes for each element was developed after numbering the model nodes and model elements. Two independent sets of sequential numbers were used for nodes and elements. These node and element numbers are used in specifying model input data.

The SCFIGSM grid was develop to reflect local conditions including:

- Geologic and Hydrogeologic Considerations,
- Hydrologic Considerations, and
- Potential Water Management Project Areas.

Each of these considerations is described below.

DRAFT

RIME Water Resources & Information Management Engineering, Inc.

STONY CREEK FAN CONJUNCTIVE WATER MANAGEMENT PROGRAM

Model Grid

DRAFT

JANUARY 2003

FIGURE 5.1

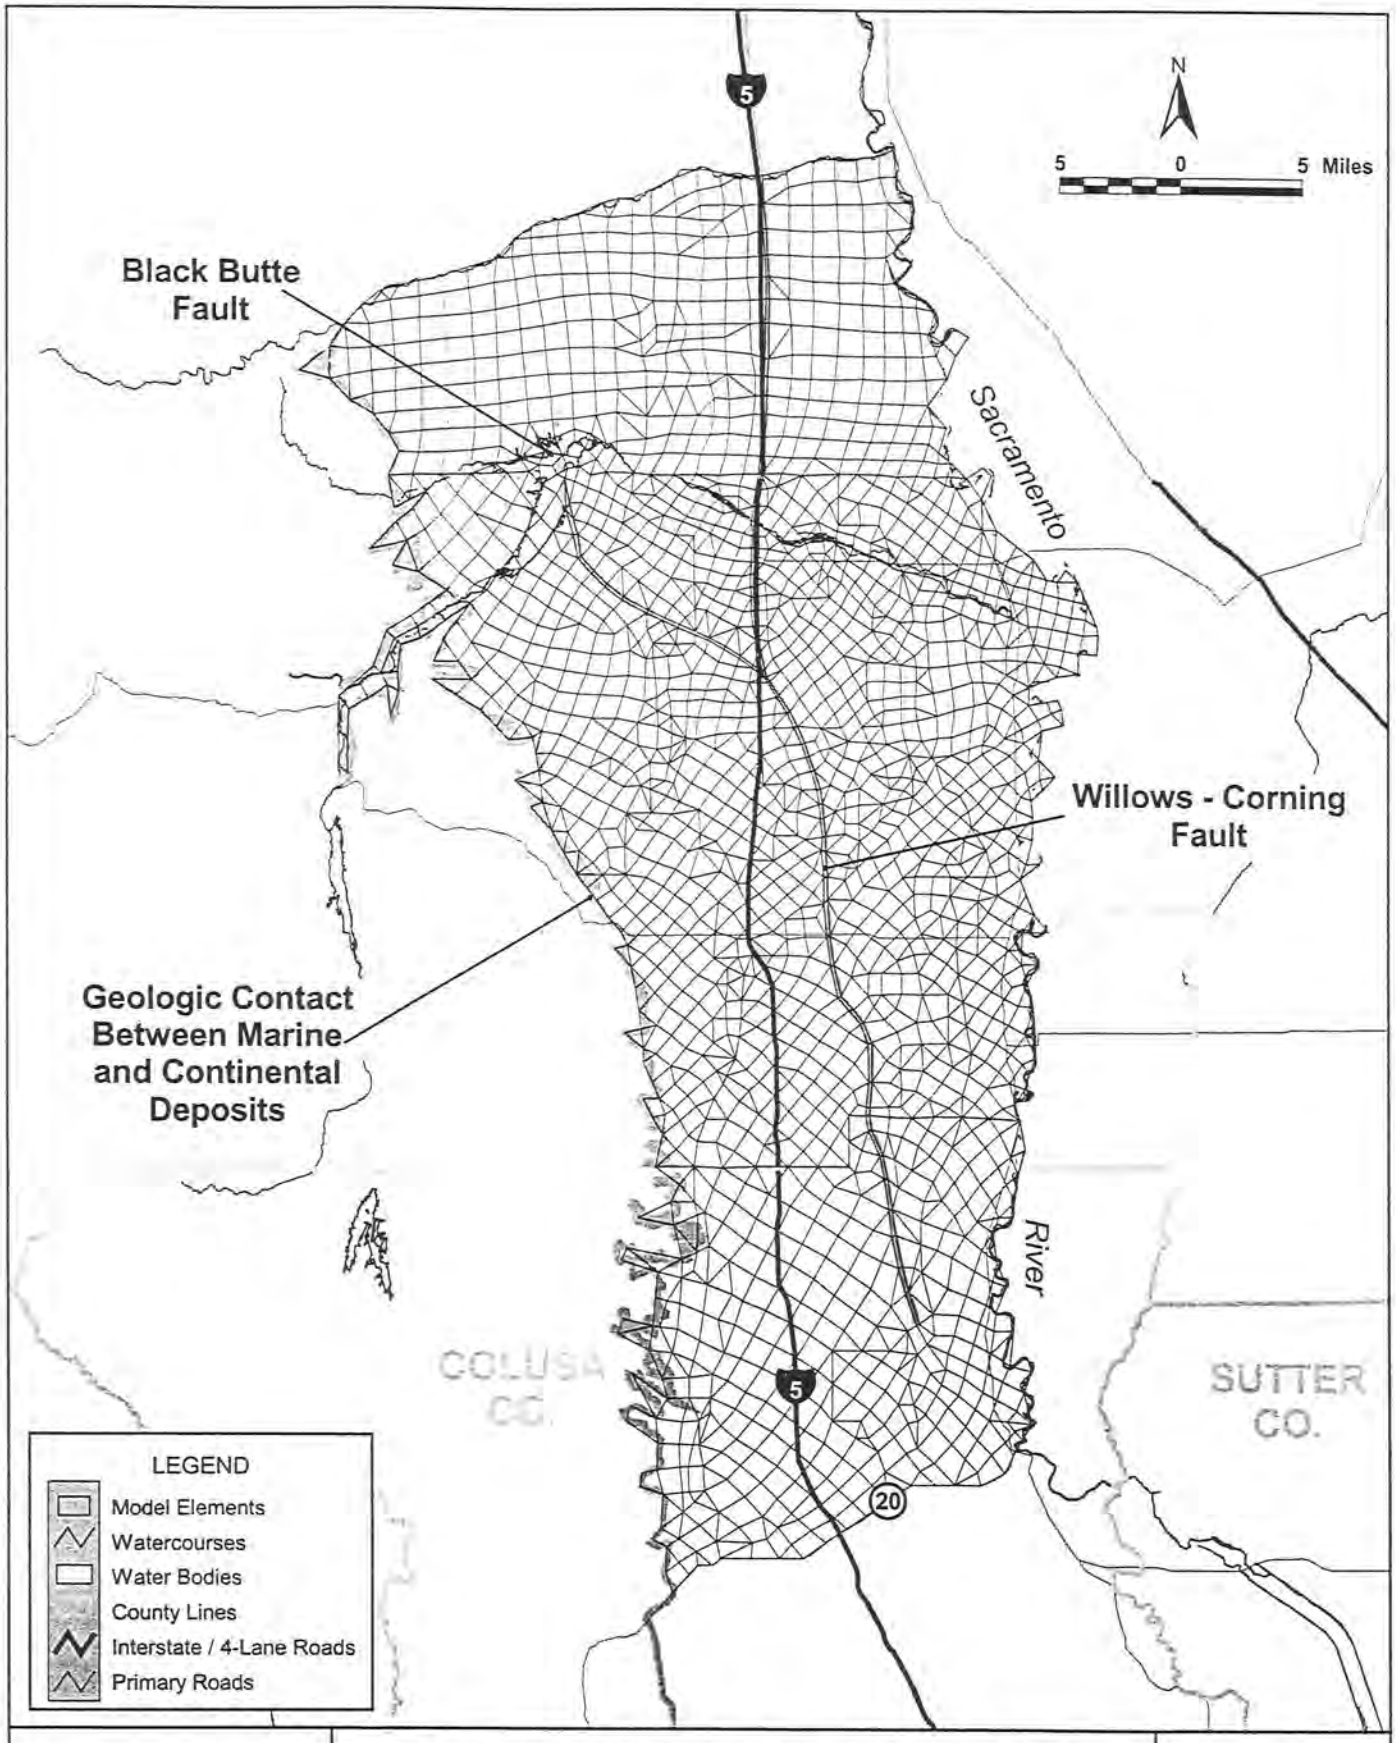
GEOLOGIC AND HYDROGEOLOGIC CONSIDERATIONS

The geologic and hydrogeologic information presented in Section 3 was considered during the SCFIGSM model grid development. These include:

- Geologic Contacts,
- Faults, and
- Groundwater Flow Direction.

Geologic Contacts

The western boundary of the SCFIGSM grid was defined as the contact between the marine basement rocks of the Coast Range and the continental and alluvial deposits of the Central Valley. The geologic contact between the marine deposits and the continental alluvial deposits is shown in Figure 5.2.



Faults

The SCFIGSM model grid was developed to reflect those faults that either may affect the flow of groundwater, or result in an abrupt change in the aquifer thickness. The SCFIGSM model grid reflects existence of faults by a narrow band of elements along the trace of the fault. After several discussions with DWR, the two faults incorporated into the model grid include the Black Butte Fault and the Willows-Corning Fault. The locations of these faults are shown in Figure 5.2.

Groundwater Flow Direction

The long-term regional groundwater flow directions were considered in the SCFIGSM grid development. Near the Stony Creek Fan, the regional groundwater flow direction is from the fan's apex to the distal portions of the fan generally in the northwest to southeast direction. North and South of the Stony Creek Fan groundwater generally flows from the upland areas in the west towards the Sacramento River near the center of the Valley.

Geologic and Hydrogeologic Considerations

DRAFT

JANUARY 2003

FIGURE 5.2

HYDROLOGIC CONSIDERATIONS

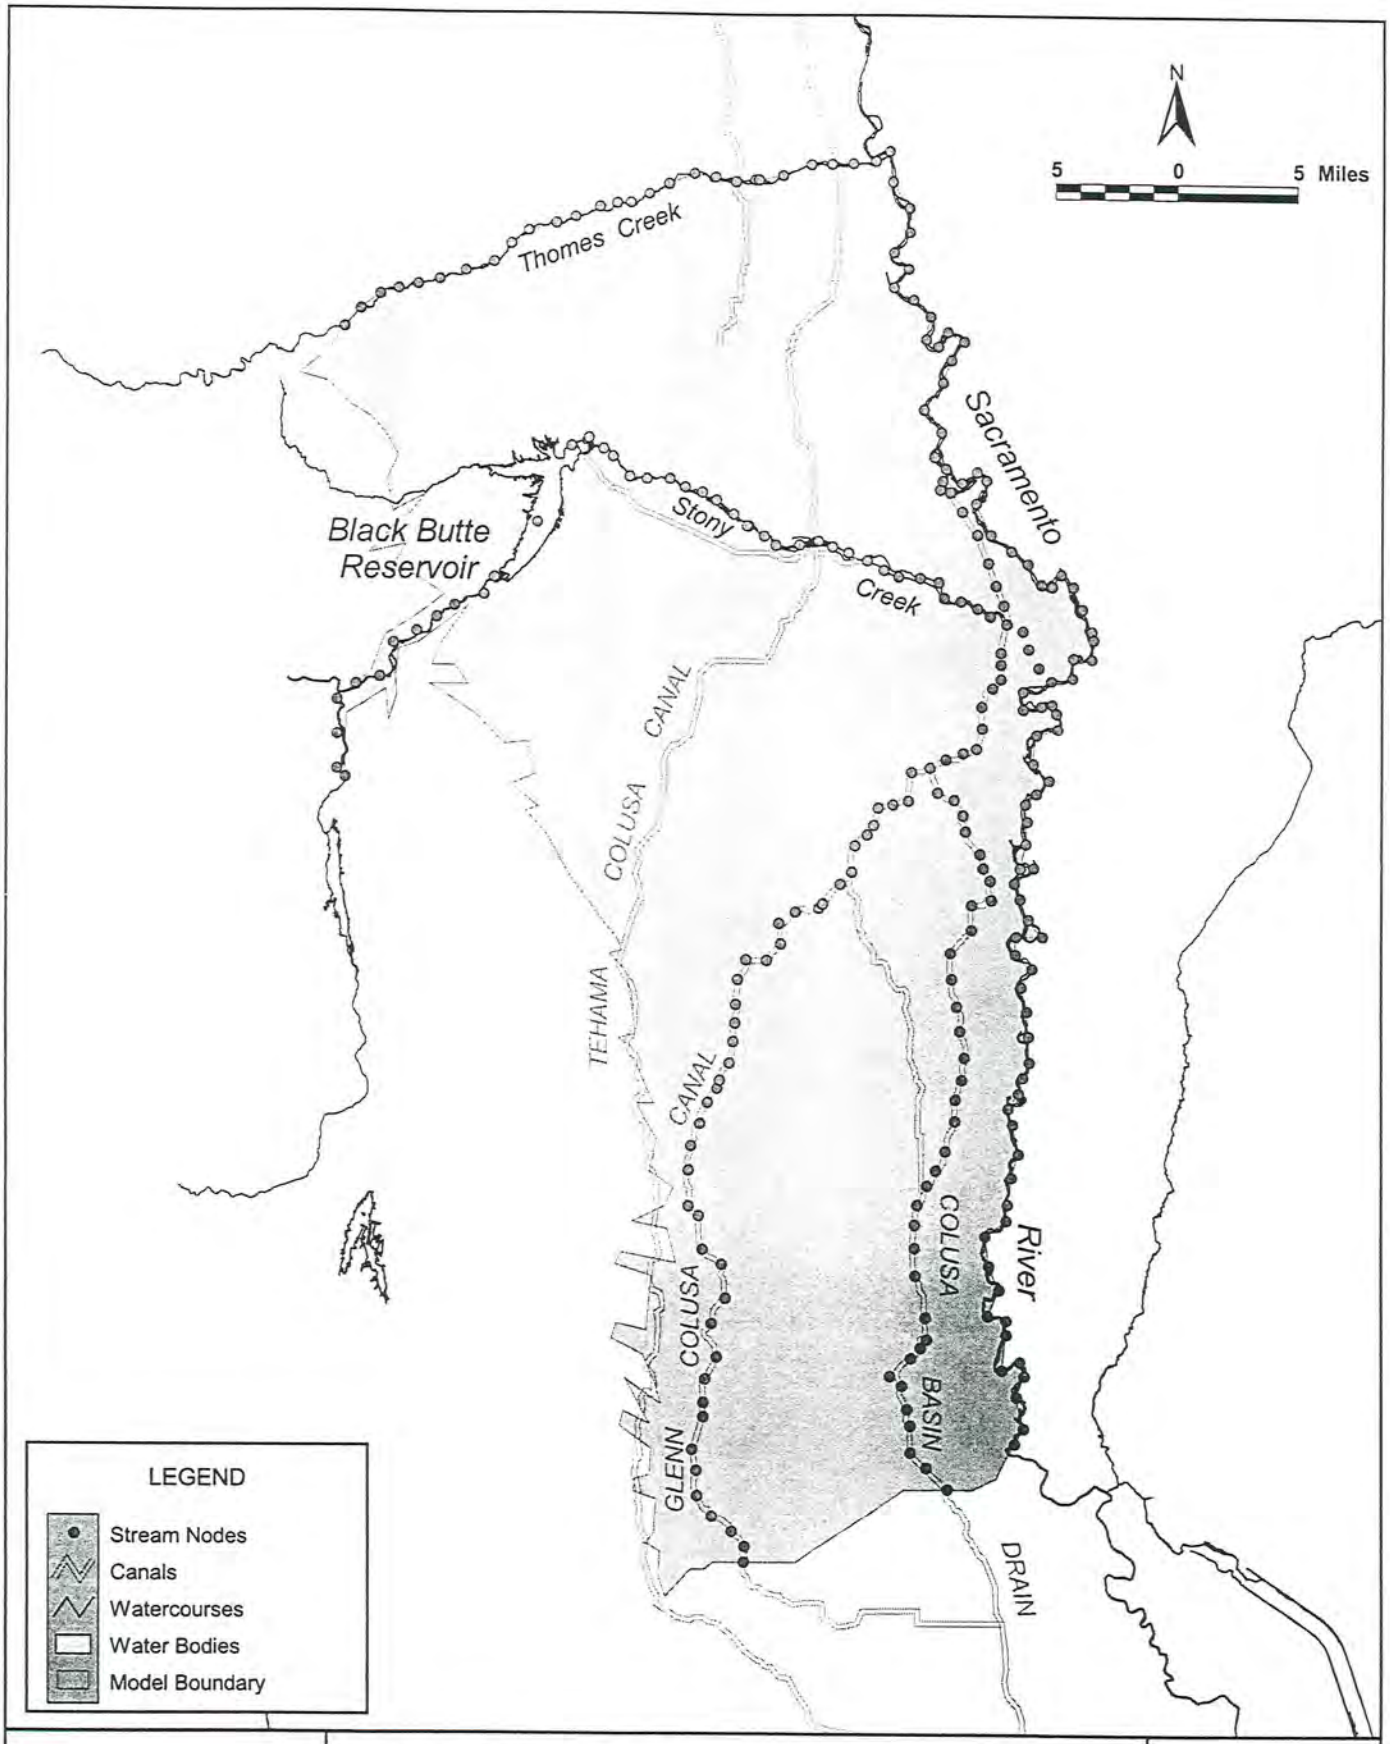
The surface water flow system is modeled by using 1-dimensional line elements along the stream courses. These line elements are defined by stream nodes that are coincident with the aquifer nodes. An independent numbering system is used to number the stream nodes. There are 266 stream nodes representing the surface water flow system in the SCFIGSM. This includes rivers, creeks, and lakes as well as major unlined water delivery canals and drains. Figure 5.3 shows the locations of the hydrologic features simulated in the SCFIGSM model area, such as:

- Rivers and Creeks,
- Lakes, and
- Canals and Drains.

DRAFT

Rivers and Creeks

There are three rivers and creeks simulated in the SCFIGSM: Thomes Creek, Sacramento River, and Stony Creek.



- **Thomes Creek** coincides with the northern boundary of the SCFIGSM, and is simulated along the stream nodes shown in Figure 5.3.
- **The Sacramento River** coincides with the eastern boundary of the SCFIGSM, and is simulated along the stream nodes shown in Figure 5.3.
- **Stony Creek** is located within the SCFIGSM model area. It is simulated both above and below Black Butte Reservoir along the stream nodes shown in Figure 5.3.

Lakes

Black Butte Lake is located entirely within the SCFIGSM model area. The model grid was developed to represent the maximum inundation area of Black Butte Lake. The extent of the Black Butte Lake is shown in Figure 5.3.

Canals and Drains

There are six major canals and drains within the SCFIGSM area. Each of these canals and drains was considered individually to determine if it should be simulated in the model. They are listed below:

RIME Water Resources & Information Management Engineering, Inc.

STONY CREEK FAN CONJUNCTIVE WATER MANAGEMENT PROGRAM

Location of Hydrologic Features

DRAFT

JANUARY 2003

FIGURE 5.3

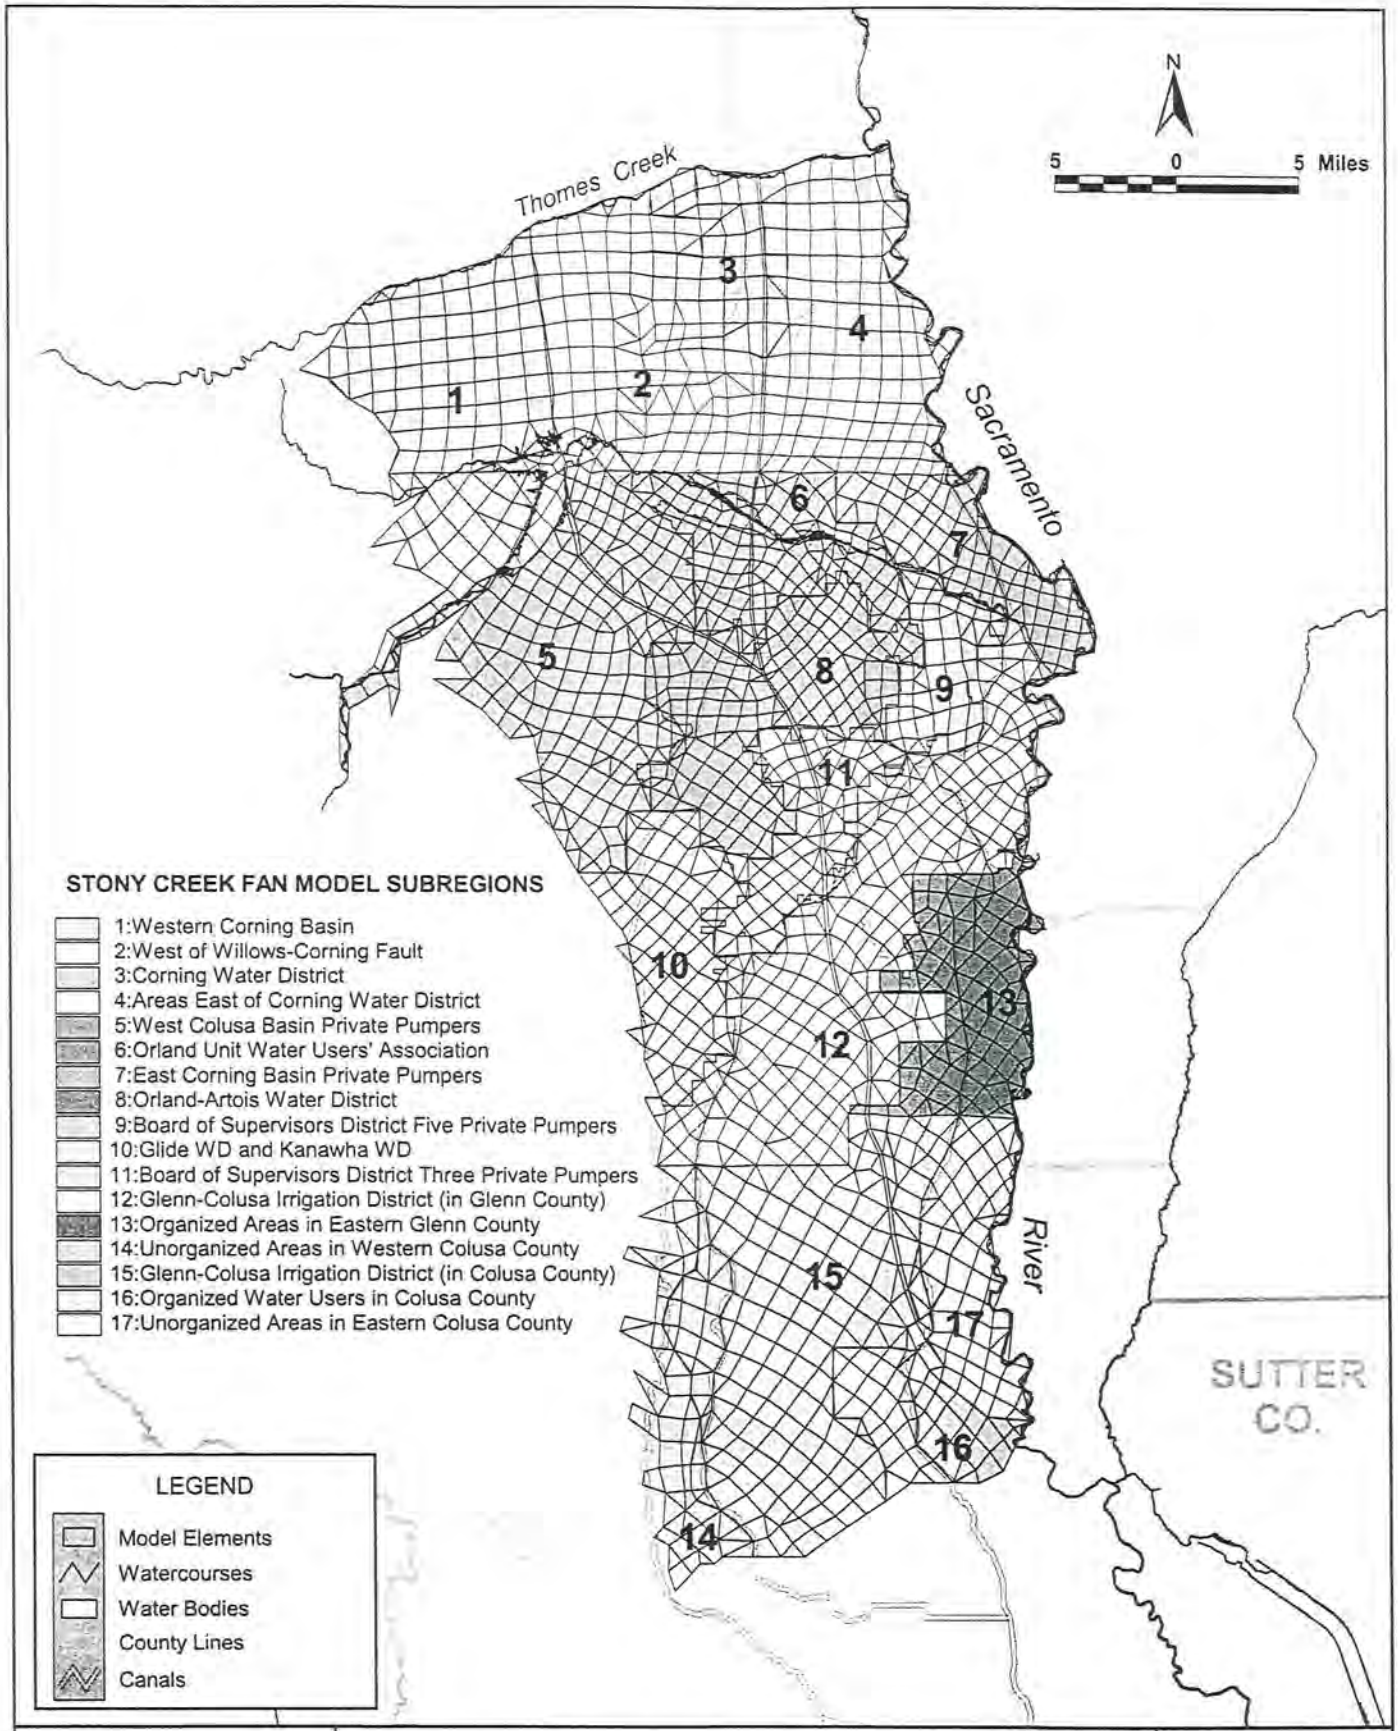
- The southern extent of the **Corning Canal** extends approximately 5 miles south of Thomes Creek into the model area. At this time the Corning Canal is not simulated in the SCFIGSM.
- The **Orland North and South Canals** are piped, so there is limited interaction with the groundwater basin. They are not simulated in the SCFIGSM.
- The **Tehama Colusa Canal** is lined through the model area, so it is not simulated in the SCFIGSM.
- The **Glenn-Colusa Irrigation District Main Canal** is unlined. It is simulated in the SCFIGSM along the stream nodes shown on Figure 5.3.
- The **Colusa Basin Drain** is unlined. It is simulated in the SCFIGSM along the stream nodes shown on Figure 5.3.

DRAFT

POTENTIAL WATER MANAGEMENT PROJECT AREAS

Water and land use management in the model area is represented in the SCFIGSM by subdividing the model area into 17 management areas called subregions. The criteria for the subregion delineation is described below and presented in Table 5.1. The location of the SCFIGSM model subregions is shown on Figure 5.4.

Stony Creek Feasibility Study Subunits



Model subregions were developed to provide geographic coverage similar to the water balance subunits used in the Stony Creek Fan Feasibility Study. This criterion was utilized to define six subregions on or adjacent to the Stony Creek Fan as presented in Table 5.1 and shown in Figure 5.4. SCFIGSM Subregions 6, 7, 8, 9, 11, and 12 were defined based on this criterion.

Glenn County Basin Management Objectives Basin Management Sub-Areas

Additional model subregions were developed to provide geographic coverage similar to the basin management subareas used in the Glenn County Basin Management Objectives. This criterion was utilized to define four subregions within the model area in Glenn County as presented in Table 5.1 and shown in Figure 5.4. SCFIGSM Subregions 1 (portion in Glenn County), 5, 10, and 13 were defined based on this criterion.

Table 5.1
Stony Creek Fan Conjunctive Use Project
SCF IGSM Model Subregions

Stony Creek Fan Conjunctive Use Project		*Primary Criteria*	*Optional Criteria*	
Subregion Number	**Model Subregion Name**	**Stony Creek Fan Feasibility Study Water Balance Subunits**	**Glenn County BMO Basin Management Sub-Area**	**Comments**
1	Western Corning Basin	NA	1 (West Corning Basin Private Pumpers)	Includes unorganized areas in western Tehama County.
2	West of Willows Corning Fault	NA	NA	Includes the area between the northern extension of the Black Butte Fault and the Willows-Corning Fault.
3	Corning Water District	NA	NA	
4	Areas east of Corning Water District	NA	NA	
5	West Colusa Basin Private Pumpers	NA	3 (West Colusa Basin Private Pumpers)	
6	Orland Unit Water Users' Association	1 (Orland Unit Water Users' Association)		
7	East Corning Basin Private Pumpers	5 (East Corning Basin Private Pumpers)

FIGURE 5.4

Tehama County

Four subregions were defined in Tehama County based on the hydrogeologic conditions and water supply source (access to surface water). Subregions 1 (portion in Tehama County), 2, 3, and 4 were defined based on this criterion.

Colusa County

Four subregions were defined in Colusa County, primarily based on the water supply source (access to surface water). Subregions 14, 15, 16, and 17 were defined based on this criterion.

DRAFT

SECTION 6 SCFIGSM STRATIGRAPHY DATA

The purpose of this section is to document the data and methodology used to develop the stratigraphy data for the SCFIGSM. The stratigraphy data is assigned to each model node in the model area (total of 1853 model nodes) for each layer included in the model.

The methodology to develop the SCFIGSM stratigraphy data involved a three-step process described below:

- **Step 1. Develop Preliminary Stratigraphy Data:** The purpose of this step is to collect and analyze the available stratigraphy data for the model area and develop a preliminary set of stratigraphy data for the SCFIGSM.
- **Step 2. Refine Stratigraphy Data:** The purpose of this step is to refine the SCFIGSM stratigraphy data set developed in Step 1 to check for accuracy and reasonableness of the data.
- **Step 3. Quality Control of Stratigraphy Data:** The purpose of this step is to complete the quality control process of SCFIGSM stratigraphy data and develop the figures and tables necessary to allow efficient presentation and review of the stratigraphy data.

DRAFT

STEP 1: PRELIMINARY STRATIGRAPHY BASED ON CROSS-SECTION DATA

The goal of Step 1 is to convert the available cross-section data (randomly spaced stratigraphy data) to each of the SCFIGSM model nodes. The six sub steps listed below were required to develop the preliminary SCFIGSM stratigraphy data file.

- **Step 1A. Collect Cross-Section Data Available From DWR**
- **Step 1B. Digitize Cross-Sections to Establish Control Points**
- **Step 1C. Aggregate Control Point Data to SCFIGSM Layers**
- **Step 1D. Distribute Stratigraphy Layer Data to SCFIGSM Area**
- **Step 1E. Distribute Stratigraphy Data to SCFIGSM Nodes**
- **Step 1F. Develop Model Layer Thickness by Model Nodes**

Each of these sub steps is described below.

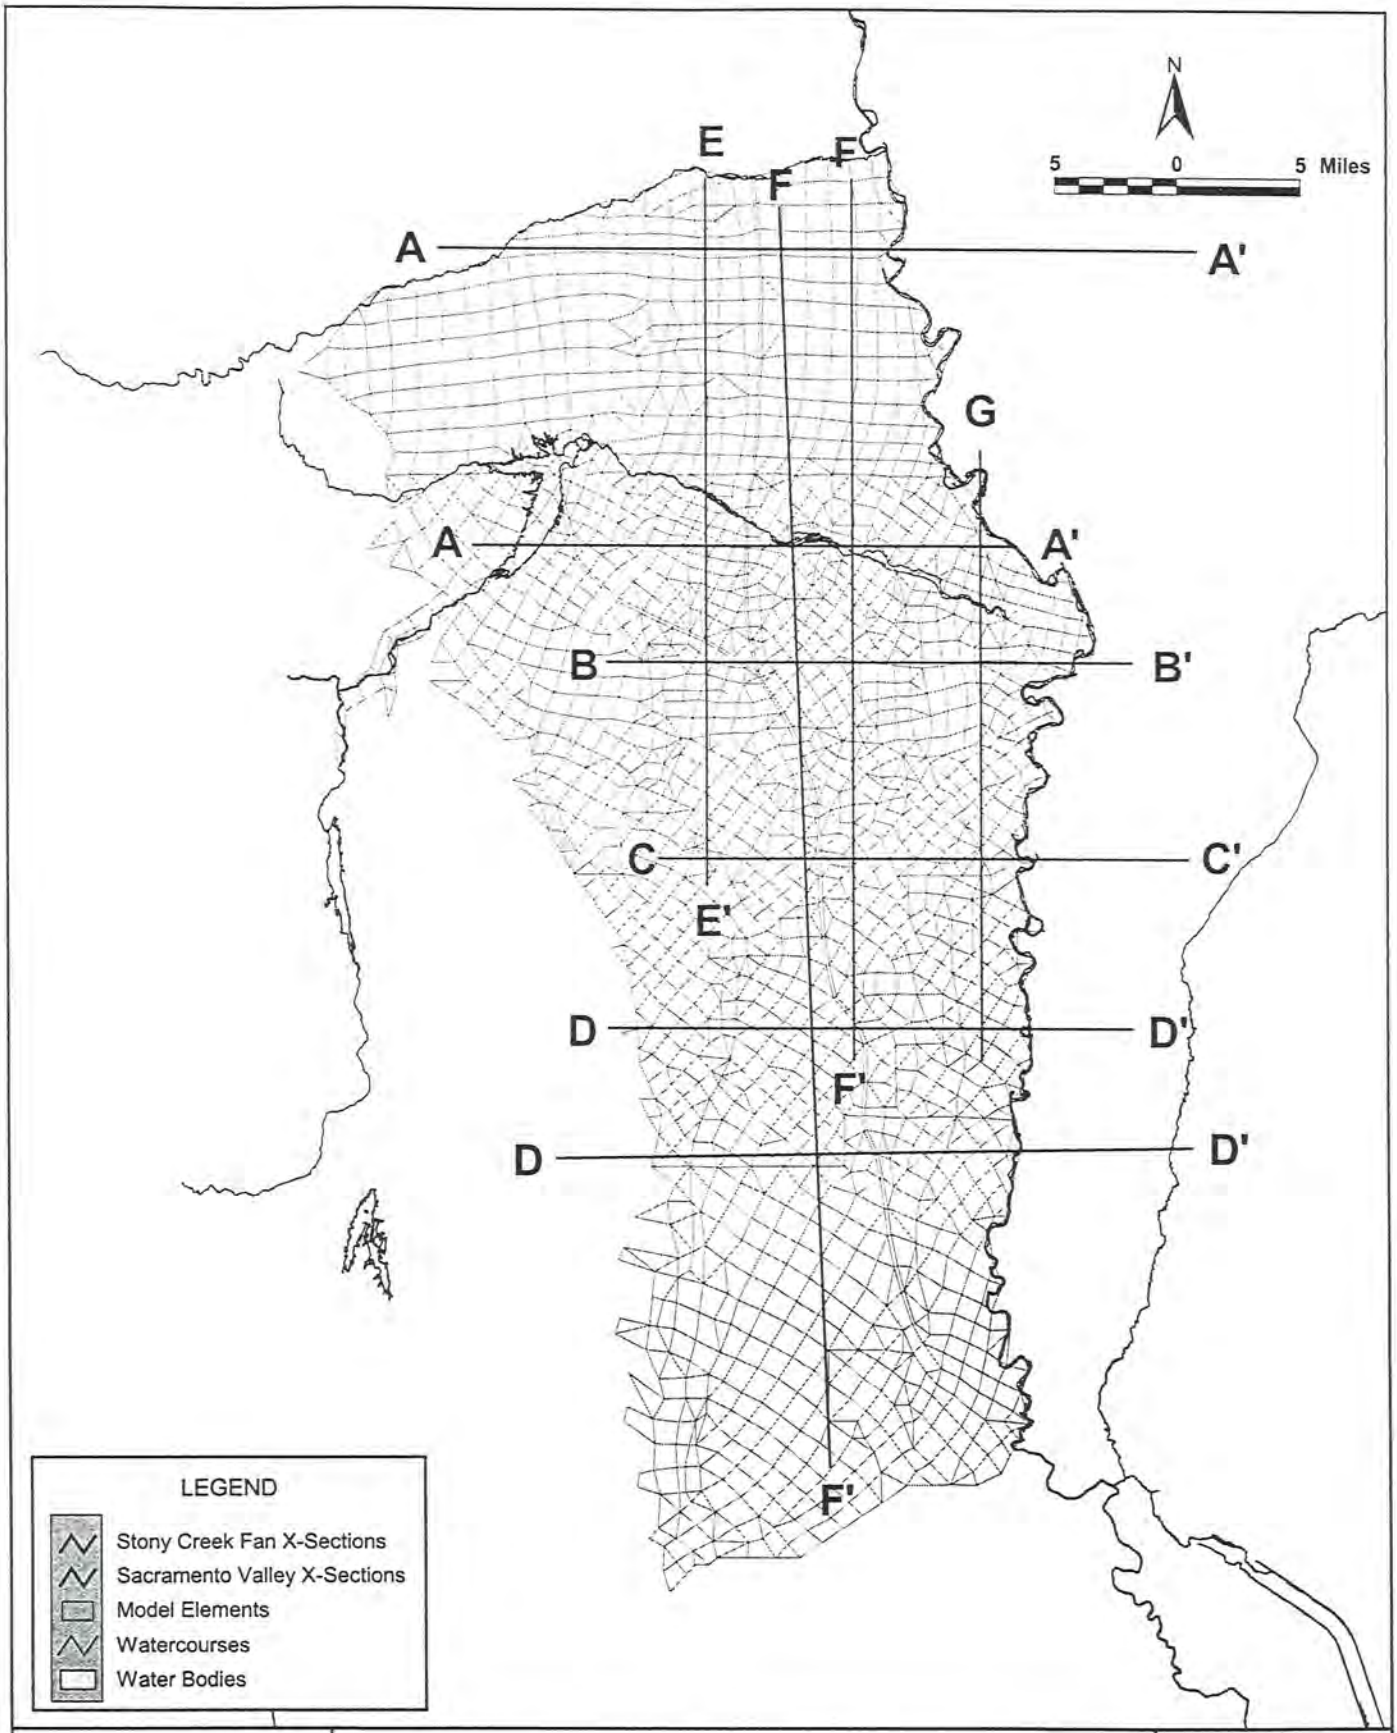
STEP 1A. COLLECT CROSS-SECTION DATA AVAILABLE FROM DWR

Based upon the review of available geologic and hydrogeologic data described in Section 2 of this technical memorandum, it was determined that the best source of data available to develop the stratigraphy data for the SCFIGSM was the recent set of cross-sections developed by the DWR Northern District. The Northern District office completed two sets of cross-sections, one for the northern Sacramento Valley, and a second set for the Stony Creek Fan Area. Each of these sets of cross-sections is described below.

Sacramento Valley

The Northern District developed six cross-sections based on electric logs for the northern Sacramento Valley. The northern Sacramento Valley generally includes the portion of the Central Valley north of the Sutter Buttes and extending north to Redding. This includes portions of Colusa, Butte, Glenn, Tehama, and Shasta Counties.

Stony Creek Fan



More recently, the Northern District developed seven cross-sections based on electronic logs for the Stony Creek Fan Area. These were developed as part of the Department's ongoing investigation of the Stony Creek Fan Area. These sections were the primary source of stratigraphy data used to develop the model layering in the SCFIGSM.

The three cross-sections from the Sacramento Valley cross-sections were used to extend the Stony Creek Fan cross-section data to the entire SCFIGSM model area for those areas that extend beyond the Stony Creek Fan. The Northern District provided electronic files for each of the cross-sections included in their analysis. Figure 6.1 shows the sections used in this analysis.

DRAFT

STEP 1B. DIGITIZE CROSS-SECTIONS TO ESTABLISH CONTROL POINTS

Once the selected DWR cross-sections within the SCFIGSM model area were identified, all geologic layers were digitized using Surfer 8.0 (Surfer). The digitization required carefully tracing each contact and fault as well as digitizing the minimum and maximum x and y

RIME Water Resources & Information Management Engineering, Inc.

STONY CREEK FAN CONJUNCTIVE WATER MANAGEMENT PROGRAM

DWR Geologic Cross Sections Used in Stratigraphic Analysis

DRAFT

JANUARY 2003

FIGURE 6.1

values from the axes of each cross section. This process established control points (points of known location and stratigraphic thickness), which would be used to develop the stratigraphic data.

STEP 1C. AGGREGATE CONTROL POINT DATA TO SCFIGSM LAYERS

This step converts the control points of the individual cross-sections developed in Step 1B to the model layers to be used in the SCFIGSM.

Approximately 500 control points were identified to represent the base for each model layer from the digitized cross-sections. This process was completed for the:

- Elevation of the Base of Model Layer 1,
- Elevation of the Base of Model Layer 2 (base aquifer system in the western portion of the SCFIGSM),
- Elevation of the Base of Model Layer 3, and
- Elevation of the Base of Model Layer 4 (base aquifer system in the eastern portion of the SCFIGSM).

The ground surface elevation was developed from digital elevation model (DEM) data developed by the USGS.

DRAFT

STEP 1D. DISTRIBUTE STRATIGRAPHY LAYER DATA TO SCFIGSM AREA

The purpose of this step is to distribute the model layer elevation control point data developed in Step 1C to the SCFIGSM nodes. The irregularly spaced control points for each model layer were distributed to a finely spaced regular grid. This was completed with Surfer using a 250 by 250 mesh grid that covered the SCFIGSM area.

STEP 1E. DISTRIBUTE STRATIGRAPHY DATA TO SCFIGSM NODES

The purpose of this step is to assign the model layer elevation data from fine mesh grid (Step 1D) to SCFIGSM model nodes. This was completed using the bilinear interpolation provided in Surfer. Note the SCFIGSM grid is generally coarser than the fine mesh grid.

STEP 1F. DEVELOP MODEL LAYER THICKNESS BY MODEL NODES

The purpose of this step was to convert the model layer elevation data to model layer thickness (for input into the SCFIGSM stratigraphy data file). This was completed by determining the difference between model layers at each node. The thickness of Model Layer 1 was calculated as the difference between the ground surface and the elevation of the base of Layer 1.

The completion of Step 1 provided a preliminary stratigraphy data file for the SCFIGSM area. Any Further refinements to the stratigraphy data in Step 2 would be completed using the SCFIGSM stratigraphy model data.

DRAFT

STEP 2. STRATIGRAPHY DATA REFINEMENT

The purpose of Step 2 is to review and refine the SCFIGSM stratigraphy data file to confirm there was no loss of stratigraphy data integrity due to the data processing completed in Step 1. The stratigraphy refinement was completed through the following steps:

- **Step 2A. Check Model Stratigraphy Data Accuracy**
- **Step 2B. Check Model Stratigraphy Data Reasonableness**
- **Step 2C. Check Level of Detail of Model Stratigraphy Data**
- **Step 2D. Refine Model Stratigraphy Data**

Each of these steps is described below.

Step 2a. Check Model Stratigraphy Data Accuracy

The purpose of this step is to check the accuracy of the model stratigraphy data by comparing it to known and widely accepted stratigraphy data, including knowledge of faults, formation transitions, and accepted ranges and thickness. One of the primary checks for model data accuracy was to compare the model stratigraphy data to the original DWR cross-sections. Figures 6.2a–g compare the cross-section data. This included:

Figure 6.2 a

SCF Section G

- Checking model data around faults to confirm location of fault and correct offset,
- Checking and modifying model data for changes in formation thickness, and
- Checking model layer thickness and comparing it to known data.

Step 2b. Check Model Stratigraphy Data Reasonableness

The purpose of this review is to confirm that the SCFIGSM stratigraphy data reflects the aquifer system identified in the hydrogeologic setting (Section 3). This step was completed by a review of model data and comparison to data not used in the stratigraphy data development process. This includes data from reports, previous studies, and expert opinions, and comparison to existing maps, aquifer thickness contours, or cross-sections.

Step 2c. Check Level of Detail of Model Stratigraphy Data

The model data should not suggest that we know information at a higher level of detail than is presented in the original source of the data. This step includes checks of the:

- Interpretation of the available (original data) to the model data; and
- Presentation of the model data.

Step 2d. Refine Model Stratigraphy Data

The stratigraphy model data is refined to reflect the information developed in Steps 2A through 2C. Stratigraphy model data refinement needs to be done carefully, recognizing that modifying the base of a model or the thickness of a model layer affects all the stratigraphic data at the corresponding model node.

DRAFT

STEP 3. STRATIGRAPHY DATA QUALITY CONTROL

The purpose of Step 3 is to evaluate each SCFIGSM model layer to confirm that the model stratigraphy data accurately reflects the conceptual hydrogeology presented in Section 4 and the original available data (DWR cross-section data). Maps showing the thickness of aquifer layers and the base of elevations were used to check the model data. The quality control for each model layer is described below.

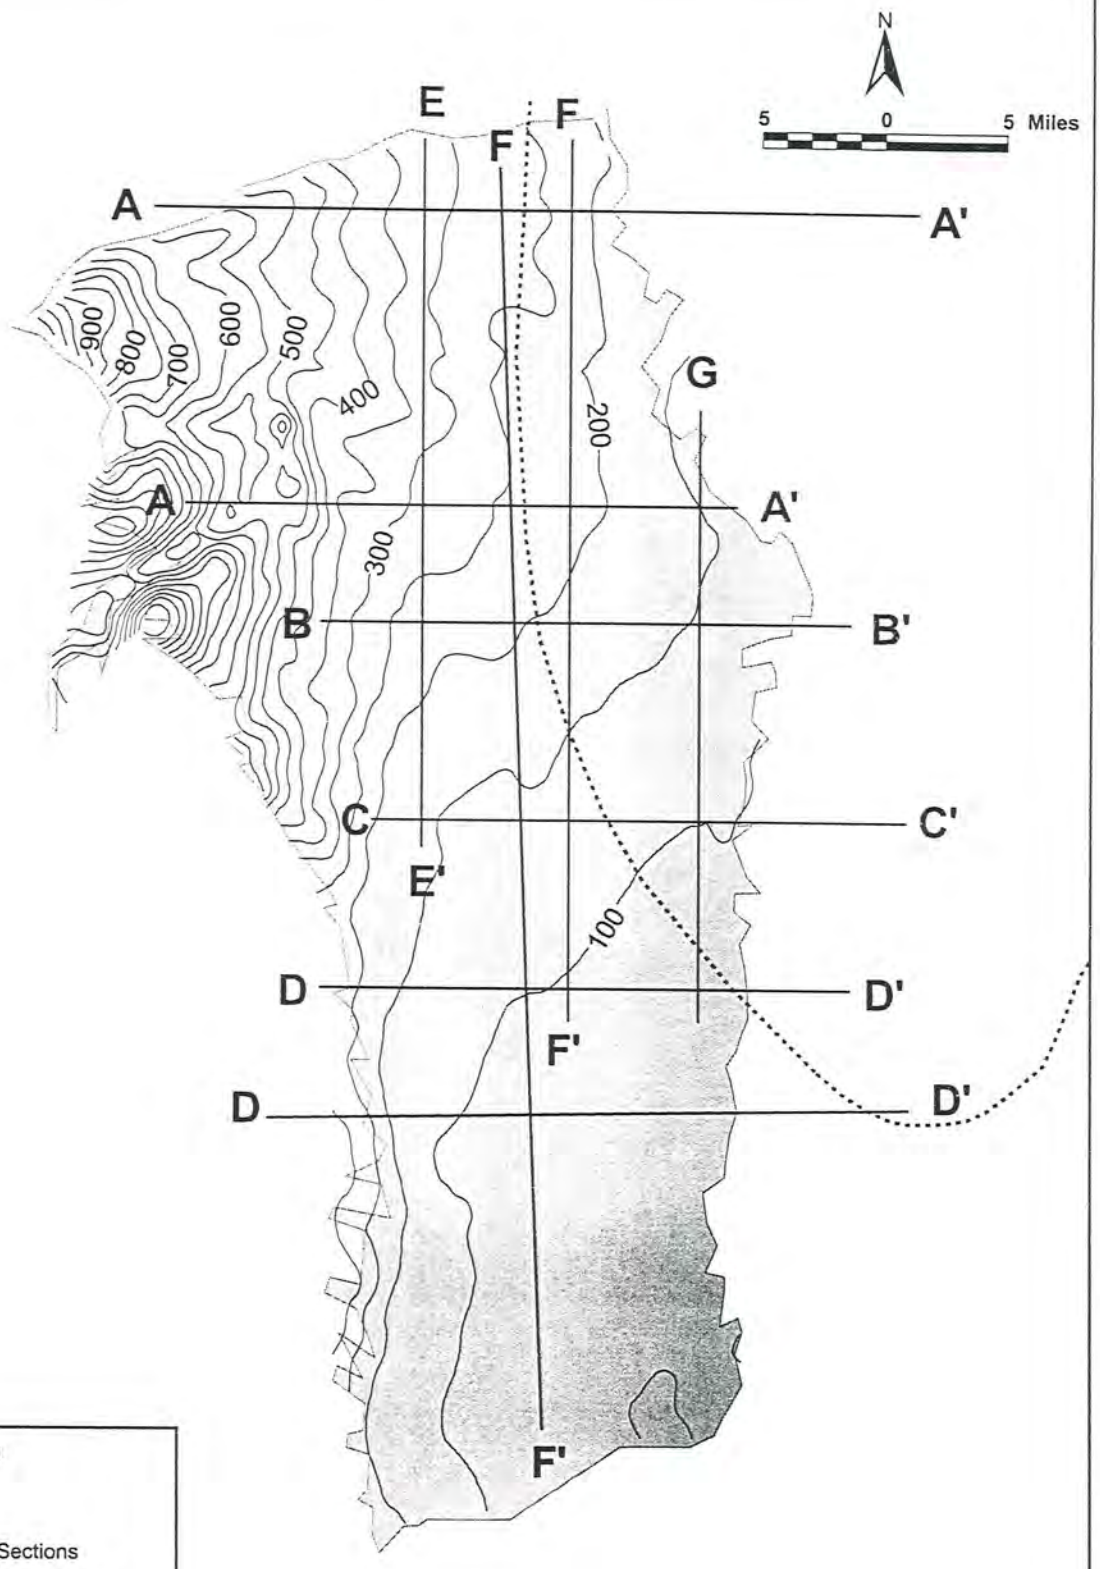
Step 3a. Check Ground Surface Elevation

The ground surface elevation data was developed from a USGS digital elevation model (DEM) for the northern Sacramento Valley. The ground surface data is shown in Figure 6.3. The model ground surface elevation was checked by comparing it to the ground surface elevation data from the USGS 1:250,000 map series.

Step 3b. Check Base of the Aquifer System

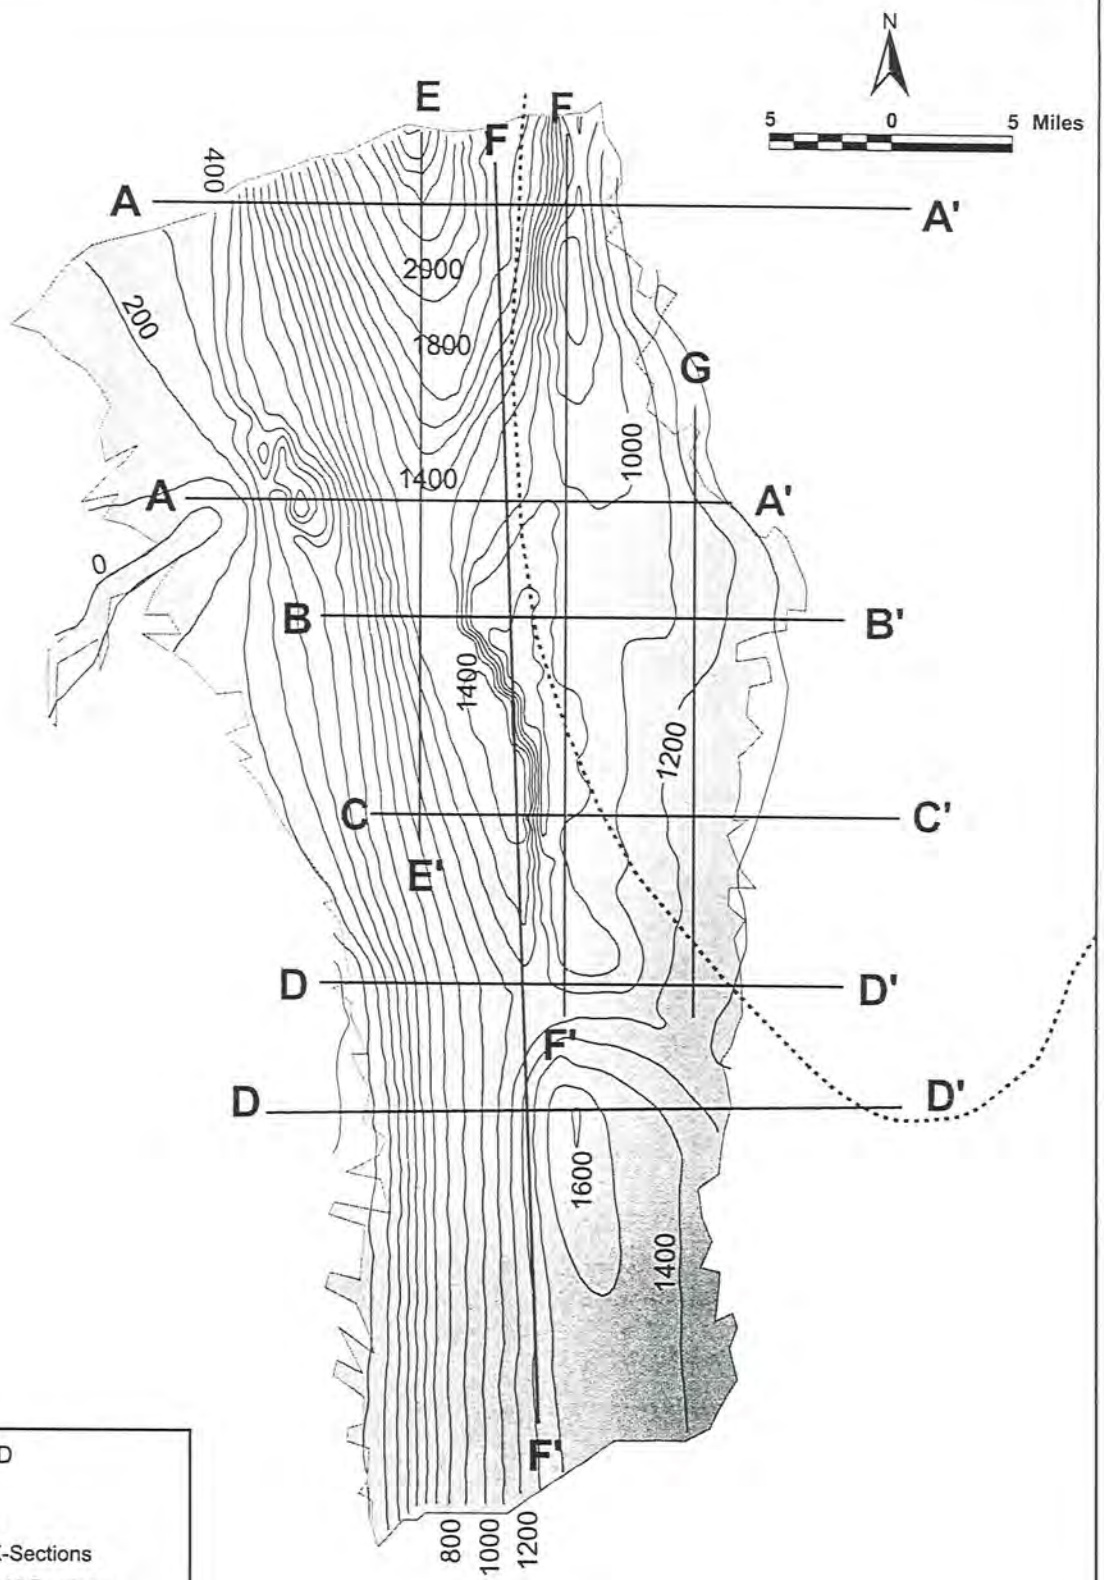
In the western half of the SCFIGSM model area, the base of the aquifer system is the base of the Tehama Formation (Layer 2). In the eastern half of the SCFIGSM model area, the base of the aquifer system is the Lower Tuscan Formation (Layer 4).

In general, the modeled aquifer system ranges from less than 50 feet thick to about 2,500 feet thick as shown in Figure 6.4. The elevation of the base of the modeled aquifer system ranges from 800 feet above sea level to 2,400 feet below sea level as shown in Figure 6.5.



Step 3c. Check Model Layer 1 (Alluvial Aquifer)

Model Layer 1 primarily represents the alluvial aquifer system. In the areas on the Stony Creek Fan, is represents the high permeability sand and gravels which generally range from 50 to 80 feet thickness (Figure 6.6). Outside the Stony Creek Fan, Layer 1 represents the upper 80 feet of alluvial and basin deposits, even in areas were the total thickness exceeds 80 feet. Layer 1 is not present in the northwest portion of the model area were the Tehama Formation is present at the ground surface, thus Layer 1 has zero thickness as shown in Figure 6.6. The elevation of the base of Layer 1 ranges from more than 900 feet above sea level in the northwest part of the model area to just below sea level in the southeast part of the model area as shown in Figure 6.7.



STEP 3D. CHECK MODEL LAYER 2 (TEHAMA FORMATION)

Model Layer 2 generally represents the Tehama Formation. As mentioned, it does include some basin and alluvial deposits. Where model Layers 3 and 4 are not present, Layer 2 is the base of the aquifer system. In this area, Layer 2 ranges in thickness from less than 100

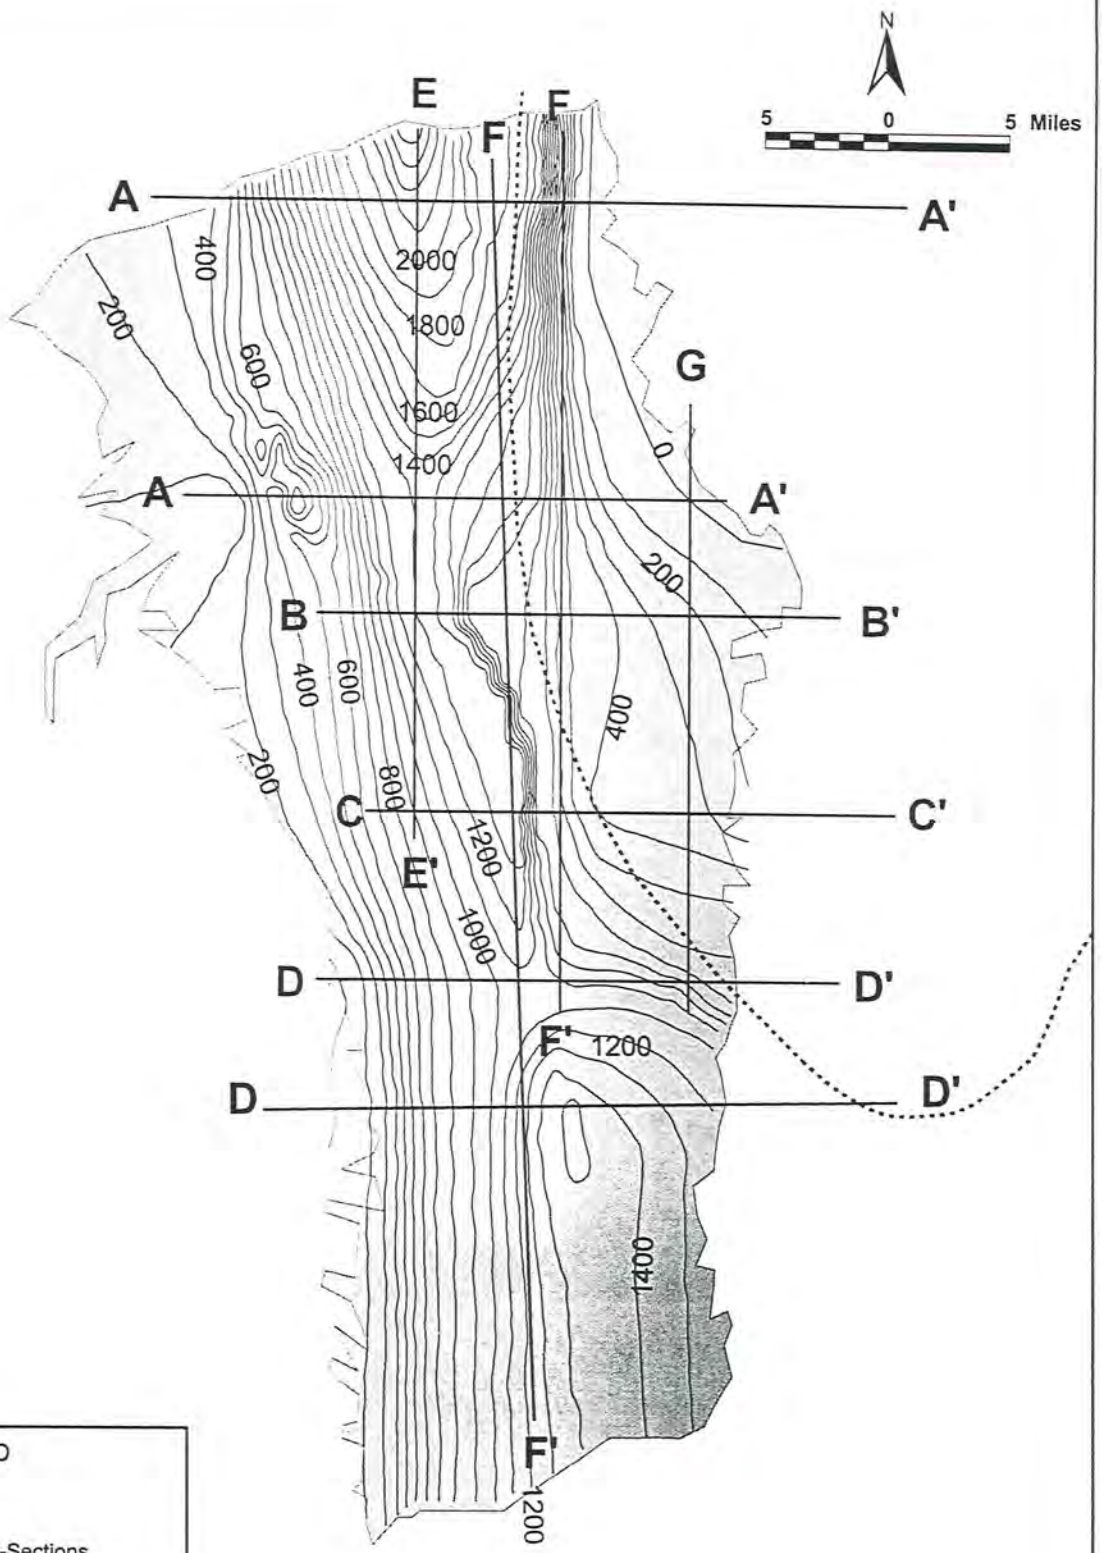
feet in to more than 2,400 feet, as shown in Figure 6.8. On the western half of the model area, Layer 2 generally increases from less than 100 feet near the western edge of the model area to about 1,200 feet near the center of the model area. In the northern portion of the model area, Layer 2 achieves its maximum thickness of more than 2,400 feet.

Where Layers 3 and 4 are present beneath Layer 2, Layer 2 decreases in thickness from about 1,200 feet thick near the center of the model are zero thickness along the northeastern edge of the model boundary.

The abrupt changes in the thickness in Layer 2 are due to offset along the Corning-Willows Fault (located near the center of the model area in a north-south direction), and the presence of the Tuscan Formation (entering the model area from the east).

Figure 6.9 shows the elevation of the base of Layer 2 ranges from 800 feet above sea level to more that 2,000 feet below sea level.



STEP 3E. CHECK MODEL LAYER 3 (UPPER TUSCAN FORMATION)

Model Layer 3 represents the Upper Tuscan Formation. It extends about halfway into the model are from the northeast ranging in thickness from zero to 700 feet as shown in Figure 6.10. Layer 3 is not present in the western or southern portion of the model area. The elevation of the Base of Layer 3 ranges from near sea level in the northern area to about 1,000 feet below sea level at its southern extent as shown in Figure 6.11.

STEP 3F. CHECK MODEL LAYER 4 (LOWER TUSCAN FORMATION)

Model Layer 4 represents the Lower Tuscan Formation. It extends about halfway into the model are from the northeast ranging in thickness from zero to about 600 feet as shown in Figure 6.12. Layer 4 is not present in the western or southern portion of the model area. The elevation of the Base of Layer 4 ranges from about 500 feet below sea level in the northern are to about 1,200 feet below sea level near the eastern edge of the model area as shown in Figure 6.13 It should be noted that in that where present, Layer 4 represents the base of the aquifer system.

SECTION 7 SUMMARY

The SCFIGSM model grid and stratigraphy data were developed using the methodology described in this technical memorandum.

SCFIGSM MODEL GRID

The SCFIGSM model grid was developed to reflect local hydrogeologic, hydrologic, and water management conditions (Section 5).

SCFIGSM STRATIGRAPHY DATA

The SCFIGSM stratigraphy data was developed after an extensive data collection and review effort (Section 2). Geologic cross-sections provided by the California Department of Water Resources Northern District Office were the primary source of data for the stratigraphy model development. The geologic and hydrogeologic setting (Section 3) was developed based on the review, analysis, and interpretation of this unpublished data. This is followed by the development of the conceptual model stratigraphy (Section 4) for the SCFIGSM. The process to develop the SCFIGSM stratigraphy data from the available data included three steps including data development, data refinement, and data quality control (Section 6).

DRAFT

Colusa Groundwater Authority

Project Management Action (Proposed)

Date Proposed:	June 11, 2021
Project Title:	Colusa Drain Mutual Water Company (CDMWC) In-lieu Groundwater Recharge
Project Type:	In-lieu Groundwater Recharge
Project Proponent:	Colusa Drain Mutual Water Company
Measurable Objectives to Benefit:	Groundwater levels and groundwater storage
Water Source:	Sacramento River through CDMWC contractual rights with USBR together with annual and multi-year transfer agreements with USBR settlement contractors utilizing the Colusa Basin Drain (Drain).
Project Area:	CDMWC service area, approx 46,000 acres, Glenn, Colusa and Yolo County (see attached Map)
Brief Project Description:	The Colusa Drain Mutual Water Company(CDMWC) encompasses approximately 46,000 acres of agricultural production and environmental habitat adjacent to the Colusa Basin Drain. Shareholders in CDMWC divert water for summer irrigation from the drain under a combination of; appropriative water rights held individually by the shareholders, a long term service supply agreement with USBR and annual and multi-year transfer agreements with neighboring USBR settlement contractors. Historically, many CDMWC diverters use both groundwater and surface water for summer irrigation because physical supplies of water in the Colusa Drain are often insufficient and unreliable to satisfy those irrigation requirements. The purpose of this project is to provide a reliable and sufficient supply of water in the Drain allowing CDMWC diverters to increase their diversions of surface water while slowing or stopping their groundwater pumping.
Implementation and Termination	
Criteria for Implementation:	This project could be implemented quickly and could be ongoing. Some of the criteria required for implementation would include: • Physical supply of surface water to be introduced into the Drain. • Necessary environmental permitting to allow for transfers into the drain by settlement contractors or others.

- Necessary permitting by Department of Water Resources (DWR) and State Water Resources Control Board (SWRCB) to allow CDMWC shareholders to divert from the Drain.
- Necessary infrastructure with CDMWC and/or its shareholders to divert from the Drain.
- Necessary infrastructure on part of settlement contractors to introduce a physical supply of water into the Drain.

Much of these criteria are already being met by potential project participants. Additional participants could be added as needed and as interest for a project increased. For example, CDMWC and GCCID have completed the necessary environmental reviews and approvals with USBR for a multi-year transfer agreement between the parties. This process could be completed for other settlement contractors as well. CDMWC's long term contract with USBR provides CDMWC diverters necessary permission to divert from the drain when individual appropriative water rights would otherwise be deficient, allowing for diversion throughout the irrigation season (April 1 through Sept 30). Most of CDMWC shareholders have the necessary infrastructure already in place to divert from the drain.

Public and/or Interagency Notice Process:

While public notice may be necessary under SGMA regulations, it is not expected that Public or Interagency Notice would necessarily be required to complete a project of this nature. At least some of the necessary permitting and noticing is in place. This part of the project requires legal review and input.

Required Permitting and Regulatory Process

This project would require, at a minimum:

- Underlying appropriative water rights; licenses and/or permits held by CDMWC and/or its individual shareholders to allow for diversion of surface water from the Drain throughout the summer irrigation season.
- Environmental Permitting allowing for the transfer of surface water from USBR Settlement Contractors or others to CDMWC.
- Transfer agreements between CDMWC and settlement contractors or others to provide a physical supply of water in the Drain.

Current Status:

Several elements of this proposal are already in place and are functioning. For example:

- Several USBR Settlement Contractors have the necessary infrastructure in place to introduce surface supplies into the Drain.
- CDMWC shareholders have the necessary infrastructure in place to divert surface water from the drain.
- GCID and CDMWC currently have a transfer agreement in place that includes the necessary environmental permitting with USBR and DWR.
- CDMWC shareholders have the necessary licenses and permits in place with DWR and SWRCB to allow those diversions.
- CDMWC has a long-term supply agreement with USBR to supply water into the Sacramento River to offset shareholders diversions from the Drain that would otherwise infringe the rights of senior water right holders in the Sacramento River.

The important element of this project that does not currently exist is the adjustment of the current economic relationship between CDMWC diverters and potential participating settlement contractors that provides settlement contractors sufficient economic incentive to introduce a physical supply of surface water to the Drain, and, at the same time, CDMWC diverters sufficient incentive to access that supply in lieu of their groundwater wells.

Estimated Cost:	$1,725,000	(See attached cost estimate analysis)
Potential Funding Sources:	Primary Source:	CDMWC and its shareholders
	Secondary Source:	CGA, Settlement Contractors, NGO's(TNC & others), Prop 1 grant funding, water export fees
Anticipated Start Date:	It is expected that this project in some form could start as early as crop year 2022 (March 2022)	
Anticipated Completion Date:	This project could be ongoing	
Measurable Objectives Expected To Benefit:	Groundwater Levels, Groundwater Storage	
Serves Disadvantaged Community:	At least some of the area within the CDMWC service area is identified as a Disadvantaged Community	

Expected Yield:	Unknown at this time. However, For the subarea within the Colusa Subbasin that approximately corresponds to the CDMWC the water budget currently included in the GSP includes an average from 1990 to 2015 of 48,000 AF/yr of surface water diversions, presumably from the Drain. For the same period, groundwater pumping averages about 40,000 AF/yr. Assuming a successful project could displace 70% of this current groundwater pumping along the drain, a yield of 28,000 af of in-lieu recharge could be realized.
Benefit Evaluation Methodology:	This needs further development, however, it is expected that the combination of information available through water budgets included within the currently proposed GSP, diversion data collected under SB88 and available publicly, evaluation of transfers contemplated under the project using the HCM developed for the GSP and the specific details of any proposed transfer subject to this project would yield sufficient data to calculate the benefits realized by the project.
Next Steps	1) Present/review with TAC committee 2) Present/Review with GSP consulting team 3) Present/Review with CGA legal counsel 4) Present/Review with potential supply partners (settlement contractors & others) 5) Complete financial analysis 6) Complete benefit analysis
Summary	CDMWC and its shareholders represent an important component of the overall groundwater demand within the Colusa Subbasin. An in-lieu re-charge project that effectively partners these groundwater users with potential supply partners to reduce or eliminate groundwater pumping represents a great opportunity for improving groundwater sustainability withing the subbasin.

Date: Monday, June 21, 2021 7:57:00 AM

Jim,

This sounds good. Even a narrow (or "conditional") policy statemen as you describe would be useful. If that's not forthcoming, we'll just describe the physical and operational elements of the project in he GSP, and discuss the agreements that will need to be negotiated in the future. One thing to keep in mind is that if the benefits of your recharge project extend beyond the CDMWC service area, then those outside beneficiaries should pay something to facilitate the project. Simple in concept, hard to put into effect.

Grant

Subject: Re: Colusa Drain Mutual Proposed Project Management Action for In-lieu groundwater re-charge

Thank you Grant. I couldn't speak with Thad on Friday but I left a message and asked for an appt. I expect both Thad and Lewis to support this project at technical level. I won't look further than that for now. But of course that is the easier discussion, objective discussion about infrastructure, quantities, timing, permitting, etc. So I am focusing on this(technical) first. To make sure that given a suitable political environment and workable economics, we can do something positive. But if you have anxiety about how the politics and economics of all this will play, then I share this anxiety. Our larger board has yet to have a productive discussion about money, priorities, fairness, public trust, and other more subjective issues. And I see a wide variety of perspective on these issues given the relatively disparate nature of key player positions(the haves and the have nots). To be blunt, I fear a policy statement that accurately reflected the position of the large SW suppliers at this point in the process would not be acceptable to many players within our community. That being said, a narrow statement from the entire board that agrees to prioritize in basin transfers for the purpose of recharge and other project management actions , for example, might be achievable. I'll ask Thad about this specifically if/when we talk. Thanks again for thinking about this and responding. Jim

settlement contractors and major proposed in-lieu rechargers (CDMWC, CCWD, and OAWD) to discuss available water quantities in non-Shasta critical years would be very helpful. Most of the necessary infrastructure is in place for these projects (some new infrastructure needed OAWD), so the key is to demonstrate to DWR (in the GSP) that the SW supply is available and there is general agreement regarding increased transfers moving forward. I am encouraged that Settlement Contractors are telling you they want to more fully utilize project water within the basin in full supply years. This is key. If the Settlement Contractors could prepare a general "policy statement" to this effect that could be included in the GSP, that would be very positive. Maybe you could float this idea?

Thanks again for your thoughtful reply,

Grant

Subject: RE: Colusa Drain Mutual Proposed Project Management Action for In-lieu groundwater re-charge

Hi Grant, Thanks for your encouragement and feedback on this proposal. I appreciate it.

1. You asked for a copy of CDMWC/USBR contract. Here is a link for that contract.
    a. https://drive.google.com/file/d/14Ab3TJDp5kC5cY000h0887iGoiyYH6yA/view?usp=sharing
2. You asked for a copy of CDMWC/GCID 2021 transfer agreement (note: this copy is a draft but I believe was the final draft for this years agreement. I will upload an executed copy when I put my finger on it.). Here is a link for that contract:
    a. https://drive.google.com/file/d/14Cw6I7NGhvdzOErv356Ot3gYWNzJFlGj/view?usp=sharing
3. You asked is more water available under this contract with GCID? I think the answer is yes, but I have not reviewed this project proposal with Thad to see if or where it fits in GCID's strategy for recharge projects. I am hoping to do that next week.
4. You asked which settlement contractors are most likely to be the source of transferred water. My answer is:

a. GCID first because:
    i. we are currently working with them
    ii. they have the largest supply
    iii. they have the most infrastructure on the drain that is relevant to a project like this
b. Maxwell Irrigation,
    i. we have worked with Maxwell in the past
    ii. they can divert and deliver directly to the drain and are upstream from much of our shareholder base
    iii. I have not reviewed this project with Maxwell
c. Princeton/Provident
    i. same reasons as Maxwell, we have worked with them previously and they have relevant infrastructure.
    ii. I have not reviewed this project with Princeton/Provident
d. RD108
    i. RD108 is located further down the drain and their ability to deliver to the drain is slightly less convenient than some of the upstream diverters (once diverted from the river, RD108 has to lift the water over their back levee to get the water into the drain. But CDMWC has executed this maneuver with RD108 successfully in the past and so I believe is a viable option.)
    ii. Direct diversion and delivery to the drain is the best option to work with RD108, in my opinion. But a second option is for RD108 to be a supplier of transfer water but have the water wheeled through another upstream diverter into the Drain.
    iii. I met today with Bill V at RD108 to review this proposal and get feedback. In general, I would describe the discussion as positive and I expect RD108 would support this project.
e. Davis Ranch. CDMWC has not worked with them before, however:
    i. They have the ability to divert from the river and deliver directly into the drain with their existing infrastructure
    ii. They have the added benefit to CDMWC of being able to deliver into the Drain below the Davis weir. This is an important distinction because a major challenge with the operations on the Drain is lack of flow below the Davis Weir and significant of CDMWC service area is below the Davis Weir.
    iii. They have a demonstrated interest in recharge in general and so might be interested in participating in a project like this
    iv. I have not reviewed this project with Davis

5. You asked about validating whether 83,000 af was reliably available from

settlement contractors to meet demands of multiple recharge projects. In Shasta Critical years I expect one could not validate that this quantity is available, especially, to the extent that settlement contractors have already committed project water to other transfers both in and out of basin. In full supply years, however, I believe the answer is yes. In speaking with Settlement Contractors I am consistently told that better (more complete or fuller) usage of project water within the basin during water flush years is a top priority with respect to groundwater sustainability. Review of settlement contractors prior year project water scheduling with USBR would give a good idea of the total quantity of water likely available for transfer to any proposed project. I have not seen any of the detail included in the other recharge projects proposed for inclusion in the GSP, but I am guessing that much of this work has already or is currently being done.

6. You asked about how could this new demand for recharge water affect prices? Simple answer is I don't know. But, for the purposes of my proposal I estimated that CDMWC would pay approx. double the amount we are currently paying for transfer water for the additional 28,000 af.
7. You asked about the current cost of groundwater pumping in CDMWC service area. This information is not readily available, however, I have some information from my own farm operations within CDMWC and I will reach out to some other shareholders to see if I can put some information together and send it over. I expect this cost to be in the range of 75-100/af for direct electric charges for pumping.
8. You asked about current transfer cost. Please reference the contract in the above link.
9. You asked about the cost estimate analysis that I referenced in the proposal. This is not complete, but as soon as I have something I will send it over.

Thanks again for looking at this project. JIM

Subject: RE: Colusa Drain Mutual Proposed Project Management Action for In-lieu groundwater re-charge

Hi Jim,

This is an excellent project, one reason being that it can be implemented at some level with existing infrastructure and expanded gradually as additional infrastructure is constructed.

Some follow up comments/questions/requests:

1. Please send a copy of CDMWC's contract with USBR, or a summary of key terms.
2. Please send a copy of CDMWC's transfer agreement with GCID, or a summary of key terms. Is more water available under this agreement than has been used historically?
3. Other that GCID are any of the "multi-year transfer agreements with USBR settlement contractors" already in place or to be negotiated?
4. Which settlement contractors are most likely to be the source of transferred water (e.g., GCID, PCGID, PID, others???)
    a. Note that the OAWD and CCWD projects are also counting on transfers to supply their in-lieu recharge projects: 25,000 AF/yr for OAWD and 30,000 AF/yr for CCWD
    b. What suggestions do you have for validating that 83,000 AF/yr (25,000+30,000+28,000) are reliably available from settlement contractors to meet these needs?
    c. How could this new demand for surface water affect prices?
5. I will forward your project description to Duncan MacEwan, the team economist, and get him thinking about financial incentives to get CDMWC shareholders to divert SW rather than pump GW. These incentives are a key element of the project.
    a. What is the current, approximate cost to pump groundwater within the CDMWC service area, energy only, not including amortization of capital?
    b. What is your best estimate of average SW costs under transfer agreements?
6. The cost estimate analysis referenced in your document was not attached; please send.

Thank you,

Subject: Colusa Drain Mutual Proposed Project Management Action for In-lieu groundwater re-charge

Hello Mary, Grant, Dave,

Please find attached a Proposed Project Management Action for In-lieu groundwater recharge proposed by Colusa Drain Mutual Water Company. I would like to add this project to the list presented at last weeks joint TAC meeting. I would also like to include this project as an agenda item at our next TAC meeting with possible action.

With the exception of the direct recharge project on Sycamore Slough, I have not yet seen any of the other projects under consideration. For this project proposal I used the project elements detailed on slide 27 of Grant and Ken's June 11 presentation to the TAC. Let me know if you have questions or comments.

Thanks, JIM

COLUSA SUBBASIN

Colusa Subbasin GSP Projects and Management Actions (PMAs) Submittal Form

Overview

The purpose of this form is to gather ideas for potential projects and management actions (PMAs) that could be evaluated and ultimately included in the Colusa Subbasin GSP. Once ideas are gathered, an initial screening and evaluation process will be conducted, followed by ranking of potential PMAs for more detailed evaluation and inclusion in the initial GSP.

Potential PMAs may fall under several categories, including but not limited to the following:

- Recharge projects
- Supply augmentation projects
- Water conservation projects
- Projects to reduce non-beneficial consumptive use
- Groundwater pumping allocations
- Monitoring programs (groundwater pumping, water levels, stream flows, etc.)

Please provide supporting documentation and/or links to that documentation for each question, if available. **NOTE: It is recognized that much of the requested information may not be available at this time. Please provide as much information as you can.**

Project Name and Contact

Project or Management Action Name:

COR artificial recharge

Contact Person:

Brad Samuelson, Water and Land Solutions on behalf of California Olive Ranch (COR)

Organization/Affiliation (Project Proponent):

California Olive Ranch

Contact Phone:

(209) 658-8487

Contact Email:

bsamuelson@waterandlandsolutions.com

Project or Management Action Description and Status

Project or Management Action Description:

Artificial recharge is proposed at the California Olive Ranch property in Artois. Potential sources of water for recharge are flood flows from White Cabin Creek and Sheep Corral Creek, as well as Section 215 water through Orland-Artois Water District (OAWD). Potential sites for recharge include a retired drainage ditch that borders the property, as well as recharge within the streambed.

Project or Management Action Location (please provide a map if available):

See attached. As shown, the proposed recharge location is within the Orland-Artois Water District.

Which Sustainability Indicator(s) does this Project or Management Action address:

1. Groundwater levels
2. Groundwater Storage
3. Groundwater Quality
4. Land Subsidence
5. Surface Water Interaction

Groundwater levels would be addressed by this project. As shown in draft Figure 3-23 of the Colusa Subbasin GSP, this area showed the greatest decline in groundwater elevations from spring 2006 to spring 2017.

Project or Management Action Status (Conceptual, In Design, Ready for Implementation):

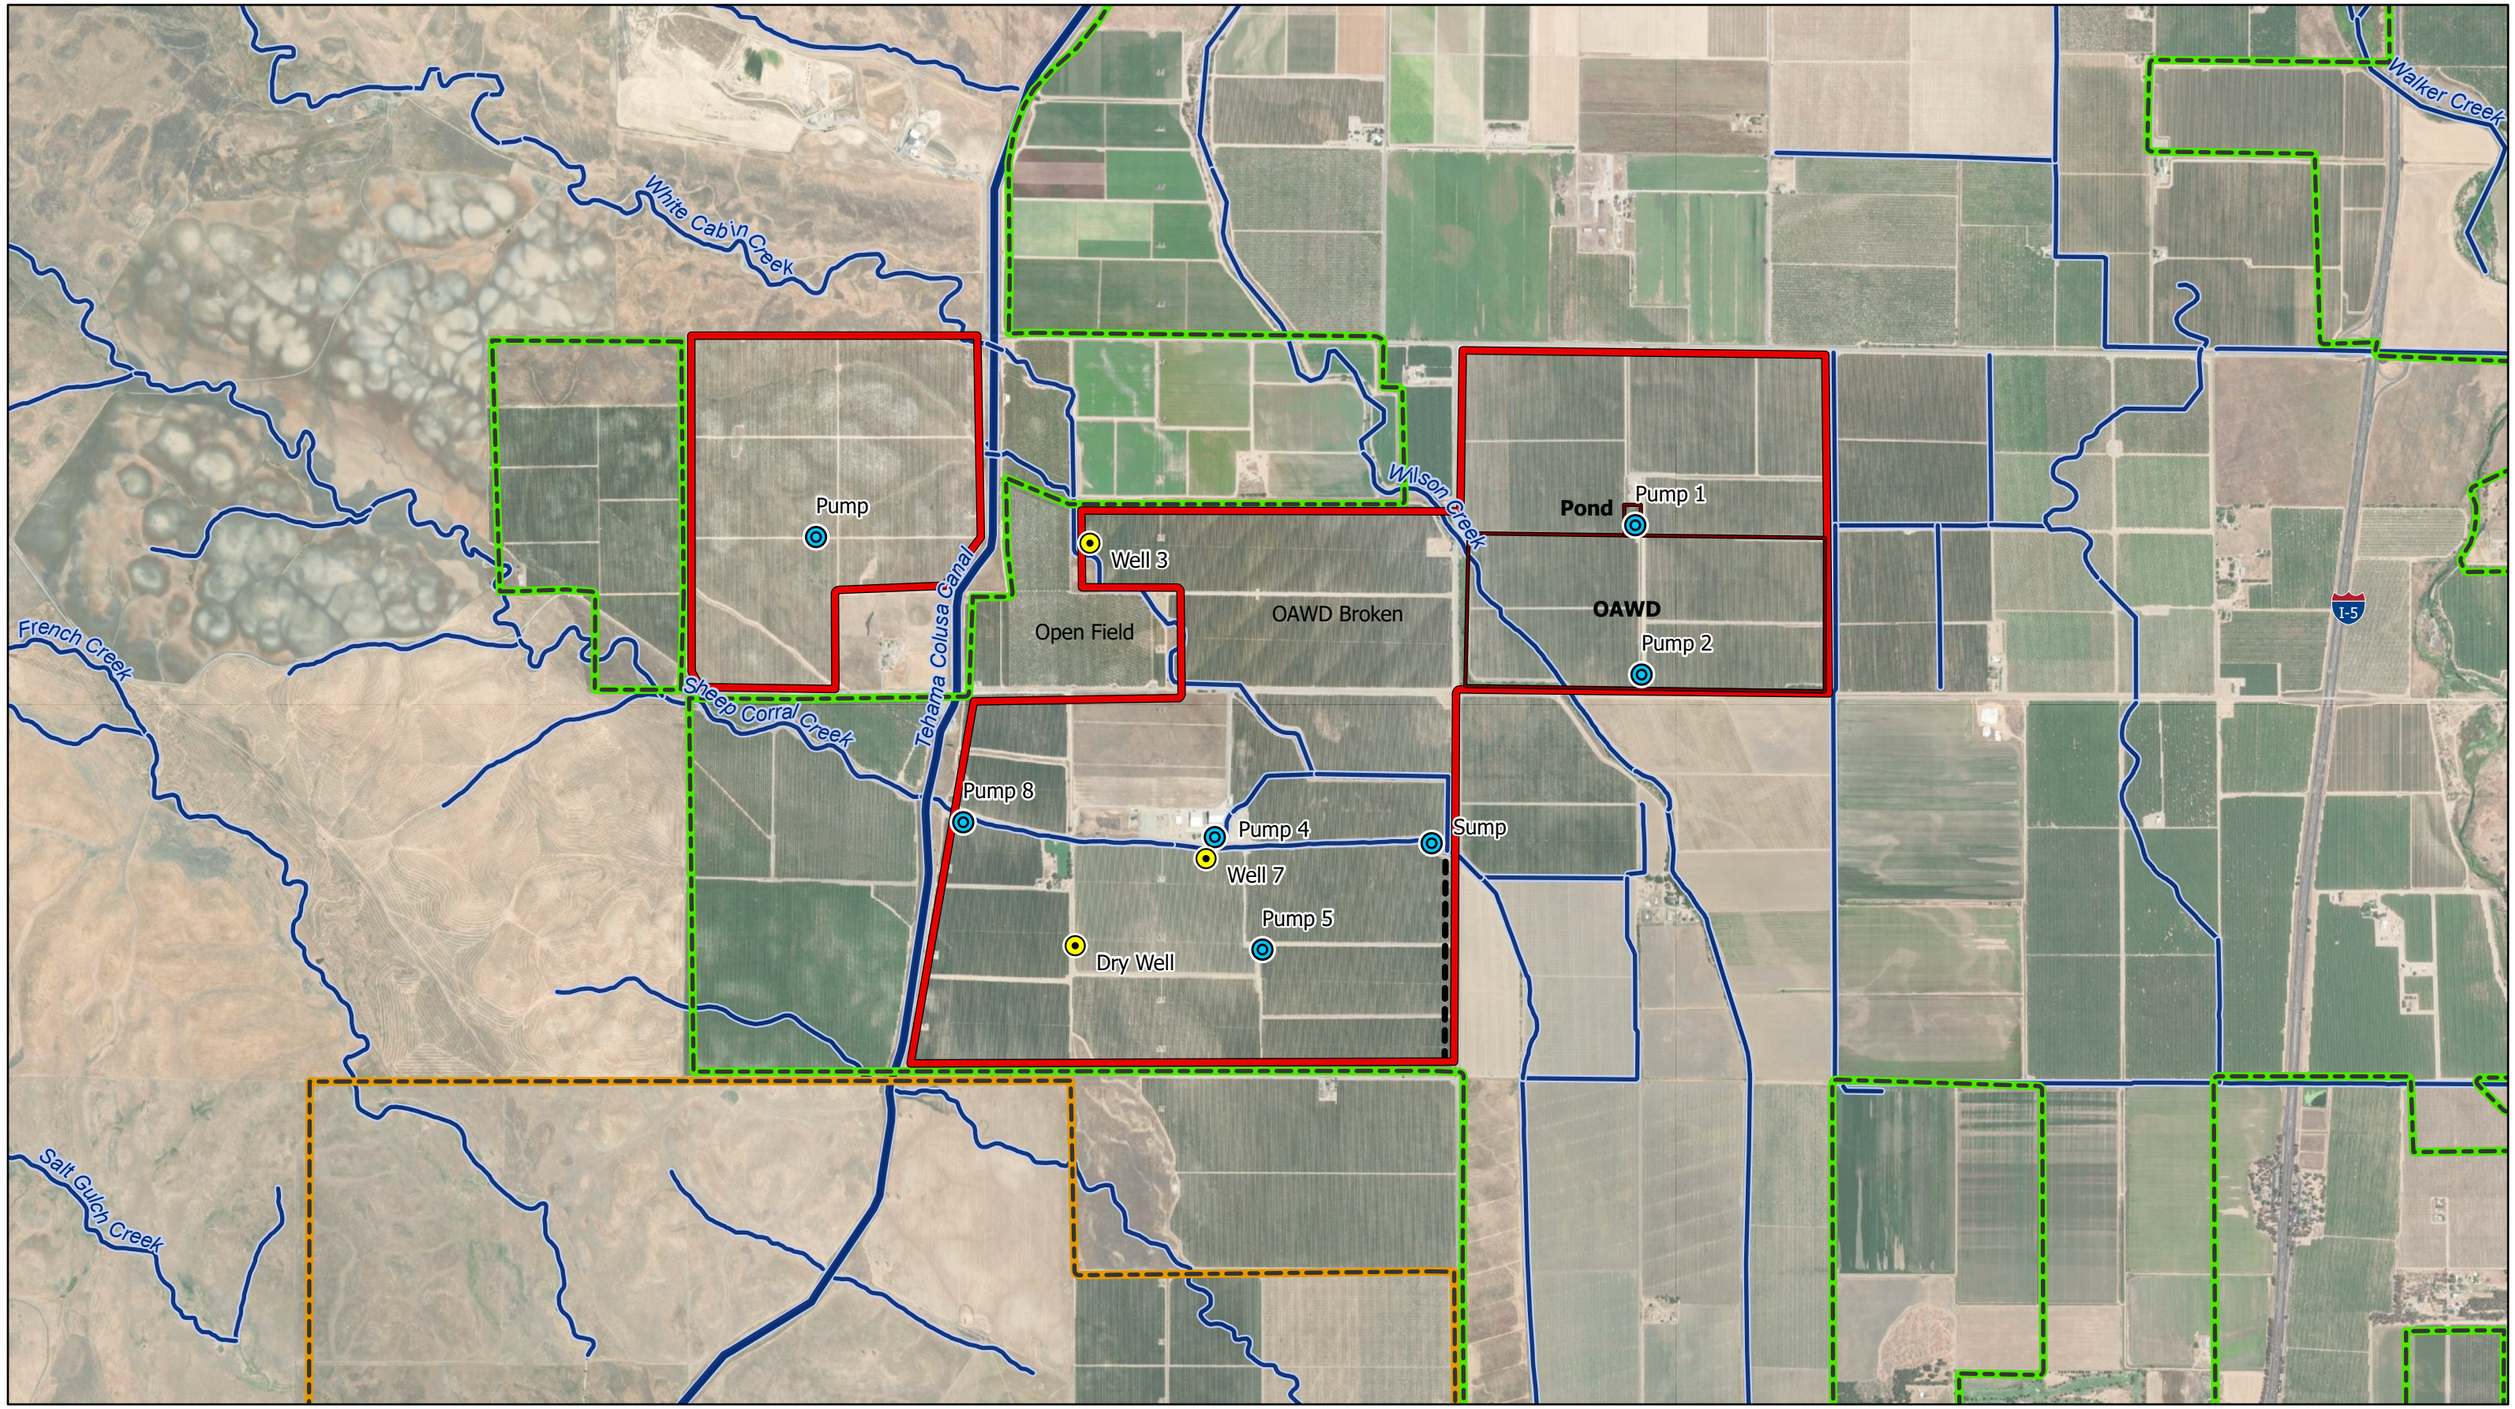
Conceptual

Has a feasibility assessment been conducted? If so, please list the agency and provide the documentation (or provide web link to download).
A feasibility study is currently being scoped and engineering firms are writing proposals to prepare the feasibility study.

Estimated Cost:
TBD

Potential Funding Sources:
TBD

Management Action or Project Yield (e.g. water contributed to the groundwater system, acre-feet per year):
TBD. It is envisioned that recharge would take place in wet years when flood flows are available.



Please describe any required Permitting and Regulatory Process and status of permitting and CEQA/NEPA compliance:
Water rights would need to be acquired if flood flows from White Cabin Creek or Sheep Corral Creek are used.

Does this Management Action or Project serve a disadvantaged community? If so, which one(s)?
N/A

Attachments: image001.png

Hi Michael,

It sounds like an interesting project. Below, I've included: 1) information on the different possible avenues for your project, 2) additional detail on temporary permits for groundwater recharge, 3) some initial thoughts on your proposal, and 4) the next steps for honing in on a clear project description. The e-mail includes a lot of information, so feel free to let me know if you have questions.

1) The first step would be to decide what type of water right permit you're applying for: temporary or standard. A temporary permit application can usually be processed more quickly, but only lasts 180 days and needs to meet certain criteria (urgent need for the water, no injury to downstream users, no unreasonable effects to fish and wildlife). A standard permit application can take several years to process, but generally lasts as long as the water is put to beneficial use. (More information on groundwater recharge and water rights can be found on our webpage: http://www.waterboards.ca.gov/waterrights/water_issues/programs/applications/groundwater_recharge/)

2) Right now, the Division of Water Right filing fees for temp. permit applications for these types of projects have been reduced to $100+, depending on how much water is diverted. One thing to note, however, is that both standard and temporary permits are subject to environmental review under the California Environmental Quality Act (CEQA), which can take some time to complete. CEQA is currently suspended for some temporary permits for recharge projects by local or state agencies while the Drought State of Emergency is in effect, but not for projects by private entities. However, a private entity may be able to partner with a public agency to qualify for the CEQA suspension.

   We have a webpage that outlines the temporary permit process and gives tips on how to avoid potential delays: http://www.waterboards.ca.gov/waterrights/water_issues/programs/applications/groundwater_recharge/tips_for_filing.shtml.

3) When applying for a temporary or standard permit, you will need to specify:
   a. the point of diversion (where you would set up the pump)
   b. a diversion season (when you'll pump water from the creek)
   c. the maximum diversion rate (one option is to propose the capacity of the pump)
   d. the maximum amount of water you would divert each season
   e. the area that will be used for recharge (the gravel excavation sites)
   f. the place of use and purpose of use of the water: groundwater recharge is a type of storage, not a beneficial use, so the application will need to specify how the recharged water will ultimately be used. If you already use groundwater on your ranch, the place of use might be the ranch itself, and the purpose(s) of use could be irrigation, domestic use and/or stockwatering, for example.

   Other questions that could come up during our review are:
   a. When were you planning to start diversions (this spring, next winter, or later)?
   b. How high are "high flows", how was that determined, and how will you know flows are high enough to start diverting?
   c. Are there existing water rights for the ponds at the gravel excavation site?
   d. If the gravel excavation site is close to Sand Creek, how does the groundwater basin interact with Sand Creek? Depending on water table levels and gradients, there is a possibility of recharged water returning to the stream as flow, rather than remaining available in the groundwater basin. Or, during high flows, water levels in Sand Creek may already contribute water to the gravel ponds.
   e. Is there information on water table depth or groundwater movement near the recharge site?
   f. Are there downstream water users with a right to the water, or fish and wildlife species that might be affected?

4) If you'd like, we could start by discussing your basic project and initial questions by phone, then set up an in-person meeting or site visit when the project description is fleshed out. We also strongly recommend looping in the California Department of Fish and Wildlife early in the process, in case changes to the project description are necessary to reduce impacts on fish and wildlife. The water rights contact for Department of Fish and Wildlife for Colusa County is Lauren Mulloy, available at (916) 358-2909, or lauren.mulloy@wildlife.ca.gov.

Again, I'm happy to answer any questions on process, fees, or your particular project be e-mail or phone.

Subject: ground water recharge

Sarah,

My name is Michael Doherty and I am a farmer/landowner in Arbuckle, south western Colusa County. I am very interested in pursuing a small scale ground water recharge project that I believe has great merit and could be a template for more projects in Northern California. My ranch is adjacent to Sand Creek which during the winter can have high flows of drain water that make it to the Colusa Basin Drain and eventually to the Sacramento River. My thought is to divert water during these high flows and hold the water so it can percolate into the groundwater basin. I would hold the water in some ponds on my property that are gravel bottomed. These ponds are really old gravel excavation sites from the previous landowner. They are not currently farmable and would be perfect for this use. There is a product called a Riverscreen pump that only needs 4 inches of water depth to function. I would put the pump into the creek at high flows and remove it when the flows are too low.

I understand the Governor himself is very interested in projects such as this and has encouraged them.

I would love to speak with you in person about this project. I am also available to show or set up a tour when needed.

Looking forward to hearing from you.

Chamisal Creek Ranch LLC.

Ephemeral Stream Recharge Field Notes

Date: 11/19/19
Participants: Mary Fahey, Bill Vanderwaal, Halbert Charter, David Henriques (Charter Oaks), Steffen M. (Chico State), Jeff Davids

General notes

1. Two different scales and approaches to managed aquifer recharge are described below. In both cases, the potential water sources are the same:
    a. Imported surface water (e.g. 3F or 215 USBR water (surplus water))
    b. Locally generated runoff in ephemeral streams and swales
    c. Mixture of the two
2. Regardless of the water supply or project conceptualization, it is critical to understand:
    a. Availability of water for recharge (in space and time)
    b. Ability to recharge available water (limited by infrastructure, land area, and infiltration rates)
3. There are also important policy and legal questions including:
    a. How will credits for groundwater recharge work?
    b. Are there any water rights concerns over impacts to downstream water users?
    c. What is the permitting process for agricultural managed aquifer recharge?

Sand Creek Project(s)

On Sand Creek, there appears to be two basic long-term project concepts, which are not mutually exclusive (i.e. the first could be part of the second):

1. Diversion of Salt Creek water during storm events (or runoff from agricultural fields or CCWD water) and application to nearby lands
    a. Michael Doherty's gravel pit to the north of Sand Creek and east of Cortina School Road may be a good place to start.
    b. Currently, runoff from field(s) to the west of Cortina School Road is diverted into the gravel pit.
    c. It may be possible to fill portions of the gravel pit with Colusa County Water District (CCWD) water from the delivery point near the northwest portion of the gravel pit.
        i. There may be some water rights issues to utilizing CCWD water for recharge
    d. In the long run, infrastructure to move water from Salt Creek into the gravel pit would be necessary and could involve either:
        i. A gravity diversion from Salt Creek upstream of Cortina School Road, an open channel to convey water to the gravel pit, and a spillway/return flow to Salt Creek from the southeastern corner of the gravel pit or
        ii. A pumped diversion from Salt Creek along with an appropriate screening facility and pipeline.
    e. Suggested next steps:

i. Determine area of agricultural lands currently draining to the gravel pit
ii. Measure runoff from these lands to the gravel pit
    1. Depending on the range of flows, either a weir box (like the one that Hal is using) on the end of the pipe can be used for measurements (this works for low flows). If higher flows are anticipated, the weir box is still helpful to keep a full pipe, but a hydroacoustic meter (e.g. SonTek IQ) should be installed.
iii. Measure infiltration capacity of several different locations within the gravel pit with:
    1. Large scale USBR ponding seepage tests
    2. Small scale double ring infiltrometer tests
iv. Perform detailed topographic survey of gravel pit and Sand Creek to facilitate conceptual design of necessary diversion and conveyance infrastructure
v. Measure rainfall and runoff from Sand Creek
vi. Draft a conceptual plan for increased utilization of the gravel pit for groundwater recharge
    1. This would include more accurate estimates of recharge potential
    2. Cost estimates for different configurations (i.e. gravity diversion vs. pumped)
vii. If these steps are of interest to the group, CSU Chico could prepare a more detailed proposal for the Agricultural Research Institute funding, and willing partners could help provide the necessary match (i.e. 25% cash and 100% total (in-kind + cash).
viii. We would also need to find a partner/student to investigate the identified policy

2. Lower Salt Creek River Restoration, Grade Control, and Recharge Project
    a. This would be a significantly larger and more complicated project involving multiple partners with multiple objects (objectives?).
    b. Objectives
        i. Decreased gravel migration and stream incision
        ii. Reduced flood flows
        iii. Restored channel grade and riparian corridor
        iv. Increased groundwater recharge
    c. Methods
        i. Construction of additional grade control structures similar to the Sand Creek Road low water crossing approximately 2.5 miles west of Cortina School Road.
        ii. Restoration of streambed materials and grade in incised locations
        iii. Diversion of runoff outside of Sand Creek for application to areas with high recharge potential (like)
        iv. The stair-stepped grade control structures would service the purposes of:
            1. Slowing water velocities in the channel
            2. Reducing gravel migration and associated downstream impacts
            3. Increasing water storage and residence time, thus decrease peak flood flows

4. Increasing recharge upstream of grade control structures
5. Allowing gravity diversions from Sand Creek to adjacent recharge projects (e.g. Michael Doherty's sand pit described above)

d. Possible partners
   i. Caltrans
   ii. Railroad
   iii. Colusa County (water resources, public works)
   iv. Colusa Basin Drainage District
   v. TNC, EDF, or ???
   vi. CSU Chico
   vii. Colusa GSA
   viii. Colusa County RCD
   ix. Landowners
e. Possible next steps
   i. Pitch the idea to potential project partners to gauge interest
   ii. Caltrans and the railroad might be the most interested because of the impact to their operations from ongoing flooding and gravel migration issues that cause the roadways/railways to be closed.
   iii. CSU Chico could play a role in understanding the hydrology, geomorphology, and recharge potential from the project, but this would require a longer term project and ongoing monitoring and investigation.

Smaller Distributed Landowner-Led Recharge Projects

1. In addition to larger publicly funded recharge projects, there may also be opportunities for landowners to construct and operate smaller recharge projects. (This could be done with incentives from the GSAs)
2. Water source
   a. Imported surface water (e.g. 3F or 215 USBR water (surplus water))
   b. Locally generated runoff in ephemeral streams and swales
   c. Mixture of the two
3. Design
   a. Constructed within existing drainage ways or in other higher permeability areas
   b. Open to the atmosphere (i.e. spreading basin) or closed (e.g. infiltration pit)
4. Water Quantity Monitoring
   a. It is critical that incremental recharge (i.e. before and after the project(s)) be measurable.
   b. Generally, directly measuring recharge will not be possible, so a water balance approach involving measuring all other inflows and outflows needs to be used to solve for recharge (i.e. recharge = inflows - outflows)
   c. If possible, inflows and outflows should be measured with a standard flow device, as described in the USBR Water Measurement Manual.
      i. Smaller full-pipe flows can be reliably measured with magnetic meters (e.g. Seametrics)

ii. Larger open channel flows can be measured with critical flow devices (e.g. weirs or flumes) and measurement of water level (e.g. Seametrics pressure transducers). For flumes and weirs, it is best to have a low range sensor (e.g. 2.3 feet or 1 PSI) with high accuracy ± 0.01 feet, such as the low pressure range Seametrics PT2X pressure transducer.

iii. When insufficient head is available, or if the range of possible flows is too great, an Acoustic Doppler Velocimeter (e.g. SonTek) can be used.

iv. If the recharge facility is open to the atmosphere, evaporation losses should be accounted for, especially if they are operated during the hot and dry summer months (see USGS Estimation of evaporation from open water).

5. Water Quality Monitoring
    a. The quality of recharged water should be measured to understand potential water quality impacts from additional recharge.

Email: hcharter69@gmail.com

To Whom It May Concern:

H&A Charter Farms successfully completed construction of a ground recharge project in the fall of 2019. This pilot project recharges water at a rate of 30-40 gallons per minute (gpm). The idea of this project was to realize proof of concept for implementing larger scaled projects of similar design at different locations on the ranch. We feel confident that after recharging nearly 1.5 million gallons of water to date, that the concept is sound and the next project will be scaled to recharge at least 150-250 gpm. The basic concept is to copy the design of a residential leach field, but supersize it.

Much of the area we farm in the Southwest corner of Colusa County, consists mostly of low foothills. It is widely known that many of these ridges are well drained and deep in gravel alluvium. With careful design, I now know that we can capture storm water runoff that flows through our orchards and allow the water to recharge back into the aquifer. When it is not raining outside, I can meter district water into the recharge structure. Currently, I am paying Colusa County Water District rates for this water. If the expectation is to meet groundwater sustainability, there is going have to be consideration to figure out a way to get the cost of recharge water at a reduced rate. I do imagine a day where the fee structure developed for the water being extracted helps offset the cost of recharge water. I hope this day is coming sooner rather than later.

This idea, and ideas like it, that capture storm water runoff and utilize surface water for groundwater recharge show benefits that cannot be denied. What is needed to move forward, is an acknowledgement of the benefit and the policy that provides assurance that the water that is recharged into the ground will be able to be utilized on our farm at a later date, like a savings account. If you have any questions, please contact me.

Thank You,

Halbert W. Charter

Subject: Colusa County Water Filtration Plant

CAUTION: This email originated from outside of the organization. Do not click links or open attachments unless you recognize the sender and know the content is safe.

Hi Mary,

Attached is a Colusa Basin GSP Project recommendations.

I believe that Colusa County needs a fresh water supply from the Sacramento River to guarantee the residents of Colusa County the human right to fresh drinking water, to preserve housing values and promote economic sustainability through growth that will come with future sustainable fresh water supplies. As you know the City of Davis and City of Woodland just installed a filtration plant and this project would give the residents of Colusa County the same access that the State and other policy makers facilitated for Yolo County residents.

As you know the public water systems of Grimes and Princeton have arsenic contamination above EPA standards. The City of Colusa has abandoned two wells due to arsenic contamination and faces future contamination from arsenic and diminished potability due to salt water intrusion into the public water system of Colusa. Williams faces a very uncertain future because it water supply aquifer is surrounded by no potable salt water and faces the risk of future deterioration in potability due to over pumping cased by groundwater substitution and contamination from future recharge projects which could harm potability or lead to contamination from nitrates and other man made contaminants. Arbuckle faces a lack of supply of fresh groundwater and faces the specter of contamination of its public supply due to over pumping and recharge projects necessary to prevent future subsidence.

My proposal is to coalesce around a filtration plant for the County while funding is available and interest rates are low. This timing of this effort may be urgent because it will need political support to benefit from likely Federal infrastructure program.

I will have two more Project recommendations – can you tell me the deadline for submittals?

Thank you for your consideration.

Best Regards,

Ben

COLUSA SUBBASIN

Colusa Subbasin GSP Projects and Management Actions (PMAs) Submittal Form

Overview

The purpose of this form is to gather ideas for potential projects and management actions (PMAs) that could be evaluated and ultimately included in the Colusa Subbasin GSP. Once ideas are gathered, an initial screening and evaluation process will be conducted, followed by ranking of potential PMAs for more detailed evaluation and inclusion in the initial GSP.

Potential PMAs may fall under several categories, including but not limited to the following:

- Recharge projects
- Supply augmentation projects
- Water conservation projects
- Projects to reduce non-beneficial consumptive use
- Groundwater pumping allocations
- Monitoring programs (groundwater pumping, water levels, stream flows, etc.)

Please provide supporting documentation and/or links to that documentation for each question, if available. **NOTE: It is recognized that much of the requested information may not be available at this time. Please provide as much information as you can.**

Project Name and Contact

Project or Management Action Name: Sycamore Slough Colusa Basin Drain Multi-benefit Recharge Project

Contact Person: Ben King

Organization/Affiliation (Project Proponent): Stakeholder

Contact Phone: (530) 723-3119

Contact Email: bking@pacgoldag.com

Project or Management Action Description and Status

Project or Management Action Description: Voluntary Landowner participation in restoring stretches of the Sycamore Slough as part of a newly formed water storage district. The Sycamore Slough ran parallel on the east side of the Colusa Basin Drain from slightly north of Tule Road all the old Farnsworth Ranch before running more east west towards the Sacramento River. Excess flows winter natural flows could be diverted from the Colusa Basin Drain for recharge as part of a water storage district and restoration could include a multi-benefit focus

for monarch butterfly and other pollinator habitat restoration. Other multi-benefits could also be included.

Project or Management Action Location (please provide a map if available): East of the Colusa Basin Drain from approximately .5 miles north of the intersection of the Colusa Basin Drain northward. Basically south end of old Balsdon Ranch north to old Farnsworth Ranch. See attached Map

Which Sustainability Indicator(s) does this Project or Management Action address:

1. Groundwater levels Yes – winter recharge
2. Groundwater Storage Yes – natural levee of Sycamore Slough has high recharge capacity
3. Groundwater Quality Yes - this will provide fresh water recharge – new deep wells are being constructed with likely long term groundwater degradation due to the present of salt water and possibly arsenic from the Sutter Buttes Rampart.
4. Land Subsidence – Yes – this area was part of a fresh water lake during the lacustrine period of the Sacramento Valley and may have Corcoran like clay stratas that may dewater due to the deep wells being drilled in the area.
5. Surface Water Interaction

Project or Management Action Status (Conceptual, In Design, Ready for Implementation): Conceptual

Has a feasibility assessment been conducted? If so, please list the agency and provide the documentation (or provide web link to download). No – will take landowner involvement and participation

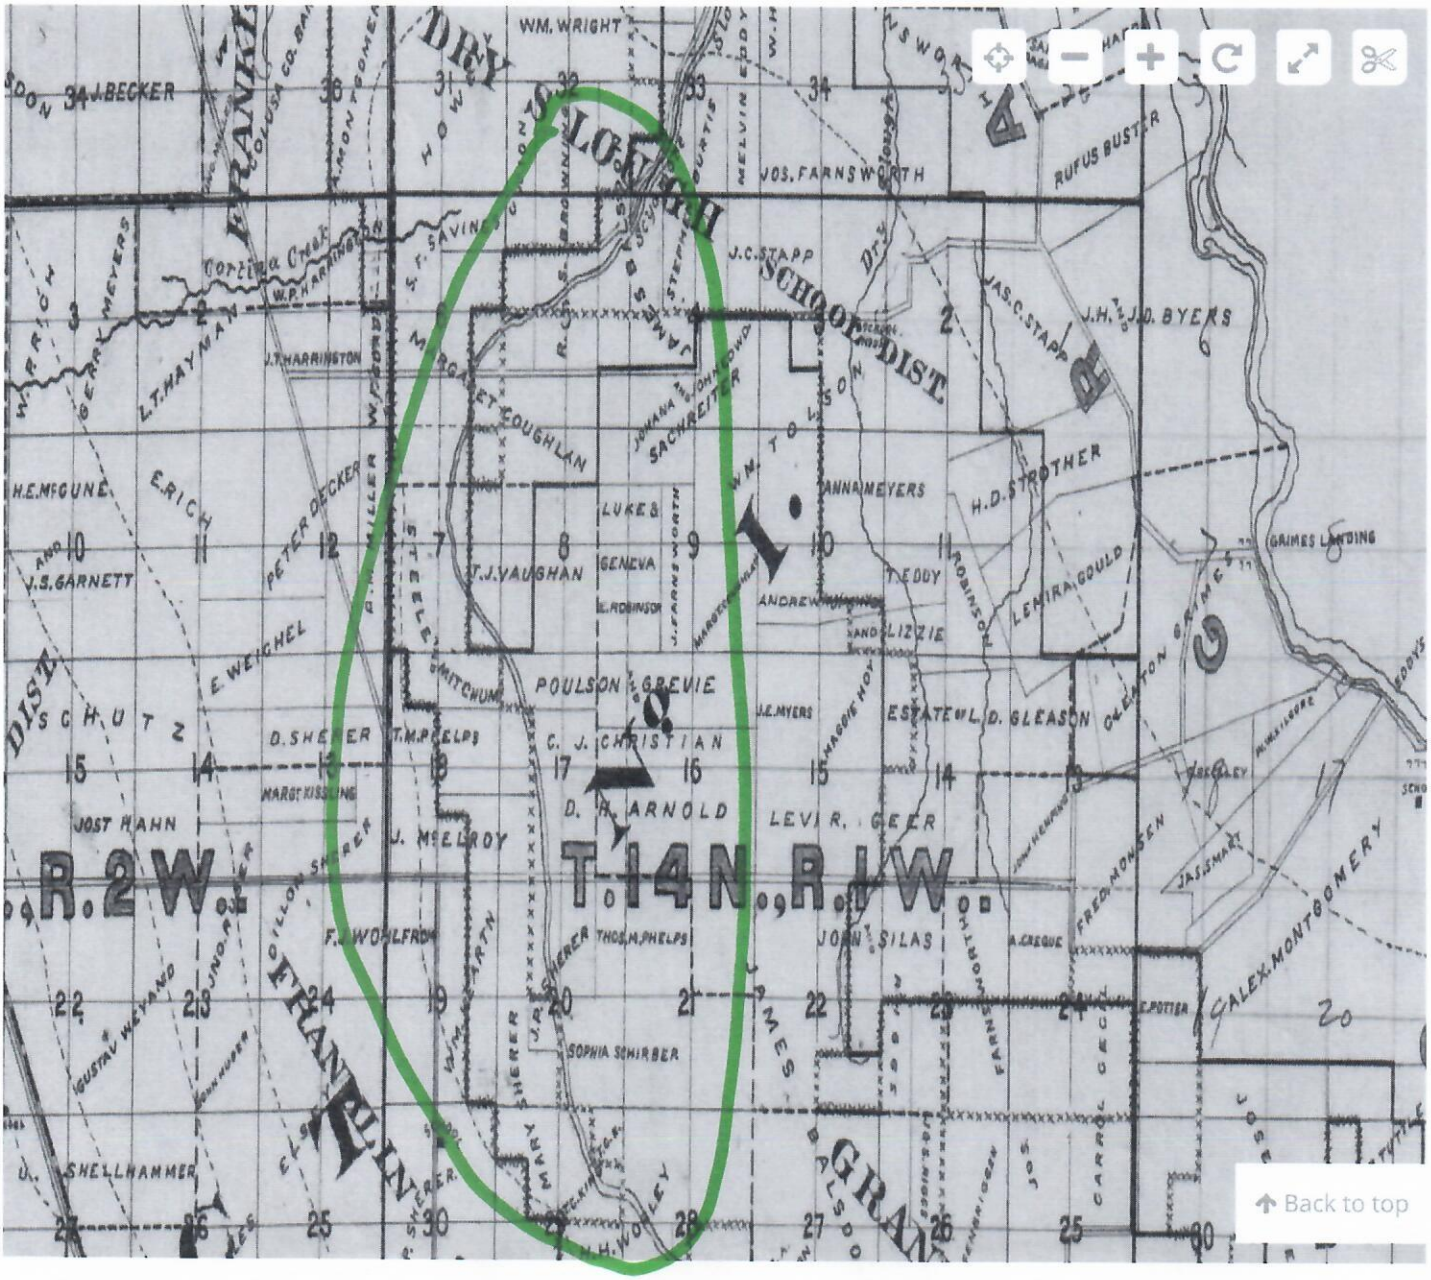
Estimated Cost: Unknown but not prohibitive - some areas of the Sycamore Slough are still in place and existing diversion infrastructure from the Colusa Basin Drain could be used.

Potential Funding Sources: State Water Bonds if Multi-benefit projects could be included.

Management Action or Project Yield (e.g. water contributed to the groundwater system, acre-feet per year): 1000 to 5000 acre feet

Please describe any required Permitting and Regulatory Process and status of permitting and CEQA/NEPA compliance: Yes – application to the SWRCB similar to the Yolo County Flood District Project

Does this Management Action or Project serve a disadvantaged community? If so, which one(s)? Yes – Grimes/College City environs



Additional Information Sources: Landowner Group should engage UC Davis Hydrology Department and Ag Extension.

Project Name and Contact

Project or Management Action Name: Colusa County Public Water System Water Filtration Plant

Contact Person: Ben King

Organization/Affiliation (Project Proponent): Stakeholder

Contact Phone: (530) 723-3119

Contact Email:bking@pacgoldag.com

Project or Management Action Description and Status

Project or Management Action Description: Build a water filtration plant on the Sacramento River between Colusa and Grimes to provide fresh drinking water to public water supply systems in Colusa and possibly Sutter and Yolo Counties.

Project or Management Action Location (please provide a map if available): Near Grimes with access to Colusa and Princeton on Hwy 45 access or old railroad easement. Access to Williams, Arbuckle, Maxwell and Dunnigan across Hahn Road, Tule Road or through Colusa and west via Lurline Road and then north/south via old Hwy 99 easement. Possible extension across river to

Meridian and Sutter. This is just conceptual with no discussion but the perfect site probably COLUSA SUBBASIN 12/22/2020 2

would be to work with Davis Ranches and purchase water rights from Sycamore Mutual or other Settlement Contractors. Use the Conway JPA as the proto-type

Which Sustainability Indicator(s) does this Project or Management Action address:

1. Groundwater levels **Arbuckle & potentially Dunnigan face loss of well supply**
2. **Groundwater Storage**
3. Groundwater Quality **Fresh Drinking water is a human right. Grimes and Princeton have arsenic contamination – Colusa has abandoned wells and faces the risk of arsenic contamination. Williams has elevated levels of dissolved solids and faces an uncertain future for a potable water supply**.
4. Land Subsidence **Groundwater Recharge and therefore potential contamination needed to mitigate Subsidence near Arbuckle**.
5. Surface Water Interaction

Project or Management Action Status (Conceptual, In Design, Ready for Implementation):

Conceptual

Has a feasibility assessment been conducted? If so, please list the agency and provide the documentation (or provide web link to download).
No

Estimated Cost:
$250 to $ 400 million

Potential Funding Sources:
Prop 1, Prop 218, EPA Funding – new Federal Infrastructure Bill.

Management Action or Project Yield (e.g. water contributed to the groundwater system, acre-feet per year): Recharge projects west of Arbuckle and Williams probably are not feasible without a safe supply of drinking water since these projects at higher elevations would likely contaminate the public supply. Settlement Contractor groundwater substitution pumping near Colusa, Princeton and Grimes are likely causing arsenic to move upward into the aquifers of the public supply systems – this system will mitigate that risk and the risk of recharge projects near the public supply systems.

Please describe any required Permitting and Regulatory Process and status of permitting and CEQA/NEPA compliance: YES

Does this Management Action or Project serve a disadvantaged community? If so, which one(s)? Yes – some of this area is/are SDACs.

Additional Information Sources:

See USGS Circular 1358 "Water Quality in Basin-Fill Aquifers of the Southwestern United State: Arizona, California, Nevada, New Mexico and Utah, 1993 by Susan A. Thiros, Angela P. Paul, Laura M. Bexfield and David W. Anning 2014. https://pubs.usgs.gov/circ/1358

USGS predictive model validates empirical evidence of arsenic contamination highlighted in the Sutter County GMP, EPA remediation site at Robbins, Grimes and Princeton. Arsenic desorbs from volcanic rock such as the Sutter Buttes into groundwater in both anoxic and high PH environments.

Dissolved soild issues likely to increase for Williams public supply system due to increase groundwater substitution pumping. 6/16 GCID wells are pumping brackish water near the William supply aquifer. Proposed recharge projects that will be integrated into the TC Canal – Sites interconnect will also lead the lateral movement of nitrates and higher concentrations of dissolved solids into the public supply systems for Williams and Arbuckle.

Other Information: Documents previously sent to Mary Fahey.

See- "Sutter-Yuba Counties Investigation "SWRCB Bulletin No. 6 September 1952 See Table 20 Page 36 for multiple brackish groundwater observations made from 1931 to 1947. See last paragraph on Page 38 regarding fresh water aquifer contamination caused by groundwater pumping. This is empirical evidence of the presence of brackish groundwater for over 100 years in groundwater flow path from volcanic geologic structure of the Sutter Buttes. Robbins is an intuitive discharge site for arsenic due to its location south of the Buttes and because the significant lower elevation due to the natural slope of the Valley.

See- "Hydrogeology Of The Sutter Basin, Sacramento Valley, Calfornia by George Curtin 1971. Discussion regarding the presence of connate or anoxic seawater in the volcanic geologic structure of the Sutter Buttes and the uncertain vertical depths of the fresh water aquifer overlying the Colusa Dome adjoining formation. See page 49 – 2nd Paragraph regarding the mound of saline water between the Buttes and the City of Colusa.

See -Sutter County Groundwater Management Plan. See general discussion concerning movement of arsenic on top of the stratigraphy of the Sutter Buttes Rampart and Figures 5 and 19 regarding the location of the Willows Fault and observed EC and Arsenic levels. Observed arsenic as high as 370 ug/L south of Sutter Buttes.

Project Name and Contact

Project or Management Action Name: **Sycamore Marsh Farm Recharge Project**

Contact Person: **Charles Marsh**

Organization/Affiliation (Project Proponent): **Sycamore Marsh Farm**

Contact Phone:**530 682 9881**

Contact Email: **sycamoremarshfarm@gmail.com**

Project or Management Action Description and Status

Project or Management Action Description:

Sycamore Marsh Farm has been in process of developing a groundwater recharge plan to store water in our aquifer by several different methods. The plan provides for 205 acres of year round recharge basins and 163 additional acres of winter recharge areas.

The fall/winter program entails impounding winter runoff in basins on our farm to eliminate or minimize runoff during winter rain events. In addition, we will supplement the rainfall with surface water supplies from the 2047 Canal to flood fields the Colusa Drain Mutual Water

Company and impound that water for recharge. This recharge program begins soon after crops are harvested.

Both methods of recharge have multiple benefits in addition to recharge. First, the recharge basins will provide habitat for waterfowl and migratory shorebirds. For many years, there has been an effort by multiple agencies to encourage these "pop up wetlands". These man made habitats provide additional winter bird food and resting sites. In addition, these sites spread out the migrating birds, potentially minimizing disease pressure among the bird populations.

Our summer program utilizes the same basins and fields as the winter program, however, recharge is obtained by use of surface water to irrigate crops or provide recharge whenever possible.

In addition, any runoff is captured in basins located in the lowest elevation of the farm and held in order to percolate into the aquifer. We are also exploring the use of post harvest application of surface water to the fields whenever possible to add to seasonal recharge.

Enclosed are maps of the proposed recharge areas. The maps show the diversion points of the 2047 canal for surface water and proposed capture basins.

Additional benefits of the project:

Greenhouse gas reduction

Reduction of sediment loading in the Colusa Basin Drain and the Sacramento River

Project or Management Action Location (please provide a map if available):

Sycamore Marsh Farm, see attached map.

Which Sustainability Indicator(s) does this Project or Management Action address:

1. Groundwater levels
2. Groundwater Storage
3. Surface Water Interaction

Project or Management Action Status (Conceptual, In Design, Ready for Implementation):

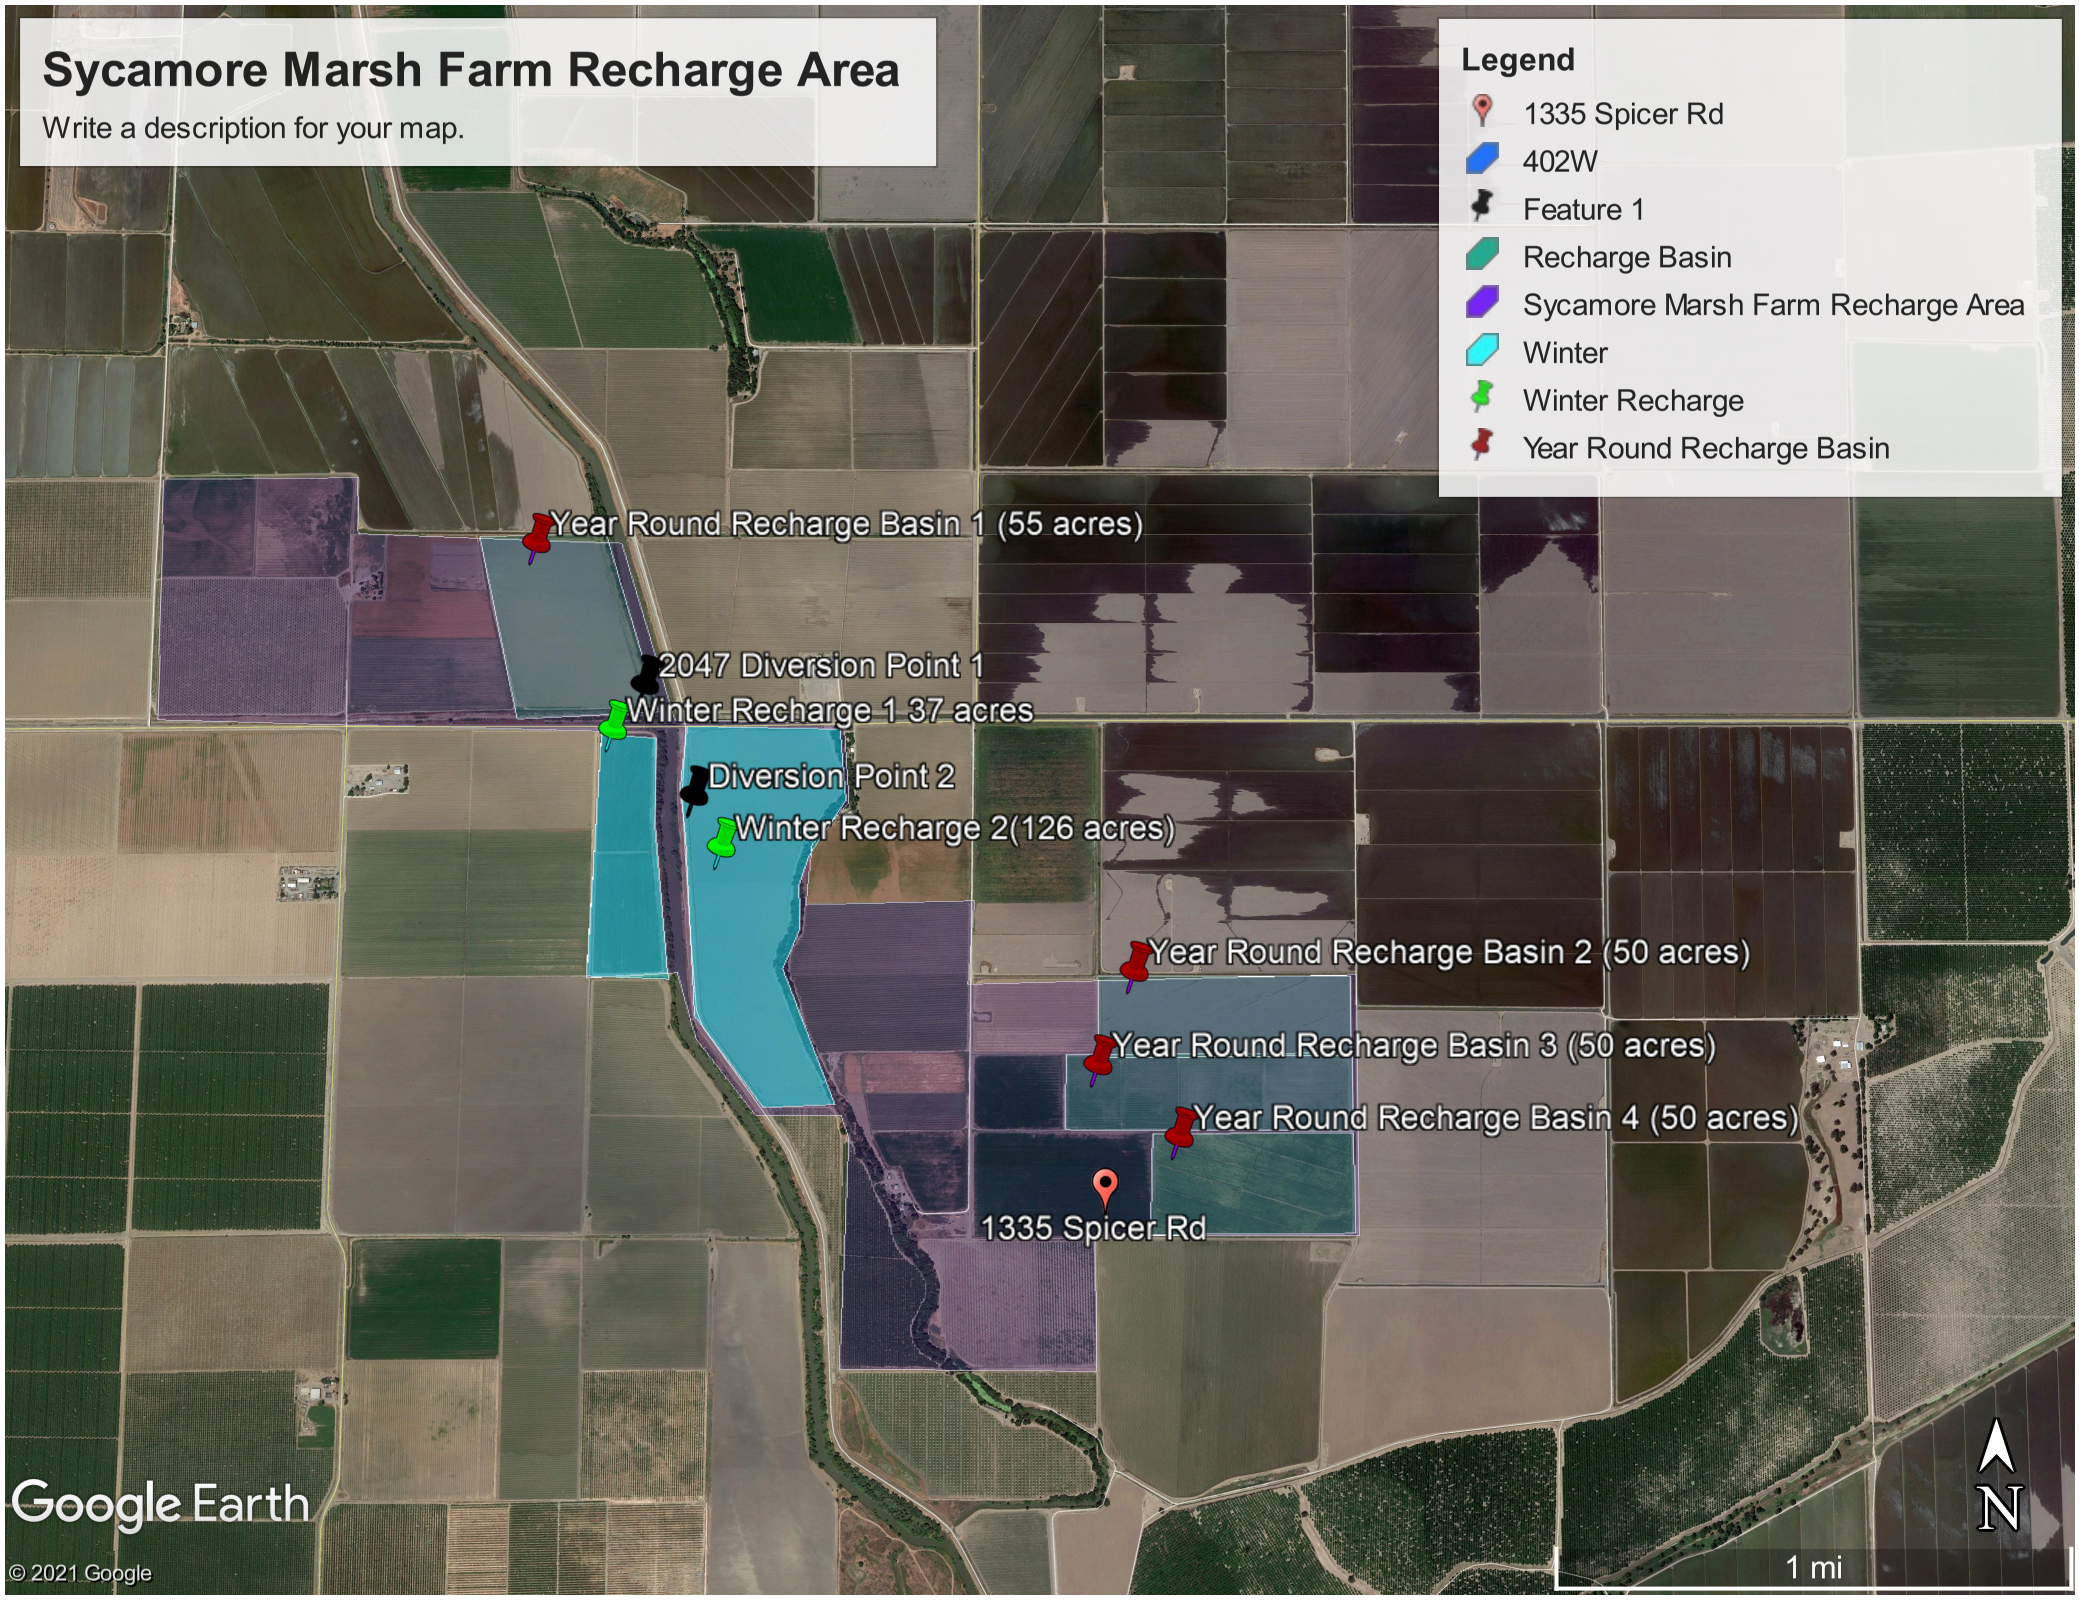
The project is ready for implementation.

Has a feasibility assessment been conducted? If so, please list the agency and provide the documentation (or provide web link to download).
No

Estimated Cost:
Pipeline from Diversion Point 2 to Recharge Basin 2 $200,000
Additional operational and maintenance expenses unknown at this time

Potential Funding Sources:
Landowners, CGA, NGO's (The Nature Conservancy and other), Prop 1 grant funding

Management Action or Project Yield (e.g. water contributed to the groundwater system, acre-feet per year):
Unknown at this time.



Please describe any required Permitting and Regulatory Process and status of permitting and CEQA/NEPA compliance:
Unknown at this time, but a supplemental permit for water storage from State Water Resource Control Board will be needed.

Does this Management Action or Project serve a disadvantaged community? If so, which one(s)?
No.

Additional Information Sources:

Other Information:

This project provides many benefits in addition to groundwater recharge/storage. Potential benefits include reduced sediment loading into the 2047 Canal and Sacramento River, increased habitat for migratory shorebirds, and reduced greenhouse gas emissions from reduced pumping from Reclamation District 479.

- Groundwater pumping allocations
- Monitoring programs (groundwater pumping, water levels, stream flows, etc.)

Please provide supporting documentation and/or links to that documentation for each question, if available. **NOTE: It is recognized that much of the requested information may not be available at this time. Please provide as much information as you can.**

Project Name and Contact

Project or Management Action Name: **Sycamore Marsh Farm Recharge Project**

Contact Person: **Charles Marsh**

Organization/Affiliation (Project Proponent): **Sycamore Marsh Farm**

Contact Phone:**530 682 9881**

Contact Email: **sycamoremarshfarm@gmail.com**

Project or Management Action Description and Status

Project or Management Action Description:

Sycamore Marsh Farm is in process of developing a in lieu groundwater recharge plan.

Sycamore Marsh Farm encompasses approximately 420 acres in the Colusa Drain Mutual Water Company (CDMWC) and has an additional 449 acres that could potentially be annexed into the CDMWC. The acreage is composed of agricultural production and environmental habitat.

Sycamore Marsh Farm can divert water from the CDMCW to provide in lieu groundwater recharge.

Greenhouse gas reduction from reduced groundwater pumping

Project or Management Action Location (please provide a map if available):

Sycamore Marsh Farm, see attached map.

Which Sustainability Indicator(s) does this Project or Management Action address:

1. Groundwater levels
2. Groundwater Storage

Project or Management Action Status (Conceptual, In Design, Ready for Implementation):

The project is ready for implementation.

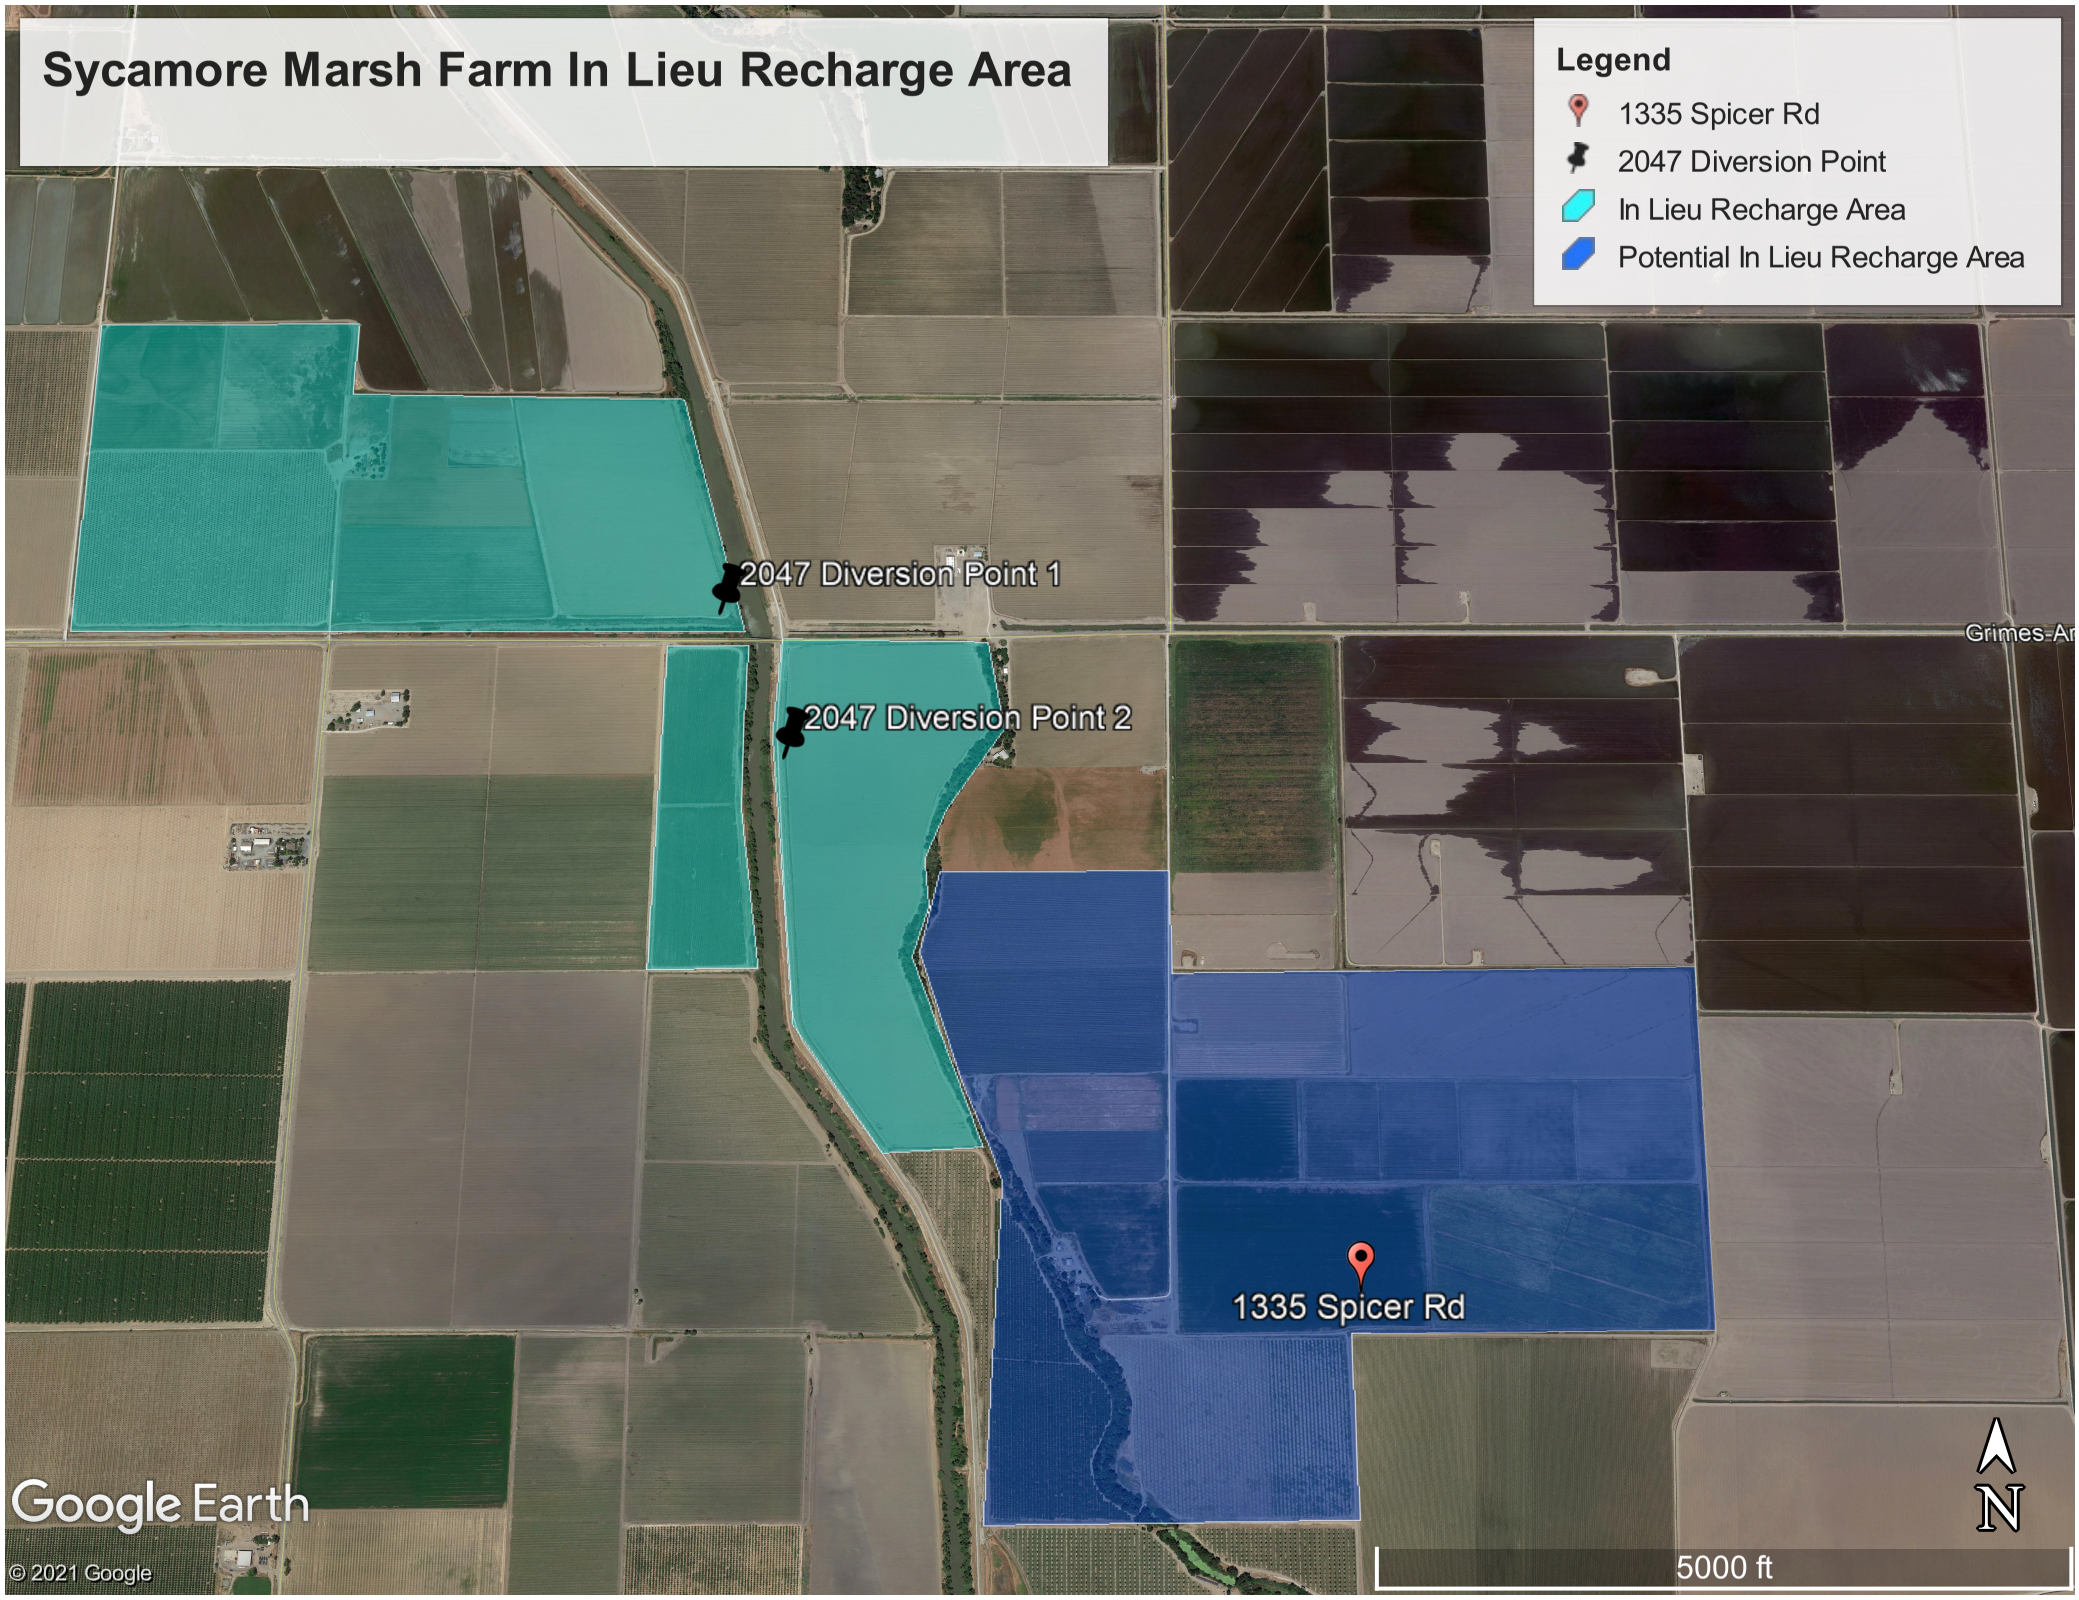
Has a feasibility assessment been conducted? If so, please list the agency and provide the documentation (or provide web link to download).
No

Estimated Cost:
Additional operational and maintenance expenses unknown at this time

Potential Funding Sources:
CGA, NGO's (The Nature Conservancy and other), Prop 1 grant funding, landowners

Management Action or Project Yield (e.g. water contributed to the groundwater system, acre-feet per year):
Unknown at this time.

Please describe any required Permitting and Regulatory Process and status of permitting and CEQA/NEPA compliance:



Unknown at this time, but a supplemental permit for water storage from State Water Resource Control Board will be needed.

Does this Management Action or Project serve a disadvantaged community? If so, which one(s)?
No.

Additional Information Sources:

Other Information:

This project provides many benefits in addition to groundwater recharge/storage. Potential benefits include reduced sediment loading into the 2047 Canal and Sacramento River, increased habitat for migratory shorebirds, and reduced greenhouse gas emissions from reduced pumping from groundwater wells.

Colusa Subbasin GSP Projects and Management Actions (PMAs) Submittal Form

Project Name and Contact

Project or Management Action Name: Colusa Subbasin In-lieu Recharge & Banking Program

Contact Person: Scott Hamilton

Organization/Affiliation (Project Proponent): South Valley Water Resources Authority

Contact Phone: (661) 303 1540

Contact Email: Scott@ResourceEconomics.net

Project or Management Action Description and Status

Project or Management Action Description: The purpose of the project is to incentivize landowners to take surplus contract surface water in-lieu of pumping groundwater by providing financial incentives (subsidizing surface water costs) to make surface water less expensive than groundwater. If needed, South Valley would subsidize the cost of new distribution systems to facilitate the delivery of additional surface water or provide funds to districts to implement other programs. The magnitude of such payments would depend on the size of the banking project but could exceed $100,000 per year per district.

A predetermined portion of the additional water brought into the districts would be dedicated to achieving local groundwater sustainability and some portion of the remaining quantities would be available for delivery, directly or by exchange, to South Valley members. Additional facilities may need to be constructed to enable recovery. Such facilities would be paid for by South Valley but located and constructed in coordination with local districts.

Project or Management Action Location (please provide a map if available): The project would be located within any districts willing to participate.

Which Sustainability Indicator(s) does this Project or Management Action address:

1. *Groundwater levels*
2. *Groundwater Storage*
3. *Groundwater Quality*
4. *Land Subsidence*
5. *Surface Water Interaction*

As an in-lieu recharge and banking project, groundwater levels would be expected to increase as a result of using surface water rather than groundwater. Groundwater storage would increase because of the groundwater not pumped. If the incentives to take surface water were strongest in the areas of subsidence, then the impacts of subsidence would also be reduced. Studies would need to be conducted to determine the impact on groundwater quality – we have not tried to assess these impacts yet.

Project or Management Action Status (Conceptual, In Design, Ready for Implementation): The project is conceptual at this time. Before proceeding to the design stage, we would need to meet with managers of districts willing to participate to really understand their concerns and objectives. The program can be structured in a variety of ways to meet the needs of the districts.

Has a feasibility assessment been conducted? If so, please list the agency and provide the documentation (or provide web link to download). Our consultants, Woodward Curran have developed an operational model for the program where inputs and parameters can be changed to consider varying circumstances and district requirements. However, it is necessary to understand the water districts goals and objectives before such a model can produce meaningful output.

Estimated Cost: It is not possible to estimate the cost of the project without understanding what size projects would best fit the water districts' needs. However, the projects are intended to generate income for participating districts without them having to pay any up-front capital costs. South Valley would also cover any increased O&M costs the districts might incur.

Potential Funding Sources: South Valley would fund projects through assessments on its members and perhaps through issuance of bonds where South Valley members would be responsible for the debt. We have not considered public grants or loans.

Management Action or Project Yield (e.g. water contributed to the groundwater system, acre-feet per year): The contribution to the groundwater would vary by district but, at the upper end, would be the difference between current deliveries and the minimum of: available but unused water, and the district irrigation demand.

Please describe any required Permitting and Regulatory Process and status of permitting and CEQA/NEPA compliance: We have not initiated any approval, permitting or environmental processes and would not do so without your consent.

Does this Management Action or Project serve a disadvantaged community? If so, which one(s)? There are ways the program can be structured to aid disadvantaged communities and we would be interested in exploring those options with you.

Other Information: South Valley members have extensive experience in water banking both as hosting agencies and project participants. These programs have provided funds, financed infrastructure and improved groundwater conditions. While we do not pretend to understand your circumstances, we would be interested in learning more and to see if this, or some other program can help achieve your objects without increasing your water costs. Financially, a program like this makes sense to us because our dry year water supplies are very expensive and a program like this could help lower those costs.

COLUSA SUBBASIN

Colusa Subbasin GSP Projects and Management Actions (PMAs) Submittal Form

Overview

The purpose of this form is to gather ideas for potential projects and management actions (PMAs) that could be evaluated and ultimately included in the Colusa Subbasin GSP. Once ideas are gathered, an initial screening and evaluation process will be conducted, followed by ranking of potential PMAs for more detailed evaluation and inclusion in the initial GSP.

Potential PMAs may fall under several categories, including but not limited to the following:

- Recharge projects
- Supply augmentation projects
- Water conservation projects
- Projects to reduce non-beneficial consumptive use
- Groundwater pumping allocations
- Monitoring programs (groundwater pumping, water levels, stream flows, etc.)

Please provide supporting documentation and/or links to that documentation for each question, if available. **NOTE: It is recognized that much of the requested information may not be available at this time. Please provide as much information as you can.**

Project Name and Contact

Project or Management Action Name: Urban Water Conservation in Willows

Contact Person: Evan Markey

Organization/Affiliation (Project Proponent): California Water Service Willows District

Contact Phone: 530-934-4735

Contact Email: infoWIL@calwater.com

Project or Management Action Description and Status

Project or Management Action Description:
Water waste prevention ordinances, Metering, Conservation pricing, Public education and outreach, Programs to assess and manage distribution system real loss, Water conservation program coordination and staffing support, and other demand management measures

Project or Management Action Location (please provide a map if available):

Willows

Which Sustainability Indicator(s) does this Project or Management Action address:

1. Groundwater levels
2. Groundwater Storage

Project or Management Action Status (Conceptual, In Design, Ready for Implementation):

Ready for Implementation

Has a feasibility assessment been conducted? If so, please list the agency and provide the documentation (or provide web link to download).

Urban Water Conservation in Willows is ready for implementation and described in Cal Water's Urban Water Management Plan Chapter 9.

Estimated Cost:

The cost of these activities is covered by the rate structure set by Cal Water for it's service areas.

Potential Funding Sources:

Collaboration and coordination with local entities is possible to extend the value of these activities.

Management Action or Project Yield (e.g. water contributed to the groundwater system, acre-feet per year):

Table 9-2 in Cal Water's 2020 Urban Water Management Plan (attached) shows the estimated water conserved from 2016-2020. From 2016-2020 an average annual savings of 2 AF was achieved.

Please describe any required Permitting and Regulatory Process and status of permitting and CEQA/NEPA compliance:

None

Does this Management Action or Project serve a disadvantaged community? If so, which one(s)?

No

Additional Information Sources:

Attached is Chapter 9 from the 2020 California Water Service Willows District Urban Water Management Plan which details the conservations activities currently in place and available in the future.

Other Information:

Chapter 9
Demand Management Measures

☑ ***CWC § 10631 (e)***

Provide a description of the supplier's water demand management measures. This description shall include all of the following:

(1) (A) For an urban retail water supplier, as defined in Section 10608.12, a narrative description that addresses the nature and extent of each water demand management measure implemented over the past five years. The narrative shall describe the water demand management measures that the supplier plans to implement to achieve its water use targets pursuant to Section 10608.20.

(B) The narrative pursuant to this paragraph shall include descriptions of the following water demand management measures:

(i) Water waste prevention ordinances.

(ii) Metering.

(iii) Conservation pricing.

(iv) Public education and outreach.

(v) Programs to assess and manage distribution system real loss.

(vi) Water conservation program coordination and staffing support.

(vii) Other demand management measures that have a significant impact on water use as measured in gallons per capita per day, including innovative measures, if implemented.

This chapter provides a summary of past and planned demand management measure (DMM) implementation in the Willows District (also referred to herein as the "District"), as well as an overview of the expected water savings.

This chapter contains the following sections:

9.1 Demand Management Measures for Wholesale Agencies

9.2 Demand Management Measures for Retail Suppliers

9.3 104Implementation over the Past Five Years

9.4 Implementation to Achieve Water Use Targets

9.5 Water Use Objectives

9.1 Demand Management Measures for Wholesale Agencies

Because the District is a retail water supplier, this section does not apply.

9.2 Demand Management Measures for Retail Suppliers

California Water Service Company (Cal Water) centrally administers its conservation programs for all the districts it operates. For purposes of this section, these programs have been grouped in accordance with the DMM categories in California Water Code (CWC) §10631(e). These categories are:

(i) Water waste prevention ordinances
(ii) Metering
(iii) Conservation pricing
(iv) Public education and outreach
(v) Programs to assess and manage distribution system real loss
(vi) Water conservation program coordination and staffing support, and
(vii) Other demand management measures

Following are descriptions of the conservation programs Cal Water operates within each of these DMM categories. The District's Conservation Master Plan, provided in Appendix I, contains additional information on Cal Water's conservation programs.

9.2.1 Water Waste Prevention Ordinances

Cal Water's enforcement of water waste prevention and water use restrictions is authorized and overseen by the California Public Utilities Commission via Rule 14.1 or Schedule 14.1. Local government in districts operated by Cal Water may also adopt ordinances regulating water use. Cal Water coordinates its efforts to prevent water waste with the appropriate local governmental entities.

Rule 14.1 defines the District's Water Shortage Contingency Plan (WSCP, Chapter 8), including its prohibitions on water waste and restrictions on water use. Prohibitions include:

- Use of potable water through a broken or defective plumbing fixture or irrigation system when Cal Water has notified the customer in writing to repair the broken or defective plumbing fixture or irrigation system, and the customer has failed to effect such repairs within seven (7) business days of receipt of such notice.
- The application of potable water to landscapes in a manner that causes runoff such that water flows onto adjacent property, non-irrigated areas, private and public walkways, roadways, parking lots, or structures.

- The use of a hose that dispenses potable water to wash vehicles, including cars, trucks, buses, boats, aircraft, and trailers, whether motorized or not, except where the hose is fitted with a shut-off nozzle or device attached to it that causes it to cease dispensing water immediately when not in use.

Restrictions on water use during shortages include, but are not necessarily limited to:

- Outdoor irrigation restrictions in terms of time of day and weekly frequency.
- Obligations to fix leaks, breaks, or malfunctions within five (5) business days of written notification by Cal Water.
- Application of potable water to driveways and sidewalks.
- The use of potable water in a water feature, except where the water is part of a recirculating system.
- The application of potable water to outdoor landscapes during and within 48 hours after measurable rainfall.
- The serving of drinking water other than upon request in eating or drinking establishments.
- Irrigation of ornamental landscape on public street medians.
- Irrigation outside of newly constructed homes and buildings with potable water in a manner inconsistent with regulations or other requirements established by the California Building Standards Commission and the Department of Housing and Community Development.
- Operators of hotels and motels shall provide guests with the option of choosing not to have towels and linens laundered daily. The hotel or motel shall prominently display notice of this option in each guest room using clear and easily understood language.
- Limits on filling ornamental lakes or ponds.
- Use of potable water for street cleaning with trucks, except for initial wash-down for construction purposes.
- Use of potable water for construction purposes, such as consolidation of backfill, dust control, or other uses unless no other source of water or other method can be used.

9.2.2 Metering

☑ ***CWC § 526 (a)***

Notwithstanding any other provision of law, an urban water supplier that, on or after January 1, 2004, receives water from the federal Central Valley Project under a water service contract or subcontract … shall do both of the following:

(1) On or before January 1, 2013, install water meters on all service connections to residential and nonagricultural commercial buildings constructed prior to January 1, 1992, located within its service area.

(2) On and after March 1, 2013, or according to the terms of the Central Valley Project water contract in operation, charge customers for water based on the actual volume of deliveries, as measured by a water meter.

☑ ***CWC § 527 (a)***

(a) An urban water supplier that is not subject to Section 526 shall do both of the following:

(1) Install water meters on all municipal and industrial service connections located within its service area on or before January 1, 2025.

The District meters all service connections and bills customers for water use monthly. Cal Water may install advanced metering infrastructure (AMI) in the future to improve metering accuracy and supply prompt feedback to customers about water use and leaks. Cal Water is currently piloting (AMI) in several districts but does not have plans for full implementation in the Oroville District at this time. AMI may be used by Cal Water in the future to detect and alert households of leaks and other possible problems as well as to provide customers with tailored water use information to help them use water more efficiently.

9.2.3 Conservation Pricing

The CPUC reviews and authorizes District water rates in a General Rate Case every three years. Currently, the District uses a three-tier increasing block rate design for residential water use and a single-tier uniform rate design for non-residential use. The District provides rate assistance to lower income households through its Customer Assistance Program (CAP).

9.2.4 Public Education and Outreach

The District's public outreach program is divided into four components, as follows:

Public Information Program – Cal Water operates an extensive public information program to provide information to customers on ways to use water efficiently and to market its conservation programs through multiple media outlets, including the Cal Water website, direct mail and bills, digital media, social media, and email.

School Education Program - Cal Water's school education program includes the Cal Water H2O Challenge, a project-based learning competition for grades 4-6, individual student competitions for grades K-12 and general information and learning materials for students and teachers. Cal Water deploys its school education program in all its districts. Cal Water H2O Challenge is a project-based competition for classrooms, grades 4-6. The program is offered in partnership with DoGoodery, the California Association of Science Educators (CASE), and the WestEd K-12 Alliance. The program aligns with the Common Core State Standards and the Next Generation Science Standards. The Cal Water H2O Challenge offers a unique opportunity for upper elementary teachers to facilitate their students' learning of standards-based content, while developing the core understanding of environmental principles necessary to becoming science-literate citizens.

Smart Landscape Tune-Up Program – This program provides customers with an irrigation system evaluation and installation of approved efficient irrigation system equipment, such as a smart irrigation controller and high-efficiency sprinkler nozzles. The program also includes irrigation system adjustments and detection and repair of irrigation system leaks. This program is available to all Cal Water customers at no charge.

Residential Customer Portal – Through its residential customer portal, Cal Water provides tailored assistance to each residential customer via customized water-efficiency targets, water savings calculators, and customer-specific recommendations for programs and water-saving tips.

Non-Residential Customer Assistance – Cal Water provides tailored assistance to commercial customers through customized incentives, commercial water surveys, and large landscape water use surveys. The non-residential assistance program helps commercial customers efficiently use water for sanitation/cleaning, heating/cooling, process, and landscape purposes.

9.2.5 Programs to Assess and Manage Distribution System Real Loss

As discussed above, reducing distribution system losses is one of the main focuses of the new Making Water Conservation a California Way of Life regulations. In preparation for these new requirements, Cal Water took part in the California Water Loss Technical Assistance Program (TAP) in both 2016 and 2017. Cal Water annually conducts distribution system audits using the American Water Works Association (AWWA) Free Water Audit Software. It has also developed a Water Loss Control Plan and Water Loss Control Policy to guide future water loss management with respect to:

- Meeting CPUC and state water loss standards and regulations
- Improving audit data and validity scores
- Implementing cost-effective water loss control actions

To coordinate and oversee water loss management actions across its multiple districts, Cal Water has added a Water Loss Program Analyst position to its conservation staff.

9.2.6 Water Conservation Program Coordination and Staffing Support

The CPUC reviews and authorizes Cal Water conservation program and staffing level in a general rate case every three years. Currently, Cal Water has nine full-time conservation positions, as follows:

- Director of Water Resource Sustainability,
- Conservation Program Manager,
- Research, Analytics and Reporting Manager,
- Water Resource Sustainability Analyst,
- Water Loss Program Analyst,
- Three Conservation Program Coordinators, and
- Conservation Assistant.

These staff manage all aspects of Cal Water's conservation programs that are run in 25 districts serving a combined population of 2.5 million people.

9.2.7 Other Demand Management Measures

In addition to the DMM programs described above, Cal Water operates rebate, give-away, and direct installation programs aimed at plumbing fixture replacement and irrigation equipment and landscape efficiency improvements. Following are brief descriptions of each of these DMMs.

High-Efficiency Toilet Replacement – This program replaces old toilets with MaP certified high-efficiency toilets via financial rebates, direct installation, or direct distribution.[41] Current rebate amounts are up to $50/toilet for residential toilet replacement and up to $100/toilet for commercial toilet replacement.

High-Efficiency Urinal Replacement – This program replaces old urinals with high-efficiency urinals meeting the state's 0.125 gallon per flush water use standard via financial rebates and direct installation. While available to all non-residential customers, the program targets sites with higher-than-average bathroom utilization, such as restaurants and office buildings. The current rebate amount is up to $150/urinal.

Clothes Washer Replacement – This program provides a financial rebate to replace an old inefficient clothes washer with a new high-efficiency washer. The program is available to all residential and multi-family customers. The current rebate amount is up to $150/washer.

Residential Conservation Kit Distribution – This program offers residential customers conservation kits featuring a range of water-saving plumbing retrofit devices. The kits are

[41] For information on MaP certified toilets, see: https://www.map-testing.com/

available at no charge and include two high-efficiency showerheads (1.5 gpm), two bathroom faucet aerators (1.0 gpm), one kitchen faucet aerator (1.5 gpd), toilet leak tablets, and an outside multi-function, full-stop hose nozzle.

Smart Irrigation Controller Installation – This program provides a financial rebate for the installation of a smart irrigation controller that automatically adjusts watering schedule in response to changing weather conditions. The current rebate amount is $125/controller for residential customers and $25/station for commercial customers.

High-Efficiency Sprinkler Nozzle Rebate – This program provides a financial rebate for the installation of high-efficiency sprinkler nozzles. This program is available to all Cal Water customers. The current rebate amount is $5/nozzle.

Large Rotary Nozzle Rebate – This program provides a financial rebate for the installation of high-efficiency large rotary nozzles. This program is available to all Cal Water customers. The current rebate amount is up to $30/nozzle toward the nozzle purchase cost and up to $8/spray body toward installation cost, if installed by a C-27 licensed landscape contractor.

Spray Body with Integrated Pressure Regulation and Check Valve Rebate – This program provides a financial rebate for the installation of high-efficiency spray bodies with integrated pressure regulation. This program is available to all Cal Water customers. The current rebate amount is up to $10/body toward the spray body purchase cost and up to $8/spray body toward installation cost, if installed by a C-27 licensed landscape contractor.

Turf Replacement Rebate – This program provides a financial rebate for replacement of turf with approved drought-tolerant landscaping. Cal Water operated this program in 2015/16 as a drought response measure. The program will be re-started as part of Cal Water's irrigation equipment/landscape upgrade program offerings.

Table 9-1 summarizes the DMMs available to Dixon District customers at the time this Plan was prepared.

Table 9-1. Cal Water DMMs Available to District Customers

Programs Offered	Customer Eligibility		
	Single-Family	Multi-Family	Commercial
Plumbing Fixture Replacement			
High-Efficiency Toilet Replacement	✓	✓	✓
High-Efficiency Urinal Replacement			✓
High-Efficiency Clothes Washer Rebate	✓	✓	
Conservation Kits	✓	✓	
Irrigation Equipment/Landscape Upgrades			
Smart Irrigation Controller Rebate	✓	✓	✓
High-Efficiency Sprinkler Nozzle Rebate	✓	✓	✓
Large Rotary Nozzle Rebate		✓	✓
Spray Body Rebate		✓	✓
Turf Replacement Rebate	✓	✓	✓
Customer Assistance			
Smart Landscape Tune-Up Program	✓	✓	✓
Residential Customer Portal	✓		
Non-Residential Customer Assistance		✓	✓

9.3 Implementation over the Past Five Years

Table 9-2 summarizes program implementation for the previous five years. Estimated water savings do not include savings from water waste prevention ordinances, conservation pricing, public information, or distribution system water loss management. Cal Water uses the Alliance for Water Efficiency's Water Conservation Tracking Tool to estimate water savings.

Table 9-2. Implementation of Customer DMMs: 2016-2020

Indoor Programs	2016 – 2020 Total	Average Annual
Toilets & Urinals (number distributed)	32	6
Clothes Washers (number distributed)	20	4
Conservation Kits (number distributed)	24	5
Outdoor Programs		
Smart Controllers (number distributed)	3	1
Nozzles & Spray Bodies (number distributed)	0	0
Turf Buy-Back (sq ft removed)	4,140	828
Residential Assistance Programs		
Surveys/Audits (homes receiving)	1	<1
Non-Residential Assistance Programs		
Surveys/Audits (sites receiving)	0	0
Estimated Water Savings (AF)	8	2
NOTES: Estimated water savings for 2016-2020. DMMs will continue to generate savings after 2020 for their useful life.		

9.4 Implementation to Achieve Water Use Targets

All the DMMs described above contributed to the District's compliance with its SB X7-7 2020 target GPCD.

9.5 Water Use Objectives (Future Requirements)

CWC §10609 requires that urban retail water suppliers develop new water use objectives that are based on specific standards for certain water use sectors. These water use objectives will not be developed until 2023. Suppliers are encouraged in this UWMP cycle to consider how they will align their conservation management actions in order to meet these future obligations.

As noted above, Cal Water's conservation programs are subject to review and approval by the CPUC through a General Rate Case every three years. In making conservation program recommendations to the CPUC, Cal Water carefully considers how they will advance multiple objectives, including compliance with the pending water use objectives. Specific objectives identified in Cal Water's most recent General Rate Case included:

- Maintaining continuity with and furthering implementation of conservation programs authorized by the previous General Rate Case.

- Preserving gains in water conservation achieved during the 2013-2017 drought.
- Ensuring Cal Water districts are well-positioned to comply with state regulations and policies pertaining to water conservation, water loss management, and groundwater management, including Executive Order B-37-16, SB 555, and the Sustainable Groundwater Management Act (SGMA).
- Advancing cost-effective water use efficiency alternatives in districts with high water supply costs.

Cal Water developed a scoring methodology to adjust conservation programs and budgets to further these objectives. The methodology specifically considers five distinct conservation policy drivers:

1. State Conservation Standards and Water Use Objectives
2. SGMA Compliance
3. SB 555 Water Loss Management Requirements
4. Commercial, Institutional, and Industrial (CII) Water Management
5. Avoided Water Cost and Affordability

The methodology assigns greater weight to the State Conservation Standards and Water Use Objectives and SGMA Compliance policy drivers, reflecting their importance in terms of overall water resources management.

Scoring for the SGMA Compliance policy driver is based on groundwater basin priority, district dependence on groundwater supply, and basin adjudication status. The highest scores are assigned to districts in unadjudicated and critically overdrafted or high priority basins where groundwater comprises more than 45 percent of the water supply. The Willows District ranked in the middle of Cal Water's districts for this policy driver.

Scoring for the State Conservation Standards and Water Use Objectives policy driver is based on four metrics that are used to gauge which districts are most likely to require adjustments to their conservation program mix or level of implementation to comply with the new standards. These metrics are:

1. Residential per capita landscape area
2. Residential per capita turf area
3. Size and number of large residential landscapes
4. Difference between a simulated water use budget and average water use for 2011-15

The Willows District ranked in the top third of Cal Water's districts for this policy driver.

Scoring for the SB 555 Water Loss Management Requirements policy driver is based on the district's infrastructure leakage index (ILI) from its most recent validated water loss audit. The ILI

is a performance indicator of real (physical) water loss from the water distribution system. A high ILI indicates possible distribution system inefficiencies and may also indicate significant water system leakage. Proposed adjustments to funding for water loss management are based on the ILI scoring criteria. The Willows District ranked in the top 15 percent of Cal Water's districts for this policy driver.

Scoring for the CII Water Management policy driver is based on the ratio of CII water uses to total water uses in a district. The Willows District ranked in the middle of Cal Water's districts for this policy driver.

Scoring for the Avoided Water Cost and Affordability policy driver is based on the District's avoided cost of water supply, as estimated by the California Urban Water Conservation Council (CUWCC)/Water Research Foundation Avoided Cost Model. The Willows District ranked in the middle of Cal Water's districts for this policy driver.

The combination of scores on each policy driver were used by Cal Water to recommend to the CPUC in its most recent General Rate Case adjustments to the conservation budgets of its districts. The purpose of the adjustments is to increase Cal Water's capacity to deploy conservation programs in districts expected to face the most significant regulatory and water management challenges in coming years. Recommended adjustments ranged from a low of 5 percent to a high of 25 percent. The recommended adjustment for the Willows District was 22.5 percent.

Colusa Subbasin Groundwater Sustainability Plan Chapter Input

Commenter Name: Donald Bills **Commenter Affiliation (if applicable):** GGA-TAC

This file introduces a table that allows you to easily enter the following key information so we have certainty about your input. The table includes the following categories:

- Chapter Number
- Section Number
- Page Number
- Paragraph Number (starting with the first full paragraph at the top of a given page)
- Figure/Table Number (if applicable)
- Comment

INSTRUCTIONS

1. Please **ONLY** use the MS Word or PDF document titled "Colusa Subbasin GSP Chapter Input" to submit your comments.

2. Review all applicable text and note each Chapter, Section, Page, and Paragraph number associated with a comment you'd like to make. For Paragraph number, please start with the first full paragraph at the top of a given page and count down.

3. Enter your name and if applicable, an organizational affiliation at the top of your table.

4. Once you have completed all your comments, please save the file with your last name at the end in parentheses. For example:
   - *Colusa Subbasin GSP Chapter Input (Jones).docx*

5. If you are located in the Glenn Groundwater Authority, please send your comment file to:
   - Lisa Hunter – Program Manager - Glenn Groundwater Authority: lhunter@countyofglenn.net

6. If you are located in the Colusa Groundwater Authority, please send your comment file to
   - Mary Fahey – Program Manager - Colusa Groundwater Authority: mfahey@countyofcolusa.com

7. If you don't affiliate specifically with either the CGA and/or GGA, please send your comments to both Mary and Lisa.

8. Please make sure that your comments are submitted by midnight May 5, 2021.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
1	1.1	1.1			
1	1.2	1.2	2		1.—Sustainable groundwater resources not only preserve, and enhance the economic viability, social well-being and culture of all beneficial uses and users, but also insure the sustainability of water for natural and environmental needs. Especially those of at risk or critical resource value (i.e. springs, wetlands, riparian habitat, and baseflow reached of perennial and/or intermittent streams). I would suggest adding something like this to the stated goal of the Colusa Subbasin GSP. 2.—there is no such thing as sustainable/safe yield. At best the term means planned depletion. I suggest you replace it with sustainable goal.
1	1.2	1.2	3		1.—Sustainable/safe yield is no longer considered to be a valid term in the context of hydrogeology. The term was originally developed as a legal term to characterize a water budget in balance by relating recharge (from precipitation) with discharge, two terms that are not related. I suggest that you replace it here with sustainable goal.
1	1.3	1.2	3		1.—Suggest that you modify Both GSAs in the last sentence to “Both the Colusa and Glenn GSAs…” for clarity.
1	1.4	1.4	1, bullet 5		1.—Suggest that you add to seawater intrusion, brackish or saline groundwater intrusion. As discussed during TAC meetings, as freshwater is removed from storage in the regional aquifer. The reduced hydraulic head will allow brackish and/or saline water at depth to seep upward into the regional aquifer. Unless

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
					monitoring of water quality at depth in the regional is intended to be the monitoring tool for this.
1	1.4	4 of 7	Article 5 sub-article 2	1-1, GSP regulation section 354.18, bullet 3	Suggest replacing estimate of sustainable yield with estimate of sustainable goals.
1	1.4	4 of 7	Article 5 sub-article 2	1-1 GSP regulation section 354.18, surface water supply	Shouldn't this also include reclaimed water and/or
1	1.4	6 of 7	Article 5 sub-article 4	1-1, GSP regulation section 354.36, representative monitoring.	Remote-sensing data was discussed as an additional proxy in addition to groundwater elevations for other sustainable indicators. Should it be mentioned here?
1	1.4	6 of 7	Article 5 sub-article 4	1-1, GSP regulation section 354.36, Assessment and Improvement	Again remote-sensing methods and data are another tool that seems suited for filling data gaps by improving monitoring frequency, accuracy, and density of data sites. Discussion of DWR INSAR and gravity data as possibilities.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
3	3.1	3-1	1, first sentence		First occurrence of abbrev. Should be spelled out in text. I.E. This section describes the hydrologic conceptual model (HCM) of the Colusa Subbasin.
3	3.1.3	3-6		3-3. Note in upper left of plot. Second sentence.	There appears to be missing or jumbled text at the start of sentence 2. “ at r y ars missing more that 30 days…”. Suggest that it be fixed is needed.
	3.1.4	3-8		3-4	Since land surface elevation is color coded on the Topography map, it might help to identify the very light shade of blue as surface water as it can be easily confused with the very light green (greenish-blue?) that is land surface less than 30 ft.
	3.1.5	3-7	Paragraph2, 1st sentence	3-5	“The regional watersheds and natural waterways are shown on Figure 3-5.” Figure 3-5 also shows principal water infrastructure. I suggest it be added to the sentence and the fig. 3-5 title.
	3.1.5	3-10	First paragraph, last sentence		“These streams are intermittent and drain the foothills that border the Coast Ranges to the west.” Perennial streams are connected to the regional groundwater table and get most of their base flow by groundwater discharge. Intermittent streams are only seasonally connected to the regional groundwater table and flow seasonally or in response to runoff. Ephemeral streams are not connected to the regional groundwater table and only flow in response to seasonal runoff. Are Foothill streams of the Coast range truly intermittent?

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
3	3.1.5.1.1	3-10			Is there no range of flow data for Stony Creek pre-Black Butte Dam (and even Stony Gorge Dam)? This would give some context to the releases from Black Butte Dam since 1996.
	3.1.5.1.2	3-13			"Sacramento River stream flows measured at the Ord Ferry-Main Channel stream gauge, in the northern part of the Subbasin, varied between 200 and 160,000 cfs during the 1984 to 2020 time period, with extreme low flows measured in the spring of 1990." Why is the time p3.1.5.1.3eriod limited to 1984 to 2020? If the intent here is to describe natural surface waters, there are documented (USGS) periods of extreme flows greater that this range extending back to the 1920 from stream-flow gaging stations in or adjacent to the Colusa subbasin.
	3.1.5.1.3	3-13			3.1.5.1.4 Glenn Colusa Canal lists acres serviced. Wouldn't it be appropriate to do the same for the Tehama-Colusa Canal? Also the length of the canal and diversions? I watched the Tehama-Colusa Canal being built less that a quarter-mile away from where I grew up on Co. Rd. 21 south of Orland. I even rode my bike in the bottom of the canal once it was cemented in. I noticed at the time there was a line of one-way valves on the bottom of the canal. I later learned they were there to relieve stress on the canal by allow rising groundwater to move into the canal. Is this something you are accounting for in your groundwater models during those wet years when WLS are very close to the surface?
	3.1.5.1.6	3-15	1		"These foothill drainages and their tributaries are classified as part of the Sacramento-Stone Corral Watershed…". I think you mean the Upper Stony Watershed.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
	3.1.5.1.6	3-15	2		"Runoff in these ephemeral and intermittent streams generally begins in late fall when the rainy season starts and may continue until late spring." Intermittent streams suggest some seasonal contact with the regional groundwater table. Probably not true for many of these streams in the north part of the subbasin. I do not know about those in the southern part of the subbasin. Springs are overlooked in this discussion (or elsewhere). Many of these smaller streams have springs at or near their headwaters that issue from either the Tehama (exposures of pre-Paleogene, would have a QW signature), Riverbank or Modesto Formations. Discuss here?... High elevation areas to the west of Orland/Willows. GW contours do not extend that far west. 3.1.11.3 does not address springs. Black butte Lake overlies mostly Tehama formation. Is there ant possibility of Reservoir water seeping into Tehama and showing up in springs to the south? QW signature, spring flow related to lake level not climate, etc.
3	3.1.6	3-18		3-9	The color for soil type C and water bodies on fig. 3-9 (light blue) are so similar it is hard to tell them apart. I suggest you consider using more contrasting colors and adding waterbodies to the explanation to make them easier to tell apart.
		3-27		3-16	Top of Cretaceous rocks contours are in meters MSL, and tops of Cretaceous rocks elevation are in feet MSL. Using both metric and SI units makes them a little difficult to compare. Can they both be in the same units? Also, there are places where the contours do not match the elevations (SE of Black Butte, Artois, Princeton, etc.). I assume this is related to structural offsets. I suggest you consider adding the principal structures (faults) to this map to help with the interpretation.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
	3.1.7.2.3	3-31	4		During a review of USGS topographic maps that cover the area west of Orland and Willows, I found about 24 marked springs, a few with actual names. Based on their location, these springs appear to be discharging from either the Tehama, Riverbank or Modesto Formations in the northwest part of the Colusa Subbasin, There is little hydrogeologic information shown on the maps of this report for this area owing to a lack or well data. Springs represent a source of hydrogeologic information that can be used in the absence of well data to extend water level contours and improve understanding of groundwater conditions in the area. Any information about these springs from land owners or site inventories by DWR or the USGS will improve the hydrogeologic characterization of this area of the subbasin. Some mention of spring discharge from the Tehama, Riverbank, and Modesto Formations might be appropriate here, with a more complete discussion in groundwater discharge.
	3.1.8.2	3-36	2-3		?... Base of the Tehama and Tuscan Formation and (or, and/or?) Base of freshwater excluding those areas where post-Cretaceous sediments contain brackish water. Freshwater is defined as 3,000, 2,000, and 1,000 mg/L depending on which reference is used (USGS, DWR, of C2VSim). Which is it? I would also suggest that you define brackish water here as its related freshwater and the freshwater boundary. The vertical extent of these boundaries shown on fig. 3-11 to 3-13 while approximate do not appear to consistently align with either of these definitions. Perhaps it would be appropriate to add queries ("?") where the degree of uncertainty is highest.
	3.1.9.2	3-38	1		"These basin faults may act as barriers or conduits to fresh groundwater flows." I think it is also important to mention that, if the faults are deep seated, they can also provide conduits for poorer quality (brackish) water from the marine sediments below to migrate up into the freshwater layer. This is particularly true if the hydraulic head of the freshwater layer is consistently reduced owing to groundwater withdrawal.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
3	3.1.10, Principal aquifers	3-39			Some text edits for clarity.
	3.1.10.3, water Quality	3-42	1		Electrical conductivity (EC) is not a measure of the quality of the water. It is a measure of how electrically conductive the water is. As a result, there is a nearly direct relationship between EC and total dissolved solids (TDS) in the water. TDS is one general measure of water quality. The more dissolved solids in the water, the more electrically conductive it is and, as a result, the quality of the water is generally poorer. For this reason, I suggest you delete reference to EC in the first sentence of the paragraph.
	3.1.10.3	3-42			Fire retardant used to be manufactured in Orland and included boron with other chemicals known for both their fire suppression properties and as chemical fertilizer. Currently, fire retardant is a mix of ammonium polyphosphate, diammonium phosphate, diammonium sulfate, monoammonium phosphate, attapulgus clay, guar gum known as Phos Chek. Over time, after a fire, this material gets watered into a watershed and may be a concern for the water quality of an aquifer. It is also highly concentrated where manufactured and distributed (Airports like Orland, Willows, and USFS and CDF fire bases).
	3.1.10.3	3-42	3		Most drycleaners use both Trichloroethylene (TCE) and Tetrachloroethylene (PCE) (as did the one in Orland). The studies I have seen on this issue for the Orland area refer mostly to TCE.

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
	3.1.11, Groundwater Inflows and Outflows	3-42 to 48	1		The section heading is groundwater inflows and outflows. The lead sentence begins “Groundwater underflows between the Colusa Subbasin and neighboring groundwater subbasins…”. Groundwater underflow is a specific type of inflow or underflow. I would suggest that a better use of this introductory paragraph would be to list all the relevant GW inflows and outflows to the Colusa Subbasin as discussed in the following subsections. I would also add the Corning Subbasin in the first sentence in relation to groundwater underflow. As water-level contours indicate (fig. 3-19), Stony Creek is not a barrier to groundwater flow.
	3.1.11.2.2, GW banking?	3-43			Groundwater banking. Not in the glossary of terms and it appears to mean something different here (recharge) as opposed to the most common definition (water management mechanism designed to increase water supply reliability through the buying, selling, and storage of surface water and groundwater rights for later use). I would suggest artificial recharge as a alternate term since the main heading (2.1.11.2) is Groundwater Recharge Areas.
	3.1.11.3, Groundwater discharge areas	3-45	2		I suggest that you consider adding a few sentences about springs in the Colusa Basin to this paragraph. Something like: “Most springs in the Colusa Subbasin occur near the western boundary and discharge from the Tehama, Riverbank, or Modesto Formations and stream channel alluvium. About 25 springs can be identified from USGS topographic maps of the subbasin. A number of these springs have been developed for agricultural use by landowners locally (apparent on satellite imagery). The flow, and water quality of these springs may exist in DWR or USGS databases based on past historical inventories.” If properly inventoried these springs would represent significant additional information about the occurrence, movement, and quality of ground water in the regional aquifer of the Colusa Subbasin, especially where this information is poorly defined.

3	3.1.11.3	3-48	2, 4th sentence		"There are also many unmetered domestic wells located throughout the study area." I suggest adding unmetered small ag wells also: "…unmetered domestic and small agricultural wells…"
			2, 5th sentence		It might be appropriate to add a sentence or two here to briefly explain how the annual rate of withdrawal from domestic wells was determined (estimated). Average pump capacity of all domestic wells, seasonal domestic water use estimates, or other. Adding small unmetered ag. wells to this total would increase significantly I imagine.
	3.1.11.3	3-48	3		I would also add a comment to this paragraph that during years when surface water deliveries are significantly cut back (drought), agricultural lands rely heavily on wells to make up the difference.
3	3.1.12.1	3-51	4		other methods or data sources: I'd like to suggest passive seismic. The method uses seismic signals already available in the environment, either anthropogenic (i.e. freeway traffic), or natural (i.e earthquakes, ocean waves, etc). the seismic signals are processed similar to standard reflection and/or refraction surveys but for much larger areas and depths. Ground-based, non-invasive CSAMT (Controlled Source Audio-frequency Magnetotellurics) and TEM (transient electromagnetic or alternately called time-domain EM (TDEM)) surveys can provide detailed subsurface information on stratigraphy, structure, depth to water and water quality in localized areas of interest. Survey lines that pass over or by existing wells provide ground-truth.

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
3	3.1.12.1	3-52	1		Different TDS thresholds to define base of freshwater. Part of the problem may also be that water use type has a lot to do with whether water is considered fresh or not. MCL for safe drinking water is 500 mg/L, Livestock can tolerate about 1,500 mg/l. A lot of commercial ag. plants can tolerate 2,000 to 3,000 mg/L. There is also not broad agreement on what constitutes fresh, saline, or brackish water. It seems to me that the standard for what constitutes freshwater should be the same for all subbasins in the Sacramento Valley, if not the entire Central Valley.
	3.2.2.1	3-53	2, second sentence		"The most notable recovery period occurred around 1983, which was both a wet year and when water users added more surface water to their supply portfolios." The recovery after the 1987 to 1991 drought seems at least as great if not greater.
		3-53		3-22	It is hard to evaluate temporal trends on this plot referring back to the average annual precipitation plot at the beginning of this chapter. To help understand and evaluate this temporal data it would seem appropriate to add a plot of the annual average precipitation to this graph.
	3.2.2.1	3-55	1		Besides showing the general direction of flow to the SE, Figure 2 appendix 3-B appears to show Walker Creek to be a gaining stream (i.e. perennial, groundwater contours point up stream) from the NW part of the subbasin to Artois. Comparing land surface contours (fig 3-4) to the groundwater contours for this area seems to indicate that the depth to water is from -10 to -30 ft below the streambed throughout. Is there a discrepancy here that needs to be resolved?

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
3	3.2.2.1	3-55	4		"Current groundwater levels are similar to those measured in 2017, indicating that regional groundwater levels have been relatively stable since the end of the previous multiple-year drought." I find this statement a little misleading. What it overlooks is the fact that the combined effect of the 2007-09 and 2012-16 droughts was an average depth to water decline of over 30 ft (fig 3-22) from which the principal aquifer has yet to recover. In addition the 2019 and 2020 wls appear to continue trending down, not stable, as cones of depression continue to expand (fig 3-24 and 3-25).
	3.2.2.1	3-55	1,3rd sentence		"Impacts due to pumping are the exception to the typical gradients and disrupt both local and regional gradients." I suggest that you add to this sentence or the first sentence of the paragraph a comment on the effects of changing hydraulic parameters on the lateral groundwater gradient.
	3.2.5	2-64	Second		Delete EC. It is not a water quality parameter.
			third		Who monitors and regulates the water quality of municipal supply systems? Worth mentioning here? Regional water quality control boards? Saline connate water? Connate water is water trapped within the pores of sedimentary rocks. For that to happen it would have to be fully confined laterally and vertically and not be faulted or fractured. In the geologic discussion it states that pre-Cretaceous rocks are faulted and fractured. Groundwater is almost always in motion and always flows in response to gravity and/or the hydraulic gradient. The flow rates can be very slow, ft per hundreds to thousands of years or more. The connate water would be in pre-

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
					Cretaceous sediments. Has anyone dated the water to see if it is, in fact, greater than 145 million years old, give or take?
	3.2.5.1.1	3-64	1		End of first sentence add "…and/or EC value (EC is a surrogate [estimate of] for TDS because it is more easily measured on site)." There appears to be a discrepancy in the Secondary MCL for TDS; 500mg/L in sentence 2 and 500 mg/L in sentence 4. Fix?
	3.2.5.1.1	3-66	1		"Wells screened in the unconfined to semi-confined zone of the aquifer (i.e. in wells less than 200 feet deep) had the highest number of wells with elevated TDS concentrations." I suggest adding "in thew central and southern part of the subbasin" to the end of this sentence.
	3.2.5.1.1	3-66	2		First sentence, …In these areas…. What areas? Suggest replacing with …southwest of Colusa…
	3.2.5.1.2	3-67	1		Anthropogenic source for increasing chloride and sulfide concentrations? Septic systems, landfills, other?

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
	3.2.5.2.2	3-67	1		Boron. Pre, late 1970's Boron was a component of fire retardant for its fire suppression characteristics. Fire retardant was manufactured in a plant in Orland and stored at firebases (airports) in Glenn and Colusa counties. Is saw wide use in suppressing forest, brush, and grass (at lower elevations) fires in Glenn and Colusa Counties.
	3.2.5.2.3	3-68	1		Known or suspected cause for increases in iron and manganese worth mentioning here? Natural or human caused? Landfill west of Artois? Junk yards? Suggest adding if appropriate.
	3.2.5.2.3	3-68	1		Known or suspected cause for anthropogenic increases in hexavalent chromium worth mentioning here? Landfill west of Artois? Suggest adding if appropriate.
	3.2.7	3-73	2 and 3 paragraphs		The second paragraph is misleading ("While Stony Creek, Sacramento River, and the Colusa Basin Drain all experience gaining and losing conditions throughout the year,…") and appears to contradict the information provided in the 3rd paragraph. I would suggest deleting the second paragraph entirely and moving the table references to the 3rd paragraph.
	3.2.8	3-74	2nd paragraph	3-34	I do not follow the scoring criteria for GDE. A GDE where groundwater is near the surface has a score of 1; least likely to be GDE when it should be more likely to be a GDE. If a GDE is not near surface water OR crop land it scores a 4; most likely to be a GDE when it should be least likely to be a GDE. How the 30 ft DTW line was derived is explained in paragraph 1 on page 3-75. But I could not find or estimate the 30 ft DTW on any or the other figures in the text or appendix. An approximated 30 ft DTW line for 2006

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
					data on figure 3-19 would run from between Arbuckle and College City, to near the boundary of the subbasin west of Williams, to just west of Artois, ending at Stony Creek just N/NW of Orland. This is nowhere near the line shown on figure 3-35. Using figure 5 in appx 3B I can approximate a 30 ft contour to the 2017 data. But it also does not compare to the 30 ft DTW contour on figure 3-35. The explanation table on figure 3-35 does not reference a time period (2014 to 2018?) for the 30 ft DTW line or any of the other features shown. Finally, there is no reference to springs and the riparian habitat they support at headwater streams in the NW part of the subbasin between Willows and Orland. These would represent some of the most important and species diverse habitat in the subbasin. I would suggest that the entire GDE section be revised so it more clearly and plainly represents GDE's that occur within the subbasin.
3	3.3 Water budget information	3-77	1		This section describes water budget components in detail but, I did not see a clear statement of what the water budget was for. Water budgets can be used for many things (i.e. GW gains or losses, basin gains or losses, etc). Is there a statement of the purpose of the water budget in the Groundwater Sustainability Plan Emergency Regulations §354.18 that could be added to the introduction here? The name suggests it is to determine groundwater sustainability of the principal aquifer in the subbasin. That implies that all the inflows and outflows are on onside of the equation and +/- change in storage is the result.
3	3.3.3	3-80		3-9	What is the Shasta non-critical and Shasta Critical, mentioned on the table? How does it relate to the Colusa Subbasin? I think it is defined two pages later under Land use. But there is still no explanation of what a Shasta critical and Shasta noncritical year is. Reservoir contents? Outflow? Both? Is there a reference for this missing? It would be worth providing a footnote to table 3-9 to define Shasta critical and Shasta non critical.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
	3.3.3.3	3-83	3, Land Use		"…modified based on planned development according to the Colusa County 2030 General Plan." Is there a 2030 Glenn County General plan worth considering here as well?
3	3.3.4	3-84	1, bullet 1		Groundwater pumping and stream accretion are described as inflows here. In paragraph 2 second bullet on page 3-85 they are described as outflows. Which is it? I would suggest they are both outflows from the principal aquifer and the text needs to be fixed accordingly.
	3.3.4	3-85	3rd bullet of first paragraph (3-84)		Change in Storage is defined as changes in soil moisture storage within the upper several feet of soil in the root zone, as well as changes in storage in surface water bodies within the basin. Neither of these are change in storage. They are either inflows or outflows components that when summed with other inflows or outflows result in a change in storage of the principal aquifer. I would suggest that the text be fixed accordingly.
		3- 86 and 3-87		3-10 and 3-11	The tables do a much better job of representing the various SW and GW components of the water budget. Is there some way change the text so it is mere consistent with the tables? Also, In both table 3-10 and 3-11 the column headings for future conditions climate change relate to a specific date (2030 and 2070). It would be useful to the reader if the other columns (historical simulation, current baseline, and future condition no climate change base line) had the time periods they are based on as well. 1990 to 2015, 2015, and 1966 to 2015 respectively.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
	3.3.4.1	3-88	4		I would suggest that ET from the riparian corridor of the Sacramento River as well as evaporation from the rivers surface can also be significant and worth discussing here. Especially during the summer months when ET is at a maximum and daytime temperatures can exceed 100 degrees for weeks at a time. This is important to consider under future climate change scenarios where temperatures and the days per year of excessive heat are predicted to increase.
	3.3.4.1	3-89		3-38	I would suggest that you add the change in storage (3taf.yr) to the graph. It is not apparent on the graph even though it is color coded in the legend. The columns look equal. In any case it should not be a color-coded box as inflow or outflow. It is the result of both.
	3.3.4.1	3-90		3-39	The GW change is storage in table 3-12 is shown as a negative number (-27.5 taf/yr, a loss). So, why is it shown as an inflow in this figure? Change in storage is neither an inflow nor a outflow but the result (sum) of both. Showing it this way graphically suggests the inflows and outflows are in balance. They are not. I would suggest that you add the actual change in storage (-27.5 taf/y) to the legend and remove it from the inflow column. I suggest you make similar changes to figures 3-40 to 3-47.
	3.3.4.1.1	3-91	1 and 2	3-12	“The primary sources of surface water in the basin are the Sacramento River and Stony Creek. Surface water supplies are relatively reliable in the basin and represent approximately 74 percent of the total water supplies.” Is this statement accurate? How do Shasta critical and non-critical years affect it? I would think that during Shasta critical years SW deliveries would be much and during Shasta non-critical years would be at or near 100 percent. The second paragraph seems to support this.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
3	3.3.4.2	3-93	2		Average annual inflows to and outflows from the groundwater system were estimated to be 997 taf/yr during the current conditions baseline simulation period on figure 3-41 are shown as 998 taf/yr not 997. Which is right?
	3.3.4.3.1	3-95	4		"There is negligible change in groundwater storage under the future condition, no climate change baseline water budget." I suggest you add the actual change in parentheses: "…negligible change (+0.6 taf/yr)…"
	3.3.4.3.2	3-97	1		"Average annual inflows to and outflows from the groundwater system were estimated to be 1.0 maf/yr." I suggest you add the type and time period to toe sentence so it is consistent with the title of this section and the figure referenced. "Average annual future conditions 2030 climate change baseline groundwater system inflows to and outflows from the groundwater system were estimated to be 1.0 maf/yr."
	3.3.4.3.2	3-98		3-45	Change in storage is not an inflow as shown…. See previous comments.
	3.3.4.3.3	3-100		3-47	Change in storage is not an inflow as shown…. See previous comments

Colusa Subbasin Groundwater Sustainability Plan Chapter Input

Commenter Name: Donald Bills **Commenter Affiliation (if applicable):** GGA-TAC Member

This file introduces a table that allows you to easily enter the following key information so we have certainty about your input. The table includes the following categories:

- Chapter Number
- Section Number
- Page Number
- Paragraph Number (starting with the first full paragraph at the top of a given page)
- Figure/Table Number (if applicable)
- Comment

INSTRUCTIONS

1. Please **ONLY** use the MS Word or PDF document titled "Colusa Subbasin GSP Chapter Input" to submit your comments.

2. Review all applicable text and note each Chapter, Section, Page, and Paragraph number associated with a comment you'd like to make. For Paragraph number, please start with the first full paragraph at the top of a given page and count down.

3. Enter your name and if applicable, an organizational affiliation at the top of your table.

4. Once you have completed all your comments, please save the file with your last name at the end in parentheses. For example:
   - *Colusa Subbasin GSP Chapter Input (Jones).docx*

5. If you are located in the Glenn Groundwater Authority, please send your comment file to:
   - Lisa Hunter – Program Manager - Glenn Groundwater Authority: lhunter@countyofglenn.net

6. If you are located in the Colusa Groundwater Authority, please send your comment file to
   - Mary Fahey – Program Manager - Colusa Groundwater Authority: mfahey@countyofcolusa.com

7. If you don't affiliate specifically with either the CGA and/or GGA, please send your comments to both Mary and Lisa.

8. Please make sure that your comments are submitted by midnight May 5, 2021.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
4	4.2.2.2.1	4-4	1		Groundwater levels should be measured from a pre-established and recorded reference point. — The reference point elevations (RPE) need to have been surveyed to the NAVD 88~~, feet~~ and shall be accurate to within 0.5 feet, at a minimum (23 CCR §352.4(a)(4). The USGS standard is 0.1 ft. The reasoning is related to the accuracy of GW model results. If the accuracy of GWLs input to GW models are not accurately known, any errors in model results propagate over time through the model runs. As a result, GWL changes and associated changes in inflow, outflow and storage become increasing less certain. In the case of the Colusa subbasin knowing the accuracy of the MP to only 0.5 ft could result in WL changes of +/- 0.5 ft and storage changes of +/- 0.5 ft (100,000s af/y potentially). Also, Accurate to within 0.5 ft at a minimum seems a little ambiguous. Do you mean that 0.5 ft is the least accurate value acceptable but greater values (1.0 ft, 5.0 ft, etc.) are also acceptable? I would suggest you change this phrase to : " accurate to within +/- 0.5 ft (+/- 0.1 ft if you are going to use the more broadly accepted standard). If you make the change here, make it throughout the rest of the text.
	4.2.2.2.1	4-4	1, bullet 2		"…Equipment should be operated and maintained in accordance with the manufacturer's instructions." The WL measuring equipment should be calibration checked annually to be sure it is still the same as the original manufacture calibration. In addition, if a well probe is stuck in is a well but can be removed. The calibration of the well probe should be verified before the probe is used again.
	4.2.2.2.1	4-4	1, bullet 3		Monitoring wells developed in partially confined or confined aquifers can have a pressure gage installed in the well cap as a further indication of potential hydraulic head.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
	4.2.2.2.1	4-4	1, bullet 4		Near pumping, recently pumping nearby. Nearby stream flowing or not recently following or not, etc.
	4.2.2.2.1	4-4	1, bullet 6		Water levels shall be measured to the nearest 0.1 foot, at a minimum (23 CCR §352.4(a)(3). Measurements to the nearest 0.01 feet are preferred and should be used if the equipment allows. — Groundwater elevations (GWE) are calculated as the RPE minus measured depth to water (DTW). See the problem here? It your RPE is only accurate to +/- 0.5 ft, your GWE is now only accurate to +/- 0.6 ft. USGS standard is to measure RPE's to +/- 0.1 ft and WLS to +/- 0.01 ft (depths less than 500 ft) and round to the nearest 0/1 ft. In addition, all depth to water measurements in wells are repeated until you can get three results within 0.1 ft of each other. The average is used.
4	4.2.2.2.1	4-5	2, bullet 5		"Recorded information should include:…" NOTE: The Height of the RPE can and will change over time. That is why it should be checked at least annually, and the new elevation noted if it has changes.
	4.2.2.3	4-6		Figure 4-1	Significant cones of depression (GW withdrawal for Ag.) occur to the NW of Orland just south of Stony Creek and to the SW of Orland. Yet, there is only one monitoring well (21N04W12A001-004M) available to evaluate these drawdowns as they develop over time. I would suggest additional monitoring wells be places in these areas. The same is true in the area to the west of Artois and Willows.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
	4.2.2.3	4-12	2		"Many of the surface waters are near wells included in the current groundwater monitoring network, except for the surface waters within the Colusa National Wildlife Refuge, east of Williams." Suggest you add the following to this: "…east of Williams, N and NW of Orland near Stony Creek, NW of Artois along the middle reaches of Walker Creek, and NW of Willows along the middle reaches of Willow Creek."
	4.2.2.3	4-12	5		Are the caved-in of casing collapsed wells going to be repaired or replaced?
	4.2.2.4	4-12	2, item 2		Consider adding: c. Areas of active drawdowns (storage decline) with minimal monitoring well coverage.
4	4.2.2.5.2	4-14			I would recommend considering adding monitoring wells in the areas mentioned in my comments on page 4-6 and 4.12. Figure 4.2 already shows one well being removed from the network in the areas near Orland mentioned in comments on page 4-6.
	4.2.3	4-14			Irrigated Ag is also known to increase salinity in shallow water-bearing zones as irrigation leaches minerals from the soil. I would also add nitrate as a constituent of concern for the Colusa subbasin. Nitrates resulting from livestock operations and areas with a high density of septic systems are known to also leach in to the subsurface.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
	4.2.3.2	4-16	1		Wilde, 2005 has been updated extensively. Newer versions od different chapters of the report were developed in 2008, 2012, 2014, 2018, 2019, 2021 The entire manual is now available online at: https://www.usgs.gov/mission-areas/water-resources/science/national-field-manual-collection-water-quality-data-nfm?qt-science_center_objects=0#qt-science_center_objects 3rd Bullet: Sample integrity, i.e. ppb protocol? Perhaps add a comment about the chain of custody (oops… bullet 14).
	4.2.3.2	4-16	2, bullet 2		And the unique identifier should be verified to already exist in the data base so the data has a home and does not end up in a "unknown site" file.
	4.2.3.2	4-16	2, bullet 6		During purging of the well field parameters should be monitored until stable to insure the well has been correctly purged. Easy to do with a QW multi meter.
	4.2.3.2	4-16	2,bullet 8		Suggest adding dissolved oxygen (DO) to the list of filed parameters. GW typically has low or near zero DO. Water sitting in well casing for a period of time will accumulate concentrations of DO. Represents another good indicator of proper well purge.
	4.2.3.2	4-16	2, bullet 9		Sample labels can be preprinted in the lab with all the appropriate info. Prevents the smearing of hand-written labels using pencil, ink and even waterproof ink (Sharpie). Also be aware that the outside of the sample bottles can "sweat" in coolers or other containers. The result is the label glue will weaken and the labels will come off. Double bag samples is one solution.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
	4.2.3.2	4-16	2, bullet 10		Field parameter DO is a good indicator of this. Laminar flow may require the use of a variable speed pump so DD is not excessive during collection of the water sample.
	4.2.3.2	4-16	2, bullet 11		DQOs? Is this a reference to Quality assurance. If so a number of duplicates, blanks and spike samples will need to be processed either in the lab or on site, depending on the type and number of water samples being collected during an individual field run. Maybe briefly explain here?
	4.2.3.2	4-16	2, bullet 12		In this case DQOs appears to be referring to lab detection limits for individual constituents. Correct or no? May need more explanation here.
	4.2.3.5	4-19	1		The lead sentence suggesting the existing QW monitoring programs as sufficient contradicts 4.2.3.4 which says they are not sufficient. If the existing monitoring wells are not spatially located enough to address salinity concerns or, not deep enough to detect upwelling of brackish GW from below, they are indeed not sufficient.
	4,2,3,5	4-19	2		Small diameter monitoring wells pose additional issues for the collection of Value QW samples. Small diameter submersible pumps (less than 2 inches) are few and far in between. Typically, they are limited to lifts of 100 ft or less, and have small pumping rates (~one gpm or less). Bailers (Teflon preferred) are another option and are readily sized to fit in 2-inch monitoring wells. Bailing a well to purge can be difficult depending on the depth. Bailers have to be pre cleaned between each water sample. Bailer sample volumes may be on the order of 1 liter or less meaning several bail volumes to collect a sample.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
					Then there is still the issue if ant of the monitoring wells are deep enough to register upwelling of brackish water from below.
	4.2.4.1 lands subsidence	4-20	2, bullet 8		Land subsidence should be measured at least as accurately as SWLs if not more accurate. Small changes in land subsidence (tenths of a foot, not half a foot or more) can have a significant impact on the surface and on GW storage. If you are measuring the elevation of ground surface to +/- 0.1 ft and the elevation of your RP to +/- 0.5 ft, again the accuracy of your subsidence measurement is no better than +/- 0.6 ft.
	4.2.5.1	4-24	1, bullet 7		Benchmarks at USGS stream-flow gaging stations are surveyed to the nearest 0.01 ft. One-hundredth foot accuracy is critical to development of a good (+/- 5 percent of the actual flow) or better stage-discharge relationship. If not, you risk losing indications of GW supported base flow and any seasonal signature of gaining or losing flow to/from GW. As an aside, the USGS also requires a minimum of 10-years of continuous (every 15-minutes) record for the data to have any statistical significance.
	4.2.5.2	4-24	3		Accuracy of stage data is +/- 0.01 ft (required).
	4.2.5.5	4-24	1		Figure 4-4 is land subsidence. I think you mean figure 4-5. The legend for figure 4-5 does not provide adequate explanation of the different stream types shown on the map (perennial, intermittent, ephemeral, canals, or drains). The line widths and colors vary from thick to very thin and light blue to very light blue respectively. It needs to be revised.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
	4.2.5.5	4-25	2		"Additionally, existing stream and drainage reports will be evaluated for additional information on the timing, stage, and magnitude of flows in ephemeral and intermittent streams in the subbasin, if necessary to fill data gaps or support projects and management actions during GSP implementation." There used to be a stream-flow gaging station on Walker Creek at Artois. Still there? Still active? There also use to be a gage on the Glenn-Colusa Canal where it crosses Stony Creek south of Hamilton City. Still there? Still Active? I imagine there are additional discontinued stream-flow gaging stations scattered across the Colusa subbasin. If the structures for these sites are still there, they can be re-established by installing stage recorders and making periodic discharge measurements to verify the old stage discharge relationships. Besides the Colusa Drain, Willow Creek west of Willows is another intermittent/ephemeral stream that would be worth the effort to gage.

1	Cover Page	Cover Page	N/A	N/A	1. Title: Change to Colusa Subbasin Groundwater Sustainability Plan. 2. Add Logo to page 3. Under "Prepared for", change Colusa GSA and Glenn GSA to: Colusa Groundwater Authority and Glenn Groundwater Authority 4. Make these same changes on the second page
All Chapters	Entire Document – footer				Change footer to read: Colusa Groundwater Authority and Glenn Groundwater Authority Colusa Subbasin Groundwater Sustainability Plan
1	1.3.1	1-3	1		Please specify that there are **two** Private Pumper Representatives from the Colusa County Groundwater Commission, **appointed by the Colusa County Board of Supervisors**
1	1.3.1	1-3	4		Second Sentence, please edit as follows: **Except for the Private Pumper representatives**, Board members are chosen in public meetings by the respective governing boards of the Member Agencies…. **Private Pumper representatives on the CGA Board are recommended by the Colusa County Groundwater Commission and appointed by the Colusa County Board of Supervisors**.
2	2.1.1	2-1	4		Glenn and Yolo County boundary should be **Colusa** and Yolo County boundary

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
2	2.1.2	2-4	1		Fourth line – Change water pumpers to groundwater pumpers: …and two appointed private **groundwater** pumpers…
2	2.1.2	2-4	2		Orland and Willows are in Glenn County. Colusa and Williams are in Colusa County.
2		2-4		Table 2-2	Grimes water district should be: Colusa County waterworks district #1 – Grimes Also in Colusa County: Colusa County waterworks district #2 - Princeton
2				Fig. 2-3	The map is titled Colusa Subbasin GSA Member Agencies but does not show/list Colusa County or Glenn County Under Note 1: There are two private pumpers from the Colusa County Groundwater Commission on the CGA Board There are no private pumpers on the GGA Board
2	2.2.1.1	2-15	6		(NSV IRWM) last sentence, add year that the update was adopted. In March, **2021**….

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
2	2.2.1.1	2-18	2		Second bullet states "The following GSAs have readily available MSRs:" Don't you mean "The following GSA Member agencies…"?
2	2.2.1.2	2-19	1		I believe CCWD has a SCADA system. There may be other districts as well that are not listed.
3	3.1.7.3.1	3-32	5		Faults: Second to last sentence, Zamora Fault should be listed along with the others that were analyzed.
3	3.1.10.2	3-42	1		Primary Users, first sentence – can this be re-worded. It sounds like there are only 20 Stakeholders in the basin.
3	3.1.11.2.3	3-45	2		– The TNC project is better described as an on-farm multi-benefit managed aquifer recharge and shorebird habitat program. Where it says migratory birds, please specify migratory shorebirds.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
3				3-19	Water source layer missing for Colusa County portion
4	4.1	4-1	1+		Should monitoring for GDEs be mentioned in the discussion about the monitoring networks?
4	4.2.2.2	4-4	1		Will this section be expanded to include more details?
4	4.2.3.3	4-17	1		Suggest spelling out Irrigated Lands Regulatory Program (ILRP) in first sentence
4					General chapter 4 comment: This Chapter will need to be updated based on recent activities/discussions/decisions, especially regarding monitoring and filling data gaps for stream interactions and GDEs. Also, information about the coordination efforts taking place along basin boundaries between the neighboring subbasin GSAs should be expanded. Overall, this chapter reads light on describing the Colusa Subbasin monitoring network and heavy on listing excerpts from the regulations.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
6	6-1	6-4	3		2nd bullet: Suggest removing the second sentence regarding demand management. This type of PMA is a last resort and should not be highlighted.
6		6-6		Table 6-2	First project: Colusa Subbasin Multi-Benefit Groundwater Recharge (TNC). This project concludes in the spring of 2021, not 2020.
6	6.3.3.1	6-29	1		Add a program benefit – Groundwater conditions (via groundwater Recharge)
6	6.3.3.1	6-29	3		Pilot program concludes in 2021. The program evaluated flooding that would provide habitat benefits for migrating shorebirds, and groundwater recharge. Both (habitat and recharge) are equal goals of the project.
6	6.3.3.1	6-30	1		While the current project is limited to SDAC communities due to grant funding requirements, ongoing, the project would not be limited to benefitting water levels in DACs.
6	6.3.3.2	6-32	1		Pilot program runs from 2018-2021. Also update dates in Table 6-13.
6	6.3.3.4	6-32	3		Depending on the farm, there may be installation of monitoring equipment required (flow meters, groundwater level monitoring devices)
6	6.3.3.6	6-32	5 (last)		Program completed in 2021
6	6.3.3.6	6-33	2		Last three bullets should be indented further
6	6.3.3.7	6-33	Last		Could the CGA and GGA also serve permitting roles?
6					General comment – excellent work on this chapter. This is a great set of tools that the GSAs can pull from as they implement SGMA in the Colusa Subbasin.

1	1.2				This is a question for the DWR. Since the DWR formally adopted a Human Right to Water ("HRTW) Policy in its Department Administrative Manual during April 2021 – does it want to state that it will be including HRTW considerations in the DWR's decision making, program activities and public engagement in SGMA and the GSP development. Wont this statement promote HRTW engagement?
	1.3.1				Typo for Private Pumpers – appointed by Colusa Groundwater BOS ? Did you mean to say recommended by the Commission and appointed by the BOS? Were there public meetings for the appointment by the Board Members by GSA's? It would be great to know that the GSA's have public meetings. Do they have websites and interested party lists? Please confirm that each GSA has websites and posts notice of meetings at a minimum.
	1.3.3				Are these costs for the Basin as a whole? It would be good to break these costs on a per acre basis and discuss how the costs are allocated to Cities and small water systems. For example – what does the CGA expect the City of Williams to pay going forward? Voters in the Cities need to know. What will the County of Glenn and the County of Colusa be expected to contribute?

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Line Number	Figure/ Table Number (if applicable)	Comment
2	2.1			Table 2-3	Table 2-3 is misleading in that it does not reflect the loss in surface supply due to water transfers. There needs to be a table that reflects the historical amount of water transfers for every water purveyor and how much of the water remains in Basin and out of Basin. Without this stakeholders can not assess the available water supply for the Basin.
	2 generally				The Colusa County GMP does a good job discussing water transfers but the GSP is silent on it. Stakeholders need transparency and understanding how water transfers work and how ground water substitution and fallowing work into the available water supply. The transparency and discussion regarding water transfers, fallowing and groundwater substitution also have potential negative DEI and HRTW outcomes because water transferred out of basin and fallowed acreage means less jobs and ground water pumped for ground water substitution could lead to aquifer degradation if the groundwater pumped is pool quality.
					Again there needs to be discussion about surface water transfers and a Table listing the number of acre feet pumped for groundwater substitution and the acres fallowed by each Settlement Contractor. Stakeholders need to know this for HRTW and DEI concerns and also for the general sustainability of economic health of the Subbasin.
	2.3.2				There needs to be a discussion regarding groundwater trading markets and how this would impact the potential water demands. The California Water Commission are holding hearings regarding groundwater trading and it is very relevant to the effects on water demands and the economic feasibility and sustainability for the subbasin. To not include any discussion is misleading and could lead stakeholders to misallocate resources or make material economic decisions without full

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Line Number	Figure/ Table Number (if applicable)	Comment
					knowledge of a likely outcome. The CWC appears to quite committed to groundwater trading and the PPIC has come out strongly in favor of water markets. It is misleading not to discuss this likelihood especially when there is such a focus on recharge in the PMAs. It would seem that some PMAs may not be economically efficient if water could be traded instead. In June of 2021, Steven Springhorn , Acting Director of SGMA discussed the framework for Water Trading for SGMA Implementation – it seems ingenious to go through this process and not discuss what the Acting Director of SGMA is presenting to the California Water Commission.
					There needs to be reference to the ERA Demand Management Actions if they remain in the GSP. If implemented these Management Actions will have the intended effect which is to limited Demand. These PMAs are DEMAND Management Actions and should be referenced and discussed in this section.
	2.5.1				Discussion about water quality testing, determination of appropriate well depth and what happens if the driller finds poor water quality. I think the answer is that this information is not captured or disclosed and therefore it is a concern for water quality and HRTW issues.
	2.6.1				The following was taken verbatim from the DWR's recent Drought Memo. This is from a footnote: DWR formally adopted the Human Right to Water (HRTW) Policy in its Departmental Administrative Manual which outlines how the HRTW should be included in DWR decision-making, program activities, and public engagement. The Water Board adopted a HRTW Resolution, recognizing HRTW as a core value and directing its implementation across programs and activities. The Water Board is also currently drafting a Racial Equity Resolution.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Line Number	Figure/ Table Number (if applicable)	Comment
					There should be a reference to the emerging HRTW and Racial Equity actions by the DRWR and the SWRCB since it is central to Stakeholder HRTW and Diversity Equity and Inclusion (DEI) concerns regarding the GSP and its future implementation.
					I strongly disagree with the statement that the GSA supported and allowed for effective engagement of all stakeholders regarding HRTW and DEI issues. I would urger the DWR to expressing prohibit GSAs taking any action against a stakeholder unless a mediator is brought in especially regarding situations where there are HRTW and DEI or potentially negative racial outcomes.
					I have asked the related emails and the Memorandum distributed to the GSA Members regarding my public comments to the Colusa City Council, Colusa County Board of Supervisors and Williams City Council be included in Appendix 2A as part of the public record. I also want to note that Mr. Ceppos firm was not brought in as a mediator nor do I think he was asked to before the GCA and Colusa County Administrator made the CGA Memo public record prior to the vote of the Colusa County Board of Supervisors vote on approving the Amended JPA. Although the Memo did probably not change the outcome of the Board of Supervisors vote, it effective took away my creditability to argue for HTRW and DEI concerns and generally challenged my reputation as a truthful and fair minded citizen.
					The concerns I expressed during the 3 to 5 minute public comment periods were the following: (1) I am concerned about the long term water quality for the public supply system in Colusa which is my home town. I pointed out that there was arsenic contamination in the abandoned public supply well for the Del Oro Walnut Ranch system and at Grimes and my concern is that it relates to the water quality surrounding the Sutter Buttes, (2) I am concerned about the long term supply and water quality resilience for the public supply system in Williams since the water quality surrounding Williams has elevated TDS levels and water levels will likely drop further due to climate change and the conversion of surrounding areas to

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Line Number	Figure/ Table Number (if applicable)	Comment
					permanent crops, and (3) like most residents in Colusa County I was against out of basin water transfers because it would hurt the long term sustainability of the County and potentially hurt groundwater quality due to ground water substitution and fallowing measures by GSA Member water sellers. Since I am against out of Basin water transfers I mentioned that I did not believe that it was the best interest of Colusa County residents to have two law firms from Bakersfield represent the CGA because the firms have an extensive list of clients who benefit from out of Basin Water Transfers and that I believed it would not serve the County well to have a CGA counsel who was also the counsel for the Sites JPA and that the former lead CGA counsel was now a Director at the Bureau or Reclamation overseeing water transfer approval, (4) I suggested that the City of Colusa, City of Williams and County of Colusa would best serve the long term interests of its residents by retaining it sovereignty and entering into a cooperation agreement with the irrigation company GSAs and pointed out that this is how the Butte Basin was structured – which is now similar to the neighboring Sutter Basin. I pointed out that Yolo County had a JPA structure but it has strong representation from UC Davis and the municipal GSAs and had other environmental protections. During the period of making these public comments I also made the same public comment and comment to the CGA in which one Member who represents a Settlement Contractor which fallows land and sells water claimed that what I said about the public record was not true which I disputed.
					Without any prior notice I noted that there was an Agenda item discussing a Memo prepared by the CGA and it was going to be distributed. I was traveling with my son in the Midwest and was not able to attend the CGA meeting which approved the Memo and its distribution. Afterwards when I prepared to comment at the Board of Supervisors meeting that had the approval of the amended JPA on the Agenda I found out that this Memo was included in the Agenda Packet. The first time I saw the Memo was when I received it from the CFO for Colusa County after the Board Meeting.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Line Number	Figure/ Table Number (if applicable)	Comment
					The related emails should be included in Appendix 2A as a public record. I would recommend that in light of the DWRs and SWRCB recent pronouncements on HRTW, DEI and Racial Equity that the GCA does not act in a manner hostile to any Stakeholder before a mediator is brought in to resolve an issue. This should especially be the case if it concerns HRTW issues or if the stakeholder is not a native English speaker or is a person of color. I would also recommend to the DWR that all CGA Members be required to be residents of the Subbasin in order to understand the long term environmental and economic sustainability issues facing the Colusa Subbasin. My experience is an example of the abuse of power granted to the CGA by SGMA and in my opinion it is important that there be accountability to the community by all CGA Board Members. Allowing CGA Board Members to be non-residents will allow this type of abuse to continue especially when there are majority owners, consultants and attorneys who also are not residents. Colusa County requires all its elected office holders to be residents and the members of the Colusa Groundwater Commission need to be residents – the residency requirement should be the same for the CGA. This is a necessary protection for HRTW and DEI concerns because it ensures community accountability.
	Public Engagement				The Stakeholder Engagement Process was materially flawed because there was no discussion about the California Water Commissions initiatives around groundwater water trading. It is unreasonable to have no public engagement and submit a GSP without any public discussion of an issue that the DWR Acting Deputy Director of SGMA is presenting at the California Water Commission. As I said, we are spending a lot of time and money considering and debating potential PMAs when we have spent no time regarding the water trading policies being considered by the California Water Commission. Water Trading will have many intended consequences on the allocation of resources and many unintended consequences – some of which could be extremely detrimental to the long term sustainability of

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Line Number	Figure/ Table Number (if applicable)	Comment
	2.7.3.6				the fresh water aquifers of the Sacramento Valley. It seems like the PMA considerations may be a real waste of time – I just found out about the Water Trading discussions of the CWC yesterday which happens to be the last business day for the comment period for this GSP. Where are the GSAs websites. There is a lot of discussion regarding the CGA website but is there any other website. Do they exists for each Member GSA ? If not – why and how can stakeholders gain transparency. Does each Member GSA have an interested person list?

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
Table 3-1					What change in Data Sources were used to incorporate the annexed area from the West Butte Basin? What sources were used for Geochemistry and water quality?
3.1.5		3-7			The Hydrology of the Colusa Subbasin is also influenced by the Geochemisty and underlying Faults. Since the Subbasin water quality is influence by the volcanic rock of the Sutter Buttes and influences from the marine and lacustrine geologic history of the Subbasin – can Hydrology be determined without Geochemistry? Faults are known to influence Geochemistry and water quality since there may be anoxic water upwhelling and lateral movement of naturally occurring contaminants via faults like the Willows Fault.
3.1.5		3-11		Figure 3-6	Why is part of the CDMWC delivery area included in ColGGWS? The CDMWC on the west side of Colusa Basin Drain south of Hahn Road receives surface water deliveries as the rest of the CDMWC. There are CDMWC subarea components on multiple sides of this area but for some reason this jurisdictional area of the CDMWC is treated differently. This area is also part of the flood zone and receives significant seepage during seasonal winter flows.
		3-16		Table 3-2	What assumptions are included in Model Diversion ID 113? As mentioned above a portion withing the jurisdictional boundaries of the CDMWC and a CDMWC surface water delivery area is left out of the CDMWC budget subarea.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
3.1.7				3-3	See Springhorn Page 22 – Table 2.1 and Page 93 Table 3.3, Need to incorporate Turlock Lake Lacustrine influence to document Corcoran like clay components to the Lithology and also need to incorporate the formation of the Sutter Buttes Rampart and Geomorphic influence of the Sutter Buttes volcanic structure. Both Springhorn and Harwood and Helly differentiate the lithology of the Pilocene and Pleistocene periods this way. Water quality and subsidence issues are related to this geologic history. Figure 3-10 is probably the most complete Geologic Map I have seen for the region – excellent!
				3.11, 3.14&3.15	See Springhorn Page 113 Figure 4.4. This Geologic Crossection needs to be incorporated in Cross Section C-C on Figure 3-11. Otherwise the Cross section leaves out the influence of the most unique Geomorphic Unit in the Sacramento Valley which is the Sutter Buttes. Also there is a critical need to address the Cross Section next to the City of Colusa because of the interrelationships of the Willows Fault, Sutter Buttes Rampart, Colusa Dome and Sacramento River. As it now stands Cross Section C-C is not consistent with the robust Geology set out in Figure 3-10 which seems to be a recent update since it references Springhorn. Regarding 3.14 how can you have a 3 Dimensional Model that omits the geology of the Sutter Buttes? Regarding 3.15 – it is important to map the area of the Corcoran like clays deposited by the Turlock Formation to know the potential area of impact for future subsidence.
3.1.9.2					See USGS Circular 1358 "Water Quality in Basin-Fill Aquifers of the Southwestern United States: Arizona, California, Colorado, Nevada, New Mexico and Utah, 1993-2009. Thiros,Paul, Bexfield and Anning 2014.(USGS Thiros et al 2014) See Page 56 – it is clear that arsenic contamination occurs and translocates along fault zones like the Willows Fault as is currently is the case in the Middle Rio Grande Basin. The water system for the City of Colusa could have the same fate as the water system for the City of Albuquerque.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
3.1.8.2 3.37		3-35 	2nd and 3rd	 3.17	The base of freshwater should not include brackish water which is defined by the USGS and others at 1000 ug/L. Water quality definitions should be consistent with the California Human Right to Fresh Water. Brackish water is not potable. The reference to brackish water in the Upper Princeton Valley is inconsistent with the outdated Olmstead and Davis referenced in paragraph 2 . See Springhorn Page 149 for additional references. The Base of Freshwater Depths in the annexed area from the old West Butte Basin seem incorrect based on the vertical depths included in Springhorn's Cross Section work. Also the area west of Colusa on Lurline near Roberts Ditch is known to have lower fresh water base levels. Levels are probably in the 300 to 400 ft levels or less in both areas.
3.1.10.2 3.1.10.3		3-39 3-42			The potential for vertical movement via abandoned gas wells and faults needs to be mention since it most likely will lead to aquifer degradidation in areas where the subsurface groundwater have elevated TDS levels and/or anoxic conditions. Arsenic contamination at the abandoned Del Oro Walnut Ranch well and the well at the CIP site which was cited by SWRCB show arsenic contamination has been found in the Colusa City limits. The USEPA reports also show arsenic contamination in the Princeton water supply system.
3.1.12.1		3-50			Additional Areas of Uncertainty: 1. See Springhorn Page 165 Figure 6.1 Areas where subsurface information is needed regarding the area outlined west of the Sutter Buttes, 2. Research regarding the vertical and lateral movement of saline water within and across the Willows Fault as generally described on Page 56 of USGS Thiros et al 2014, 3 The predicted desorption of arsenic from a volcanic structure like the Sutter Buttes in Figure 6-5 of Thiros on Page 58, 3. The breadth and depth of the Corcoran type clays from the Turlock Lake formation highlighting the potential for future

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
					subsidence, 4 – the water quality issues near the Freshwater area west of Williams as described in the Colusa County Groundwater Management Plan.
3.1.12.1 3.1.12.3				3-5 3-51	The C2VSimFG Model has to incorporate the saline and anoxic seawater around and south of the Sutter Buttes. According to the Sutter- Yuba investigations (SWRB Bulletin No. 6, 1952) a TDS level as high as 10,000 was observed near Robbins. Others including the DWR and Curtin have observed TDS levels from 4,000 to 6,000 south of the Sutter Buttes. What are the statutory obligations to address the Human Right to Fresh Water in the HCM?
3.2.5				3-64	The worst reported arsenic contamination for any public water system in the Sacramento Valley water supply system is in Grimes. The USEPA has documented arsenic contamination in the Princeton public supply system. There has been two incidences of arsenic contamination in supply wells within the boundaries of the City of Colusa. The wide scope of arsenic contamination around the extent of the Sutter Buttes Rampart and south of the Sutter Buttes in the Colusa Basin needs to be disclosed as an area of grave concern. See Springhorn Page 164 highlighting the need for more research about the need for more work regarding the relationship of arsenic contamination and the health risks from arsenic.
3.2.5.1.1				Figure 3-30	What is the source for this data? Is there a time series? Stakeholders should have access to time series for water quality data and it should be included in the Appendix like the hydrograph data concerning water levels. Arguably water quality data should have a higher level of access and transparency due to the Human Right to Fresh Water.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
		3-66			According to the 2020 Tehama-Colusa Canal Water Authority Initial Study/Environmental Assessment there were several wells used for Groundwater Substitution with elevated Specific Conductance. As reported in the Appendix for the report GCID, 7 of the 16 reported wells had a consistent annual reported level of Specific Conductance greater than 1000 ug/L. Three of these wells had levels greater than 1500 and the other 4 were between 1000 and 1500. Are these wells included in the data points of Figure 3-30 and the discussion on page 3-66?
3.2.5.2.1		3-67			Where is the location of the well near Grimes with Arsenic at 200 ug/L.? Grimes arsenic levels are reported to be approximately 25 ug/L. The USGS publication by Thiros et al has an extensive discussion of the desorption process of arsenic for volcanic rocks in saline groundwater with PH greater than 8. The USGS predictive model predicts the occurrence of arsenic in basin discharge areas like Robbins and the areas south of Grimes. This USGS publication also highlights how arsenic had moved into the groundwater of Albuquerque via a fault. The Willow fault crosses the Sacramento River at Colusa and runs south towards Grimes and the area where the two arsenic contaminated wells were found at the Del Oro Walnut Ranch site and CIP which is now in the boundary of the City of Colusa. The Sutter GMP includes a Figure showing elevated areas of TDS and Arsenic with levels as high as 370 ug/L. There is discussion of a biotic response that coincides with anoxic groundwater becoming oxidated from soil microbial activity that release arsenic as a bi-product. Arsenic contamination of the Colusa public water supply would be disastrous and a violation of the Human Right to Fresh Water.
3.2.6		3-72		Figure 3.31	Figure 3.31 should overlay the area of the Corcoran like clays from the Turlock Lake geological formation to show a potential relationship of subsidence and the presence of this clay formation The relationship between the Corcoran like clay formation and the presence of inelastic subsidence should be discussed based off the history in the San Joaquin Valley.

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
3.3.3	3-80 3-81,2			Table 3-9	Using only 2013 and 2015 water diversion data would lead to a wrong outcome if the diverter did not use surface water available during those years. It is an extremely small and not representative data set. Landowners could have not diverted during those years because they were trying to help other landowners out with their surface water allocations since they had wells or the landowner could have been converting land for orchard development with a new filter system. Using Land Use data only for the years of 2003,2009 and 2014 is not representative if there was a conversion from rice to row crops or row crops to orchards. The impact of this narrow assumption set could lead to incorrect Budget Subareas.
3-4	3-102				Management Areas should not be set until the GSP is approved and implemented for several years. The history and genesis of the Colusa Groundwater Authority JPS was for collective management of the Subbasin and there is no basis to change the jurisdictional management of the Subbasin in contravention of those principals. Stakeholders and property owners who are paying Prop 218 Assessments must know there is a rational basis for any changes in jurisdictional oversight within the Basin to maintain confidence in the GCA's governance. What should not happen are actions which may lead to a perception that a few powerful members have manipulated the process for their own benefit.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Line Number	Figure/ Table Number (if applicable)	Comment
3.	3.1.1				Section 3.1.8.2 can not be satisfied because the DWR has not released it revised BFW contours and any updated research. This work was presented by the DWR in 2013. The lateral depths in the current version of the GSP are clearly wrong and are based on outdated TDS levels which are inconsistent with HRTW concerns. Consequently the Water Budget derived from the assumed BFW levels is also wrong and misleading.
				Table 3.1	The work presented by Springhorn et.al at the US Geological Society and GRA in 2013 needs to referenced and incorporated in the BFW. The water budget and HRTW issues will be materially impacted by this new work.
	3.1.5.1.6				Are these all the Streams - Sand Creek near Arbuckle? Is Salt Creek Arbuckle – Elk Creek? We should have consistent names for PMAs and across the GSP
	3.1.7.3.5				Discussion regarding the Sutter Buttes Rampart as described in Springhorn 2008 is necessary to raise the issue of any stratigraphic induced lateral movement of connate saltwater around the Sutter Buttes volcanic rampart footprint.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Line Number	Figure/ Table Number (if applicable)	Comment
	3.1.8.2				The Vertical Boundaries can not be determined with enough reliability to determine Groundwater Storage or to address the existence and sustainability of fresh water for HTRW concerns. The reliance on Olmstead is clearly challenged by the outdated TDS threshold and empirical evidence that the BFW assumptions are wrong for substantial parts of the Colusa County portion of the Subbasin. Please refer to CRC Well 16RIM (Figure 5D-22) which has a depth of 25 to 30 feet. The most recent EC reading is over 6000. Please refer to USGS GAMA Site EASC 21 which is a well with a depth of 369 feet with a Arsenic level of 80.5 ug/L and Boron level of 1,010 ug/L. Clearly Olmstead is wrong for a substantial part of the Subbasin and for a substantial part of the Sacramento Valley as a whole.
				3-17	Clearly this Figure is wrong. The EC threshold is outdated and it relies on the 60 year old Olmstead report rather than the work held by the DWR since at least 2013. The Base of Fresh Water for the Colusa Subbasin is materially different and this Figure is clearly misleading.
					Here is the excerpt from the DWR BFW Work as of 2013: A base of fresh groundwater (BFW) contour map was created to identify the approximate lower limit and the thickness of the fresh groundwater aquifer system in the Sacramento Valley. The BFW map is useful for groundwater resource and storage analyses, groundwater modeling, and delineating structural geologic features in the Sacramento Valley. Two BFW maps covering the Sacramento Valley were previously created; Olmsted and Davis (1961) and Berkstresser (1973). The BFW map in this study relies on a substantial amount of new subsurface geophysical and water quality data that has been collected since the earlier BFW maps. Fresh groundwater is defined in this study as water containing less than 1,000 mg/l total dissolved solids (TDS), approximately 1,550 µmhos/cm specific conductance, instead of 2,000 mg/L TDS used in the earlier studies. The BFW was estimated based on a

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Line Number	Figure/ Table Number (if applicable)	Comment
					comparative analysis of geophysical logs and lithologic data from approximately 2,800 geophysical logs from water resource wells and CA Division of Oil and Gas well records. The BFW selection criteria were calibrated using water chemistry data and constrained by comparing multiple well-logs and lithologic information in the same geographic area. The BFW boundary occurs primarily in late Tertiary to Quaternary unconsolidated sediments at depths near land surface to more than 3,500 feet below ground surface. The BFW is an uneven boundary that in some places reflects the major geologic structures underlying the Sacramento Valley, and in other areas, transgresses underlying geologic structures. In some areas, the BFW boundary is well above the base of post-Eocene marine strata. **This is most likely caused by high artesian pressures and upward vertical gradients in deep aquifers in the Sacramento Valley, which have been documented in DWR monitoring wells.** This suggests that migration of poor quality water into continental sediments that previously contained freshwater has occurred over geologic time**. This finding has implications for brackish and saline water upconing beneath areas of prolonged groundwater pumping in the Sacramento Valley.** ***Figure 3-17 should be based off the most recent DWR work as described above for the calculation of the Water Budget , Groundwater Storage, Sustainable Yield and HTRW Concerns***
	3.19				Sutter Buttes Rampart description from Springhorn 2008 is needed.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Line Number	Figure/ Table Number (if applicable)	Comment
	3.1.10.3	3-42			The discussion about water quality should reference the DWR 2013 work and the recent work by Susan Thiros and Laura Bexfield from the USGS regarding Redox and degradation due to overpumping. CRC Well 16R1M in Figure 5D-22 should be highlighted since EC has 4000 to 6000 over the last 17 years. This illustrates that the BFW assumptions are wrong and the upconing identified by the DWR is having a material impact on the fresh water aquifer. Where is this salt water going? Does upconing and Redox degrade our future resiliency for drinking water and other HTRW issues?
		3.1.11.2			How is recharge effected by the upconing and redox discussed by the DWR and USGS? Can you recharge in high water table areas like Maxwell are where there is degraded water and drainage tiles?
		3.1.12			The fact that the DWR has not supplied the most recent BFW studies is fatal to the reliability for the GSP. It can be used as an approximation but raises significant HRTW risks and can not be relied on to develop a reliable Water Budget.
		3.1.12.1			We don't know what is certain or uncertain. The only thing we can be certain about is that we do not have the best and most recent information regarding the BFW and the BFW water quality standards are outdated elevated levels which are not consistent with the DWR's HRTW Departmental Policy.
		3.1.12.3			The requirements of 354.14 can not be met without the DWR BFW research that has been withheld. All that can be achieved is an approximation but substantial HRTW risk exist regarding the potential for the degradation of the fresh water aquifer. CRC Well 16R1M seems to indicate it has been occurring during the last 17 years.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Line Number	Figure/ Table Number (if applicable)	Comment
	3.2.3 3.2.5 3.68	3-64			Groundwater storage can not be adequately calculated without the correct BFW model and correct water quality standards. The area where the TDS standards are above maximum levels for TDS should not be included in the aggregate storage for the Subbasin. Need to discuss the redox process and how overpumping can degrade water quality Discuss elevated Cloride levels and its relationship to redox. Also discuss CRC 16R1M and its location as indicative of the legacy TDS issues east of Maxwell. This well has a known depth of less than 30 feet and is draining into the Subbasin.
	3.2.6 3.28	3-73 3.82 -4			There needs to be a discussion about what we do not know about the cause of sbsidence near Arbuckle. The CGA needs to engage Cal Trans to find out what they think the cause of this is. We cant have I-5 collapse – there already has been issues south of Arbuckle immediately east of Pierce High School. It would be a disaster for the State and County if I-5 had to be diverted at Arbuckle. There should be a discussion regarding the elevated TDS and other naturally occurring contaminants under the GDE around the Sutter Buttes. EASC 21 is a well centrally located in a GDE on the east side of the Subbasin with Boron levels of 1,010 ug/L. Adjacent overpumping could harm the GDE and there have been reports of dead fish in this area caused by the release of contaminated well water from 500 feet in depth.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Line Number	Figure/ Table Number (if applicable)	Comment
	3.3 3.11 3.3.4.3.1	3.85			The Water Budget can not be relied on until the correct BFW study is included in the GSP. Table 3.11 - Where is the accounting for water transfers. Where is the historical data for water transfers – what are the future assumption for water transfers?

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
4.2.3.3		4-17		Table 4-4	The Monitoring Network is woefully inadequate to protect against groundwater quality degradation and to protect the Human Right to Fresh Water. All wells used for Groundwater Substitution should be used to collect water quality samples and to preserve public accountability against over pumping. There is an incentive for quantity rather than quality and Stakeholders should be entitled to publicly available water quality data from groundwater substitution wells. In order to protect Colusa County Resident's Human Right to Fresh Water Monitoring Wells should be placed in the study area suggested by Springhorn as referenced in the Comments on Section 3. Springhorn raised concerns about high Saline TDS levels and arsenic levels in a large area west and southwest of the Sutter Buttes. Several monitoring wells should be placed in this area. Monitoring wells may also need to be placed around the City of Williams to provide a historical time series to monitor TDS levels over time. If water banking activities start with the development of Sites, this enhanced Monitoring Network and time series will become critical to protect the water supply for the City of Williams.
4.2.3.4		4-19			Springhorn highlighted a wide area where there are water quality monitoring data gaps. Monitoring wells should be placed in this area in consultation with the DWR and Springhorn's personal input since he highlighted this concern in the first place. Additional monitoring wells may be needed around the City of Williams and any potential water banking sites that could cause degradation of drinking water supplies for on the west side of the Subbasin.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
4.2.4.4		4-20			One or two Extensometers need to be installed near Arbuckle and Dunnigan. One site should be near the intersection of Bailey Road and Hwy 99 since it is the site of greatest subsidence and because the infrastructure of I-5 is there in addition to the Arbuckle Cemetery and old railroad tracks. The other Extensometer should be installed near Dunnigan working with the Yolo County GSA to choose a site. There are approximately 500 residences in the area and an evergrowing commercial infrastructure.

Chapter Number	Section Number	Page Number	Line Number	Figure/ Table Number (if applicable)	Comment
4	4.2.5.2				The Groundwater quality network does not adequate monitor the TDS contamination around Maxwell and Williams. CRC 16R1M is very concerning and represents an area where there is known water quality problems but there are no multi-completion wells to monitor upconing or provide a way to monitor upconing. The lack of multi-completion wells in this area and next to the public supply systems for Williams and Maxwell raise concerns about having enough information to protect the HRTW. Additionally, if the proposed Sites reservoir is completed there will be an urgent need to add monitoring sites to monitor possible contamination caused by the hydraulic head differential from Sites.
				4-7	It is unfortunate that the SVWQC observation wells were placed in areas where there are not any known water quality problems. It was clear from the Colusa County GMP that the problem areas are near Williams and Maxwell. The extreme variance between CRC Well 16 R IM and the nearby SVWQC wells highlight this disparity.
	Appendix 5				Since the public supply systems for Grimes and Princeton are know to have elevated arsenic levels, there should be a Figure monitoring arsenic over time at these sites and included in the GSP. The Appendix should include water level and water quality observations for each observation zone for all the multi-completion wells. Since there is abundant empirical evidence of upconing in the Colusa Subbasin this phenomenon needs to be continuously monitored by zone of depth for both gradient and water quality constituients. Where there is a concern for arsenic the monitoring should be for both EC and Arsenic. Additionally there should be more mulit-completion wells installed on the West side of the Sacramento Valley down hill from Sites since the

COLUSA SUBBASIN

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
5.3.1.3		5-6			Last paragraph should include impact of SWRCB water curtailments to TC Contractors. The example just refers to Federal curtailments. Comment should also highlight the fact that TC Member groundwater pumpers will have no alternative but to pump groundwater during curtailments because they need to irrigate their permanent plantings.
	3.1.4				Comment should address the dewatering of small water systems and domestic wells and the impact on DAC and SDAC households in the affected areas. This is not a hypothetical issue – domestic wells in College City and Arbuckle have run dry. This should be highlighted in the GSP.
	3.1.5				Discussion should include the impact on small water systems and domestic wells. The number of reported domestic wells should be recorded and highlighted. It is my understanding that over 19 domestic wells have already ran dry. The impact on households in SDAC and DAC areas should be highlighted.
5.3.4.1		5-10			Discussion of the role of the USEPA should be included. The USEPA has cited the small water systems of Grimes and Princeton for arsenic contamination. It is very important that that the discussion includes the degradation of fresh water aquifers caused by upwhelling of poor quality water. There is a possibility that over pumping could cause or exasperate this undesired outcome.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
	3.4.2	5-11			Impact on SDAC and DAC areas should be identified and discussed by the GSA. Water quality of monitoring wells with multi-completion stages should be documented for each depth stage to identify degraded fresh water aquifers caused by upwhelling. We should avoid water quality monitoring cherry picking and record the data for all depth stages and monitor trends over time to identify possible upwhelling.
	3.4.3	5-11			If Sites is contructed, water quality may be adversely impacted by the elevation gradient between the elevation of sites and the bowels of wells on the valley flow. This gradient could be 600 to 900 feet of elevation head and may take decades to document. Especially around the Sutter Buttes Rampart we need to monitor for potential effects of a redox reaction when connate water upwhells and starts an oxidation process. Arsenic desorption is a predicted outcome when the pH of the connate water is greater than 8. There are also potential biotic outcomes again arsenic related when connate salt water starts the oxidation process. Certain anoxic microbes may add to the arsenic contamination similar to the cause of arsenic contamination in Chesapeake Bay. Earthquake activity could also affect the movement of upwelled contaminants. The west side of the valley has a history of geothermal conditions which could be impacted by earthquakes and earthquakes could also be a catalyst for upwhelling via active faults.
	3.4.4.	5-12			How about birth defects, mother health and other arsenic contamination related outcomes Rather than adverse effect to property values – loss homeowner values and loss of housing if a domestic well becomes contaminated.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
	3.4.5	5.12			USEPA and SWRCB Citations should be evaluated.
	4.1	5-16			The stakeholder input regarding the 80 pct level should be documented and recorded for future public comment. As you may know there has been over 20 domestic wells reported dry with several in the College City area. The domestic well threshold should be an area of future discussion and stakeholder input as the drought progresses. The advocates of the 80 pct threshold should be documented and disclosed and the issue of domestic wells should have a future public discourse. Was there a GSA vote on the 80 percent level?
	5.4.1.1.1				The adverse degradation from the redox process for connate salt water will most likely be permanent. Significant lowering of groundwater near Grimes and the East Side of the Sacramento River could be the most vulnerable are for redox and potential adverse biotic outcomes. On the west side where there is natural geothermal pressures the lowering of groundwater levels could affect the hydrologic balance of groundwater and result in more upwhelling. Again another reason to measure all water quality at all observable depths.
	5.4.4.1				There should be a Minimum Threshold for Arsenic Contamination. There are two small water supply systems in Colusa County with USEPA Citations, two abandoned wells at the southern part of the City of Colusa and a reported observation of 200 ug/L near Grimes. Trends in arsenic contamination should be monitored over time due to the potential for continued redox of connate salt water and potential movement via faults which could be adversely aggravated by future techtonic activity.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
	5.4.4.2				The Measurable Objective for arsenic should be the USEPA MCL of 10 ug/L
	5.4.4.4				The Interim Milestone discussion should include the GSA's role in working with the State of California to guarantee the Human Right to Fresh Water to the residents of the Colusa Subbasin. The State has the responsibility to uphold this Human Right and the GSA will likely have to work with the State on targeted solutions or mitigation efforts.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
5A		2	Outreach		Since the majority of the Outreach and Public Involvement Process was done before the severity of the current drought was known the outreach process does not reflect the impact on domestic well users nor does have domestic well users had the opportunity to give their input. The reported number of domestic well problems should be documented and there should be a concerted outreach program to get their input on the Minimum Threshholds and mitigation measures. The GSA has an opportunity to truly understand the impact on domestic wells from lowered groundwater levels and act in a proactive manner to help manage and mitigate adverse outcomes for the future. The current Memorandum does not reflect input from domestic well users.
			Hydrographs		The hydrograph for 14N02W22A002 does not have any data on the two pages it is presented.
5B		1			The statement " This appendix describes an economic analysis of MT's that was developed and presented to the TAC at the May 13,2021 Meeting" is false. While it is clear that the economic analysis was included in the presentation there is no indication that the economic analysis was presented or discussed at the meeting. The Minutes of the May 13, 2021 TAC Meeting do not reflect any discussion of the ERA proposal and states on Page 8 of the Minutes in Agenda Item 4.b Projects and Management Actions (PMAs) - **" This Agenda item was not discussed during the TAC meeting due to time constraints"**

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
5B		2			What are the assumed capital cost for refurbishing potentially dewatered domestic wells? What are the assumptions for energy costs caused by additional pumping? What rate schedule? As you probably are aware there are many critical assumptions depending on season and time of use.
		4		Figure 2	What does the Table Crop and Acres mean? There is not explanation for the inclusion of this table of the documentation for and reference source.
		2			Why does the economic analysis assume that demand management would be adopted by the GSA? The economic analysis in Chapter 6 appears to be highly speculative and is difficult to assess since the assumptions for the analysis have not been disclosed.
		All	General Comment		Regarding the costs of replacing the domestic well it is hard to assess whether or not the analysis is based on representative costs because the assumptions were not disclosed. The analysis seems to make rudimentary assumptions and not real life assumptions. In the crisis of a drought, local drilling capacity and well repair services are very limited and usually focused on serving the biggest and best customers. Domestic well owners are likely to have to wait until the growing season is over and pay for the costs to maintain their personal health and livelihood during the loss of the well. Some domestic well owners may not have access to the capital they need to make the repairs and most would not be able to secure 20 year financing unless they had equity in their houses and could refinance. Having a well run dry and being ablet to get an appraisal for refinancing is probably near impossible and ultimately the loss of a well may mean substantial loss of market value of their house.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
					To make this a meaningful analysis, there is a timely opportunity to contact the County administrators and survey the domestic well users that have lost their wells during the current drought and ask them about direct and consequential economic costs and costs due to loss of income due to their well depletions. There are more than 20 such dry domestic wells in Colusa County alone.
5C	General				Arsenic levels should be included for Grimes and Princeton since the USEPA has continuously reported that observed levels are above the USEPA MCL. Arsenic should also be reported for all the wells for the Colusa Supply system since there has been the Del Oro Walnut Ranch well abandonment and the CIP enforcement action. Also the well near Grimes with the 200 ug/L observation should be included and reported for each observable depth if it is a multi-completion well.
					All of the reported locations should have EC observations for each observable stage if any of the reported locations are multi-completion wells. The new well drilled by the County of Darrin Williams property should be included in the appendix and water quality observations should be tracked for each observable depth. Mr. Williams reported upwhelling near the 1000 foot depth and the water quality from the upwhelling aquifer should be observed and tracked.
					Overall the Appendix needs to incorporate the wells discussed in Section 3.2.5.11. There is a multicompletion well near Maxwell with 4 stages and TDS levels as high as 1640 mg/L. There is a shallow well west of Grimes with a measurement of 2,040 mg/L. Wells near College City with TDS concentrations greater than 1000 should be of immediate concern since domestic wells are running dry and bowls are being lowered. Where are the measurements for the shallow wells west of Colusa with TDS levels greater than 2000 mg/L.
					Generally we should have up to date observations for all reported wells. The data for the Maxwell public supply system ends before 2013. The data for the Princeton public supply system ends before 2014 Arbuckle only has 3 observations ending in 2016. Since the Williams supply system has elevated EC levels, all the supply wells for Williams should be reported so as to avoid cherry picking and also to monitor any adverse trends.

Chapter Number	Section Number	Page Number	Line Number	Figure/ Table Number (if applicable)	Comment
5	5.3.4	5-11	33		Why isn't upconing being addressed since it is a known common occurrence? How does this reconcile with the HRTW goals of the DWR? The public supply systems of Williams and Maxwell seem particularly vulnerable to heightened TDS levels like at least one of its wells has experienced lately. This would be a primary concern from the head gradient from Sites and this trend needs to be monitored more closely than the current monitoring network would do.
	5.3.4.2	5-12			What are the minimum thressholds for each site? These levels should be in a Table because it is confusing to understand what they may be? What are the historical numbers that will be used? Shouldn't there be a Table like Table 5-2 for quality thresholds?
	5.3.4.3	5-12/13			There is no discussion about redox causing degradation? The potential from upwhelling caused by the gradient differential from Sites and possibly in combination with earthquake and fault activity?
	5.3.5	5-13			This SMC seems to be very dangerous because the current problem area for subsidence is so close to I-5. If the subsidence monitoring site next to I-5 dropped by 5 feet would the SMC be triggered? It would seem that there should be zero tolerance for more additional subsidence next to I-5 and that Cal Trans should be engaged now to figure out the cause and what can be done. Perhaps funding could come from Cal Trans – especially given all the infrastructure money being allocated right now.

6				6-2, 6-4 ect	The boundary for the CDMWC needs to be corrected to reflect the acreage south of Hahn Road west of the Colusa Basin Drain.
	6.3.1				Since there was not a project submittal for this project how can Stakeholders obtain the proposal submitted? It was mentioned that there was a planned annexation in the public meetings – how can stakeholders know what acreage is intended to be annexed? Who is paying for this PMA development? How can Stakeholders know that proprietary consulting activities are not also being done with public funded 218 assessments since many of the PMAs are being considered by legacy clients of the Consultants? What control procedures are in place to prevent abuse of the PMA financing process by consultants and legacy clients?
	6.5.1.2			Westside Diversions	The Salt Creek potential diversion should be closely analyzed for potential harm to Williams public supply system from both a quantity and quality perspective. There are substantial HRTW and DEI considerations to be considered with any diversion of Salt Creek or any other west side stream above a public supply system or in an area where subsidence is a problem or an emerging problem
	6.5.1.3			Sites	The top of Sites Reservoir is expected to be 500 feet above sea level which is likely 800 feet above the intake levels for the public supply systems of Maxwell and Grimes and all wells generally on the Valley floor. This head gradient could materially degrade water quality generally and/or the public supply systems for Williams and Maxwell. Additionally lateral movement via localized faults and/or future earthquake

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Line Number	Figure/ Table Number (if applicable)	Comment
					activity could materially negatively impact groundwater quality at any point in the future. This again has HRTW and DEI potential negative material impacts.
	6.5.2	6-81			Why hasn't the GSP covered the proposed groundwater trading program being considered by the California Water Commission? It appears that this is being seriously considered but it was not discussed our considered in the public engagement process for the GSP.
					The Short Term and Long Term Demand Management Actions need to be reviewed by the Economic Development departments of the Counties and Cities in the Colusa Subbasin. How does the costs of these Demand Actions compare to the cost of groundwater trading as discuss? Who is going to pay to administer these type of Demand Actions and what are the estimated costs for the administration?
	7.1.1				What is the status of the GSA establishment cost reimbursement requests that are part of the JPA? Is this reimbursement possible ? How much is the amount and how much will be paid to each entity? Is this amount included in the estimates? If the GCA is sued for a settlement contractor issue such as the Aqua Alliance suit – who pays for the legal fees for the suit?
	7.1.2				How do Stakeholders have confidence that 218 fees are not being used to pay costs that are not appropriate to charge the GCA bit should be charged to the Member GSA.? What type of audit and control procedures are in place to protect against abuse

Subject: Fwd: attached map and ideas for potential recharge

HI Grant and Lisa
Sorry the previous emails were hand written and hopefully legible for you to review. I have been very busy spraying long hours for potential blight from the past rain prediction that panned out to be a waste of time and money in spray as very little precipitation.
I could not get a hold of the people I wanted to over the weekend to give you more information to use for this potential project.
First off, the land owner of the property has changed hands from Pete Galaya to:
RD 45 , LLC
1380 East Ave, Ste 124
Chico, CA
Parcel number 020-240-0140
There is 41.5 acres of Glide water district in the block of Habitat, not waterfowl wetlands like I thought. Not sure what plain ole Habitat is but definitely good percolation in this area. Of course this is a statement made only by experience and not as a geologist/hydrologist which would have to be confirmed by science. A rice farmer to the west of the proposed property for recharge used almost 10 acre feet one year for his crop. Again, the cost of water and other crop costs combined with returns have forced this farmer to sell part of his land using the sale of his land from many generations in his family to develop orchards so that he can keep some of the remaining 4rth or 5th generation family farm. Sad but true for many farmers.
From what I was told by Mike Alves regarding there are 41.5 acres of glide district land within the 300+/- acres of Habitat. When available from the Bureau, water can be surface water that can be purchased at each year's allocation rate for the **only the 41.5**, but not more than the allocation for each year. In addition to the glide surface water yearly allocation, any Bureau excess flow water could be captured in the 41.5 acres **and** remaining property acres as well. So using the Glide means of transportation from the TC canal, possible surface water available year to year could increase throughout the year time to time as the Bureau sees fit to call in "excess flows available" Of course, they still charge a fee and Glide a fee as well, but usually at a more reasonable price.
Because this property lies between the 2 creeks, it does flood during wet years. So, maybe some improvements could be made to capture more of the flood water that flows so quickly away and allow for more time to capture excess flood water to our groundwater storage. Maybe it will be so simple and cost effective as placing Check damns? and/or doesn't need them just some drainage management.
I do not know who the RD 45 LLc people are or if they would even consider working with the ground water recharge project. Even to the north of Wilson Creek is land in the habitat. It is a very large piece of property. 300 +/- acres.

Hope all this helps and let me know if you have any questions.
Thank you
Leslie Nerli

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
2	2.1.2		1	Plan Area	Paragraph 2 The obvious and probably already corrected is... Primary urban . . . . Colusa & Williams in Glenn Co. . . . wrongly printed for both counties
2	2.4	23		Conjunctive use Programs	Paragraph 3 – Purveyors (water) along TC Canal — Re: 0% – 100% depending on available water – truely dependant on what Bureau feels to allow each year and is announced very early in year. Thus Paragraph 4 – also wrote well but I would like to add that Ag users try to utilize these transfers which are always at a very high price per A/F instead of pumping ground water. Or some Ag user combine the very costly cost of transfers with ground water pumping to survive and turn a profit. These costs are what have driven the Agriculture users to change crop planting from row crops to tree crops due to costs. (or rice)

cont 2.2.4 Conjunctive Use programs

Some Ag users have no groundwater availible and dare not plant trees, therefore fallow when either cost of water is prohibited and/or Not availible to buy — Fallow ground means less money for county in many ways — labor / Tractor equip purchases for improvements / taxes etc. . . . Not sure how or if this needs to be addressed but just saying . . . . Ag $ cost of transfers should be reognized — Nothing high is reasonable and is driving land use to demand more ground water and less land use to replenish what is taken.

Potential Recharge Project

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
		32		Areas of Sustainability Concerns	- Glide Water District - Please see attached MAP
					of what I believe to be an excellent area of land to recharge. The land owner is Pete Galaya from Colusa
					Not sure how to approach the whole thing but maybe Grant David can - It is wetlands for waterfowl
					hunting and between the 2 creeks where as you could divert water from creek when flow allows. I know it floods when wet years flood. Maybe build
					up catch ment areas to hold flood water longer. Surface water from Glide could be used

Cont'

when excess Bureau water is availible. This past February we were offered excess flow water, of course always for a fee from both the Bureau and Glide wheeling fees — Maybe we can lease the ground from Pete and somehow determine what we put into ground water system could be credit for when we have to pump — Could approach Districts or a group of local ag. users to develop land to better utilize rain/s.w. for recharge and somehow get credit to pump g.w. when s.w. is not available. ? ? Maybe the land just needs some check dams? Might be already to capture (recharge) water.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Line Number	Figure/ Table Number (if applicable)	Comment
Executive Summary			22-27		(Executive summary-Line 22-27 and corresponding sections in the text) I believe that the foundational assumptions with the water budgets do not reflect the reality of future climate change and the assumptions of data used as the baseline were not indicative of drought years. In addition, the idea that using a central tendency for climate change is short sighted at best. It seems to me that a "critical' tendency for climate change should also be included in the analysis—one that looks at a serious increase in overall earth temperature above 2.5*C. Otherwise, we are just putting our heads in the sand with regard to future water/crop issues. What mitigation factors could be planned for? How is water distributed equitably in times like that? What future cropping patterns might be considered? (maybe more annual crops when water is available..)
Executive Summary			17-21		(Executive summary-Line 17-21 and corresponding sections in the text)) I also would like to add that the assumptions of surface water use and a reduction in irrigated acreage from Shasta in critical years would be less is actually inaccurate. Since much of the irrigated agriculture in the Glenn and Colusa area are permanent crops (almonds and walnuts), they need to be irrigated no matter what…what it does trigger is a significant increase in ground water use.
Additional Comment					Finally, what I find distinctly disturbing is that in the entire plan there is no individual accountability for ground water use by individual growers, no monitoring of private wells or individuals who are excessive consumers of our precious and shared resource. For example, I am aghast at the practice of almond farmers extensively irrigating to "fatten up" the nuts just prior to harvest. Seriously!!! What a waste of water!!! The extra moisture has to be dried out using more energy in the drying process. Why is there no individual accountability for each well and that each grower pay the price for water just like most consumers have to do? I believe this is something that truly needs to be included in the plan.

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
1	1.1	1-1	2		The priority being to halt overdraft and bring basins into balance? This is not even close to being complied with. The overdraft is far greater than the recharge with the ground water tables lowering each year.
1	1.1	1-1		1, 2 & 6	Sounds good but is NOT will not work and is not doable.
1	1.1	1-1	4		Achieving the groundwater management within 20 years WILL BE TOO LATE.
1	1.2	1-2	1		SEE ABOVE!
1	354-10	3 OF 7		1-1	The whole process has been trotally lacking in "public engagement". Nor has the GGA encuraged any "active involvement". As the times we have given input we have been overridden by councel.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
2	2.1.2	2-4	2.1.2.1		With the Colusa Subbasin depending on ground water for their potable water the ground water for these wells should be closely watched as the number of wells are going dry or having to be lowered at an alarming rate.
2				2-6	The table shows the density of Ag. wells around Orland. Is anyone reporting the number of domestic wells that are being affected by this?
2	2.2	2-16	2.2.1.1		"Manage and reduce invasive plant populations" This has been one of my main talking points for many years. The Salt Ceder and the Bamboo are non native and are using more water than any other source. Especally in this dry year these plants need to be eradicated!
2	2.2	2-17	2.2.1.1		"Ensure long-term Gropundwater Sustainability" At the rate this is going and where it is headed the train has left the station and we in Glenn County will have little or no ground water in the very near future. Domestic and livestock wells MUST be protceted.
same as above					The defination of sustainable: "related to, or being a method of harvesting or using a resource so that the resource is NOT depleted or PERMANENTLY damaged". To date all that I have seen and hear coming from the GGA has been a JOKE!!!

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
2		2-23	2.2.4		With 2021 being one of if not the dryest years on record to transfer serfice water OUT of the subbasin should be at the very least suspended. To transfer serfice water then pump ground water as a substitute should not be allowed.
2		2-29	2.5.1.2		Chowchilla?????
3		ALL OF IT!			Anyone reading this needs a Masters degree in Geology. Anyone looking for something to put them to sleep at night can try this chapter. Most of what is contained is FAR above most people and especally those here in Nrthern California. Maybe this chapter is necessary but it is way over the top on so much detail that it loses the normal person. It certently lost me.
4		ALL OF IT.			There is no mention of using those locals that are drillers and or anyone that repairs pumpa and wells. It should be noted that those working in the "field" just might have a better idea as to what is happening to our groundwater than someone sitting at a computer someplace other then in the field in Glenn County.
	FINAL THOUGHTS				After reading through this whole draft. Witch I will have to admit was in many places very boring, I see no offers of solutions. Lots of "we will Keep lookionmg at it" but nothing to address what some are saying is a major overdraft of our gropund water. Domestic and stock wells are having to be lowered or are running out of water. The word on the street is that the ground water is dropping by over 1' per year and that was BEFORE the current very dry year. To me this is nothing more than a "make someone feel good" and a waste of time and energy of some that are well meaning but this is NOT getting the job done.

Comments on the Glenn Subbasin GSA
Comments by Holly E. Reimers, Landowner

Page	Line	Table	Figure	Comments
ES-14	14-15			What happened to the wells between 200' and 2,000'?
ES-16		ES-3		Wells falling below their MT should be monitored more often than every 24 months. Every two years allows for a severe lowering of the ground water level that might not be recoverable. Any well falling below it's MT should be checked at least twice a year. Any land subsidence should not be acceptable. This is not something that is recoverable.
ES-17	12-15			"..not currently occurring..." WHAT?? Has anyone noted the number of dry and going dry wells in Glenn County? Granting that this is an usually dry year and that Stony Creek has not run all year it is almost amazing that there have not been more dry wells. Yet there are those around the County that continue to pump great amounts of ground water from their deep wells. Sort of like putting a straw on a glass and sucking. The top part of the glass will go dry first as the water is pulling from the bottom.
2-1				The basin boundaries should be redrawn to exclude those lands that do not have access to groundwater primarily those lands in the western portion of the basin. Not only is there little to no groundwater these lands are receiving no benifit from being in the basin, only an expense.
3-15	3.1.5.16			Why is Hambright creek not mentioned? When running it is a major source of groundwater recharge.
6.5.1		6-27		The OUWUA is acknowledged as direct Groundwater Recharge. The land owners in the OUWUA should also be acknowledged as having the ability to assist in the ground water recharge. Those that apply only surface water should be given credit and not charges as they are helping the recharge when ever they apply surface water.
7.6	8-23			Charging the landowners on the west side of the basin, with no groundwater, the same amounts as those that have the water under their ground and are pumping for their perennial crops is unfair. Paying a "tax" or "fee" when

there is no benefit to the landowner, there should be some benefit but so far we on the west side are seeing none. To place this additional burden on these land owners may force them to look at other uses of their ground to be able to "pay" for your additional fees.

Appendix 7A
Page 3 Table 1

All "fees" should be passed only by a majority approval vote. Any "vote" should be conducted on a per/acre basis and should take into consideration what benefit there is to the landowner(s). You can call it is "fee" BUT if it looks like a duck, quacks like a duck IT IS A DUCK! A "fee" by any other name is still a tax on our property.

General Comments

It has been said that there are outside groups purchasing ground in the basin with the only purpose of mining the ground water. This is not a supportable option for the basin to be able to sustain its self. **NO GROUND WATER SHOULD BE EXPORTED FROM THE BASIN - EVER!**

Chapters 3, 4 & 5 one needs to have a Doctorate Degree in Hydrology, Geology and Engineering to even start to understand any of this. This should be written so that the general public and landowners would have some kind of understanding as to what some of these proposals are and how they as landowners will be effected. Or at least put in a summary that the landowner can understand, it may be included I might have missed it in all the other "stuff".

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
6	5.1.7	6-70	1 (above Table 6-35)		**Question**: What do you mean by "newly formed water storage district"? We are already within an existing water district (Sycamore Mutual Water Company). Davis Ranches is the participating Landowner within the district that will be hosting the recharge site.
6	5.1.7	6-70	1 (above Table 6-35)		Water would be sources from Sacramento River during high flows in the system. Currently, Sycamore Mutual Water Company (a Sacramento River Settlement Contractor). We will be looking to rely on our Riparian water rights in order to do winter flooding (beneficial use). We will not have 215 water from the Colusa Drain. Should project start before Nov. 1, we would use some of our settlement contract water to recharge.
6	5.1.7	6-70	1 (above Table 6-35)		Habitat benefits also include winter floodplain habitat for migrating shorebirds/waterfowl as we pulse flood the field
6	5.1.7	6-71	Table 6-35	Water Source & Reliability	Source is Sacramento River. Reliability is good, but still unknown at this time.
6	3.5.1	6-42	1		30 – 45 days during fall/winter. We aren't tied to a specific start date. There is flexibility built into the project to allow for water availability, etc. The target is Fall/Winter for the habitat benefits as well as availability of water in the system. Settlement contract waters would be used if the project starts before Nov. 1.

COLUSA SUBBASIN

Chapter Number	Section Number	Page Number	Paragraph Number	Figure/ Table Number (if applicable)	Comment
6	3.5.1	6-42	2		We do not have contract for 215 water. We do have riparian rights that we would be exercising for this project for beneficial use (habitat).
6	3.5.1	6-42	2		5,000 acre feet over 10-years is our goal.
6	3.5.5	6-44	1		No 215 water.
6	3.5.7	6-45	2		No 215 water.
		6-8		Table 6-2	Diversion of winter flows from Sacramento River (riparian) or settlement contract flows (should project start before Nov.1).

1. Introduction & Background

The content of the report is the result of staff recommendations resulting from regional inter-basin coordination staff meetings in the Northern Sacramento Valley (2020-2021). The content will be presented to inform discussions among Groundwater Sustainability Agencies (GSAs) and gather public input through existing public venues, such as advisory committees, groundwater commissions, and GSA Board meetings.

Inter-basin coordination is critical in the Northern Sacramento Valley as GSAs develop and implement Groundwater Sustainability Plans (GSPs). Since groundwater subbasins in the Northern Sacramento Valley are hydrologically interconnected, water management decisions and actions in subbasins (i.e., groundwater pumping and processes affecting recharge, water demand, and supply including climate change) could change aquifer conditions. Understanding and accounting for these processes is important towards achieving sustainability in all subbasins.

Figure 1. Map of the Northern Sacramento Valley

Inter-basin coordination is described in the GSP Regulations in Article 8. Under the regulations, GSAs must describe how they coordinate with adjoining subbasins to demonstrate implementation will not adversely affect adjoining subbasins. The Department of Water Resources (DWR) is required to evaluate whether a GSP adversely affects the ability of an adjacent basin to implement their GSP or impedes achievement of sustainability goals in an adjacent basin (Water Code 17033(c)). Coordination among GSAs can be formalized in different ways and inter-basin agreements are voluntary. Appendix A describes components of Sec 357.2.

Inter-basin coordination discussions among staff representatives from 11 subbasins (Antelope, Bowman, Butte, Colusa, Corning, Los Molinos, Red Bluff, Sutter, Vina, Wyandotte Creek, and Yolo), with facilitation support from the Consensus Building Institute (CBI) began during the summer of 2020. While efforts have focused on these subbasins, coordination will occur, as warranted, with other neighboring subbasins (Anderson and North Yuba).

Initial stages of inter-basin coordination efforts (May-December 2020) were closely aligned with the GSP Regulations in Article 8 components and delineated in Section 3 *Evolution of Inter-basin Coordination Efforts*. After an initial attempt to compile technical information to better understand basin conditions at respective boundaries, staff realized differing timelines for the completion of Basin Setting content in each subbasin meant there would not be sufficient time during initial GSP development to fully characterize or address major inconsistencies. Therefore, the goal for regional inter-basin coordination shifted towards establishing a framework for long-term inter-basin coordination and dialogue (post GSP submittal in 2022). Informal coordination discussions among staff and consultants between neighboring subbasins continued during the GSP development process.

This report outlines the intent and purpose of inter-basin coordination in the Northern Sacramento Valley. It describes the process followed and materials developed throughout the process. It also outlines foundational elements, referred to as "key pillars," of a framework for sustained coordination through GSP implementation.

2. Intent & Purpose

Inter-basin coordination efforts in the Northern Sacramento Valley are focused on establishing a foundation and guidelines for sustained inter-basin coordination through GSP implementation, following the initial submittal of GSPs by January 31, 2022. GSAs intend to:

1. *Establish a framework allowing for continued dialogue and a venue to address issues and discrepancies during the implementation of the GSPs;*
2. *Coordinate on consistent messaging and communicate shared expectations at a regional level;*
3. *Demonstrate regional coordination efforts and outcomes; and*
4. *Leverage existing agreements and arrangements in the region (e.g., Northern Sacramento Valley Integrated Regional Water Management (NSV IRWM), the Six County Memorandum of Understanding among Butte, Colusa, Glenn, Tehama, Shasta, and Sutter).*

The proposed deliverable from this effort is the development of a common approach and draft language for incorporation into each subbasin's GSP. This narrative describes the facilitated effort as well as the framework and scope for long-term coordination during plan implementation. The public will have opportunities to weigh in and provide input on the proposed framework through each subbasin's existing public venues, such as advisory committees, groundwater commissions, and GSA board meetings.

3. Evolution of Inter-basin Coordination Efforts

Inter-basin coordination efforts, facilitated by the Consensus Building Institute (CBI) began in summer 2020 among Subbasin staff from Antelope, Bowman, Butte, Colusa, Corning, Los Molinos, Red Bluff, Vina, and Wyandotte Creek subbasins to identify priorities and resources available for inter-basin coordination. Soon after, staff representatives from the Sutter and Yolo subbasins joined the meetings. To date, CBI has facilitated nine inter-basin coordination meetings with staff and periodically with technical consultants from the subbasins. Subbasin staff and/or CBI communicated regular updates to GSA Boards and advisory committees in each of the subbasins regarding the status of inter-basin coordination activities [Access Webpage Here].

Initial stages of inter-basin coordination efforts were closely aligned with the GSP Regulations in Article 8:

1. ***General information*** *of subbasins, plans and agencies participating in the coordination agreement,*
2. ***Technical information*** *including consistent and coordinated data or methodology for inter-basin boundary flows and stream-groundwater interactions at basin boundaries, and information on sustainable management criteria and monitoring that would confirm that no adverse impacts of implementing the GSPs would result to any party to the agreement,*
3. *A description of the* ***process for identifying and resolving conflicts*** *between Agencies that are parties to an inter-basin coordination agreement.*
   Reference: *Sections 10727.2, 10733, and 10733.2, Water Code.*

The goal at the initial stage was to compile general and technical information identified by DWR in a consistent manner to establish an accurate basis of comparison and to identify any significant inconsistencies that may need to be addressed or resolved. This included developing a series of information-sharing documents and outreach materials, summarized below.

1. ***Inter-basin Coordination Directory–*** *This document provides an updated and centralized directory with contact information for GSA managers, technical consultants, and facilitators in the various subbasins. This document seeks to facilitate communication among the various representatives leading GSP development [Access Here].*
2. ***Technical Information-Sharing Template–*** *This template was developed among the managers and technical consulting teams to compile and compare information on modeling tools and water budget results for inter-basin flows, stream-aquifer interactions, and hydro-geologic conditions in the subbasins. Potentially, this document could be used to compile information about Sustainable Management Criteria and Monitoring Networks [Access Draft Template Here]. The first output from the technical information-sharing template summarizes the highlights of compiled model information across the subbasins [Access Here].*
3. ***Outreach Presentation****–This PowerPoint presentation provides updates on inter-basin coordination activities to the various SGMA public venues (GSA boards, advisory committees, etc.) and an overview of the scope and timeline of inter-basin coordination efforts. This presentation is continuously updated*

after each inter-basin coordination staff meeting for use in consistently communicating with GSA Boards/advisory committees and the public throughout the region [Access Here].

4. ***Outreach Factsheet–*** *The inter-basin coordination factsheet aims to support public outreach and information sharing in the various subbasins. This two-page flier or factsheet summarizes why regional coordination is important under SGMA, who is involved in ongoing efforts, what the coordination priorities are, and includes a table with links to each subbasin's website for additional subbasins' specific information [Access Here].*
5. ***Inter-basin Coordination Webpage****– Butte County hosts a webpage to provide the most up-to-date information on inter-basin coordination efforts in the Northern Sacramento Valley. The webpage provides an overview of the scope and makes available documentation and results of the inter-basin coordination work, including meeting agendas, summaries, and outputs [Access Here].*
6. ***Meeting Summaries****–CBI develops meeting summaries after each regional inter-basin coordination staff meeting to summarize key discussion themes, action items, and next steps. These summaries are publicly available on the inter-basin coordination webpage [Access Here].*

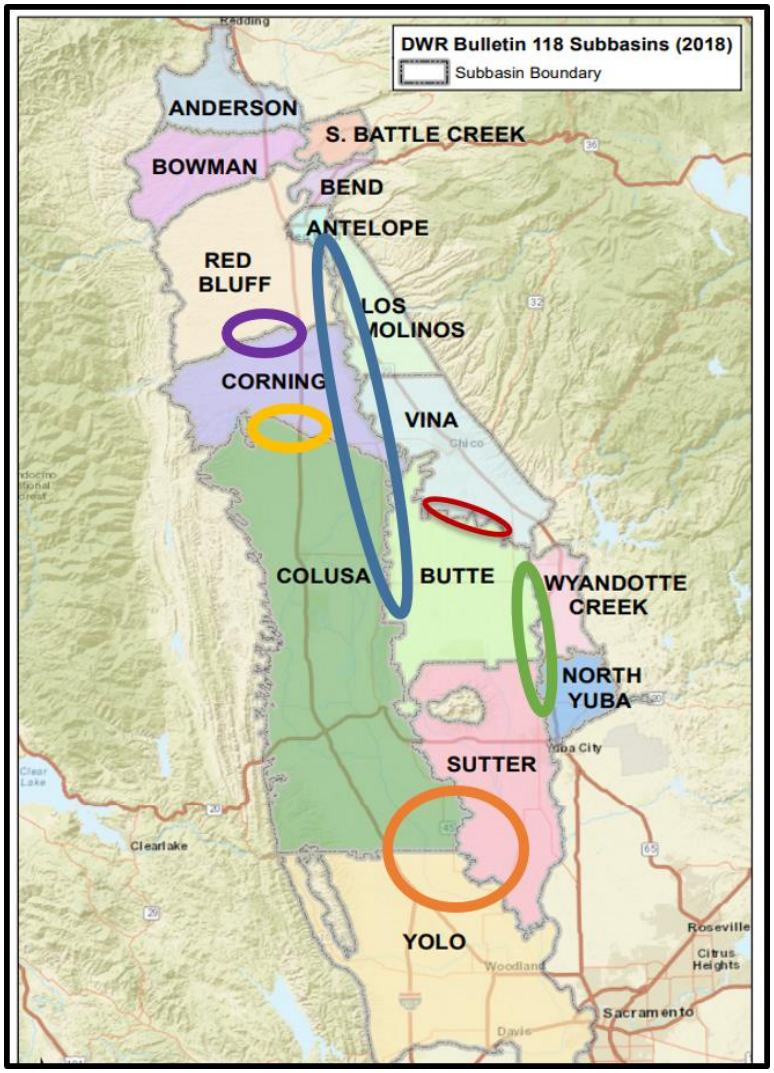
After an initial attempt to compile technical information, staff realized the broad aspirations were not feasible during the initial stages of GSP development. The process of compiling and comparing modeling outputs from the diverse regional hydrological models required a significant amount of time, resources, and varying levels of data. Further, subbasins were at different stages of GSP development and GSAs were facing tight timelines, competing priorities, and capacity limitations to meet the regulatory deadline. While communication on a neighbor-to-neighbor basis on technical components was encouraged through GSP development, subbasin staff representatives realized more robust technical analysis and coordination between and among subbasins was not possible until initial plans (including water budgets) were more fully developed or after adoption of the initial GSPs.

Following reflection from the separate inter-basin efforts and priorities moving forward, subbasin staff recommended shifting the focus of regional coordination meetings to establishing a framework for long-term inter-basin coordination and dialogue following GSP submission in January 2022. To do so, subbasin staff identified desired outcomes in the short-term (during initial GSP development), mid-term (first 5-year update), and long-term (GSP Implementation through 2042) [Access Here]. This approach recognizes adoption of the 2022 GSPs as an initial step in sustainable groundwater management, not the final step. Subbasin staff acknowledged while model outputs may not match perfectly, the main objective is to identify and acknowledge significant discrepancies, understand why those differences exist, and evaluate to the extent they need to be reconciled. Inter-basin coordination has been characterized as "a marathon not a sprint," and current efforts will serve to pave the path for long-term collaboration. Further, GSAs can take advantage of annual reporting and five-year GSP updates to identify and address discrepancies. Lastly, subbasin staff representatives acknowledge public participants are interested in inter-basin coordination efforts and concerns from some subbasins can easily affect others. Subbasin staff understand the need to share and educate the public on what is in the various GSPs, and the SGMA requirements for inter-basin coordination. Staff will continue to provide updates and gather GSA Board and public input related to the direction of current efforts and desired priorities, shared concerns, and possible ideas for inter-basin coordination during GSP implementation.

4. Inter-basin Coordination Framework

This section outlines the foundational pillars that comprise the framework for inter-basin coordination under SGMA between and among subbasins in the Northern Sacramento Valley. These pillars build upon a long-standing history of regional collaboration and embody a commitment for continued coordination, collaboration, and communication for successful groundwater management in the region. Honoring the individual authorities of the GSAs, these pillars represent a menu of options neighboring subbasins can draw upon, based on individual or neighboring subbasins' needs and challenges. GSA Boards can decide which of these options they would like to support and implement, acknowledging circumstances may change over time.

Pillars	Scale(s)	Timing
1. Information-sharing a. Inform each other on changing conditions (i.e., surface water cutbacks, land use changes, policy changes that inform groundwater management) b. Share annual reports and interim progress reports c. Share data and technical information and work towards building shared data across and/or along basin boundaries (e.g., monitoring data, water budgets, modeling inputs and outputs, and Groundwater Dependent Ecosystems)	• Neighbor-to-neighbor • Coordination groups [Refer to section 4.1 below]	• *Ongoing (GSP Development)* • *Near-term (5-year update)* • *Long-term (GSP implementation)*
2. Joint analysis & evaluation a. Evaluate and compare contents of GSPs with a focus on establishing a common understanding of basin conditions at boundaries b. Identify significant differences, uncertainties, and potential issues of concern related to groundwater interaction at the boundaries c. Engage in analysis and evaluation of SMCs between GSPs to assess impacts and identify significant differences and possible impacts between subbasins that could potentially lead to undesirable results	• Neighbor-to-neighbor • Coordination groups [Refer to section 4.1 below]	• *Near-term (5-year update)* • *Long-term (GSP implementation)*
3. Coordination on mutually beneficial activities a. Communicate, coordinate, and collaborate on mutually beneficial activities, which could include joint monitoring, joint reporting, regional modeling, and other efforts to address data gaps at subbasin boundaries b. Collectively pursue funding and collaborate on mutually agreed upon projects and management actions that provide benefits across boundaries c. Leverage existing collaboratives (NSV IRWM, NCWA etc.)	• Neighbor-to-neighbor • Coordination groups • Regional: NSV IRWM, NCWA Groundwater Task Force	• *Ongoing (GSP Development)* • *Near-term (5-year update)* • *Long-term (GSP implementation).*
4. Coordinated communication and outreach a. Coordinate and collaborate on regional-scale public engagement and communication strategies that promote awareness on groundwater sustainability, enhance public trust, and maintain institutional knowledge b. Maintain list of GSP/subbasin staff contacts and websites	• Regional: NSV IRWM and NCWA Groundwater Task Force	• *Ongoing (GSP Development)* • *Near-term (5-year update)* • *Long-term (GSP implementation)*
5. Issue-resolution process a. Establish and follow an agreed-upon process for identifying and resolving conflicts between GSAs by the first five-year update [Refer to Appendix D for more details and discussion prompts on issue resolution processes]	• Neighbor-to-neighbor • Coordination groups	• *Near-term (5-year update)* • *Long-term (GSP implementation).*



4.1. Inter-basin Coordination Groups

Inter-basin coordination efforts, as outlined in the pillars above, would require resources and technical support. Subbasin staff recommend organizing inter-basin coordination priorities by specific subbasin boundaries. One suggested approach identifies specific "Coordination Groups" (see Figure 3 and list below). Some of these groups are pairs and others include multiple subbasins around a river boundary.

1. ***Feather River Corridor***- *Butte, Wyandotte Creek, North Yuba, Sutter*
2. ***North Sacramento River Corridor***- *Antelope, Los Molinos, Red Bluff, Corning, Vina, Butte, Colusa*
3. ***South Sacramento Corridor***- *Colusa, Sutter, Yolo*

Neighbor to Neighbor, examples:

4. ***Stony Creek***- *Corning, Colusa*
5. ***Thomes Creek***- *Red Bluff, Corning*
6. ***Butte/Vina***- *Vina, Butte*

5. Conclusion and Next Steps

In sum, this report outlines a framework for inter-basin coordination for sustainable groundwater management in the Northern Sacramento Valley. The inter-basin coordination framework describes a menu of options for ongoing communication and collaboration around substantive issues over the twenty-year implementation of SGMA.

The pillars and other content from this report could be used by GSAs to support GSP development and implementation in a number of ways. This inter-basin coordination report could be included as an Appendix to the GSP and could be updated on a yearly basis. Individual subbasins can incorporate sections of the report into the body of the GSP, depending upon specific boundary conditions at adjoining subbasins. Finally, subbasins could draw on the inter-basin coordination framework if they would like to consider entering into one or more voluntary inter-basin agreements during GSP implementation.

The content of the report is the result of staff recommendations resulting from regional inter-basin coordination staff meetings. Staff will present the framework as a supporting document to guide and inform discussions with the GSA Boards and other existing public venues, such as advisory committees or groundwater commissions. GSAs in turn will discuss the menu of options for inter-basin coordination outlined in this report to determine their priorities and desired approach to draw on the inter-basin coordination framework in their individual GSPs. Lastly, Subbasin staff will come together to share input received and determinations from their respective GSAs.

Subbasin staff acknowledge that while this report builds upon a long-standing history of regional collaboration, this is just the beginning of inter-basin coordination efforts under SGMA. Therefore, this framework and inter-basin coordination activities will be continually refined throughout GSP implementation.

Appendices

Appendix A: GSP Emergency Regulations, Article 8: Interagency Agreements §357.2

§ 357.2. Inter-basin Agreements (access here)

Two or more Agencies may enter into an agreement to establish compatible sustainability goals and understanding regarding fundamental elements of the Plans of each Agency as they relate to sustainable groundwater management. Inter-basin agreements may be included in the Plan to support a finding that implementation of the Plan will not adversely affect an adjacent basin's ability to implement its Plan or impede the ability to achieve its sustainability goal. Inter-basin agreements should facilitate the exchange of technical information between Agencies and include a process to resolve disputes concerning the interpretation of that information. Inter-basin agreements may include any information the participating Agencies deem appropriate, such as the following:

(a) General information:
  (1) Identity of each basin participating in and covered by the terms of the agreement.
  (2) A list of the Agencies or other public agencies or other entities with groundwater management responsibilities in each basin.
  (3) A list of the Plans, Alternatives, or adjudicated areas in each basin.

(b) Technical information:
  (1) An estimate of **groundwater flow across basin boundaries**, including consistent and coordinated data, methods, and assumptions.
  (2) An estimate of **stream-aquifer interactions** at boundaries.
  (3) A **common understanding of the geology and hydrology** of the basins **and the hydraulic connectivity** as it applies to the Agency's determination of groundwater flow across basin boundaries and description of the different assumptions utilized by different Plans and how the Agencies reconciled those differences.
  (4) **Sustainable management criteria and a monitoring network** that would confirm that no adverse impacts result from the implementation of the Plans of any party to the agreement. If minimum thresholds or measurable objectives differ substantially between basins, the agreement should specify how the Agencies will reconcile those differences and manage the basins to avoid undesirable results. The Agreement should identify the differences that the parties consider significant and include a plan and schedule to reduce uncertainties to collectively resolve those uncertainties and differences.

(c) A description of the **process for identifying and resolving conflicts** between Agencies that are parties to the agreement.

(d) Inter-basin agreements submitted to the Department shall be posted on the Department's website.

Note: Authority cited: Section 10733.2, Water Code.
Reference: Sections 10727.2, 10733, and 10733.2, Water Code.

Appendix B: Inter-basin Coordination Fact Sheet

Northern Sacramento Valley | Sustainable Groundwater Management Act

Regional Coordination Between Subbasins

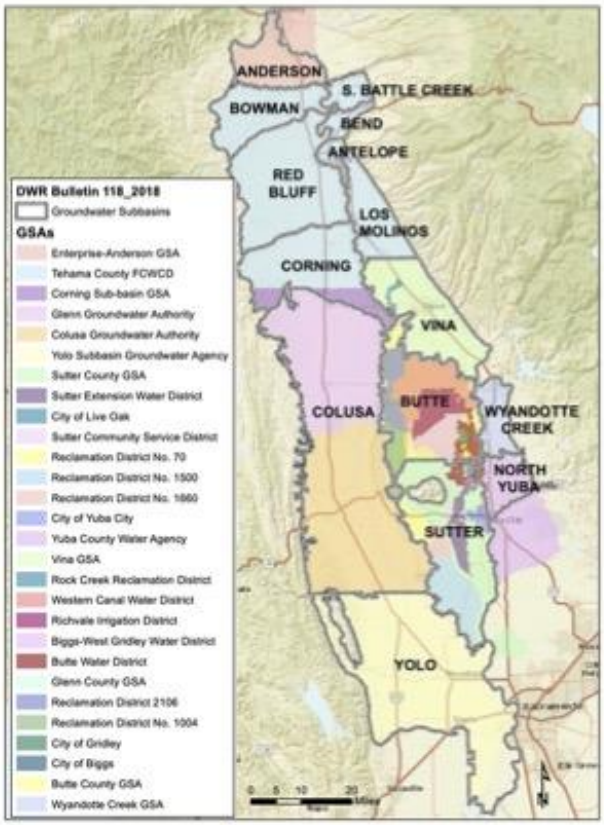
Antelope | Bowman | Butte | Colusa | Corning | Los Molinos | Red Bluff | Sutter | Vina | Wyandotte Creek | Yolo

Sustainable Groundwater Management Act

What is SGMA? California enacted the Sustainable Groundwater Management Act (SGMA) in 2014 to better manage groundwater over the long term. Sustainability is achieved by avoiding significant and unreasonable conditions for the six "sustainability indicators."

- Lowering of Groundwater Levels
- Reduction of Groundwater Storage
- Land Subsidence
- Surface Water Depletion
- Water Quality Degradation
- Sea Water Intrusion

Why is regional coordination important? In the Sacramento Valley, inter-basin coordination is critical as Groundwater Sustainability Agencies (GSA) develop their Groundwater Sustainability Plans (GSP). Since groundwater subbasins in the Northern Sacramento Valley (NSV) are hydrologically interconnected, water management decisions and actions in one subbasin (e.g. groundwater pumping) and processes like climate change could change aquifer conditions and affect flows to other subbasins. Understanding and accounting for these processes is key to achieve sustainability in all subbasins.



Who is involved in ongoing efforts?

Collaborative efforts have begun among representatives from 11 subbasins (Antelope, Bowman, Butte, Colusa, Corning, Los Molinos, Red Bluff, Sutter, Vina, Wyandotte Creek, Yolo), with facilitation support from the Consensus Building Institute. While efforts have focused on the subbasins mentioned, coordination will occur, as warranted, with other neighboring subbasins (Anderson and North Yuba).

What are the coordination priorities?

Groundwater Sustainability Agencies are working together to establish a foundation for open and transparent inter-basin coordination and communication by developing tools to:

- SHARE & COMPILE INFORMATION IN A CONSISTENT WAY
- OUTLINE A PROCESS TO IDENTIFY & RESOLVE ISSUES
- DOCUMENT COORDINATION EFFORTS

Memorandum of Understanding
Four County (Butte, Colusa, Glenn, and Tehama Counties)
Regional Water Resource Coordination, Collaboration, and Communication

Memorandum of Understanding
Four County (Butte, Colusa, Glenn, and Tehama Counties) Regional Water Resource Coordination, Collaboration, and Communication

1. BACKGROUND
The counties of Butte, Colusa, Glenn, and Tehama share common surface water and groundwater resources. Based on these common resources, local water resource managers understand that regular coordination, collaboration, and communication can result in an improved water resource understanding at both the county and regional level.

2. PURPOSE
The purpose of this document is to establish the mutual understandings of the four counties with respect to their voluntary joint efforts toward regional coordination, collaboration, and communication.

3. GOALS
The goals of the Four County Memorandum of Understanding (MOU) are:

2.1. To foster coordination, collaboration and communication between the four counties on water-related issues, to achieve greater efficiencies, and enhance public services.

2.2. To provide a framework for the management and disbursement of funding associated with activities pursued jointly under this MOU.

2.3. To improve competitiveness for State and Federal grant funding.

4. DEFINITIONS
4.1. Four County. Participants including the counties of Butte, Colusa, Glenn, and Tehama, with representation by the following:

- Butte County: Department of Water and Resource Conservation
- Colusa County: Department of Planning and Building
- Glenn County: Department of Agriculture
- Tehama County: Flood Control and Water Conservation District

4.2. Project Manager. A project manager will be determined by the Counties signatory to this MOU for any given project regardless of funding source to meet the goals set forth in this MOU.

5. MUTUAL UNDERSTANDINGS
5.1. Participation. Signatories to this MOU constitute the current participants. Participation is strictly on a voluntary basis and may be

terminated at any time without recourse. Neighboring counties who share water resources common to the participating counties and who are engaged in similar activities will be invited to be signatory to this MOU. Signatories aspire to work collaboratively with other regional programs and technical outreach efforts.

5.2. Activities. Efforts pursued under this agreement will remain consistent with and will not exceed the current authority for any individual participating county. Efforts will include the study and investigation of water resources common to participants, monitoring and reporting, information dissemination and sharing between counties and with other county departments, public outreach and education, and other activities at the agreement and direction of individual county governing bodies.

5.3. County Funding. Counties are not required to commit funding associated with activities completed under this MOU. It is understood that activities under this MOU may result in the more efficient use of existing and future department funding resulting from improved collaboration and coordination.

5.4. External Funding. Signatories will work collaboratively in pursuit of external funding associated with common interest activities based on voluntary participation and agreement. When required, a mutually agreed upon County representative will serve as the Project Manager for activities completed under a contract with an external funding source. Existing county contracting mechanisms will be utilized where available for contractual and invoicing purposes between participating counties. Nothing in this MOU precludes individual counties from the individual pursuit, contracting and completion of work from an externally funded source regardless of a real or perceived regional interest.

5.5. Decision-making. Consensus will be sought when the need for a decision arises.

5.6. Non-binding nature. This document and participation under this MOU are nonbinding, and in no way suggest that a county may not continue its own activities as each county is expected to continue its own policies and procedures and undertake efforts to secure project funding from any source. A county may withdraw from participation at any time.

5.7. Termination. Because the MOU will require periodic review and updating for use into the future, it is envisioned that the joint efforts of those involved will be ongoing in maintaining a living document. Thus this document will remain as a reflection of the understandings of the participants. Individual signatories of this MOU may terminate their involvement at any time with no recourse.

6. SIGNATORIES TO THE MEMORANDUM OF UNDERSTANDING

We, the undersigned representatives of our respective counties, acknowledge the above as our understanding of how the Four County Coordination, Collaboration, and Communication MOU will be implemented.

8. Approval of Four-County Regional Water Resource Coordination- MOU: Ernie Ohlin reviewed that in August 2004, the Board authorized staff to participate in the four county water effort. The MOU attached is allowing all counties to participate together in water resource collaboration and communication. This non-binding voluntary MOU recognizes coordination among Butte, Colusa, Glenn and Tehama County.

Roger Sherrill encouraged the four-county groups to participate and noted in Item 5.1 "Participation" is strictly voluntary. Shasta County provides a major part of the recharge for the northern part of the Sacramento Valley and to move forward could only make for a stronger overall group.

Mark Black, Ag Commissioner for Glenn County, added this will be presented to Glenn County next Tuesday for support. Discussions with Sutter and Yuba County brings interest and they are awaiting the outcome of the four counties. This is a good collaborative effort, giving us strength of possible capturing of funding.

Motion by Director Warner to approve the MOU for signature.

Director Willard questioned if this has been reviewed by County Counsel. Upon his approval, signature will be completed.

Motion revised by Director Warner to approve the MOU for signature by the Chair upon review of County Counsel. Second by Director Avilla and carried by those present 3-0 with 2 absent.

Ayes: Directors':, Charles Willard; Ron Warner; Gregg Avilla

FOUR COUNTY MEMORANDUM OF UNDERSTANDING
ADDENDUM ONE:
Statement of Principles Regarding Water Related Programs and Projects

In recognition that certain activities related to water resources do not recognize jurisdictional boundaries and require regional solutions, the parties identified in the Four County Memorandum of Understanding hereby agree to adhere to the following Statement of Principles Regarding Water Related Programs and Projects:

1. Programs and projects related to groundwater level and water quality monitoring shall be conducted in a cooperative manner and related data shall be shared between the participants to prevent negative impacts to our constituents.
2. Environmental documents associated with water projects and programs will automatically be circulated to all four counties for review and comment.
3. Incidents of abnormal water level or water quality readings will be immediately communicated to all participating counties resulting in a collaborative review and dissemination of related information.
4. Project and program related information will be disseminated on a regional basis through the independent county websites, augmented by regional public outreach meetings.
5. The parties will work cooperatively to acquire grant funding to conduct aquifer studies that further identify the linkages of the common groundwater resources.
6. Efforts pursued under this agreement will remain consistent with and will not exceed the current authority of any participating county.

We, the undersigned representatives of our respective counties, agree to adhere to the conditions of **Addendum One to the Four County MOU: Statement of Principles Regarding Water Related Programs and Projects.** The original MOU was signed by the Counties of Butte, Glenn, Colusa and Tehama in 2006.

FOUR COUNTY MEMORANDUM OF UNDERSTANDING:
ADDENDUM THREE
Expression of a Commitment to Begin An
Integrated Regional Water Management Planning Process
Within the Counties of Butte, Colusa, Glenn, Tehama and Sutter

Through adoption of this addendum, the signatories agree to begin a regional water management planning process pursuant to the Four County MOU, geographically covering the area of Butte, Colusa, Glenn, Tehama and Sutter Counties. The planning process shall utilize and incorporate existing plans and processes. The California legislature has recently adopted new criteria associated with the Integrated Regional Water Management Planning process. This new legislative criteria requires that acceptance and approval of the composition of all Integrated Regional Water Management Planning Areas be completed prior to accepting public funding associated with IRWMP grant funds. All IRWMP planning Regions and Plans must comply with the requirements as set forth in the Final Regional Acceptance Process Program Guidelines.

We, the undersigned as representative of our respective counties, agree to adhere to the conditions of **The Four County Memorandum of Understanding; Addendum One to the Four County MOU: Statement of Principles Regarding Water Related Programs and Projects; Addendum Two: Adding Sutter County to the Four County MOU; Addendum Three: Expression of a Commitment to Begin An Integrated Regional Water Management Planning Process Within the Counties of Butte, Colusa, Glenn, Tehama and Sutter.**

FOUR COUNTY MEMORANDUM OF UNDERSTANDING:
ADDENDUM THREE
Expression of a Commitment to Begin An
Integrated Regional Water Management Planning Process
Within the Counties of Butte, Colusa, Glenn, Tehama and Sutter

Through adoption of this addendum, the signatories agree to begin a regional water management planning process pursuant to the Four County MOU and geographically covering the area of Butte, Colusa, Glenn Tehama and Sutter Counties. The planning process shall utilize and incorporate existing plans and processes. The California legislature has recently adopted new criteria associated with the Integrated Regional Water Management Planning process. This new legislative criteria requires that acceptance and approval of the composition of all Integrated Regional Water Management Planning Areas be completed prior to accepting public funding associated with IRWMP grant funds. All IRWMP planning Regions and Plans must comply with the requirements as set forth in the Final Regional Acceptance Process Program Guidelines.

We, the undersigned as representative of our respective counties, agree to adhere to the conditions of **The Four County Memorandum of Understanding; Addendum One to the Four County MOU: Statement of Principles Regarding Water Related Programs and Projects; Addendum Two: Adding Sutter County to the Four County MOU; Addendum Three: Expression of a Commitment to Begin An Integrated Regional Water Management Planning Process Within the Counties of Butte, Colusa, Glenn, Tehama and Sutter.**

Chair, Butte County Board of Supervisors	Date	County Counsel Approved As to Form	Date
Chair, Glenn County Board of Supervisors	5/21/09 Date	County Counsel Approved As to Form	Date
Chair, Tehama County Board of Supervisors	Date	County Counsel Approved As to Form	Date

Chair, Colusa County Board of Supervisors	Date	County Counsel Approved As to Form	Date
Chair, Sutter County Board of Supervisors	Date	County Counsel Approved as to Form	4/14/09 Date

FOUR COUNTY MEMORANDUM OF UNDERSTANDING:
ADDENDUM THREE
Expression of a Commitment to Begin An
Integrated Regional Water Management Planning Process
Within the Counties of Butte, Colusa, Glenn, Tehama and Sutter

Through adoption of this addendum, the signatories agree to begin a regional water management planning process pursuant to the Four County MOU and geographically covering the area of Butte, Colusa, Glenn, Tehama and Sutter Counties. The planning process shall utilize and incorporate existing plans and processes. The California legislature has recently adopted new criteria associated with the Integrated Regional Water Management Planning process. This new legislative criteria requires that acceptance and approval of the composition of all Integrated Regional Water Management Planning Areas be completed prior to accepting public funding associated with IRWMP grant funds. All IRWMP planning Regions and Plans must comply with the requirements as set forth in the Final Regional Acceptance Process Program Guidelines.

We, the undersigned as representative of our respective counties, agree to adhere to the conditions of **The Four County Memorandum of Understanding; Addendum One to the Four County MOU: Statement of Principles Regarding Water Related Programs and Projects; Addendum Two: Adding Sutter County to the Four County MOU; Addendum Three: Expression of a Commitment to Begin An Integrated Regional Water Management Planning Process Within the Counties of Butte, Colusa, Glenn, Tehama and Sutter.**

Chair, Butte County Board of Supervisors	Date	County Counsel Approved As to Form	Date
Chair, Glenn County Board of Supervisors	Date	County Counsel Approved As to Form	Date
George Lowell Chair, Tehama County Flood Control & Water Conservation District	6-23-09 Date	County Counsel Approved As to Form	Date

FOUR COUNTY MEMORANDUM OF UNDERSTANDING:
ADDENDUM FOUR
Expression of a Commitment to Begin An
Integrated Regional Water Management Planning Process
Within the Counties of Butte, Colusa, Glenn, Tehama, Sutter and Shasta

Through adoption of this addendum, the signatories agree:

1. Shasta County shall join the parties involved in the original Four County Memorandum of Understanding (MOU) and Addendum Two;

2. Signatories to the MOU and its addenda shall be called the Northern Sacramento Valley Integrated Regional Water Management Planning Group; and,

3. Begin a regional water management planning process pursuant to the Four County MOU, geographically covering the area of Butte, Colusa, Glenn, Tehama, Sutter and Shasta Counties. The planning process shall utilize and incorporate existing plans and processes. The California legislature has recently adopted new criteria associated with the Integrated Regional Water Management Planning process. This new legislative criteria requires that acceptance and approval of the composition of all Integrated Regional Water Management Planning Areas be completed prior to accepting public funding associated with IRWMP grant funds. All IRWMP planning Regions and Plans must comply with the requirements as set forth in the Final Regional Acceptance Process Program Guidelines.

4. The signatories to the MOU and its addenda reaffirm the provisions of section 5.6 of the MOU that the MOU and its addenda and participation under the MOU and its addenda are nonbinding.

We, the undersigned as representative of our respective counties, agree to adhere to the conditions of **The Four County Memorandum of Understanding; Addendum One to the Four County MOU: Statement of Principles Regarding Water Related Programs and Projects; Addendum Two: Adding Sutter County to the Four County MOU; Addendum Three: Expression of a Commitment to Begin An Integrated Regional Water Management Planning Process Within the Counties of Butte, Colusa, Glenn, Tehama and Sutter; Addendum Four: Expression of a Commitment to Begin An Integrated Regional Water Management Planning Process Within the Counties of Butte, Colusa, Glenn, Tehama, Sutter and Shasta.**

Appendix D: Issue Resolution Process for Discussion Purposes

This document aims to guide discussions and provide pertinent information as subbasins consider inclusion of an issue resolution process in the Northern Sacramento Valley inter-basin coordination framework. These discussions will take place in the period leading up to the first five-year GSP update.

Discussion Prompts

1. *What are potential benefits/challenges or concerns of including an issue/dispute resolution process in the inter-basin coordination framework?*
2. *What are shared expectations between and among subbasins?*
3. *What are the GSAs preferences for addressing conflicts if/when they arise?*

Background

The Groundwater Sustainability Plan Regulations in Article 8 recommend including a "description of a process for identifying and resolving conflicts between Agencies" as a part of inter-basin coordination (Sections 10727.2, 10733, and 10733.2, Water Code). A recent study by Tara Moran, Janet Martinez, and William Blomquist, part of Stanford University's Water in the West found that the ability of interagency coordination "to solve complex challenges will be contingent on the ability of these organizations to effectively prevent and manage conflicts before they arise and to resolve these conflicts equitably and efficiently when they do." (Moran, Martinez, and Blomquist, 2021). Further, given how likely it is for disagreements at a local level to occur during SGMA implementation, the study suggests investing in establishing issue resolution processes before disagreements arise. Meanwhile, deferring their development could complicate the resolution process in times of conflict. Given these recommendations, consider the following questions for reflection and discussion.

Purposes of issue resolution processes

There are many options to identify and resolve issues that involve different parties, goals/objectives, and resources. Ideally, issue resolution processes are thoughtfully designed and tailored to specific contexts. **The broader goal for such a process can be to meet the agencies' long-term needs, considering local dynamics, desired outcomes, and expected uses**. Goals can include keeping things simple and efficient, maintaining relationships, ensuring quality of the process, fostering participation and community engagement, etc.

The figure below shows different types of dispute resolution processes. In some cases, agencies draft clauses that outline a tiered approach. They often begin with negotiation, which gives the parties control over the process and outcomes. Then, mediation, which brings in a neutral third-party (mediator) to facilitate the discussion and help parties work towards resolving issues. Often, negotiation and mediation lead to "non-binding" outcomes, non-enforceable by courts. Parties could opt to move towards arbitration or litigation, which are controlled by a third party (arbitrator or judge/jury) and can lead to binding and non-binding outcomes (Moran, Martinez, and Blomquist, 2019).

Figure 2. The spectrum of dispute resolution process. Modified from Amsler et al. (2020a).

Negotiation	Mediation	Arbitration	Trial
• No third party	• Third part (mediator)	• Third party (arbitrators)	• Third party (judge/jury)
• Non-binding	• Non-binding	• Non-binding or binding	• Binding

From Moran, Martinez, and Blomquist, 2019

Examples

1. Example from Moran, Martinez, and Blomquist, 2019

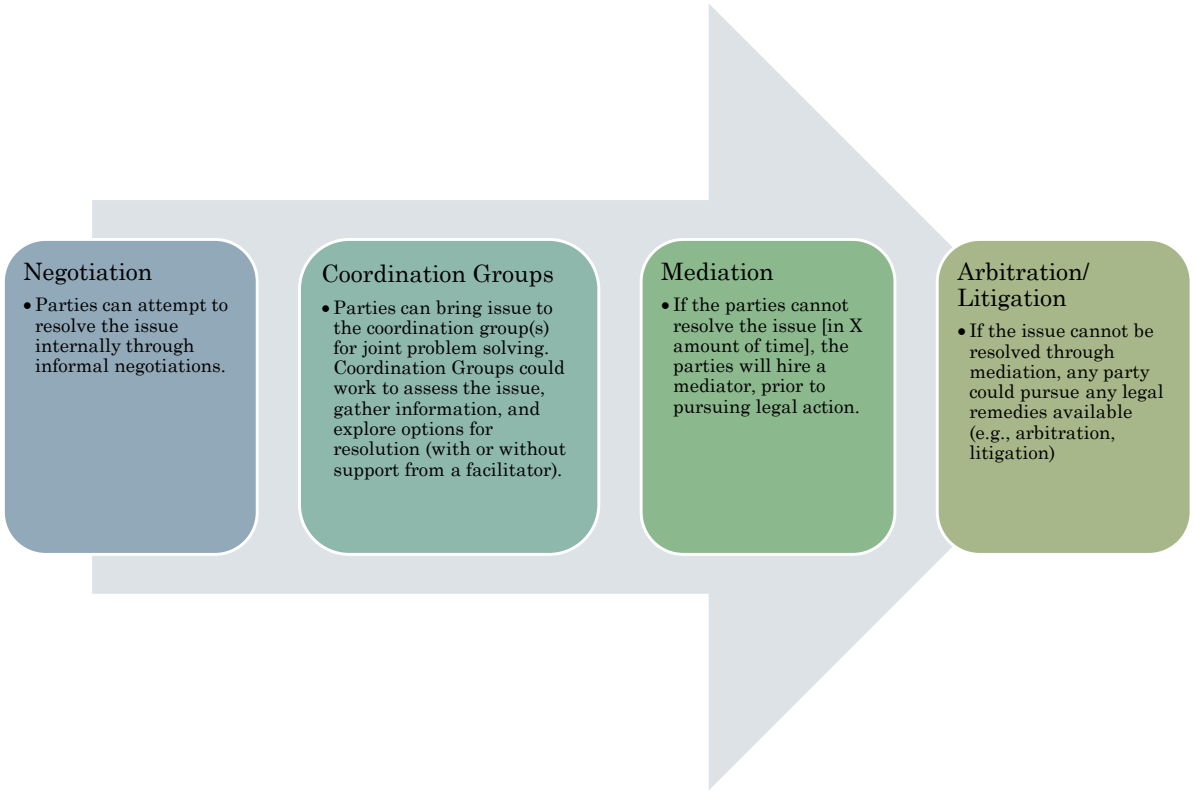
Box 2. A Draft Dispute Resolution Clause.

The blue text notes indicate how each of the preceding five questions are incorporated into the dispute resolution language.

In the event that any dispute [Q1: Provides instruction on what disputes can be addressed. Additional process goals, while not explicit should be subject to discussion.] arises among the Members relating to (i) this Agreement, (ii) the rights and obligations arising from this Agreement, (iii) a Member proposing to withdraw from membership in the Agency, or (iv) a Member proposing to initiate litigation within the Basin or the management of the Basin, the aggrieved Member or Members proposing to withdraw from membership shall provide written notice to the other Members of the controversy or proposal to withdraw from membership [Q2: Provides instruction on who can initiate and participate in the process.]. Within forty-five (45) days after such written notice, the Members shall attempt in good faith to resolve the controversy through informal negotiation [Q3: Describes a series of processes for dispute resolution, beginning with negotiation. Also includes a timeline for process stages.]. If the Members cannot agree upon a resolution of the controversy within forty-five (45) days from the providing of written notice specified above, the dispute shall be submitted to mediation prior to commencement of any legal action or prior to withdrawal of a Member proposing to withdraw from membership. The mediation shall be no less than a full day (unless agreed otherwise among the Members) and the cost of mediation shall be paid in equal proportion among the Members [Q4: Provides instruction on who will pay for dispute resolution processes.]. The mediator shall be either voluntarily agreed to or appointed by the Superior Court upon a suit and motion for appointment of an impartial mediator [Q3a: Provides a clear process for choosing an impartial mediator.]. Upon completion of mediation, if the controversy has not been resolved, any Member may exercise all rights to bring a legal action relating to the controversy or withdraw from membership as otherwise authorized pursuant to this Agreement. The Agency may, at its discretion, participate in mediation upon request by a stakeholder [to be defined by the parties to the Agreement] concerning a dispute alleged by the stakeholder concerning the management of the Basin or rights to extract groundwater from the Basin, with the terms of such mediation to be determined in the sole discretion of the Member Directors [Q2: Allows third-party participation in the dispute resolution process].

Note: This above dispute resolution clause is not intended to serve as an endorsement or illustration of effective practice.

2. Example from Butte Subbasin Cooperation Agreement



Note: This example doesn't provide much specificity. However, acknowledges shared intent to resolve disputes.

ARTICLE 9. DECISION-MAKING AND DISPUTE RESOLUTION

9.1. Decision-making Authority. Topics where the Members desire coordinated decision-making will be considered by the Advisory Board, and the Member Directors will strive for unanimous recommendations that will be presented to each Member's governing body for consideration. Such topics include, but are not limited to, development and implementation of the GSP, and associated financial arrangements. When unable to reach unanimous recommendations, the Advisory Board will outline the areas in which it does not agree, providing some explanation to inform the respective GSAs' governing bodies. Despite the recommendations of the Advisory Board, ultimate decision-making authority for topics considered by the Advisory Board resides with each Member's governing body.

9.2. Dispute Resolution. It is the desire of Members to informally resolve all disputes and controversies related to this Agreement, whenever possible, at the least possible level of formality and cost. If a dispute occurs, the disputing Members shall meet and confer in an attempt to resolve the matter. If informal resolution cannot be achieved, the matter will be referred to the Advisory Board for resolution. The Advisory Board may engage the services of a trained mediator or resort to all available legal and equitable remedies to resolve disputes.

Possible Process in the Northern Sacramento Valley

Worksheet: Key Questions and Considerations for Issue Resolution Process

The questions below could be used to guide the development of a specific issue resolution process in the context of inter-basin coordination in the Northern Sacramento Valley by the first 5-year GSP update. These questions could help to clarify the level of specificity that subbasins would find beneficial and mutually agreeable when/if conflict occurs.

Adapted from Moran, Martinez, and Blomquist, 2019

1) What are the process goals? a) Consider what disputes the process aims to address – all disputes arising at basin boundaries or only a subset? b) Consider inclusivity and transparency of the process, cost efficiency for parties and the GSA(s), timeframes, and other factors important to your agency(ies). c) Other potential objectives include dispute prevention, enhanced relationships, procedural and substantive fairness, legal compliance, durability of resolution and organizational improvement.	
2) Who can initiate and participate in the dispute resolution process? a) Consider what parties can initiate the dispute resolution process – is it only parties to the agreement or can external parties invoke it? There are pros and cons to both choices, so discussing this in advance will ensure thoughtful consideration.	
3) What processes are used to make decisions related to dispute resolution and what information is necessary? a) What is the process for selecting a mediator, facilitator, lawyer or other impartial party? b) Consider including a range of processes beginning with internal negotiations and escalating based on clear timelines.	
4) Who pays for the dispute resolution process? a) Consider who will pay for the mediator, facilitator, lawyer or other impartial party. Will it be paid for by the disputing parties, the GSA(s) or through a state-funded program? b) How could you assess whether the outcome of the dispute resolution process was successful?

(THIS PAGE LEFT BLANK INTENTIONALLY)

The Sustainable Groundwater Management Act

Key elements of the law, early implementation steps and expected benefits for Colusa County

Presentation Outline

I. SGMA Background

II. Preparing to Advance SGMA Locally

III. Recent SGMA Activities

IV. Early Implementation in Colusa County

V. Next Steps

SGMA Background

Comprehensive statewide legislation that creates a framework for sustainable groundwater management

- Became law on January 1, 2015
- All medium and high priority basins managed sustainably
- Emphasis on local control with State oversight
- Groundwater Sustainability Agencies
- Groundwater Sustainability Plans

SGMA Background

SGMA affects all citizens of Colusa County

- Offers beneficial opportunities to achieve sustainable groundwater conditions
- Supports agriculture, industry and domestic/public uses
- Requires residents to work together and address our common interest in groundwater resources
- The County supports a collaborative approach to implement SGMA

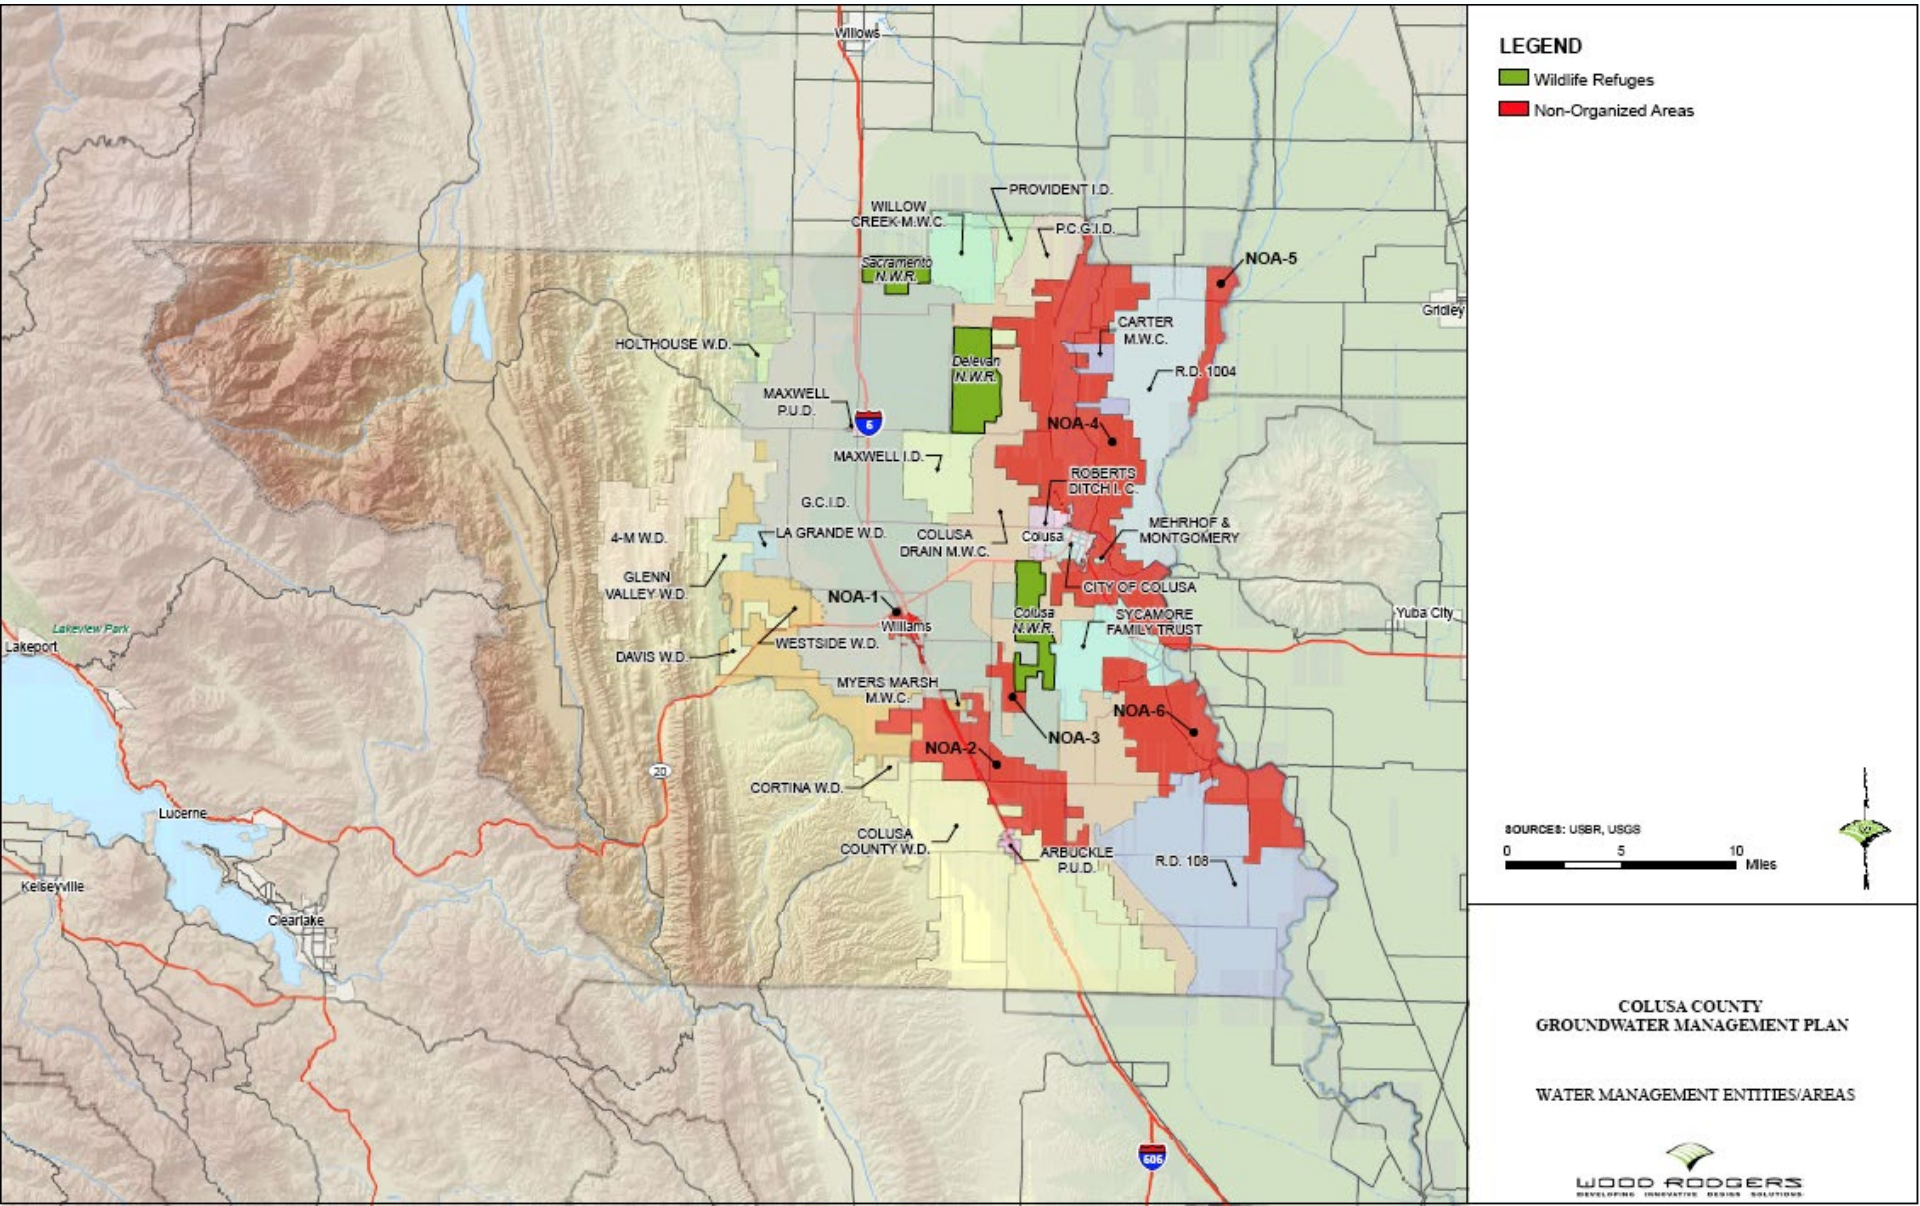
SGMA Background

How does SGMA define sustainability?

Sustainability: Manage groundwater to prevent undesirable results (significant and unreasonable):

- Chronic lowering of groundwater levels
- Reduction of groundwater storage
- Seawater intrusion
- Degraded water quality
- Land subsidence
- Depletions of interconnected surface waters

SGMA Background



Formation of Groundwater Sustainability Agencies (GSAs)

- SGMA requires formation of GSAs to implement SGMA at the local level

- Public agencies with land or water use authority are eligible to become GSAs
  - Counties, cities, water agencies, irrigation districts, PUDs
  - GSA may include one or more local public agencies

- May include a single GSA or multiple GSAs per basin
  - Multiple GSAs must coordinate planning efforts

Colusa Water Management Entities/Areas

SGMA Background

GSA Roles and Responsibilities – *At their discretion, GSAs may…*

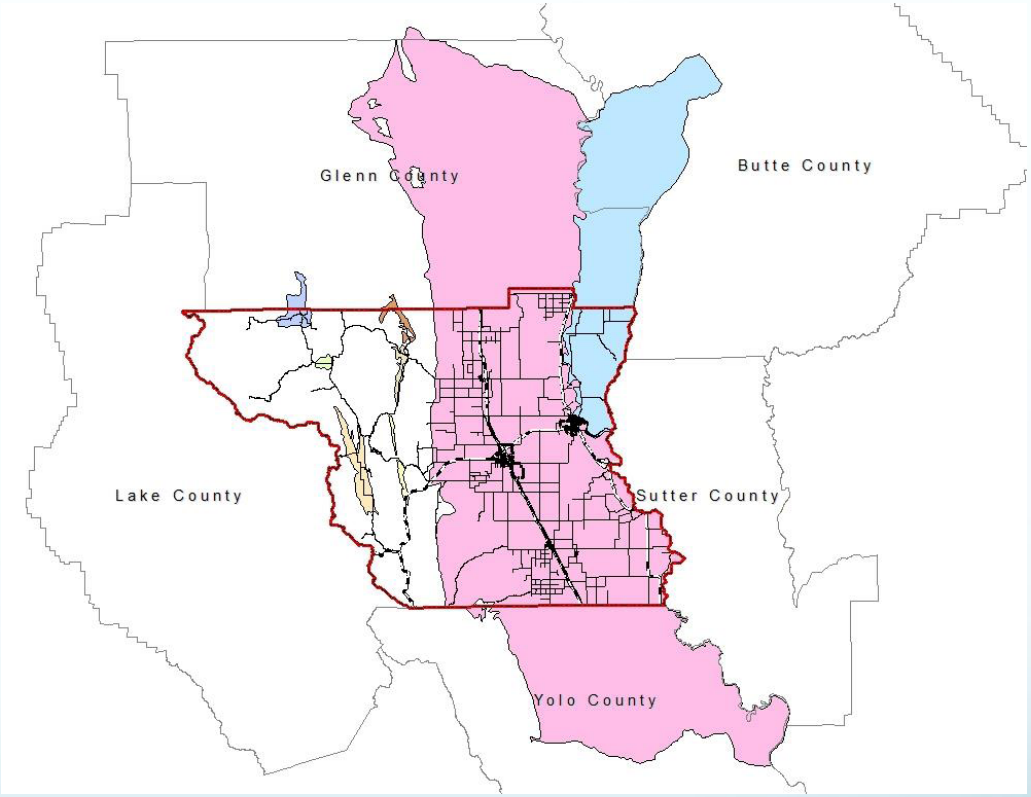
- Adopt rules, regulations and ordinances
- Conduct groundwater studies / investigations
- Register and monitor wells
- Require reports of groundwater extraction
- Implement capital projects to meet goals
- Assess fees to cover management costs

SGMA Background

GSA Roles and Responsibilities – *Interested parties must be included in SGMA planning:*

- All Groundwater Users
- Holders of Overlying Rights (agriculture and domestic)
- Municipal Well Operators and Public Water Systems
- Tribes
- County
- Planning Departments / Land Use
- Local Landowners
- Disadvantaged Communities
- Business
- Federal Government
- Environmental Uses
- Surface Water Users (*if connection between surface and ground water*)

SGMA Background



How are domestic well owners affected by SGMA?

- Referred to in SGMA as “de minimis” users IF…
  - Use 2 acre-feet per year or less for domestic purposes
- De minimis users are subject to SGMA, depending on local needs
  - GSAs will decide how de minimis users are addressed
  - GSAs can decide to exclude or include
  - GSAs can decide on fees but *cannot* require metering
  - May be subject to reporting / fees to State if intervention occurs
- Domestic wells can also be regulated by authorities (counties, water districts, etc.) outside scope of SGMA

SGMA Background

"White Areas"

- County is presumed to be the GSA over areas that are not covered by another GSA-eligible agency
- If the County opts out, the State will manage those areas

SGMA Background

Development of Groundwater Sustainability Plans (GSPs)

- GSAs are responsible to develop GSPs
- Every high and medium priority groundwater basin must be covered by a GSP or GSPs
- Option of a single GSP covering the entire basin, or a combination of GSPs, developed by multiple GSAs, covering the entire basin
- Multiple GSPs must coordinate, utilize the same data / methodologies, and have a coordination agreement

SGMA Background

Key Implementation Milestones

- June 1, 2016 – GSP regulations
- **June 30, 2017 – GSAs formed**
- July 1, 2017 – Counties affirm GSA status
- January 31, 2020 – GSPs complete for critically over-drafted basins
- **January 31, 2022 – All other GSPs complete**

SGMA Background

DWR and State Water Board Roles

- DWR:
  - Develop Basin Boundary and GSP regulations
  - Review GSPs, decide on adequacy, implementation

- State Water Board:
  - Implement State intervention
  - Reporting
  - Assess fees
  - Designate Probationary Basins
  - Develop Interim Plans, implement those Plans

SGMA Background

State Water Board Intervention – In all triggering events, intervention is the result of failure by locals to create a GSA(s) and/or adopt and implement a GSP.

- Data
  - Same data needed by a GSA, but now managed by State
  - Higher frequency (monthly minimum reporting)
- Fees
  - Fees associated with reporting
  - Board recovers cost for all intervention-related activities (monitoring plans, well construction, facilitation, technical studies, models)
- Interim plans
  - Pumping restrictions are most straight-forward
  - State developed physical solutions are unlikely

Initial comments and/or questions

Preparing to Advance SGMA Locally

What has the County done to advance SGMA locally?

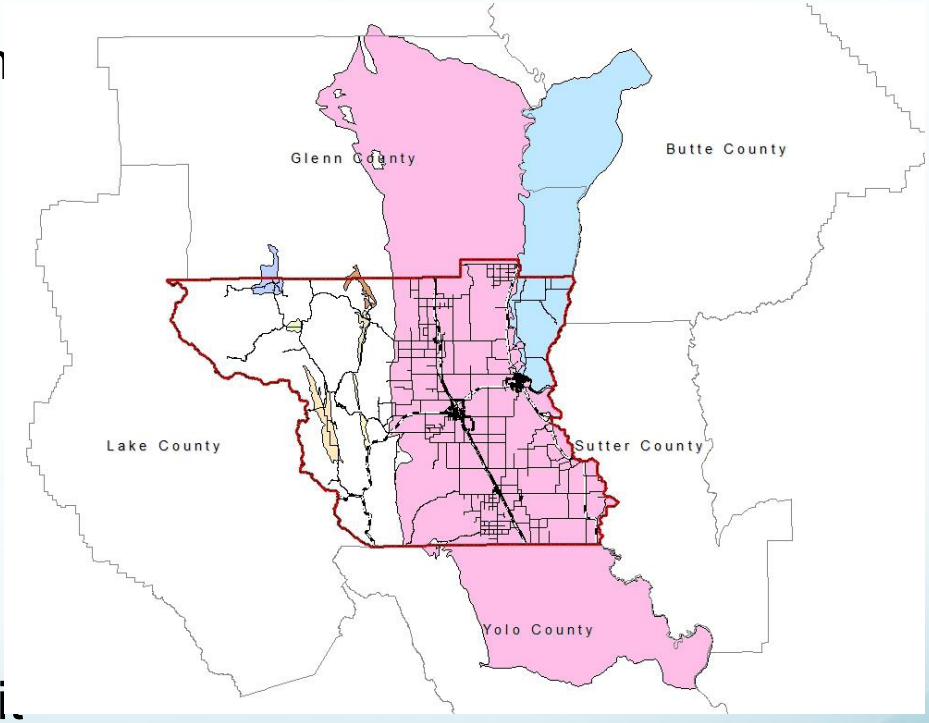
- Dedicated staff resources
- Fostered early communication with GSA filers, many of whom are here tonight to join the conversation
- Maintained communication with surrounding counties
- Received grant for impartial facilitation services from the Center for Collaborative Policy
- Initiated a local groundwater assessment
- Pursued DWR grant to support local planning efforts
- Committed to sharing resources with local partners

Recent SGMA Activities

GSA Notifications in Colusa County

- Provident Irrigation District and Princeton-Codora-Glenn Irrigation District
- Glenn-Colusa Irrigation District
- Colusa County Water District
- Reclamation District 1004
- Reclamation District 108
- County of Colusa

Recent SGMA Activities



SB 13 Amendment – Interpreted by DWR as retroactive

- Removed the Notice of Intent to be a GSA
- Allows a mutual water company to be part of a GSA through a legal agreement
- **Prohibits overlap of service area boundaries**
- **Prohibits local agencies from imposing fees or reg. requirements on entities outside their boundaries**
- Requires DWR to post all “complete” notices within 15 days of receipt

Recent SGMA Activities

Basin Boundary Modifications

- Existing groundwater basins or subasins defined in DWR's Bulletin 118
- Local agencies may request boundary modifications
- May include scientific or jurisdictional modifications
- Starting January 1, 2016: 90 day window for local agencies to submi requests for DWR consideration

Recent SGMA Activities

Groundwater Sustainability Plan Regulations

- By June 1, 2016 DWR shall adopt regulations for:
  - Evaluating GSPs
  - Implementing GSPs
  - Coordination agreements

- The regulations shall identify:
  - Required GSP components and additional elements
  - Coordination of multiple GSPs in a basin
  - Additional information that assists GSAs

Proposed Process in Colusa County

Background Preparation

- Review background materials
- Conduct initial interviews with eligible GSA agencies
- Prepare 90-Day Plan
- Prepare initial facilitation strategy

Proposed Process in Colusa County

Outreach and Education

- Prepare education and outreach materials
- Coordinate and facilitate local outreach and education meetings for agencies and private well owners
- Facilitate collaboration so all interested parties can participate and work together towards sustainability

Proposed Process in Colusa County

GSA Governance

- Coordinate and facilitate public meetings about governance
- Coordinate and facilitate meetings of several GSA eligible agencies
- Conduct meetings with individual GSA eligible agencies
- Support representation of domestic well owner interests

Panel Discussion with Eligible GSAs

Summary of Steps Towards Sustainability

Step 1

- Local agencies form GSAs by June, 2017

Step 2

- Local agencies in medium and high priority basins adopt GSPs by January, 2022 (faster if in critical overdraft)

Step 3

- Local agencies have 20 years to demonstrate they are meeting measurable goals and achieving sustainability

Key Considerations as We Move Forward

The County believes a partnered approach is best

- We all have a vested interest in our groundwater
- GSA formation, GSP preparation, and and long-term implementation will create costs for many users
- Pooling resources will improve efficiencies and capitalize skills and strengths of various partners

Panel Questions / Topics

- Implications of SGMA to your District members and all groundwater users in the County?
- Steps you've taken so far to form a GSA?
- What you want to be sure your District achieves and avoids as you, the other organizations, and the County form GSAs?
- Thoughts you have about impacts to private well owners?

Next Steps

So where do we go from here?

- Convene Governance Workgroup
- Hold additional public meetings
- Continued coordination with adjacent subbasins

Discussion

Your comments, questions and input

Colusa Subbasin
Sustainable Groundwater Management Act |Public Meeting
Local Planning Effort

Monday, January 11, 2016
6:00 p.m. – 8:00 p.m.
Location: Colusa County Fairgrounds, Atwood Hall

Meeting purpose

- Provide an overview of the Sustainable Groundwater Management Act (SGMA)
- Review expected SGMA benefits and early implementation steps in Colusa County
- Create an opportunity for public input: questions, comments and considerations

Time	Topic
6:00	**Introduction** • Welcome and opening remarks • Agenda review and meeting purpose
6:15	**SGMA Background, Overview and Requirements** • Need and rationale for sustainable groundwater management • Implementation across the State • Core SGMA elements, associated requirements and timeline • Expected benefits for Colusa County and its residents • Q&A session
6:35	**Early SGMA Outreach and Implementation Steps in Colusa County** • County support role to-date • Process to form Groundwater Sustainability Agencies • Partnerships between County and other Water Managers • Role and involvement of private well owners • Q&A session
7:15	**Open Discussion / Public Comment** • Comments, questions, suggested considerations
7:45	**Next Steps** • Groundwater Sustainability Agency formation and function • Ongoing outreach / role of the public and groundwater users
8:00	**Meeting Adjourns**

Sustainable Groundwater Management Act (SGMA)
Public Meeting on Local Planning Efforts

For immediate release

Contact: Mary Fahey, Colusa County Water Resources Coordinator
mfahey@countyofcolusa.org
530-458-7709

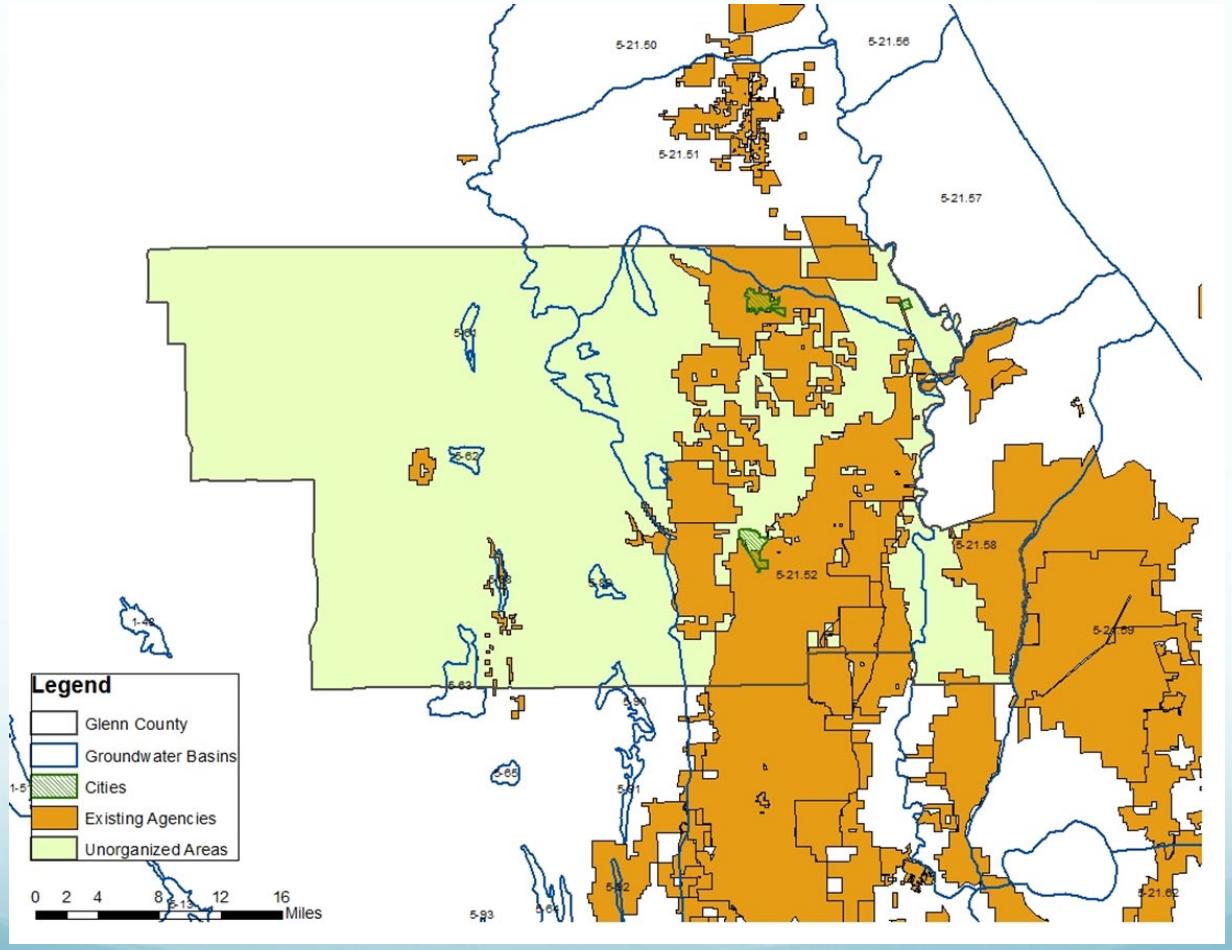
Colusa County officials and other local groundwater managers will host a public meeting on the Sustainable Groundwater Management Act (SGMA). SGMA is a new law that offers beneficial opportunities to achieve sustainable groundwater conditions and support Colusa County's vital agricultural economy, industry, and domestic and public water uses.

The meeting will provide an overview of SGMA, expected responsibilities and benefits for groundwater users, and describe early steps taken to implement the new law. The public is encouraged to attend to learn more about SGMA, ask questions of local water managers and submit comments.

"SGMA implementation has begun throughout California," says Supervisor Denise Carter. "We hope groundwater users throughout Colusa County will attend to learn more. SGMA is an important change in how groundwater is managed and everyone needs to be aware and involved to manage and sustain our precious water resources."

To support local planning efforts, the County has secured facilitation support from the Department of Water Resources (DWR), initiated a county-wide groundwater assessment and applied for a groundwater planning grant through the Water Bond. The County is committed to sharing these resources with local SGMA partners.

"County officials have worked closely for decades with managers of local water agencies and knows them to be exceptional water leaders and partners," says Water Resources Coordinator Mary Fahey. "We expect these water leaders to fill a similar role as partners implementing SGMA, and thereby working together to keep our citizens ahead of the curve on groundwater management policies."



Meeting date, time and location:

January 11, 2016
6:00 p.m. – 8:00 p.m.
Colusa County Fairgrounds
1303 10th Street (Highway 20)
Colusa, CA 95932
Atwood Hall

For more information please visit DWR's SGMA webpage: http://groundwater.ca.gov/

The Sustainable Groundwater Management Act

Implementation in Glenn County

Presentation Outline

I. SGMA Background

II. Preparing to Advance SGMA Locally

III. Recent SGMA Activities

IV. Early Implementation

V. Next Steps

SGMA Background

Comprehensive statewide legislation that creates a framework for sustainable groundwater management

- Became law on January 1, 2015
- All medium and high priority basins managed sustainably
- Emphasis on local control with State oversight
- Groundwater Sustainability Agencies
- Groundwater Sustainability Plans

SGMA Background

SGMA affects <u>all citizens</u> of Glenn County

- Offers beneficial opportunities to achieve sustainable groundwater conditions
- Supports agriculture, industry and domestic/public uses
- Requires residents to work together and address our common interest in groundwater resources
- Glenn County supports a collaborative approach to implement SGMA

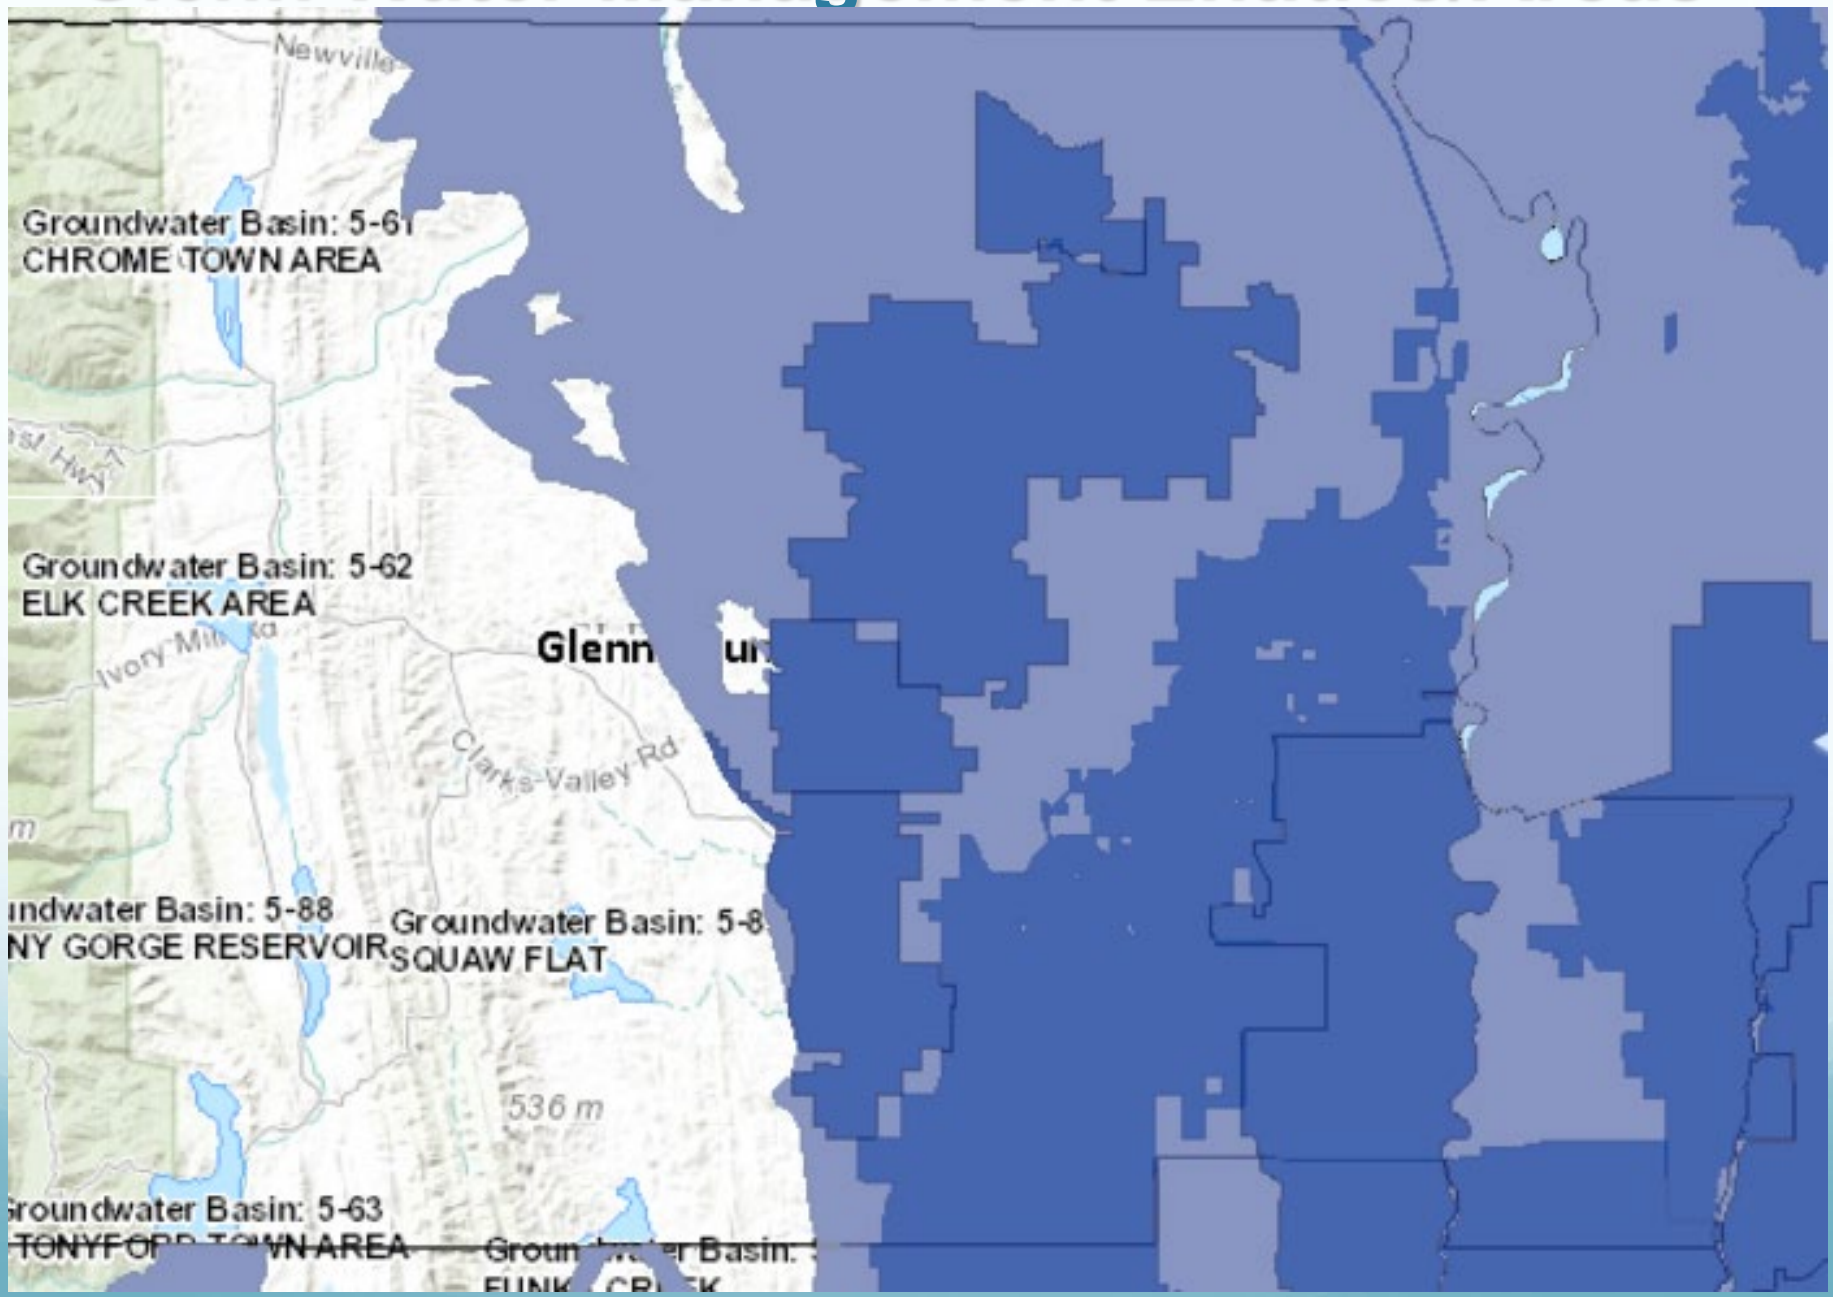
SGMA Background

How does SGMA define sustainability?

Sustainability: Manage groundwater to prevent undesirable results (significant and unreasonable):

- Chronic lowering of groundwater levels
- Reduction of groundwater storage
- Seawater intrusion
- Degraded water quality
- Land subsidence
- Depletions of interconnected surface waters

SGMA Background



Formation of Groundwater Sustainability Agencies (GSAs)

- SGMA requires formation of GSAs to implement SGMA at the local level

- Public agencies with land or water use authority are eligible to become GSAs
  - Counties, cities, water agencies, irrigation districts, PUDs
  - GSA may include one or more local public agencies

- May include a single GSA or multiple GSAs per basin
  - Multiple GSAs must coordinate planning efforts

Glenn Water Management Entities/Areas

SGMA Background

GSA Roles and Responsibilities
At their discretion, GSAs may…

- Adopt rules, regulations and ordinances
- Conduct groundwater studies / investigations
- Register and monitor wells
- Require reports of groundwater extraction
- Implement capital projects to meet goals
- Assess fees to cover management costs

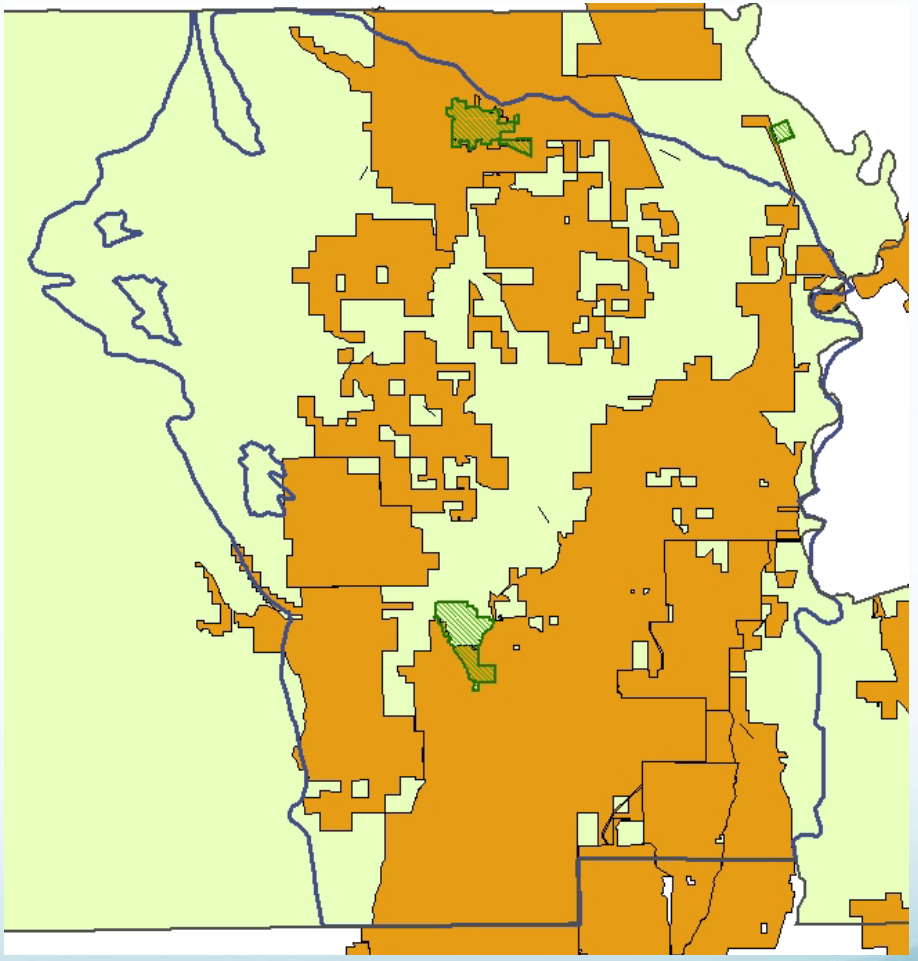
SGMA Background

GSA Roles and Responsibilities

Interested parties must be included in SGMA planning:

- All Groundwater Users
- Holders of Overlying Rights (agriculture and domestic)
- Municipal Well Operators and Public Water Systems
- Tribes
- County
- Planning Departments / Land Use Agencies
- Local Landowners
- Disadvantaged Communities
- Business
- Federal Government
- Environmental Uses
- Surface Water Users (*if connection between surface and groundwater*)

SGMA Background



How are domestic well owners affected by SGMA?

- Referred to in SGMA as "de minimis" users IF…
  - Use 2 acre-feet per year or less for domestic purposes
- De minimis users are subject to SGMA, depending on local needs
  - GSAs will decide how de minimis users are addressed
  - GSAs can decide to exclude or include

Recent SGMA Activities

GSA Notifications in Glenn County

- Glenn-Colusa Irrigation District
- Reclamation District No. 1004
- County of Glenn
- Orland-Artois Water District
- City of Orland
- Glide Water District
- Kanawha Water District
- Provident Irrigation District and Princeton-Cordora-Glenn Irrigation District
- Western Canal Water District

Recent SGMA Activities

SB 13 Amendment – Interpreted by DWR as retroactive

- Removed the Notice of Intent to be a GSA
- Allows a mutual water company to be part of a GSA through a legal agreement
- Prohibits overlap of service area boundaries
- Prohibits local agencies from imposing fees or reg. requirements on entities outside their boundaries
- Requires DWR to post all “complete” notices within 15 days of receipt

Recent SGMA Activities

Basin Boundary Modifications

- Existing groundwater basins or subasins defined in DWR's Bulletin 118
- Local agencies may request boundary modifications
- May include scientific or jurisdictional modifications
- Starting January 1, 2016: 90 day window for local agencies to submit requests for DWR consideration

Recent SGMA Activities

Groundwater Sustainability Plan Regulations

- By June 1, 2016 DWR shall adopt regulations for:
  - Evaluating GSPs
  - Implementing GSPs
  - Coordination agreements

- The regulations identify:
  - Required GSP components and additional elements
  - Coordination of multiple GSPs in a basin
  - Additional information that assists GSAs

Draft GSP Regulations

- Require a course to achieve sustainable groundwater management within 20 years of plan implementation
- Fundamental Principle - Local control and management
  - Preserve role of local agencies to manage basins and achieve sustainability,
  - Local flexibility to define problems in basins,
  - Establish minimum thresholds,
  - Set measurable objectives,
  - Determine projects and management actions that will be required to achieve sustainability.
  - Recognize adaptive management as an important tool to address plan uncertainties and improve

Draft GSP Regulations - Timeline

- 57 Pages
- Available for public review at www.water.ca.gov/groundwater/sgm/gsp.cfm
- Public comments in writing through March 25, 2016.
- 3 public meetings and a statewide webinar in March
- Final GSP Regulations Completed – June 1, 2016

Draft GSP Regulations - Timeline

Public Meetings and Webinar

- Monday, March 21, 2016 - Visalia
  - 4:00 P.M. to 6:00 P.M.
- Tuesday, March 22, 2016 – Santa Ana
  - 1:00 P.M. to 3:00 P.M.
- Thursday, March 24, 2016 - Webinar
  - 1:00 P.M. to 3:00 P.M.
- Friday, March 25, 2016 - Sacramento
  - 9:00 A.M. to 11:00 A.M.

Proposed Process In Glenn County

The County received Department of Water Resources grant funding for facilitation services from the Center For Collaborative Policy.

- Background preparation
- Outreach and education
- GSA Governance development

Proposed Process in Glenn County

Background Preparation

- Review background materials
- Conduct initial interviews with eligible GSA agencies
- Prepare 90-Day Plan
- Prepare initial facilitation strategy

Proposed Process in Glenn County

Outreach and Education

- Prepare education and outreach materials
- Coordinate and facilitate local outreach and education meetings for agencies and private well owners
- Facilitate collaboration so all interested parties can participate and work together towards sustainability

Proposed Process in Glenn County

GSA Governance

- Coordinate and facilitate public meetings about governance
- Coordinate and facilitate meetings of several GSA eligible agencies
- Conduct meetings with individual GSA eligible agencies
- Support representation of domestic well owner interests

Key Considerations as We Move Forward

The County believes a collaborative approach is best

- We all have a vested interest in our groundwater
- GSA formation, GSP preparation, and and long-term implementation will create costs for many users
- Pooling resources will improve efficiencies and capitalize skills and strengths of various partners

Next Steps

So where do we go from here?

- Convene Governance Workgroup
- Hold additional public meetings
- Continued coordination with adjacent subbasins

Discussion

Your comments, questions and input

Sustainable Groundwater Management Act (SGMA)
Public Meeting on Local Planning Efforts

For immediate release
Contact: Lisa Hunter, Glenn County Water Resources Coordinator
LHunter@countyofglenn.net
(530) 934-6501

Willows, California- Glenn County officials and other local groundwater managers will host a public meeting on the Sustainable Groundwater Management Act (SGMA). SGMA is a new law that offers beneficial opportunities to achieve sustainable groundwater conditions and support Colusa County's vital agricultural economy, industry, and domestic and public water uses.

The meeting will provide an overview of SGMA, expected responsibilities and benefits for groundwater users, and describe early steps taken to implement the new law. The public is encouraged to attend to learn more about SGMA, ask questions of local water managers and submit comments.

"Water supply issues in Glenn County are challenging, but SGMA provides the tools to develop local solutions for local problems" said Willow-area farmer Larry Domenighini. "In the next couple of years we will need to craft a plan to address the sustainability issues we all face here. Water supply sustainability issues affect everyone in the County whether they recognize it or not. This is not going to be a quick or easy solution, so it is important that everyone keeps up with our local water issues and be engaged so that we can develop our solutions."

To support local planning efforts, the County has secured facilitation support from the Department of Water Resources (DWR), initiated a county-wide groundwater assessment and applied for a groundwater planning grant through the Water Bond.

"Glenn County is committed to working through local challenges to ensure that our groundwater resources are protected" said Lisa Hunter, the County's Water Resources Coordinator". "Groundwater resources are especially important for our household water uses and our agricultural economy, as well as other water uses in our area. Glenn County is committed to work collaboratively with local water managers to ensure sustainable water supplies into the future for all County citizens."

Meeting date, time and location:

March 8, 2016
6:00 p.m. – 8:00 p.m.
Orland Memorial Hall
320 Third Street
Orland, CA 95963

For more information please visit DWR's SGMA webpage: http://groundwater.ca.gov/

Glenn County

is Hosting a Public Meeting

About California's

Sustainable Groundwater Management Act (SGMA)

Tuesday, March 8, 2016
6:00-8:00 PM
Orland Memorial Hall
320 Third Street, Orland

The meeting will include:

- An overview of the Sustainable Groundwater Management Act (SGMA)
- A presentation of SGMA early implementation in Glenn County
- Discussion of anticipated SGMA benefits and impacts
- Public input: questions, comments and considerations

(THIS PAGE LEFT BLANK INTENTIONALLY)

Notice of Workshop Regarding Implementation of SGMA by the Colusa Groundwater Authority, and Proposed Funding

The Colusa Groundwater Authority (CGA or Agency) is a 12-Member, multi-agency Joint Powers Authority that was formed on June 29, 2017 to meet the Groundwater Sustainability Agency formation deadline under the Sustainable Groundwater Management Act (SGMA). The CGA is responsible for implementation of SGMA in the County of Colusa (County) portion of the Colusa Subbasin (8-21.52) and the County portions of the West Butte Subbasin (5.21-58) outside of Reclamation District 1004. The Board of the CGA is composed of representatives of the following Agencies (1 seat per agency): County, City of Colusa, City of Williams, Colusa County Water District, Glenn-Colusa Irrigation District, Princeton-Codora-Glenn/Provident Irrigation District, Westside Water District/Maxwell Irrigation District, Reclamation District 108, Reclamation District 479, and Colusa Drain Mutual Water Company. In addition, there are two Private Pumper representatives appointed by the Colusa County Board of Supervisors, as recommended to the Board by the County Groundwater Commission. The CGA was formed to comply with and implement SGMA.

As a groundwater regulating agency, the CGA (in partnership with other adjacent GSAs such as the Glenn Groundwater Authority [GGA]) is tasked with achieving and maintaining sustainable groundwater conditions in the above mentioned subbasins over a 20-year window starting on January 31, 2022 and extending to 2042. Compliance with SGMA during this time period is done through the preparation and implementation of a Groundwater Sustainability Plan (GSP or Plan). GSP development is just getting underway in the Colusa and West Butte Subbasins and the Plans must be adopted by the aforementioned January 31, 2022 date. If any of the SGMA deadlines are not met, or if the CGA cannot fund the necessary activities committed to in the GSPs, the State Water Resources Control Board will take over groundwater management responsibilities. In order to ensure initial SGMA compliance and as an effective start to this long-range effort, the Member Agencies on the CGA Board agreed to fund CGA activities for the first two years of operation (July 2017 – June 2019), after which a long-term funding plan would need to be in place including contributions from landowners. The CGA has retained Provost & Pritchard Consulting Group to prepare a fee study to review the best options to fund CGA operations over the next five years. An operations cost and fee analysis is to be included in the study.

A public workshop will be held January 31, 2019, at 6:00 pm at the Colusa Indian Community Event Center, 3720 Highway 45, Colusa, CA 95932 to provide information about the cost and fee analysis and what this may mean for landowners. The public workshop will also provide an opportunity for you to provide input for the study, will inform you of SGMA requirements and current implementation status in the CGA jurisdictional area, and the consequences of not managing the groundwater subbasins (e.g. State intervention). One of the foundational Guiding Principles committed to by all CGA Members during the Agency's inception is to ensure that the areas under CGA jurisdiction **avoid extremely expensive and intrusive State groundwater intervention actions** to all beneficial users of groundwater.

Additional Background:

CGA operations include a variety of administrative activities, development of the GSP, monitoring groundwater conditions, annual reporting to the California Department of Water Resources, five-year updates to the GSP, and potentially conducting special studies. As stated above, the CGA is just beginning development of the GSP for the CGA jurisdictional areas, in coordination with other GSAs in the basins, including the Glenn Groundwater Authority, among others. State Proposition 1 grant funding has been awarded to cover a large portion of GSP development, however this grant does not and cannot support long-range operations and implementation of SGMA. The member agencies of the CGA will continue to pursue any grant funding opportunities that become available to support SGMA activities.

More information about the CGA and additional SGMA outreach meetings can be found at https://colusagroundwater.org/

Protest Process Required for any CGA Operations Fee or Charge:

If after the cost and fee analysis study is completed, the CGA Board opts to propose a fee or charge for its operations to avoid State intervention fees, landowners will have the option to protest under California's Proposition 218 requirements. More information about CGA, SGMA, and alternatives for funding SGMA compliance activities and Proposition 218 requirements will be provided at the January 31st public workshop.

Opportunity to Provide Input:

SGMA is a complex and important new law requiring statewide management of groundwater. The upcoming workshop is an opportunity for you to be informed about SGMA implementation, the funding process, and to ask questions. Please come to the public workshop. If you are unable to attend and want to be notified of other opportunities to provide input, please contact Mallory Serrao (mserrao@ppeng.com; 916-918-2002).

Colusa Groundwater Authority Information Meeting

Sustainable Groundwater Management Act Implementation and Funding

January 31, 2019

Program

1. Sustainable Groundwater Management Act (SGMA) Overview
2. Colusa Groundwater Authority (CGA) Background
3. Financing SGMA Implementation
   - CGA Activities and the Need for Funding
   - Proposition 218 Majority Protest
4. SGMA Local Compliance and Potential State Intervention
5. CGA Panel Questions and Answers

SGMA: Who is Affected

Agriculture

Municipal

Industrial

Environmental

SGMA Foundations

- Sustainable Groundwater Management Act of 2014
- **Groundwater Sustainability Agency(ies) (GSA)** by **June 30, 2017**
- **Groundwater Sustainability Plan(s) (GSP)** by **January 31, 2022**
- Yearly reporting and GSP Update every 5 years, demonstrating progress towards sustainability
- 20 years to achieve Sustainability – 2042
- **SGMA is a completely different program than the Irrigated Lands Regulatory Program!**

SGMA Foundations

- 517 Groundwater Basins / Subbasins Statewide
- 127 Basins / Subbasins required to comply with SGMA
- Compliance based on basin prioritization as mandated by State Legislature in 2009.
- Prioritization variables include (but not limited to):
  - Population
  - Socioeconomics
  - Number of wells
  - Groundwater elevation
- Approx. 18 Basins / Subbasins in Sacramento Valley are High or Medium priority

SGMA Foundations

- One or more GSAs must be formed per Basin / Subbasin
- A GSA may be formed by a single eligible agency or by legal agreement between two or more eligible agencies.
- Two or more GSAs must prepare a Coordination Agreement (a legal agreement) between them if preparing more than one GSP. (Water Code§10721, 10727)(b)(3), etc.)
- Counties represent / manage all groundwater conditions outside another managed area (Water Code§10724)

SGMA Foundations

Six "**Undesirable Results**"

1. Chronic lowering of groundwater levels
2. Land subsidence
3. Reduction of groundwater storage
4. Depletions of interconnected groundwater and surface water
5. Degraded water quality
6. Seawater intrusion (*not applicable in the Colusa Subbasin*)

SGMA: Who is Affected

Agriculture

Municipal

Industrial

Environmental

<u>De minimis</u> (less than 2 acre/feet pumped per year for domestic purposes)

SGMA: Who is Affected

De Minimis Well Owners

- **Pump less than 2 acre/feet per year for domestic purposes**
- **GSAs can include De Minimis in GSP**
- **CGA will seek to avoid impacts**

SGMA Foundations

Beneficial Users (Water Code§10723.2)

- All Groundwater Users
- Holders of Overlying Rights (agriculture and domestic)
- Municipal Well Operators
- Public Water Systems
- Tribes
- Local Land Use Planning Agencies
- Counties
- Local Landowners
- Disadvantaged Communities
- Business
- Federal Government
- Environmental Users
- Surface Water Users (*if connection between surface and ground water*)

GSA Roles and Responsibilities

- **Governance** – Colusa Groundwater Authority
- **Outreach/Engagement (Transparency)** with all beneficial users
- **Compliance** with local ordinances, state and federal laws and regulations, and similar
- **Funding** which may include one or more of the following: regulatory fees, property-related fees or assessments, local taxes, local general obligation bonds, contributions from member agencies, grants from other state or federal agencies

GSA Roles and Responsibilities

- **Authorities**

  General:

  - Do anything "necessary and proper" to carry out SGMA's purposes
  - Adopt rules, regulations, ordinances and resolutions
  - Use any other authority allowed to the GSA to apply and enforce SGMA requirements

  Information Gathering

  Groundwater Extraction Oversight

  Property Acquisition and Management

  Enforcement:

  - Sue to collect delinquent fees, interest, or penalties or order extraction stopped until delinquent fees are paid
  - Pursue civil penalties for extraction exceedances
  - Pursue civil penalties for violations of SGMA-related rules, regulations, ordinances, or resolutions

GSA Roles and Responsibilities

- **Coordination** with adjacent Subbasins and Counties (if applicable), and between Management Areas (if applicable)
- **Technical** – access technical expertise; conduct/oversee monitoring, data collection and reporting; develop water budget and identify sustainable yield; assess basin history and potential paths to sustainable management; remediate or oversee remediation of polluted groundwater.

GSA Roles and Responsibilities

- **Summary**
  - SGMA is the law.
    - Foundational change to groundwater management in California
  - SGMA allows for significant Local Control
  - SGMA has "Few Shalls…Many Mays…"
    - Shall…Create GSA
    - Shall…Prepare GSP
    - Shall…Do Public Engagement
  - GSAs are new, local government, **Regulating Agencies**

Colusa Groundwater Authority

- CGA Formation; 2 years, Guiding Principles
- CGA formed June 29, 2017 as mandated by SGMA
- CGA is the GSA-covering the Colusa County portions of the Subbasins within the county, outside of RD 1004
- CGA is a 12-member Joint Powers Authority Board
- Board includes two Private Pumper representatives

Colusa Groundwater Authority

Board of Directors

County of Colusa
Denise Carter (Chair) / Alternate: Gary Evans

City of Colusa
Tom Reische / Alternate: Dave Markss

City of Williams
Alfred Sellers, Jr. / Alternate: TBD

Colusa County Water District
Knute Myers / Alternate: Shelly Murphy

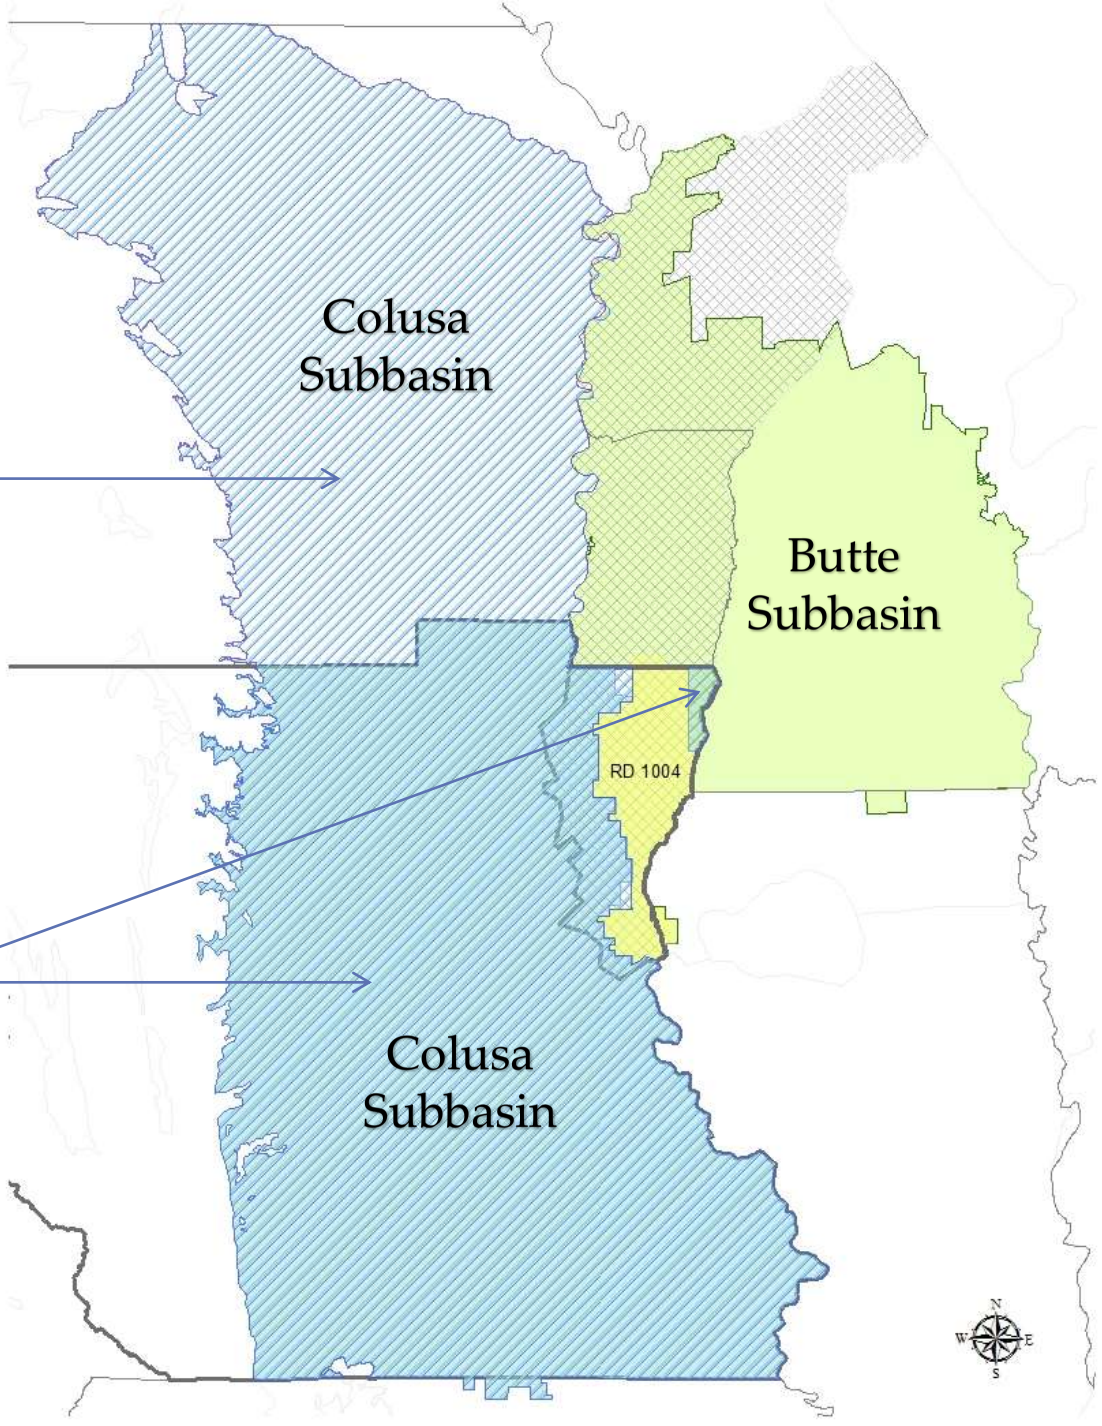
Glenn-Colusa Irrigation District
Blake Vann / Alternate: Thad Bettner

Maxwell I.D. and Westside I.D.
Zachary Dennis / Alternate: Dan Ruiz

Princeton-Codora-Glenn I.D. and Provident I.D.
David Alves / Alternate: Lance Boyd

RD 108
Hilary Reinhard, PE (Vice Chair)
Alternate: Bill Vanderwaal

RD 479
Charles Marsh / Alternate: Derick Strain



Colusa Drain Mutual Water Company
Jim Wallace / Alternate: Lynell Pollock

2 Private Pumper Representatives from the Colusa County Groundwater Commission:
Darrin Williams and Jeff Moresco

Subbasin Locations

Glenn Groundwater Authority (GGA) GSA

Colusa Groundwater Authority (CGA) GSA

CGA Activities

- Groundwater Sustainability Plan (GSP) for the Colusa Subbasin (CGA & GGA)
  - Awarded $1 million Proposition 1 grant funding for GSP development
  - Consultant team is developing Basin Setting for GSP
- Installing a new monitoring well in the Arbuckle area (DWR funded)
- Coordinating with GGA on GSP development and other activities in the Colusa Subbasin
- Coordinating with GSAs in other surrounding basins/counties
- Organizing ongoing public meetings and public outreach activities
- Developing long-term funding strategy for the CGA to maintain local control of Groundwater Management under SGMA

Financing SGMA

- CGA members working together, pooling resources to keep costs to a minimum
- Leveraging grant funding, Facilitation Support and Technical Support services
- **Need for Long-term funding for day to day operations of the CGA:**
  - **Technical:** GSP development ($1.5 million), technical studies, monitoring and data management, coordination and outreach efforts, implementation of the GSP, yearly reporting to DWR, Plan updates every five years
  - **O&M:** Staff, insurance, legal services, bookkeeping, office needs, etc.
- CGA Member Agencies agreed to fund the JPA for the first two years (July, 2017 – June, 2019) = $616,181.00 + over $150,000 in donated staffing and special studies prior to GSA formation
- Fees are needed to comply with SGMA and fund the GSP and basin monitoring activities

Financing SGMA

Proposition 218 Option

- Approved by voters in 1996, Prop 218 imposes certain requirements relative to the imposition of certain assessments, fees and charges by local agencies.
- Procedures act to fully inform the Agency's landowners while simultaneously giving them a direct say in the matter.
- Two processes for approval of revenue generation under Proposition 218
  - Land-based assessments (per acre charge)
  - Fees or charges on a unit basis.

Financing SGMA

Proposition 218 Majority Protest Requirements

- CGA contracted with Provost and Pritchard Engineering to initiate a Proposition 218 Majority Protest
- Consultants will complete a rate study to determine a fee structure based on CGA budget and acreages in the CGA's jurisdiction
- Amount of fee cannot exceed the reasonable cost of the activity to be funded
- Public information meetings being planned, January – March
- A similar process is beginning in the GGA portion of the Colusa Subbasin

Financing SGMA

Proposition 218 Majority Protest Requirements

- Fees must be based on the reasonable cost of providing service
  - CGA's annual operating budget
- Fees must proportionally recover costs from ratepayers (i.e. no subsidies)
  - $/acre fee
- Fees in the Prop 218 notice are the max fees that may be adopted
  - Board may lower fees without conducting another Prop 218 notice and hearing process

Financing SGMA

Proposition 218 Majority Protest Requirements

- Hold public informational meeting (NOT required)
- Mail a protest notice to property owners
- Hold a public hearing minimum of 45 days later – anticipated in May, 2019
- Absent majority protest, CGA may adopt fees
- If the Proposition 218 effort passes, a fee will appear on December 2019 property tax roll

Financing SGMA

Initial Estimate: Proposition 218 Majority Protest Fee Calculation

	Estimates
Budget	$540,000
Acres	413,256
Fee ($/acre)	$1.31

- Pending outcome of fee study
- Pending CGA Board approval and budget review
- SGMA is a new program, many unknowns
  - Budget is the best estimate at this time
  - The fee cannot exceed the reasonable costs of the CGA activities
- This fee is for day to day operations of the CGA. Additional project-specific fees may also apply in the future

Financing SGMA

Statewide GSA Fee Examples

1. GSA 1 – in Fresno County - $19.00/acre – entirely dependent on groundwater

2. GSA 2 – in Kings County - $5.00/acre initially, reduced to $3.00/acre in second year

3. GSA 3 – Salinas Valley - $2.27/non-ag acre to $4.81 irrigated ag acre

Financing SGMA

Who is Subject to Fees?

- All property owners have an overlying right and benefit from a healthy groundwater system
- Small Community Water Systems: homeowners in the Cities of Colusa and Williams and the small communities of Arbuckle, Grimes, Maxwell and Princeton may be charged through their water suppliers.
  - This will save money processing multiple property tax bills on these small parcels

Financing SGMA

What if the Prop 218 Effort Fails?

- If the CGA cannot be funded, it will dissolve.
- If a basin is not covered entirely by a GSA(s) and/or approved GSP, the State Water Resources Control Board assumes SGMA responsibilities.
- Lose local control of the groundwater resource.

State Intervention

- **State Board intervention actions can include:**
  - Well Head fees
  - Volumetric fees (fee per acre-foot of water pumped)
  - Late fees (subject to backdating to 2017)
  - Mandatory extraction reporting including monthly pumping data
  - May require installation of meters on wells at owner's expense
  - Technical reporting and special studies at landowners' expense
  - Any corrective actions will likely result in pumping restrictions

State Intervention

SWRCB Fees, 2018

BASE FEE (per well)	**$300**
Volumetric Fee (per AF)	
Unmanaged, metered	**$10/AF**
Unmanaged, unmetered	**$25/AF**
An unmanaged area is a part of a basin not within the management area of a GSA before July 1, 2017	
Probation	**$40/AF**
If locals fail to form a GSA, fail to develop an adequate sustainability plan, or fail to implement the plan successfully, the Board may designate the entire basin probationary. The Board may require the use of a meter to measure extractions and reporting of additional information.	
Interim Plan	**$55/AF**
If local agencies are unable to fix the deficiencies, the Board will develop an interim plan to directly manage groundwater extractions.	
De minimis (less than 2 AF/year)	**$100/well**
Late Fee	**25% per month**

https://www.waterboards.ca.gov/water_issues/programs/gmp/sgma.html

State Intervention

Sample Fee Comparison

100 acre irrigated parcel with one well, probationary basin

- **SWRCB Fees: $14,300**
  - 1 well = $300
  - 3.5 AF/ac = 350 AF X $40 = $14,000

- **Estimated CGA Fee: $131**
  - 100 Acres X $1.31 = $131

CGA Panel Questions & Answers

Panel Members:

- Denise Carter, County Supervisor, CGA Board Chair
- Hilary Reinhard, RD 108, CGA Vice Chair
- Darrin Williams, Private Pumper
- Jesse Cain, City Manager, City of Colusa

Thank You

Landowner input is essential to GSP development and SGMA planning and implementation.

CGA Website: www.colusagroundwater.org

Colusa County Groundwater Commission Informational Forum
February 13
10:00 a.m. – noon
Colusa Industrial Properties Conference Room

COLUSA GROUNDWATER AUTHORITY
NOTICE OF PROPOSED FEE

In compliance with California State Law, a **public hearing will be held:**

June 5, 2019 at 5:00 p.m. at the Colusa Industrial Properties, 100 Sunrise Blvd., Colusa, CA 95932 to consider a proposal by the Colusa Groundwater Authority (CGA) to adopt a **new fee in the amount of $1.21 per acre annually**, indexed to Consumer Price Index, Western Region, for the 2019 Fiscal Year and the subsequent four fiscal years, for everyday operations of the CGA.

Background:

The Colusa Groundwater Authority is a 12-Member, multi-agency Joint Powers Authority that was formed on June 29, 2017 to meet the Groundwater Sustainability Agency (GSA) formation deadline under the Sustainable Groundwater Management Act (SGMA). The CGA is responsible for implementation of SGMA in the County of Colusa (County) and Yolo County portions of the Colusa Subbasin (5-021.52) and the County portions of the Butte Subbasin (5.021-70) outside of Reclamation District 1004 (Basins). The Board of the CGA is composed of representatives of the following Agencies (1 seat per agency): County of Colusa, City of Colusa, City of Williams, Colusa County Water District, Glenn-Colusa Irrigation District, Princeton-Codora-Glenn Irrigation District / Provident Irrigation District, Westside Water District / Maxwell Irrigation District, Reclamation District 108, Reclamation District 479, and Colusa Drain Mutual Water Company. In addition, the Board includes two Private Pumper representatives appointed by the Colusa County Board of Supervisors, as recommended to the Board by the County Groundwater Commission. The CGA was formed to comply with and implement SGMA.

As a groundwater regulating agency, the CGA (in partnership with other adjacent GSAs such as the Glenn Groundwater Authority [GGA]) is tasked with achieving and maintaining sustainable groundwater conditions in the Basins. Compliance with SGMA is done through the preparation and implementation of a Groundwater Sustainability Plan (GSP or Plan). GSP development is underway in the Basins and the Plans must be adopted by January 31, 2022. If any of the SGMA deadlines are not met, or if the CGA cannot fund preparation of the GSP(s) or the necessary activities committed to in the GSPs, the State Water Resources Control Board may take over groundwater management responsibilities.

Long-Term Funding:

In order to ensure initial SGMA compliance and as an effective start to this long-range effort, the CGA Member agencies agreed to fund the CGA for the first two years of operation (July 2017 – June 2019), after which a long-term funding plan (proposed CGA Operations Fee) would be initiated to cover everyday operations of the CGA related to SGMA implementation and compliance. CGA operations include administration, legal services, consultant services, insurance, office and outreach materials, accounting, monitoring and reporting to DWR, and potentially some special studies. The CGA has received Proposition 1 grant funding to cover a majority of the work to develop a GSP however, costs for GSP preparation and initial implementation that can't be covered by grants will also need to be covered by the CGA Operations Fee. It is anticipated that any necessary management actions resulting from GSP implementation that cause a funding shortfall will be funded by other localized fees or assessments.

CGA has developed a budget for annual operations expenses and GSP preparation costs not covered by grant funding for a five-year period spanning fiscal years 2019/20 to 2023/24. Based on the Agency's needs, the CGA Board of Directors is seeking to collect the Operations Fees to generate sufficient revenue to fund CGA operations. GSP development is scheduled to occur over the next several years and GSA operations expenses are anticipated to be on-going during that period and beyond.

The proposed CGA Operations Fee is a property-related fee governed by Proposition 218. Each parcel of land within the CGA's boundary that will be subject to the CGA Operations Fee shall pay the CGA Operations Fee in proportion to the cost of providing services to each acre of land comprising each parcel. SGMA provides authority for CGA to charge fees to support its operations. The CGA has retained Provost & Pritchard Consulting Group to prepare a fee study to review the best options to fund CGA operations over the next five years. An operations cost and fee analysis is included in the study.

One of the foundational Guiding Principles committed to by all CGA Members is to ensure that the areas under CGA jurisdiction **avoid extremely expensive and intrusive State groundwater intervention actions**.

If the State Water Resources Control Board intervenes in the Basins, it may impose annual fees ranging from $100 per de minimis well, to $300 per well plus up to $55 per acre-foot pumped per well, with no guarantee of assistance in bearing costs to address the groundwater issues that prompt its intervention. See https://www.waterboards.ca.gov/water_issues/programs/gmp/docs/intervention/intervention_fs.pdf. for more complete information. By collecting the Operations Fees, CGA will provide landowners with a more affordable and locally managed option for managing the Basins.

As stated above, the CGA is just beginning development of the GSP for the CGA jurisdictional areas, in coordination with other GSAs in the Basins. State Proposition 1 grant funding has been awarded to cover a large portion of GSP development, however this grant does not and cannot support long-range operations and implementation of SGMA. The CGA will continue to pursue any grant funding opportunities that become available to support SGMA activities.

Proposed Charges:

This notice is for the CGA's proposal to implement a per-acre charge to fund the CGA operations, supplement GSP preparation, and begin initial GSP implementation. The CGA is requesting a maximum charge of:

- **$1.21 per acre** (in 2019 dollars, indexed for Consumer Price Index, Western Region, for the subsequent four years).
- The proposed charges, if approved, will become effective for the 2019/20 Colusa County fiscal year, with the first payment due by December 10, 2019.

The actual amount of the CGA Operations Fee may vary from time to time however, absent a subsequent Proposition 218 proceeding, it will not exceed the fee set forth above, plus the indexed inflation factor.

For more information, including the fee study summarizing the findings, please visit the CGA website at **https://colusagroundwater.org/long-term-funding/**

Public Hearing:

Under the California State Constitution, owners of land subject to the proposed CGA Operations Fee have the right to protest its adoption. If you have received this notice, parcel(s) under your ownership will be subject to the CGA Operations Fee if adopted. In the event of a majority protest, the fee will not be instituted.

Landowners desiring to protest the proposed CGA Operations Fee should send their written protest to:

Colusa Groundwater Authority
c/o Provost & Pritchard Consulting Group
P.O. Box 8929
Chico, California 95927

Protests may also be submitted to the Board Secretary at the Public Hearing, located at 100 Sunrise Blvd., Colusa, California. **All protests must be received by 5:00 p.m. June 5, 2019 or in person by the close of the Public Hearing on June 5, 2019**.

There are multiple ways to obtain additional information about this topic:

- Call CGA's Consultant at **(916) 918-2002.**
- View more information online at **https://colusagroundwater.org**
- To read this notice in Spanish, please visit the CGA website: https://colusagroundwater.org/long-term-funding/
- For more information about SGMA, see the California Department of Water Resources website: https://water.ca.gov/Programs/Groundwater-Management/SGMA-Groundwater-Management

If you do not wish to protest the proposed CGA Operations Fee, you need not take any action.

To Protest:

All protests must include:

- Landowners printed name(s),
- Parcel number for each property affected by the CGA Operations Fee,
- Reason for the protest, and
- Valid signature(s)

Each parcel is entitled to one protest. If a parcel has more than one owner, all must sign the protest; otherwise the protest will be counted in accordance with the percentage of ownership of the person or persons signing the protest.

For your convenience, you may utilize the Protest Form below:

COLUSA GROUNDWATER AUTHORITY
AVISO DE PROPUESTA DE TARIFA

En cumplimiento de la Ley del Estado de California, se **llevará a cabo una audiencia pública:**

El día 5 de Junio del 2019 a las 5:00 p.m. en las Propiedades Industriales de Colusa, 100 Sunrise Blvd. Colusa, CA 95932 para considerar una propuesta de la Colusa Groundwater Authority (CGA) para adoptar **una nueva tarifa anual de $1.21 por acre**, indexada de acuerdo al Índice de Precios al Consumidor, Región Occidental, para el Año Fiscal del 2019 y los cuatro años fiscales subsiguientes, para la operación regular de la CGA.

Antecedentes:

La Colusa Groundwater Authority es una Autoridad de Poderes Conjuntos y una multi-agencia de 12 miembros que se formó el 29 de Junio del 2017 para cumplir con la fecha límite de formación de la Agencia de Sostenibilidad de Aguas Subterráneas (GSA) bajo la Ley de Administración Sostenible del Agua Subterránea (SGMA). La CGA es responsable de la implementación de SGMA en las porciones del Condado de Colusa (Condado) y el Condado de Yolo de la Subcuenca de Colusa (5-021.52) y las porciones del Condado de la Subcuenca Butte (5.021-70) fuera del Reclamation District 1004 (Cuencas). La Junta de la CGA está compuesta por representantes de las siguientes Agencias (1 asiento por agencia): Condado de Colusa, Ciudad de Colusa, Ciudad de Williams, Colusa County Water District, Glenn-Colusa Irrigation District, Princeton-Codora-Glenn Irrigation District / Provident Irrigation District, Westside Water District / Maxwell Irrigation District, Reclamation District 108, Reclamation District 479, y la Colusa Drain Mutual Water Company. Además, la Junta incluye dos representantes privados nombrados por la Junta de Supervisores del Condado de Colusa, según lo recomendado por la Comisión del Agua Subterránea del Condado. La CGA se formó para cumplir e implementar SGMA.

Como una agencia reguladora del agua subterránea, la CGA (en asociación con otras GSA adyacentes como la Glenn Groundwater Authority [GGA]) tiene la tarea de lograr y mantener condiciones sostenibles del agua subterránea en las Cuencas. El cumplimiento con SGMA se realiza a través de la preparación e implementación de un Plan de Sostenibilidad del Agua Subterránea (GSP o Plan). El desarrollo del GSP está en marcha en las Cuencas y los Planes deben adoptarse antes del 31 de enero del 2022. Si no se cumple alguno de los plazos de SGMA, o si la CGA no puede financiar la preparación del (los) SGP o las actividades necesarias a las que se han comprometido en los GSPs, la State Water Resources Control Board pueden asumir las responsabilidades de la administración del agua subterránea.

Financiamiento a Largo Plazo:

Con el fin de garantizar el cumplimiento inicial de la SGMA y como un inicio efectivo de este esfuerzo de largo alcance, las agencias de Miembros de la CGA acordaron financiar la CGA durante los primeros dos años de operación (Julio de 2017 - Junio de 2019), después del cual se iniciaría un plan de financiamiento de largo plazo (Tarifa Propuesta para las Operaciones del CGA) se iniciaría para cubrir las operaciones diarias de la CGA relacionadas con la implementación y el cumplimiento de SGMA. Las operaciones de CGA incluyen administración, servicios legales, servicios de consultoría, seguros, materiales de oficina y educación, contabilidad, monitoreo e informes a DWR, y potencialmente algunos estudios especiales. La CGA ha recibido fondos de la Proposición 1 para cubrir la mayor parte del trabajo para desarrollar un GSP. Sin embargo, los costos para la preparación del GSP y la implementación inicial que no pueden ser cubiertos por los fondos recibidos también deberán cubrirse con la Tarifa Propuesta para las Operaciones del CGA. Se anticipa que cualquier acción de administración necesaria que resulte de la implementación del GSP que cause un déficit de financiamiento será financiada por otras tarifas o evaluaciones puntuales que sean necesarias.

CGA ha desarrollado un presupuesto para los gastos de operación anuales y los costos de preparación del SGP no cubiertos por los fondos recibidos para un período de cinco años que abarca los años fiscales 2019/20 al 2023/24. Basado en las necesidades de la agencia, la Junta de Directores de CGA está buscando cobrar la Tarifa de Operaciones para generar ingresos suficientes para financiar las operaciones de CGA. El desarrollo del SGP está programado para ocurrir en los próximos años y se anticipa que los gastos de operaciones de GSA continúen durante ese período y más allá.

La Tarifa de Operaciones del CGA propuesta es una tarifa relacionada con la propiedad y gobernada por la Proposición 218. Cada parcela de tierra dentro del límite de la CGA estará sujeta a la Tarifa de Operaciones de la CGA y pagará la Tarifa de Operaciones de la CGA en proporción al costo de proporcionar servicios a cada acre de terreno que incluye cada parcela. SGMA otorga autoridad a CGA para cobrar tarifas para respaldar sus operaciones. La CGA ha contratado a Provost & Pritchard Consulting Group para preparar un estudio de tarifas para revisar las mejores opciones para financiar las operaciones de CGA en los próximos cinco años. Se incluye un análisis de costos y tarifas de operaciones en el estudio.

Uno de los Principios Rectores fundamentales a los que se comprometen todos los Miembros de la CGA es el de garantizar que las áreas bajo jurisdicción de la CGA **eviten acciones de intervención del agua subterránea extremadamente costosas e intrusivas por parte del Estado**.

Si la State Water Resources Control Board interviene en las cuencas, puede imponer tarifas anuales con un mínimo de $100 por pozo, y hasta de $300 por pozo, y adicionalmente hasta $55 por acre-pie bombeado por pozo, sin garantía de asistencia en los costos de soporte para resolver los problemas de agua subterránea que causan su intervención. Consulte https://www.waterboards.ca.gov/water_issues/programs/gmp/docs/intervention/intervention_fs.pdf. para información más completa. Al cobrar la Tarifa de Operaciones, CGA les brindará a los propietarios una opción más accesible y localmente administrada en relación con la administración de las Cuencas.

Como se indicó anteriormente, la CGA está recién comenzando el desarrollo del GSP para las áreas jurisdiccionales de la CGA, en coordinación con otras GSA en las Cuencas. La financiación que ofrece la Proposición Estatal 1 se ha otorgado para cubrir una gran parte del desarrollo del GSP, sin embargo, este fondo no apoya y no puede respaldar las operaciones de largo plazo y la implementación de SGMA. La CGA continuará buscando cualquier oportunidad de financiamiento que esté disponible para apoyar las actividades de SGMA.

Cobros Propuestos:

Este aviso es para la propuesta de la CGA de implementar un cobro por acre para financiar las operaciones de la CGA, complementar la preparación del GSP, y empezar la implementación inicial del GSP. La CGA está solicitando un cargo máximo de:

- **$1.21 por acre** (en dólares corrientes del año 2019, indexados por el Índice de Precios al Consumidor, Región Occidental, para los siguientes cuatro años).
- Los cargos propuestos, si se aprueban, entrarán en vigor para el año fiscal 2019/20 del Condado de Colusa, con el primer pago que debe realizarse antes del 10 de Diciembre del 2019.

El monto real de la Tarifa de Operaciones de la CGA puede variar de vez en cuando, sin embargo, en ausencia de un procedimiento posterior de la Propuesta 218, no excederá la tarifa establecida anteriormente, más el factor de inflación indexado.

Para más información, incluido el estudio de tarifas que resume las recomendaciones, visite el sitio web de CGA en **https://colusagroundwater.org/long-term-funding/**

Audiencia Pública:

Según la Constitución del Estado de California, los propietarios de tierras sujetas a la Tarifa de Operaciones propuesta del CGA tienen derecho a protestar por su adopción. Si ha recibido este aviso, las parcelas de su propiedad estarán sujetas a la Tarifa de Operaciones de CGA si se adoptan. En el caso de una protesta mayoritaria, la tarifa no será instituida.

Propietarios que deseen protestar por la Tarifa de Operaciones propuesta del CGA deben enviar su protesta por escrito a:

Colusa Groundwater Authority
c/o Provost & Pritchard Consulting Group
P.O. Box 8929
Chico, California 95927

Las Protestas también pueden presentarse al Secretario de la Junta en la Audiencia Pública, ubicada en el 100 Sunrise Blvd., Colusa, California. **Todas las protestas deben ser recibidas antes de las 5:00 p.m. día 5 de Junio del 2019 o en persona al cierre de la Audiencia Pública el 5 de Junio del 2019.**

Hay varias maneras de obtener información adicional sobre este tema:

- Llame al Consultor del CGA al **(916) 918-2002.**
- Vea más información en línea en la página **https://colusagroundwater.org**
- Para leer este aviso en Español, visite el sitio web de CGA: https://colusagroundwater.org/long-term-funding/
- Para más información sobre SGMA, consulte el sitio web del Departamento de Recursos Hídricos de California: https://water.ca.gov/Programs/Groundwater-Management/SGMA-Groundwater-Management

Si no desea protestar por la Tarifa de Operaciones propuesta del CGA, no necesita realizar ninguna diligencia.

Para Protestar:

Todas las protestas deben incluir:

- Nombre escrito del dueño(s),
- Número de parcela para cada propiedad afectada por la Tarifa de Operaciones del CGA.
- Razón para la protesta, y
- Firma(s) válida(s)

Cada parcela tiene derecho a una protesta. Si una parcela tiene más de un propietario, todos deben firmar la protesta; de lo contrario, la protesta se computará de acuerdo con el porcentaje de propiedad de la persona o personas que firman la protesta.

Para su conveniencia puede utilizar el Formulario de Protesta que está a continuación:

COLUSA GROUNDWATER AUTHORITY

AFFIDAVIT OF MAILING OF NOTICE OF HEARING AND MAJORITY PROTEST FORM TO CERTAIN LANDOWNERS WITHIN THE BOUNDARIES OF THE COLUSA GROUNDWATER AUTHORITY

STATE OF CALIFORNIA)
) ss.
COUNTY OF COLUSA)

The undersigned says:

That I, Linda G. Sloan, am Vice President of Provost & Pritchard Consulting, an agent of the Colusa Groundwater Authority, and was responsible for managing the mailing the Notice of Public Hearing to landowners from a list prepared from the County's tax roll on the Authority's proposed property-related fee.

I declare that at or before 5:00 p.m. on April 17, 2019, I supervised the mailing of copies of the "**NOTICE OF PROPOSED FEE**", and protest form, both in the form attached hereto marked Exhibit "A", to all landowners that would be affected by the Authority's proposed fee within the boundaries of the Authority as shown on the roll attached as Exhibit "B". Each Notice contained the specific applicable information taken from the roll.

That said mailing was accomplished by depositing in the United States Mail at Chico, California, with proper and necessary postage prepaid, envelopes addressed as aforesaid.

I CERTIFY under penalty of perjury that the foregoing is true and correct.

Executed at ~~Colusa~~ Siskiyou County, California, this 30th day of May, 2019.

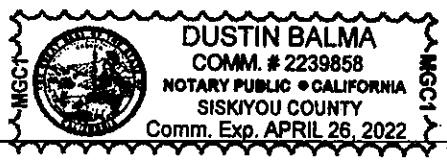
Linda G. Sloan

Please see attached sheet
for CA Acknowledgment/Jurat
As per CA Civil Codes 1189/8202

Exhibit A: Notice and Protest Form
Exhibit B: County's Tax Roll

CALIFORNIA ALL-PURPOSE ACKNOWLEDGMENT

A notary public or other officer completing this certificate verifies only the identity of the individual who signed the document to which this certificate is attached, and not the truthfulness, accuracy, or validity



State of California)
)
County of Siskiyou)

On 05-30-2019 before me, Dustin Balma, Notary Public, personally appeared

Linda G Sloan, who proved to me on the basis of satisfactory evidence to be the person(s) whose name is/are subscribed to the within instrument and acknowledged to me that he/she/they executed the same in his/her/their authorized capacity(ies), and that by his/her/their signature(s) on the instrument the person(s), or the entity upon behalf of which the person(s) acted, executed the instrument.

I certify under PENALTY OF PERJURY under the laws of the State of California that the foregoing paragraph is true and correct.

WITNESS my hand and official seal.

SIGNATURE OF NOTARY

Colusa Groundwater Authority

Groundwater Sustainability Agency

100 Sunrise Blvd., Suite A | Colusa, CA 95932 | 530.458.7709

AGENDA

Informational Meeting
Sustainable Groundwater Management Act (SGMA)
Implementation and Funding

January 31, 2019
6:00 - 8:00 p.m.
Colusa Indian Community Events Center,
3740 Highway 45, Colusa, CA 95932 (Just south of Casino)

6:00 **Meeting Kickoff and Agenda Review*** (Facilitator – Dave Ceppos, Sacramento State)

6:05 **Welcome and Introductions** (Denise Carter, Chair – Colusa Groundwater Authority [CGA] and Colusa County Supervisor)

6:15 **Presentation**

- **Sustainable Groundwater Management Act Overview** (Dave Ceppos)
- **Colusa Groundwater Authority Background** (Denise Carter)
- **Financing SGMA** (Dave Ceppos, Linda Sloan, Provost & Pritchard Consulting Group)
- **SGMA Local Compliance and Potential State Actions** (Dave Ceppos)

7:10 **CGA Board Member Panel – Questions and Answers** (Denise Carter, Hilary Reinhard - RD 108, CGA Vice Chair; Darrin Williams – Private Pumper, Jessie Cain - City Manager, City of Colusa)

8:00 **Adjourn**

*Every agenda item will include an opportunity for public questions and answers.
*Breaks will be taken as time permits and at the discretion of the facilitator

Public Workshop

Sustainable Groundwater Management Act and Proposed Funding

Hosted by the Glenn Groundwater Authority

YOUR Local Groundwater Management Agency

March 21, 2019 at 6:00 pm, Glenn Success Square Conference Center, 131 E. Walker St., Orland, CA 95963

Workshop topics include:

Sustainable Groundwater Management Act (SGMA)

- ✓ SGMA Requirements
- ✓ Deadlines and Milestones
- ✓ Local control vs. State Intervention
- ✓ Groundwater Basins/Subbasins
- ✓ Groundwater Sustainability Agencies
- ✓ Groundwater Sustainability Plan development and implementation

The Glenn Groundwater Authority (GGA)

- ✓ Agency responsible for SGMA planning and implementation in Glenn County portion of the Colusa subbasin
- ✓ Board of Directors with membership from local cities, irrigation districts and the County
- ✓ Coordinates with the Colusa Groundwater Authority and neighboring agencies
- ✓ Long-term funding

Glenn Groundwater Authority
PO Box 351
Willows, CA 95988

Process Required for GGA Operations Fee or Charge:

Your Input is Needed:

SGMA is a complex new state law requiring management of groundwater. This workshop is an opportunity to learn about SGMA, the funding process and proposed assessment. **Questions and input are encouraged**. If you are unable to attend and want to be notified of other opportunities to provide input, please contact Mallory Serrao (mserrao@ppeng.com; 916-918-2002).

For more information regarding GGA: www.countyofglenn.net/dept/agriculture/water-resources/glenn-groundwater-authority

Additional SGMA information available at:

- ✓ Department of Water Resources: https://water.ca.gov/Programs/Groundwater-Management/SGMA-Groundwater-Management
- ✓ State Water Resources Control Board: https://www.waterboards.ca.gov/water_issues/programs/gmp/sgma.html

GLENN GROUNDWATER AUTHORITY
NOTICE OF HEARING ON PROPOSED FEE

In compliance with California State Law, notice is hereby given that the Glenn Groundwater Authority (GGA) will conduct a **public hearing on:**

July 8, 2019 at 5:30 p.m. at the City of Willows Council Chamber, 201 N. Lassen St., Willows, CA to consider the adoption of a **new property related fee in the amount of $1.93 per acre annually** for the 2019 Fiscal Year and the subsequent four fiscal years, to fund operations of the GGA.

Notificación en Español:

Para leer este aviso en Español, visite el sitio web de GGA https://www.countyofglenn.net/dept/agriculture/water-resources/glenn-groundwater-authority o llame (916) 918-2020 para solicitar que se le envíe un aviso por correo o correo electrónico.

Background:

The GGA is a nine-member, multi-agency Joint Powers Authority that was formed on June 20, 2017. The GGA is the Groundwater Sustainability Agency (GSA) responsible for implementation and compliance of the Sustainable Groundwater Management Act (SGMA) in the Glenn County portion of the Colusa Subbasin (5-21.52). The Board of the GGA is composed of representatives of the following:

> County of Glenn, City of Orland, City of Willows, Glenn-Colusa Irrigation District, Glide Water District, Princeton-Codora-Glenn/Provident Irrigation District (1 seat), Orland-Artois Water District, and Kanawha Water District.

As a groundwater regulating agency, the GGA (in partnership with other adjacent GSAs such as the Colusa Groundwater Authority [CGA]) is tasked with achieving and maintaining sustainable groundwater conditions in the Colusa Subbasin (Basin). Compliance with SGMA is achieved through the preparation and implementation of one or more Groundwater Sustainability Plans (GSP or Plan). Plan development is underway in the Basin and the Plan(s) must be adopted by January 31, 2022. If the local GSAs do not comply with SGMA including the development of the Plan(s) and the necessary activities required to implement the Plans, the State Water Resources Control Board may take over groundwater management responsibilities.

Long-Term Funding:

In order to ensure initial SGMA compliance and to provide a mechanism to begin this long-range effort, the GGA Member agencies agreed to fund the agency operations for the first two years. GGA operations include administration, legal services, consultant services, insurance, office and outreach materials, accounting, monitoring and reporting to DWR, and special studies, if needed. The GGA has received Proposition 1 grant funding to cover a majority of the work to develop a Plan; however, costs for Plan preparation and initial implementation that are in excess of grant funding will also need to be covered by the GGA Operations Fee.

To fund its activities and the development of an adequate Plan, the GGA developed a budget for annual operations expenses for a five-year period spanning fiscal years 2019/20 to 2023/24. This budget includes projected costs for Plan preparation and initial implementation, administration, legal services, insurance, printing/copying, accounting, facilitation, monitoring and reporting to the Department of Water Resources (DWR), and special studies, if needed.

SGMA provides authority for GGA to charge fees to support its operations. The GGA has retained Provost & Pritchard Consulting Group to prepare a fee study to review the best options to fund GGA operations over the next five years. An operations cost and fee analysis is included in the study. Each parcel of land within the GGA's

boundary is receiving SGMA management services from the GGA and the fee was developed by allocating the GGA budget in proportion to the cost of providing services to each acre of land in its service area. By law, the GGA may not collect more revenue from property related fees than is necessary to provide the cost of the water related service.

One of the GGA's foundational Guiding Principles is to protect its service area from **extremely expensive and intrusive State groundwater intervention actions**.

If the State Water Resources Control Board intervenes in the Basin, it may impose annual fees ranging from $100 per de minimis well, to $300 per well plus up to $55 per acre-foot pumped per well, with no guarantee of assistance in bearing costs to address any groundwater issues that prompt its intervention. See https://www.waterboards.ca.gov/water_issues/programs/gmp/docs/intervention/intervention_fs.pdf. for more complete information. By collecting the Operations Fees, GGA will provide landowners with local groundwater management with a tailored, more affordable approach for managing the Basin.

Notice:

In addition to this notice, the GGA has also posted the notice on the GGA website at https://www.countyofglenn.net/dept/agriculture/water-resources/glenn-groundwater-authority and has been published in accordance with Government Code 6066 and Water Code section 10730.

Proposed Property Related Fee:

This notice is for the GGA's proposal to implement a per-acre charge to fund the GGA operations, supplement Plan preparation, and begin initial GSP implementation. The GGA is considering the adoption of a property related fee in the amount of:

- **$1.93 per acre** (in 2019 dollars)
- The proposed charges, if approved, will become effective for the 2019/20 Glenn County fiscal year, with the first payment due by December 10, 2019.

For more information, including the fee study summarizing the findings, please visit the GGA website at https://www.countyofglenn.net/dept/agriculture/water-resources/glenn-groundwater-authority or call Provost & Pritchard (GGA's Consultant) at (916) 918-2002. The fee study is also available for review during normal business hours at 720 N Colusa St., Willows, CA 95988.

Public Hearing and Majority Protest:

The proposed GGA Operations Fee is a property related fee governed by Proposition 218. Under the California State Constitution, owners of land subject to the proposed GGA Operations Fee have the right to protest its adoption. If you have received this notice, parcel(s) under your ownership will be subject to the GGA Operations Fee if adopted. If written protests are submitted accounting for a majority of the total assessed parcels, GGA will not adopt the Operations Fee. Absent a majority protest, GGA is authorized to adopt the proposed Operations Fee at the public adoption hearing.

Landowners desiring to protest the proposed GGA Operations Fee should send their written protest to:

Glenn Groundwater Authority
c/o Provost & Pritchard Consulting Group
P.O. Box 8929
Chico, California 95927

Protests may also be submitted to the Board Secretary at the Public Hearing, located at the City of Willows Council Chamber, 201 N. Lassen St., Willows, California. **All protests must be received by the close of the Public Hearing on July 8, 2019 to be counted**.

Information Availability:

- Call Provost & Pritchard (GGA's Consultant) at **(916) 918-2002**
- View more information online at https://www.countyofglenn.net/dept/agriculture/water-resources/glenn-groundwater-authority
- Para leer este aviso en Español, visite el sitio web de GGA https://www.countyofglenn.net/dept/agriculture/water-resources/glenn-groundwater-authority o llame (916) 918-2020 para solicitar que se le envíe un aviso por correo o correo electrónico.

- The Fee Study is available for review during normal business hours at 720 N Colusa St., Willows, CA 95988
- For more information about SGMA, see the California Department of Water Resources website: https://water.ca.gov/Programs/Groundwater-Management/SGMA-Groundwater-Management

If you do not wish to protest the proposed GGA Operations Fee, you need not take any action.

To Protest:

All protests must include:

- Landowners printed name(s),
- Parcel number(s) or street address for each property affected by the GGA Operations Fee,
- Statement of opposition or protest, and
- Valid signature(s)

Each parcel is entitled to one protest. The protest may be mailed in or hand delivered at the hearing but must be received by the GGA by the close of the hearing to count toward the protest vote.

For your convenience, you may utilize the Protest Form below:

GLENN GROUNDWATER AUTHORITY
AVISO DE AUDIENCIA SOBRE LA TARIFA PROPUESTA

En cumplimiento de la Ley del Estado de California, se notifica que la Glenn Groundwater Authority (GGA) realizará una **audiencia pública el día:**

8 de Julio del 2019 a las 5:30 p.m. en la Cámara del Consejo de la Ciudad de Willows ubicada en 201 N. Lassen St., Willows, CA para considerar la adopción de una **nueva tarifa relacionada con la propiedad en la cantidad de $ 1.93 por acre por año** para el Año Fiscal 2019 y los cuatro años fiscales subsiguientes, para financiar las operaciones de la GGA.

Antecedentes:

La GGA es una multi-agencia de Autoridad de Poderes Conjuntos constituida por nueve miembros que se formó el 20 de Junio del 2017. La GGA es la Agencia de Sostenibilidad del Agua Subterránea (GSA) responsable de la implementación y el cumplimiento de la Ley de Administración Sostenible del Agua Subterránea (SGMA) en el Condado de Glenn en la porción correspondiente de la Subcuenca de Colusa (5-21.52). El Consejo de la GGA está compuesta por representantes de las siguientes agencias:

> Condado de Glenn, Ciudad de Orland, Ciudad de Willows, Glenn-Colusa Irrigation District, Glide Water District, Princeton-Codora-Glenn Irrigation District / Provident Irrigation District (1 asiento), Orland-Artois Water District, y Kanawha Water District.

Como agencia reguladora del agua subterránea, la GGA (en asociación con otras GSA adyacentes, como la Colusa Groundwater Authority [CGA]) tiene la tarea de lograr y mantener condiciones sostenibles de las aguas subterráneas en la Subcuenca de Colusa (Cuenca). El cumplimiento con SGMA se logra a través de la preparación e implementación de uno o más Planes de Sostenibilidad de Agua Subterránea (GSP o Plan). El desarrollo del plan está en marcha en la Cuenca y el (los) Plan (es) debe (n) ser adoptado (s) antes del 31 de Enero del 2022. Si las GSA locales no cumplen con SGMA, incluido el desarrollo del (los) Plan (es) y las actividades necesarias para implementar los Planes, la Junta de Control de los Recursos Hídricos del Estado puede asumir las responsabilidades de administración del agua subterránea.

Financiamiento a Largo Plazo:

Con el fin de garantizar el cumplimiento inicial de SGMA y proporcionar un mecanismo para comenzar este esfuerzo de largo plazo, las agencias de Miembro de GGA acordaron financiar las operaciones de la agencia durante los primeros dos años. Las operaciones de GGA incluyen administración, servicios legales, servicios de consultoría, seguros, materiales de oficina y educación, contabilidad, monitoreo e informes al DWR, y estudios especiales, si son necesarios. El GGA ha recibido fondos de la Proposición 1 para cubrir la mayoría del trabajo para desarrollar un Plan; sin embargo, los costos para la preparación del Plan y la implementación inicial que excedan los fondos iniciales disponibles deberán también cubrirse con la Tarifa de Operaciones de GGA.

Para financiar sus actividades y el desarrollo de un Plan adecuado, el GGA desarrolló un presupuesto para los gastos de operaciones anuales para un período de cinco años que incluye los años fiscales 2019/20 a 2023/24. Este presupuesto incluye los costos proyectados para la preparación e implementación inicial del Plan, la administración, los servicios legales, los seguros, la impresión / copia, la contabilidad, la facilitación, el monitoreo y la presentación de informes al Departamento de Recursos Hídricos (DWR), y estudios especiales, si son necesarios.

SGMA otorga autoridad a GGA para cobrar tarifas para apoyar sus operaciones. GGA ha contratado a Provost & Pritchard Consulting Group para preparar un estudio de tarifas para revisar las mejores opciones para financiar las operaciones de GGA en los próximos cinco años. El estudio incluye un análisis de costos y tarifas de operaciones. Cada parcela de terreno dentro del límite de GGA recibe servicios de administración de SGMA de GGA y la tarifa se desarrolló asignando el presupuesto de GGA en proporción al costo de proporcionar servicios a cada acre de terreno en su área de servicio. Por ley, la GGA no puede recaudar más ingresos de las tarifas relacionadas con la propiedad de lo que es necesario para proporcionar el costo del servicio relacionado con el agua.

Uno de los Principios Rectores fundamentales es el de proteger su área de servicio de **acciones de intervención estatales del agua subterránea extremadamente costosas e intrusivas**.

Si la Junta de Control de los Recursos Hídricos del Estado interviene en la cuenca, podría imponer tarifas anuales con un mínimo de $100 por pozo, y hasta de $300 por pozo, y adicionalmente hasta $55 por acre-pie bombeado por pozo, sin garantía de asistencia en los costos de soporte para resolver los problemas de agua subterránea que causan su intervención. Para mayor información consulte el vínculo https://www.waterboards.ca.gov/water_issues/programs/gmp/docs/intervention/intervention_fs.pdf.
Al cobrar la Tarifa de Operaciones, la GGA les brindará a los propietarios una administración local del agua subterránea con un enfoque personalizado y más accesible para la administración de la Cuenca.

Notificación en Español:

Para leer este aviso en Español, visite el sitio web de la GGA https://www.countyofglenn.net/dept/agriculture/water-resources/glenn-groundwater-authority o llame al (916) 918-2020 para solicitar que se le envíe un aviso por correo o correo electrónico.

Aviso:

Además de este aviso, la GGA también publicó el aviso en el sitio web de la GGA en https://www.countyofglenn.net/dept/agriculture/water-resources/glenn-groundwater-authority y se publicó de conformidad con el Código de Gobierno 6066 y la sección 10730 del Código de Aguas.

Tarifa de Propriedad Propuesta:

Este aviso es para la propuesta de la GGA para implementar un cobro por acre para financiar las operaciones de la GGA, suplementar la preparación del Plan, y empezar la implementación inicial del GSP. La GGA está solicitando un cargo de:

- **$1.93 por acre** (en dólares del 2019)
- Los cargos propuestos, si se aprueban, entrarán en vigencia para el año fiscal 2019/20 del Condado de Glenn, con el primer pago que debe realizarse antes del 10 de Diciembre del 2019.

Para obtener más información, incluido el estudio de tarifas que resume los resultados, visite el sitio web de la GGA en https://www.countyofglenn.net/dept/agriculture/water-resources/glenn-groundwater-authority o llame a Provost & Pritchard (Consultor de GGA) al (916) 918-2002. El estudio de tarifas también está disponible para revisión durante las horas normales de trabajo en 720 N Colusa St., Willows, CA 95988.

Audiencia Pública y Protesta Mayoritaria:

La Tarifa de Operaciones del GGA propuesta es una tarifa relacionada con la propiedad que se rige por la Proposición 218. Según la Constitución del Estado de California, los propietarios de tierras sujetas a la Tarifa de Operaciones de la GGA propuesta tienen el derecho de protestar por su adopción. Si ha recibido este aviso, las parcelas bajo su propiedad estarán sujetas a la adopción de la Tarifa de Operaciones de la GGA. Si se presentan protestas por escrito que representan la mayoría del total de parcelas evaluadas, la GGA no adoptará la Tarifa de Operaciones. A falta de una protesta mayoritaria, la GGA está autorizada para adoptar la Tarifa de Operaciones propuesta en la audiencia pública de adopción.

Los propietarios que deseen protestar la Tarifa de Operaciones de la GGA propuesta deben enviar su protesta por escrito a:

Glenn Groundwater Authority
c/o Provost & Pritchard Consulting Group
P.O. Box 8929
Chico, California 95927

Las protestas también pueden presentarse al Secretario de la Junta en la Audiencia Pública, ubicada en la Cámara del Consejo de la Ciudad de Willows, 201 N. Lassen St., Willows, California. **Todas las protestas deben recibirse antes del cierre de la audiencia pública del 8 de Julio del 2019 para ser contadas.**

Disponibilidad de Información:

- Llame a Provost & Pritchard (Consultor de GGA) al **(916) 918-2002**
- Vea más información en línea en https://www.countyofglenn.net/dept/agriculture/water-resources/glenn-groundwater-authority
- Para leer este aviso en Español, visite el sitio web de la GGA https://www.countyofglenn.net/dept/agriculture/water-resources/glenn-groundwater-authority o llame al (916) 918-2020 para solicitar que se le envíe un aviso por correo o correo electrónico.
- El Estudio de Tarifas está disponible para revisión durante las horas normales de trabajo en 720 N Colusa St., Willows, CA 95988
- Para obtener más información sobre SGMA, consulte el sitio web del Departamento de Recursos Hídricos de California: https://water.ca.gov/Programs/Groundwater-Management/SGMA-Groundwater-Management

Si no desea protestar por la Tarifa de Operaciones de la GGA propuesta, no necesita realizar ninguna acción.

Para Protestar:

Todas las protestas deben incluir:

- Nombre escrito del(los) dueño(s),
- Número de la(s) parcela(s) o dirección para cada propiedad afectada por la Tarifa de Operaciones de la GGA.
- Declaración de oposición o protesta, y
- Firma(s) válida(s)

Cada parcela tiene derecho a una protesta. La protesta puede ser enviada por correo o entregada personalmente en la audiencia, pero debe ser recibida por la GGA antes del cierre de la audiencia para el conteo de los votos de protesta.

Para su conveniencia puede utilizar el Formulario de Protesta que está a continuación:

FORMULARIO DE PROTESTA PARA LA ADOPCIÓN DE LA TARIFA DE OPERACIONES

Nombre escrito del(los) Dueño(s): _____

_____

_____

Número(s) de Parcela(s): _____

_____

Razón para la Protesta:

Firma del(los) propietario(s): _____

GLENN GROUNDWATER AUTHORITY

AFFIDAVIT OF MAILING OF NOTICE OF HEARING AND MAJORITY PROTEST FORM TO CERTAIN LANDOWNERS WITHIN THE BOUNDARIES OF THE GLENN GROUNDWATER AUTHORITY

STATE OF CALIFORNIA)
) ss.
COUNTY OF GLENN)

The undersigned says:

That I, Linda G. Sloan, am Vice President of Provost & Pritchard, an agent of the Glenn Groundwater Authority, and was responsible for managing the mailing the Notice of Public Hearing to landowners from a list prepared from the County's tax roll on the Authority's proposed property-related fee.

I declare that at or before 5:00 p.m. on May 23, 2019, I supervised the mailing of copies of the "**NOTICE OF PROPOSED FEE**", and protest form, both in the form attached hereto marked Exhibit "A", to all landowners that would be affected by the Authority's proposed fee within the boundaries of the Authority as shown on the roll attached as Exhibit "B". Each Notice contained the specific applicable information taken from the roll.

That said mailing was accomplished by depositing in the United States Mail at Chico, California, with proper and necessary postage prepaid, envelopes addressed as aforesaid.

I CERTIFY under penalty of perjury that the foregoing is true and correct.

Executed at Siskiyou County, California, this 8 day of July, 2019.

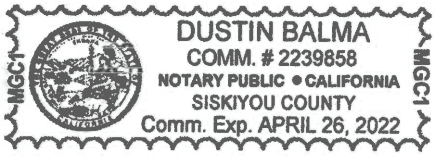
Linda G. Sloan

Please see attached sheet for CA
Acknowledgment/Jurat
As per CA Civil Codes 1189/8202

Exhibit A: Notice and Protest Form
Exhibit B: County's Tax Roll

CALIFORNIA ALL-PURPOSE ACKNOWLEDGEMENT

A Notary Public or other officer completing this certificate verifies only the identity of the individual who signed the document to which this certificate is attached, and not the truthfulness, accuracy, or validity of that document.



State of California
County of Siskiyou }

On 8th July 2019, before me, Dustin Balma, Notary Public,

personally appeared Linda G Sloan

who proved to me on the basis of satisfactory evidence to be the person(s) whose name(s) is/are subscribed to the within instrument and acknowledged to me that he/she/they executed the same in his/her/their authorized capacity(ies), and that by his/her/their signature(s) on the instrument the person(s), or the entity upon behalf of which the person(s) acted, executed the instrument.

I certify under PENALTY OF PERJURY under the laws of State of California that the foregoing paragraph is true and correct.

PROOF OF PUBLICATION

No. 3778

In the Matter of

Glenn Groundwater Authority- Notice of Public Hearing on July 8, 2019 at 5:30 pm Pursuant to Water Code section 10730(b)(2) and Government Code section 6066...

State of California)
County of Glenn) ss

The undersigned resident of the County of Glenn, State of California, says:

That I am, and at all time herein mentioned was a citizen of the United States and not a party to nor interested in the above entitled matter; that I am the principal clerk of the publisher of:

The Sacramento Valley Mirror

That said newspaper is one of general circulation as defined by Section 6000 Government Code of the State of California, Case No. 27,207 by the Superior Court of the State of California, in and for the County of Glenn,Case #02CV00614; that said newspaper at all times herein mentioned was published twice a week (on Wednesdays and Saturdays) in the town of Willows and County of Glenn; that the notice of which the annexed is a true printed copy, was published in said newspaper on the following days:

June 22, 29, 2019

I certify (or declare), under penalty of perjury, that the foregoing is true and correct, at the County of Glenn,Willows, California.

Date July 1, 2019
at Willows, California.

Tim Crews, Publisher

NOTICE OF PUBLIC HEARING

Pursuant to Water Code section 10730(b)(2) and Government Code section 6066, notice is hereby given that the Glenn Groundwater Authority will hold a public hearing on **July 8, 2019** at 5:30 pm, or as soon thereafter as may be heard, at the Willows City Council Chambers, 201 North Lassen Street, Willows, CA 95988, to consider the adoption of a new property related fee in the amount of $1.93 per acre annually for the 2019 Fiscal Year and the subsequent four fiscal years to fund the operations of the Glenn Groundwater Authority to comply with the Sustainable Groundwater Management Act of 2014.

Information regarding the proposed fee is available online at https://www.countyofglenn.net/dept/agriculture/water-resources/glenn-groundwater-authority/gga-information, by calling the Glenn Groundwater Authority Consultant at (916) 918-2002, or by visiting the Glenn Groundwater Authority office at 720 North Colusa Street, Willows, CA 95988.

AGENDA

Public Information Workshop
Sustainable Groundwater Management Act (SGMA)
Implementation and Funding

March 21, 2019
6:00 - 8:00 p.m.
Glenn Success Square Conference Center
131 E. Walker Street, Orland, CA

6:00 **Welcome and Introductions** (John Viegas – Glenn Groundwater Authority [GGA])

6:10 **Meeting Kickoff and Agenda Review*** (Facilitator – Dave Ceppos - Sacramento State)

6:15 **Presentation** (Dave Ceppos)

- **Sustainable Groundwater Management Act Overview**
- **Glenn Groundwater Authority Background**
- **Financing SGMA Implementation**
- **SGMA Local Compliance and Potential State Intervention**

7:15 **Questions and Answer Session**

8:00 **Adjourn**

*Attendees will be given cards to write questions they would like answered during the Question and Answer Session. Board members and staff will be available to help formulate questions, bring new comment cards, and collect comment cards.
*Breaks will be provided as time permits and at the discretion of the facilitator

Glenn Groundwater Authority

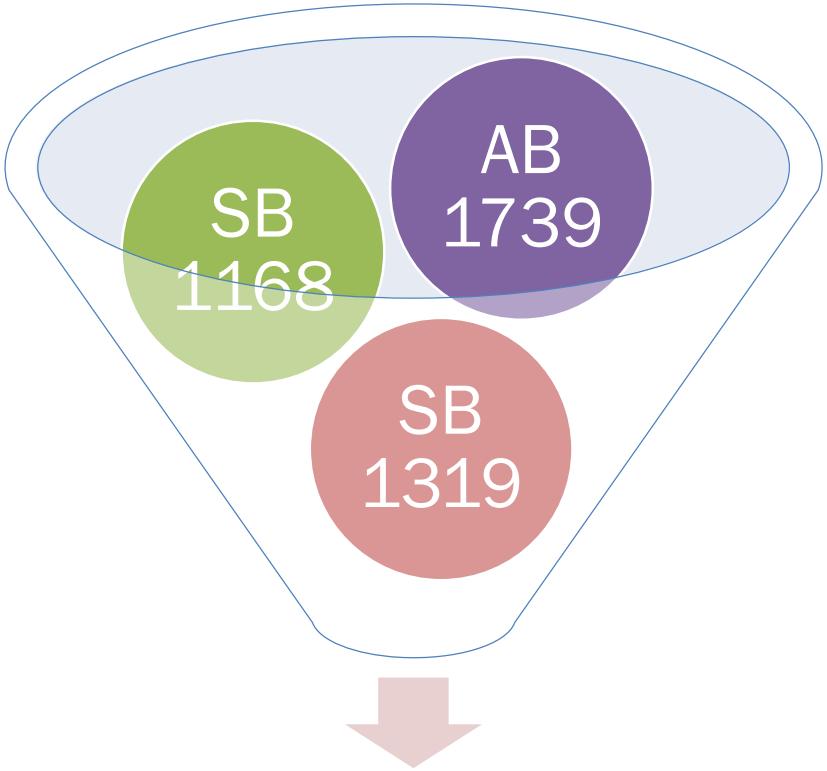
Public Hearing on Proposed Property Related Fee

July 8, 2019

Dave Ceppos
Consensus and Collaboration Program
College of Continuing Education, Sacramento State

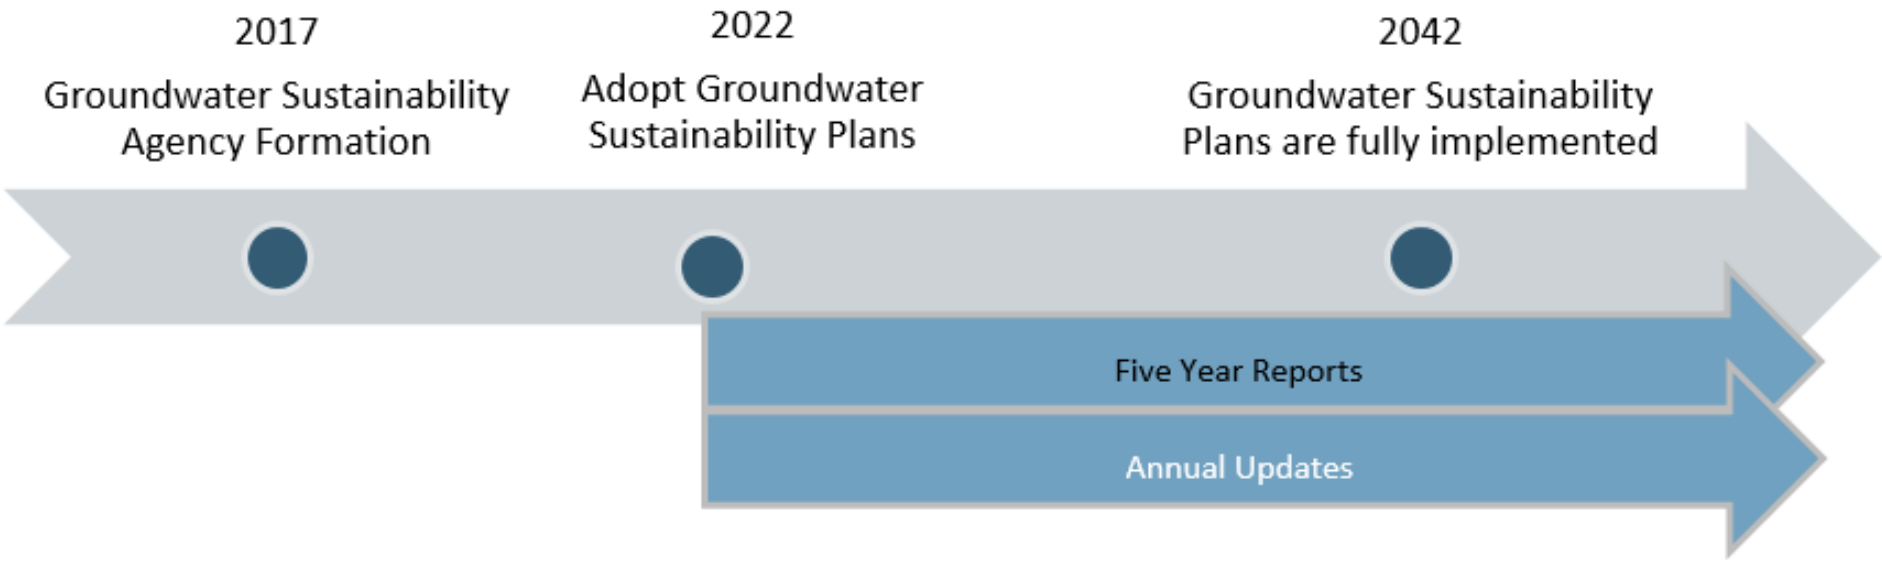
Program

- Sustainable Groundwater Management Act (SGMA) Overview
- Glenn Groundwater Authority
- Financing SGMA Implementation



SGMA Overview

SGMA: Sustainable Groundwater Management Act of 2014



SGMA is Law

- Collection of Three Bills signed into law in 2014
- Established new structure for managing groundwater resources in California
- SGMA is NOT the Irrigated Lands Regulatory Program (Colusa-Glenn Subwatershed)

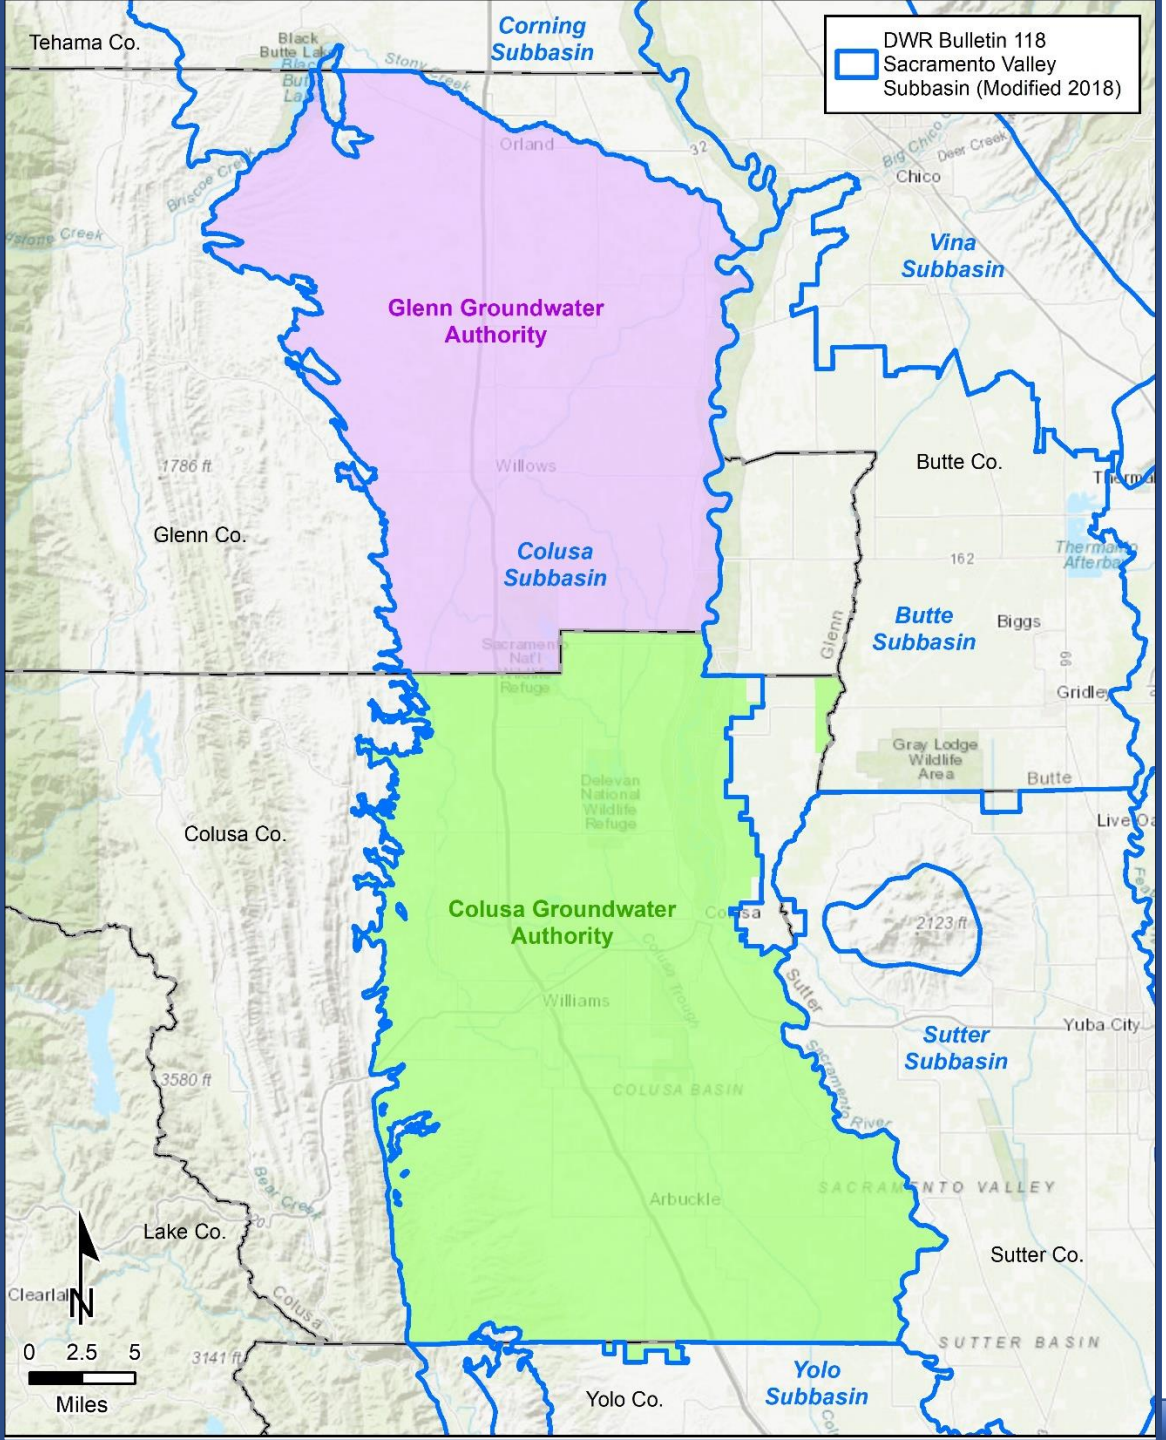
Sustainable Groundwater Management Act of 2014

SGMA Timeline-
Basins not in Critical Overdraft

Note: Critically overdrafted subbasins have a compressed timeline

SGMA: Who is Affected

Agriculture



Municipal

Industrial

Environmental

Groundwater Basins & Subbasins

- Department of Water Resources defines:
  - Basin/Subbasin Boundaries (Bulletin 118)
  - Basin Priority
  - Designation of Critical Overdraft (or not)

Map of the Colusa Subbasin

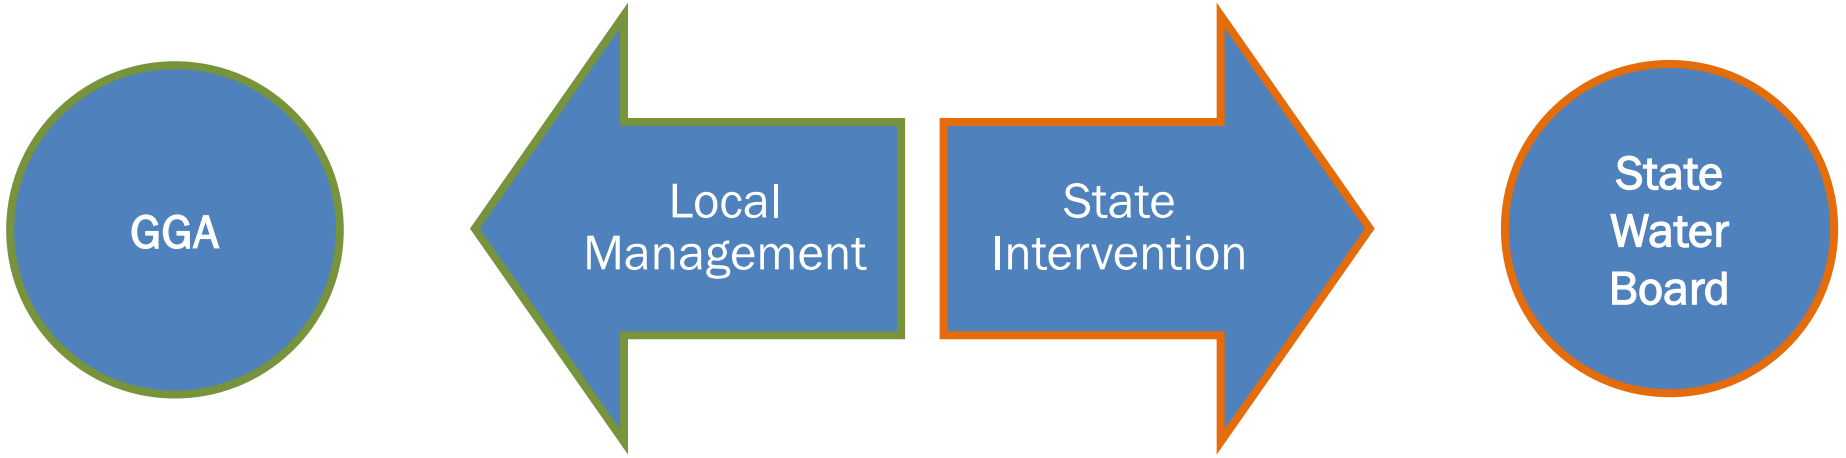
Who Can Manage the Basin?

- Groundwater Sustainability Agency
  - Local Public Agency
  - Land Use
  - Water Supply
  - Water Management

(Glenn Groundwater Authority)

- State Water Resources Control Board

(State Intervention)



Managing Agency Roles & Responsibilities

- Groundwater Sustainability Plan
  - Development
  - Implementation
  - Reporting
- Consider Interests of Beneficial Uses and Users (Water Code §10723.2)
- Enforcement

Sample Fee Comparison

Scenario:

- 100 acre irrigated parcel
- 1 well
- GGA Local Control

Maximum Local GGA Fees: $193

- 100 acre X $1.93= $193

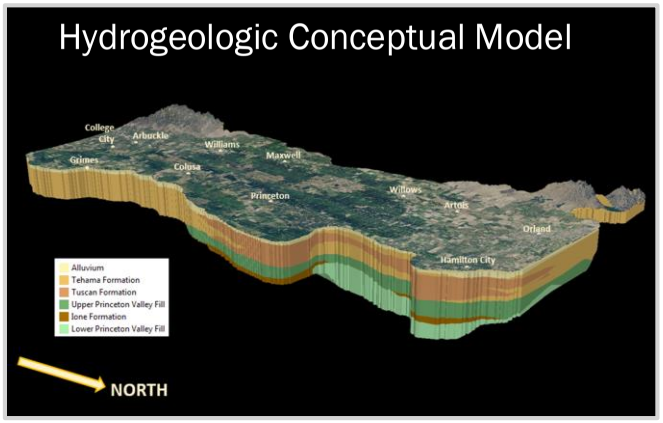
Scenario:

- 100 acre irrigated parcel
- 1 well
- Probationary basin status

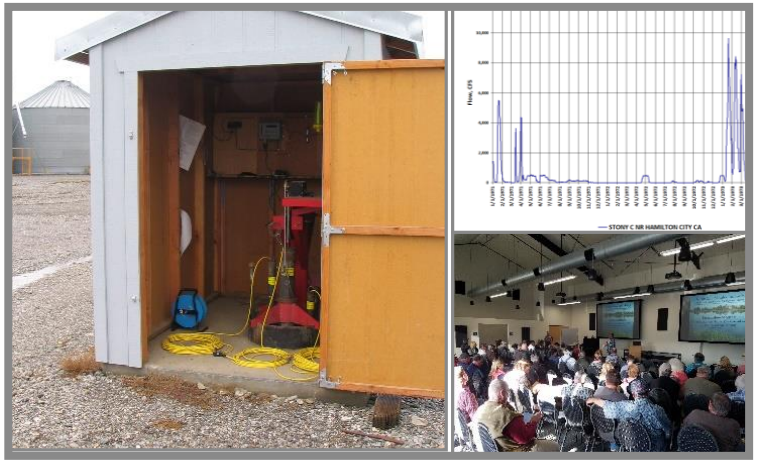
State Water Board Fees: $14,300

- 1 well = $300
- 3.5 AF/ac = 350 AF X $40 = $14,000

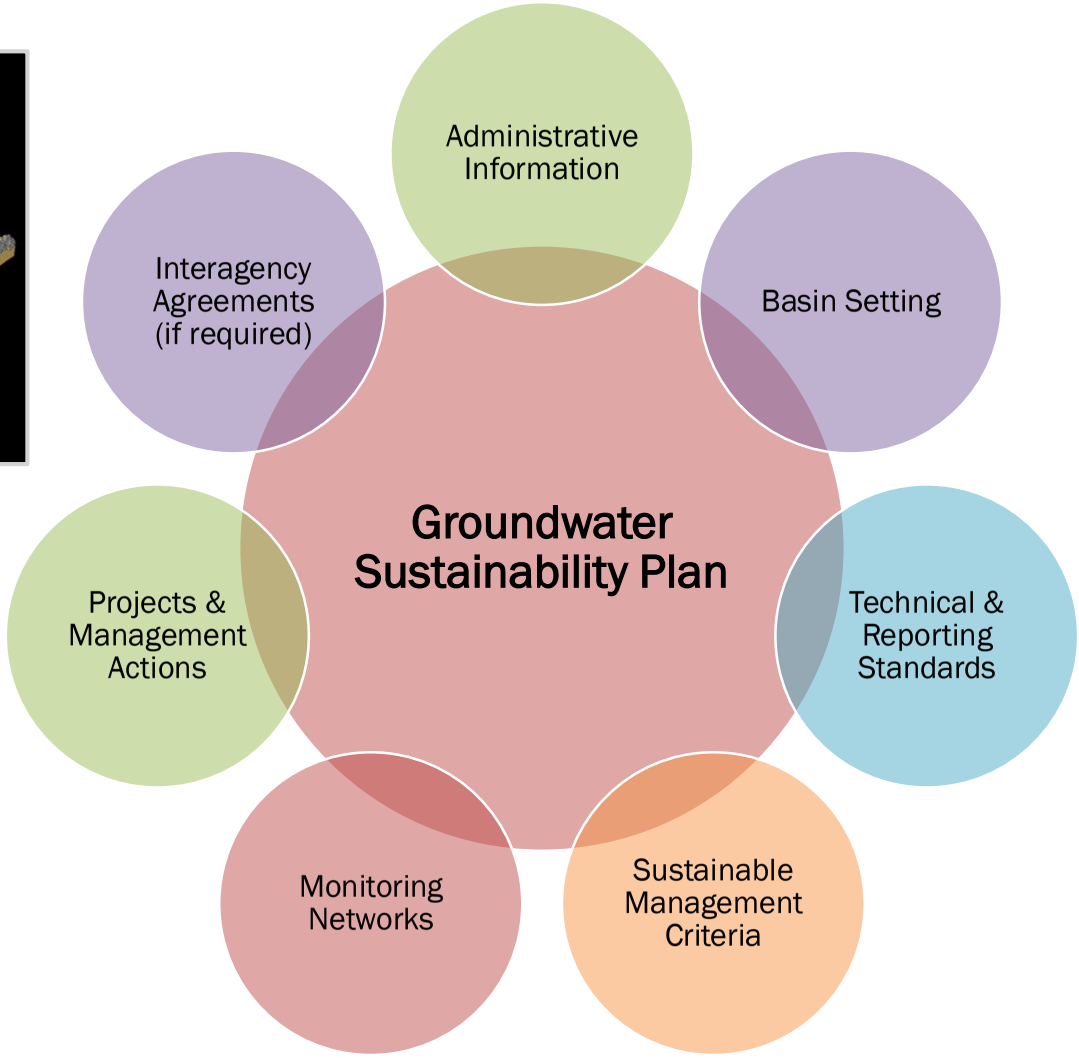
Sustainability



What is Sustainability?

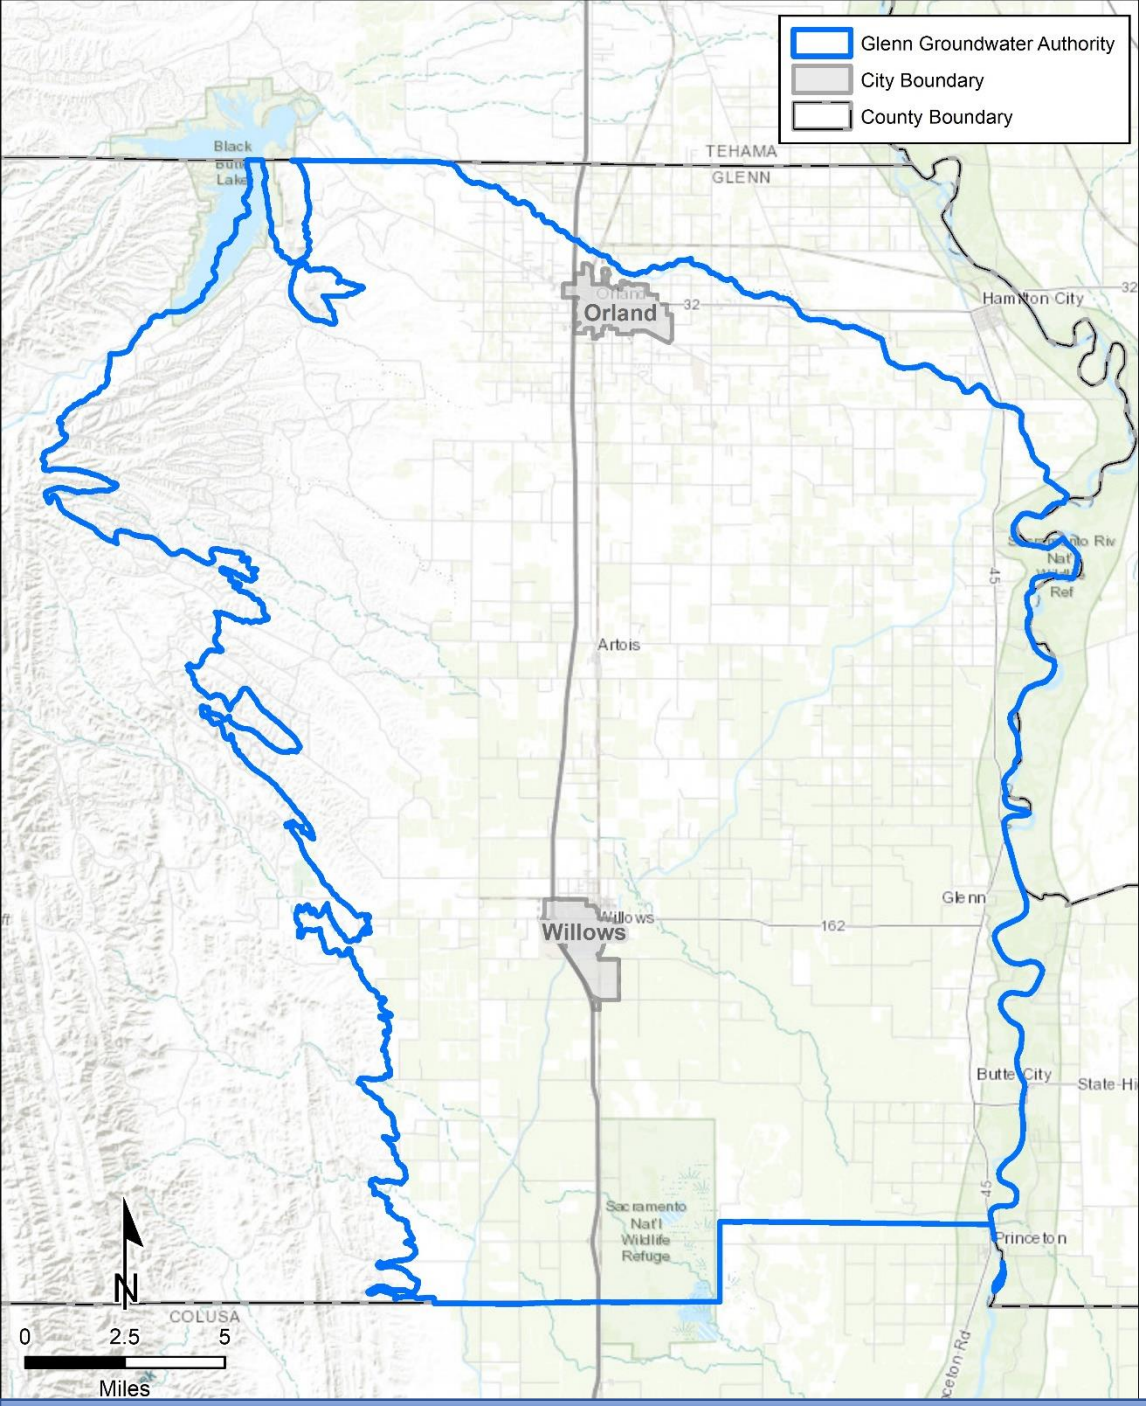


Manage groundwater to prevent significant and unreasonable undesirable results



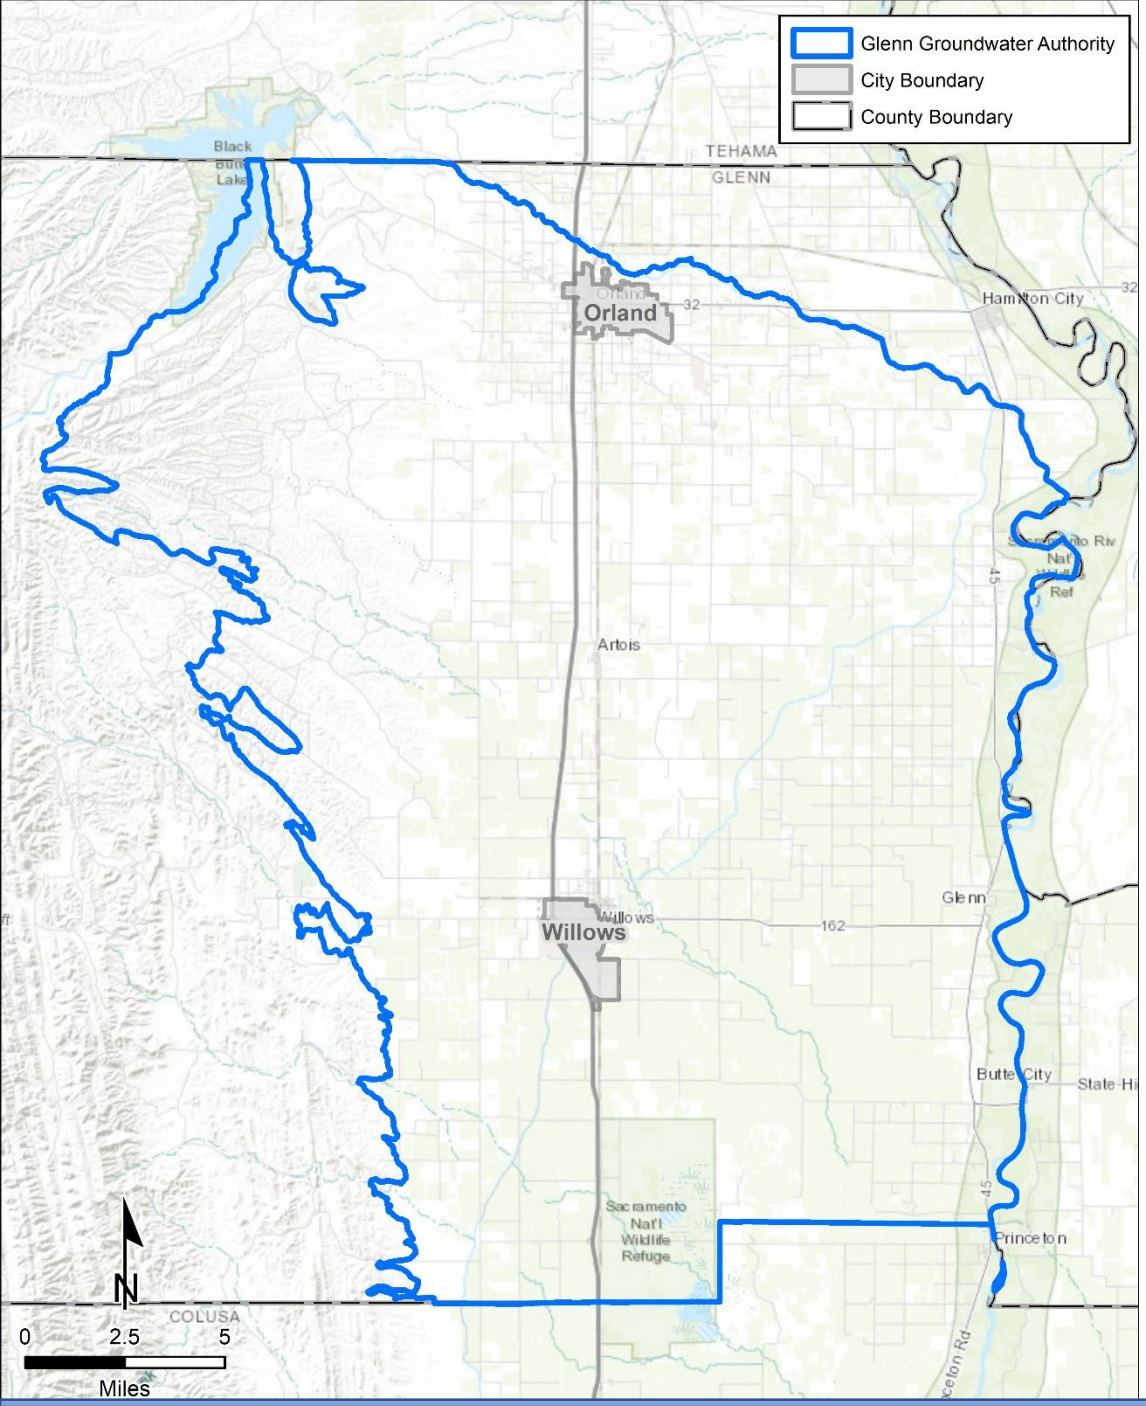
Groundwater Sustainability Plan

What is in a Plan?



Glenn Groundwater Authority

Your Groundwater Sustainability Agency: Local Management



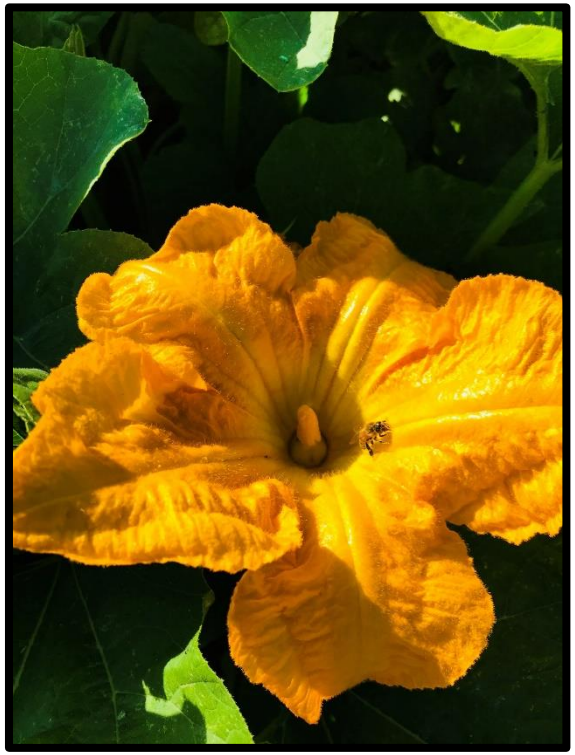
Glenn Groundwater Authority members:

- City of Orland
- City of Willows
- County of Glenn
- Glenn-Colusa Irrigation District
- Glide Water District
- Kanawha Water District
- Orland-Artois Water District
- Princeton-Codora-Glenn Irrigation District
- Provident Irrigation District

One new member pending:

- Glenn Ground Water District

Activities:



- **Proposition 1 GSP Grant**
- MOU with Colusa Groundwater Authority
- Basin Setting work
  - Hydrogeologic Conceptual Model
  - Water Budget
- **Facilitation Support Services**
  - Stakeholder Communication & Engagement Plan
- **Technical Support Services**
  - Monitoring Well installation
- Request for Proposals for GSP development
- Long-Term Funding Process

Financing SGMA

Financing SGMA

- Activities funded by member agencies for 2 years- beginning in 2017
- Pursued basin-wide funding opportunities with Colusa Groundwater Authority
  - Proposition 1 GSP Development Grant
  - Technical Support Services
  - Facilitation Support Services

Financing SGMA

- **Need long-term funding for day to day operations of the GGA:**

  •Technical: GSP development ($1.5 million), technical studies, monitoring and data management, coordination and outreach efforts, implementation of the GSP, yearly reporting to DWR, Plan updates every five years

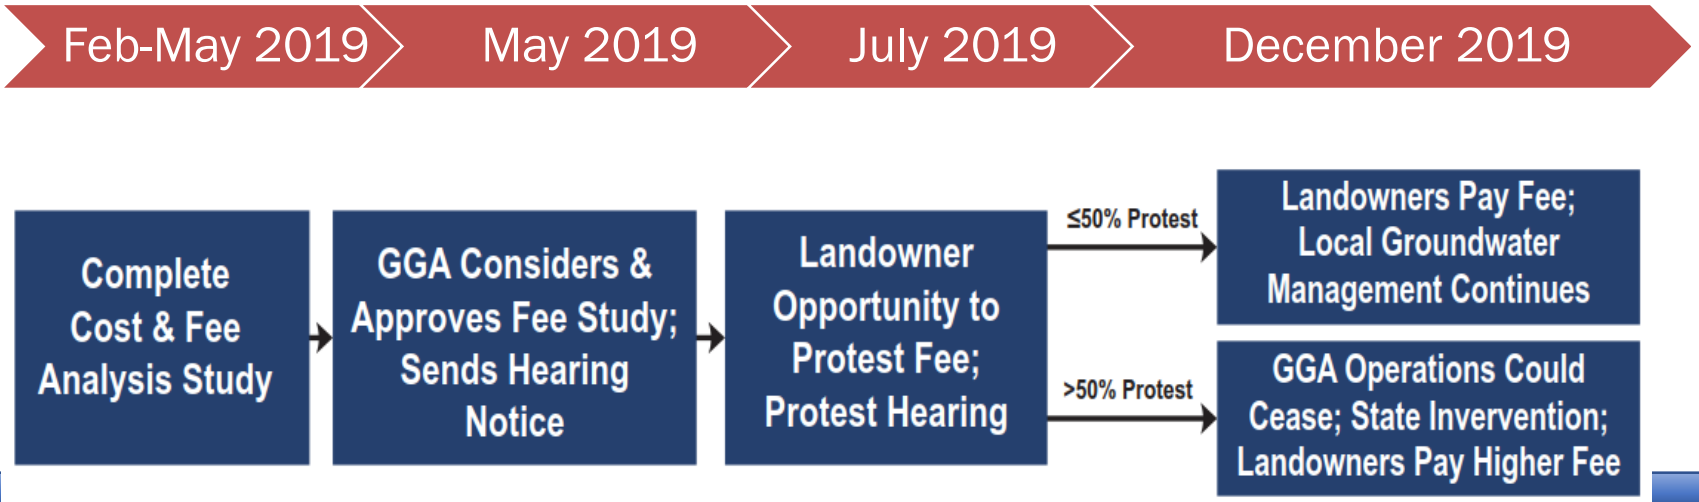
  •O&M: Staff, insurance, legal services, bookkeeping, office needs, etc.

Financing SGMA

Proposition 218 Requirements

- GGA contracted with Provost and Pritchard Engineering (P&P) to conduct a Proposition 218 Majority Protest
- P&P completed a fee study to determine a fee structure based on GGA budget and acreages in the GGA's jurisdiction
- Amount of fee cannot exceed the reasonable cost of the activity to be funded
- Three Public Information Workshops were held March-April 2019
- A similar process was completed for the Colusa Groundwater Authority

Financing SGMA

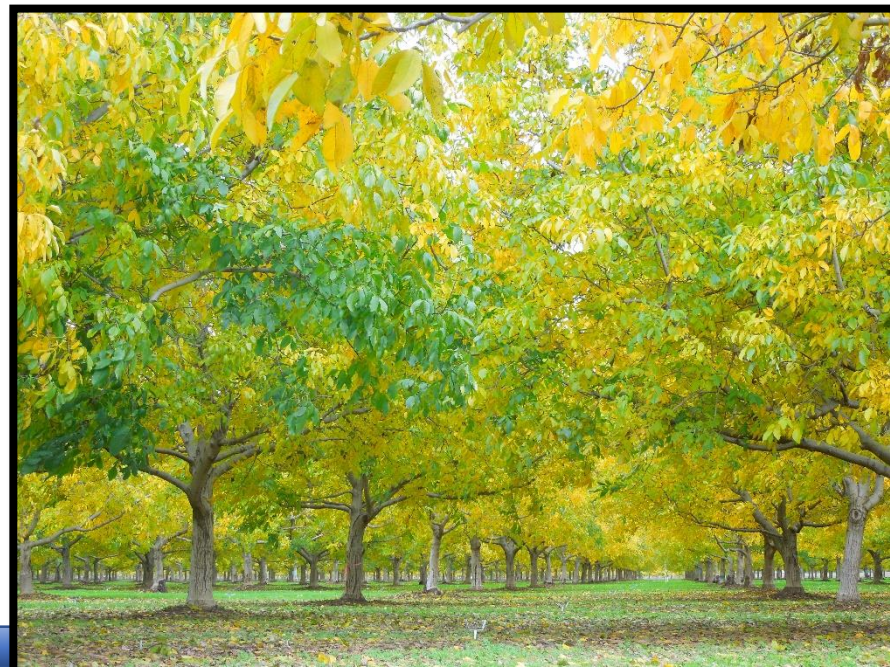


Proposition 218 Requirements

- Fees must be based on the reasonable cost of providing service
  - GGA's annual operating budget
- Fees must proportionally recover costs from ratepayers (i.e. no subsidies)
  - $/acre fee
- Fees in the Prop 218 notice are the max fees that may be adopted
  - Board may lower fees without conducting another Prop 218 notice and hearing process

Financing SGMA

Proposition 218 Requirements



- Hold public informational meeting (NOT required)
- Mail a protest notice to property owners
- Hold a public hearing minimum of 45 days later
- If there is NOT a majority protest, GGA may adopt fees
- If the Proposition 218 effort passes, a fee will appear on December 2019 property tax roll

Financing SGMA

Who is Subject to the Fees?

- All property owners have an overlying right and benefit from a healthy groundwater system
- If the fee is adopted, the City of Orland and the City of Willows agreed to pay the GGA directly on behalf of the landowners for all acreage within the cities' boundaries

Financing SGMA

What Benefits Do I Receive?

- All property owners have an overlying right whether exercised or not
- All property owners benefit from a healthy groundwater system
- Local Representation (GGA Represents You)
  - Seeks funding opportunities for GSP development and studies
  - Venue for local input & stakeholder engagement
  - Local Control & Planning
  - Coordinate with other local plans & build on previous efforts
- Avoid State Intervention (Control & Fees)

Financing SGMA

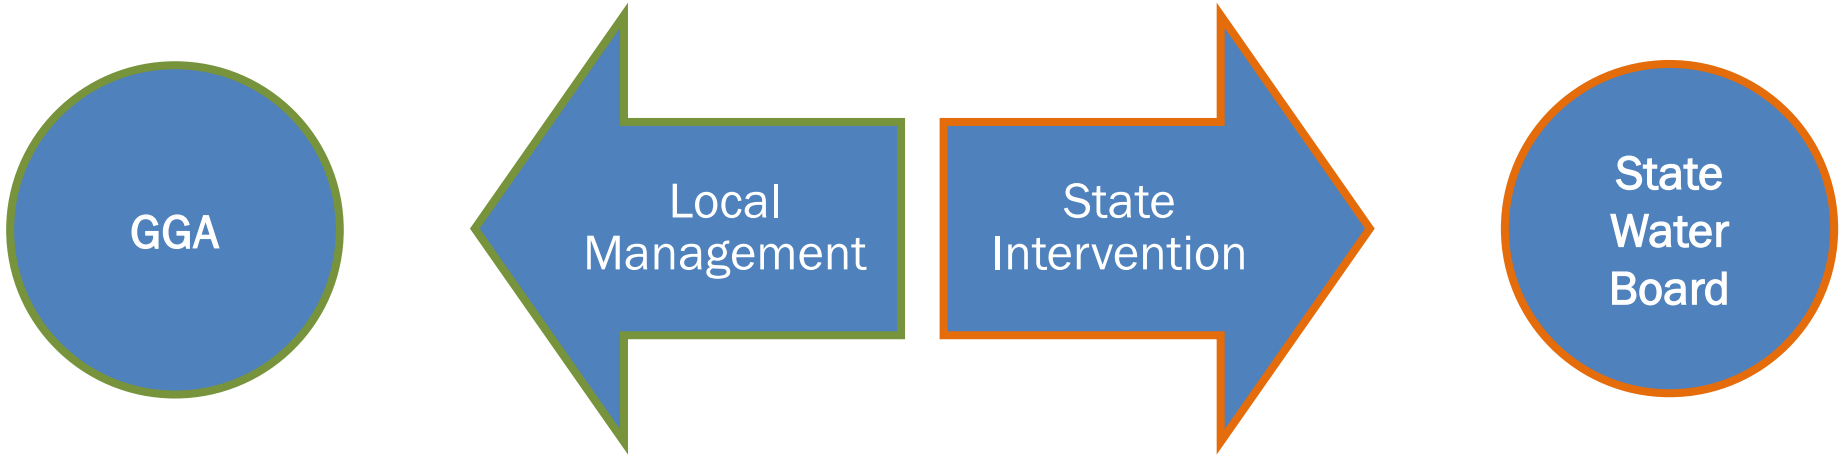
GGA Fee Calculation

Category	Calculation
Budget	$550,900
Acres	285,190.63
Max Fee ($/acre)	$1.93

State Intervention

State Board intervention actions can include:

- Well Head fees
- Volumetric fees (fee per acre-foot of water pumped)
- Late fees (subject to backdating to 2017)
- Mandatory extraction reporting including monthly pumping data
- May require installation of meters on wells at owner's expense
- Technical reporting and special studies at landowners' expense
- Any corrective actions will likely result in pumping restrictions



State Intervention

SWRCB Fees, 2018

BASE FEE (per well)	**$300**
Volumetric Fee (per AF)	
Unmanaged, metered	**$10/AF**
Unmanaged, unmetered	**$25/AF**
An unmanaged area is a part of a basin not within the management area of a GSA before July 1, 2017	
Probation	**$40/AF**
If locals fail to form a GSA, fail to develop an adequate sustainability plan, or fail to implement the plan successfully, the Board may designate the entire basin probationary. The Board may require the use of a meter to measure extractions and reporting of additional information.	
Interim Plan	**$55/AF**
If local agencies are unable to fix the deficiencies, the Board will develop an interim plan to directly manage groundwater extractions.	
De minimis (less than 2 AF/year)	**$100/well**
Late Fee	**25% per month**

https://www.waterboards.ca.gov/water_issues/programs/gmp/sgma.html

Sample Fee Comparison

Scenario:

- 100 acre irrigated parcel
- 1 well
- GGA Local Control

Maximum Local GGA Fees: $193

- 100 acre X $1.93= $193

Scenario:

- 100 acre irrigated parcel
- 1 well
- Probationary basin status

State Water Board Fees: $14,300

- 1 well = $300
- 3.5 AF/ac = 350 AF X $40 = $14,000

   Sustainable Groundwater Management Act (SGMA), Colusa Groundwater Authority, Financing SGMA

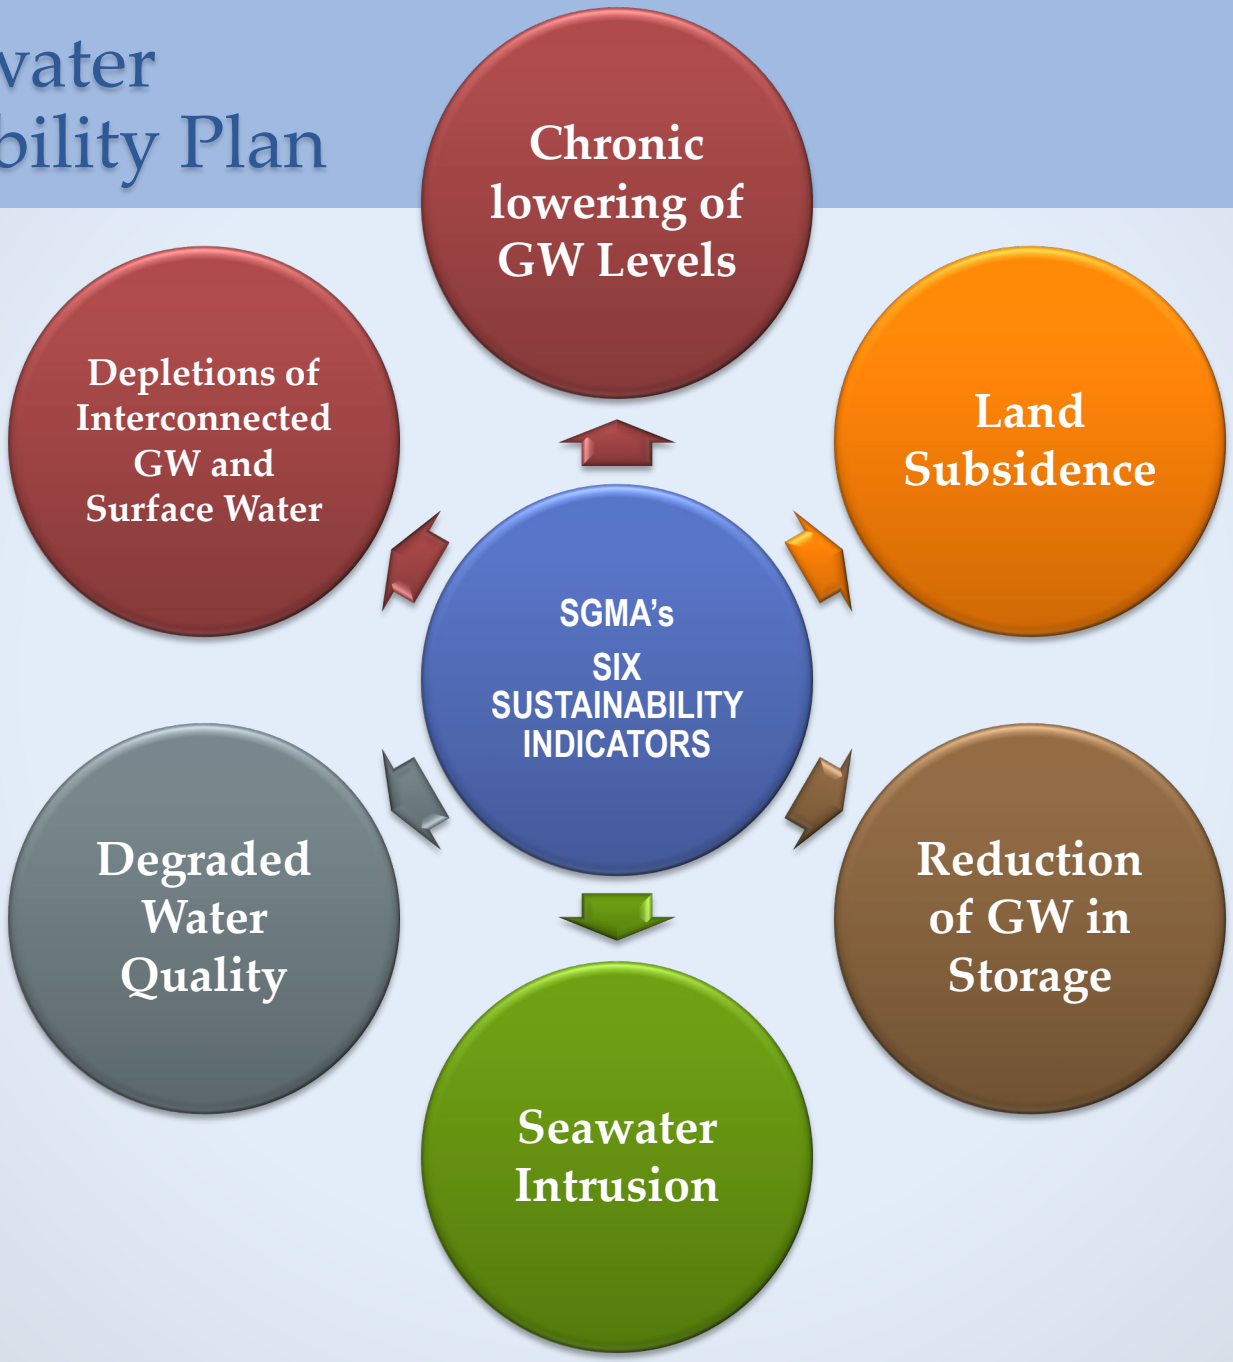
2. **Board Member Comments**

3. **Q&A**

SGMA: Sustainable Groundwater Management Act of 2014

SGMA: Sustainable Groundwater Management Act of 2014

* Historic Law, signed by Gov. Brown Dec., 2014
* First time Groundwater is regulated in California



CFBF: "SGMA is the most significant change to water law in a century and will significantly impact farmers and ranchers throughout California."

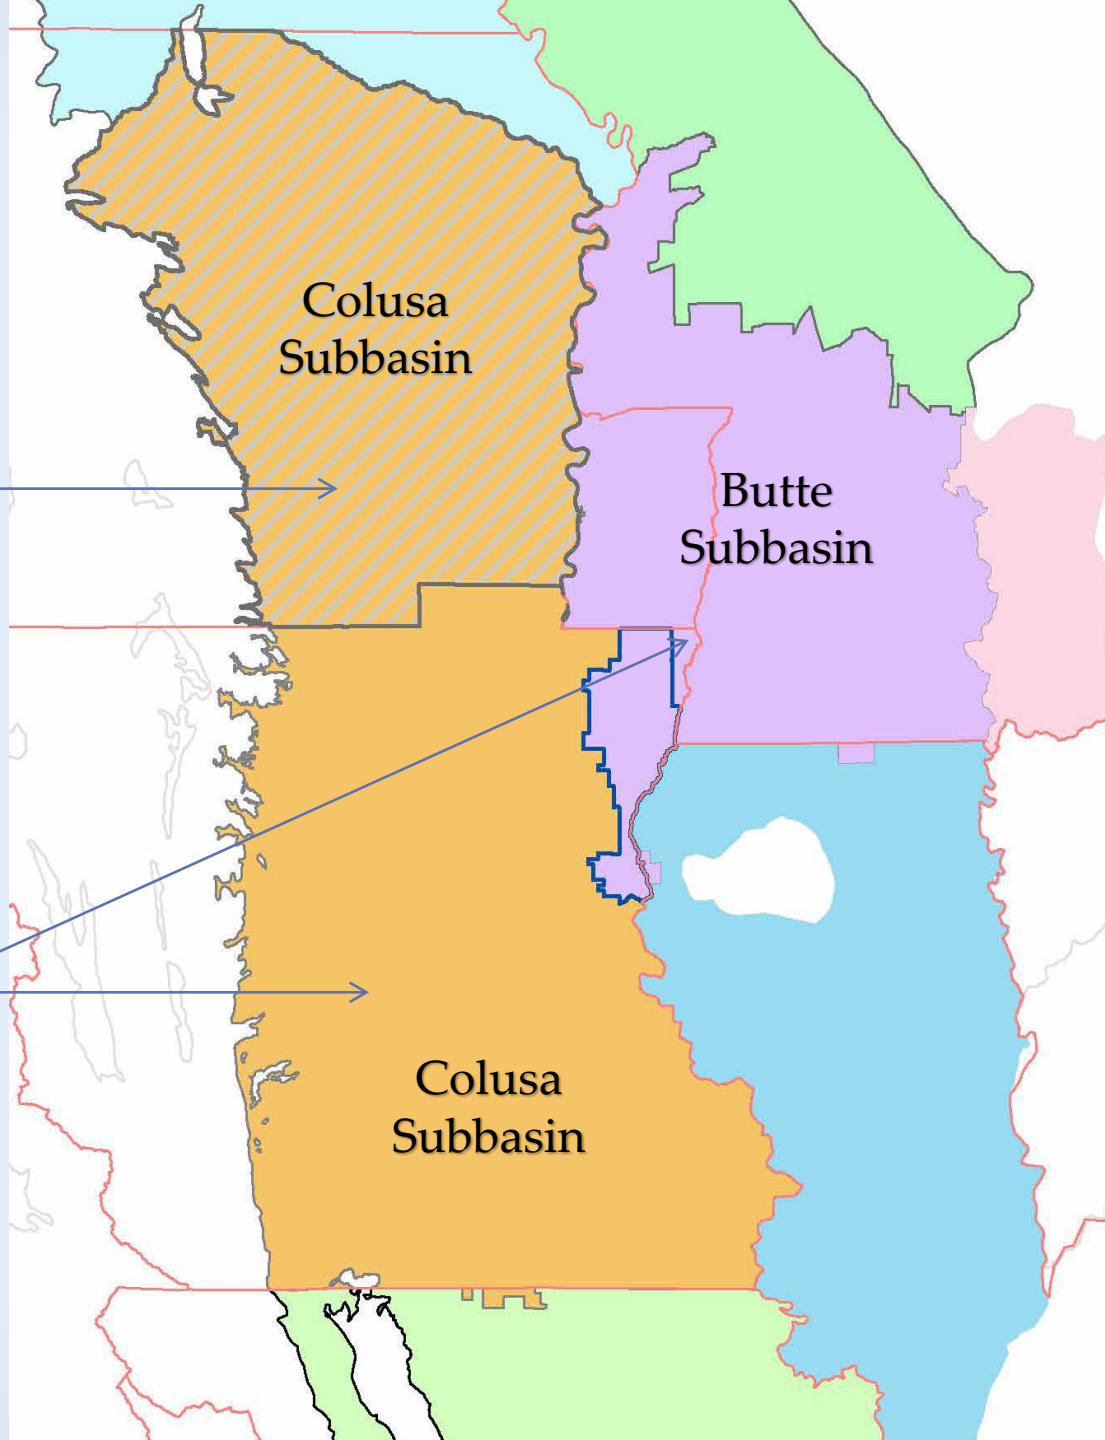
SGMA is a completely different program than the Irrigated Lands Regulatory Program.

SGMA: Sustainable Groundwater Management Act of 2014

Groundwater Sustainability Plan

Colusa Groundwater Authority, GSA

CGA formed June 29, 2017 as mandated by SGMA, after 2 years of meetings



CGA is a 12-member Joint Powers Authority Board

Efficiencies gained by forming one multi-agency GSA

- Public Meetings were held over the period of January, 2016 – June, 2017 to determine the best governance structure for the Colusa County portions of the groundwater basins
- JPA structure provides many efficiencies:
  - Allows the agencies to pool resources and work together closely, keeping expenses to a minimum
  - SGMA requires coordinated basin-wide planning and implementation – multiple GSAs/GSPs creates added expense and duplication of efforts
  - It is much easier for the public to have one agency and one set of meetings to go to for information

Develop and Implement a Groundwater Sustainability Plan
Public Outreach
Monitoring and Reporting
Compliance with local, state and federal laws and regulations
Coordination with other GSAs and Basins
Funding (grants, regulatory fees, property-related fees, local taxes, contributions, etc.)
Enforcement Actions
Adopt Rules, Regulations, Ordinances
GSA Roles, Responsibilities, Authorities

Develop and Implement a Groundwater Sustainability Plan
Public Outreach
Monitoring and Reporting
Compliance with local, state and federal laws and regulations
Coordination with other GSAs and Basins
Funding
(grants, regulatory fees, property-related fees, local taxes, contributions, etc.)
Enforcement Actions
Adopt Rules, Regulations, Ordinances
GSA Roles, Responsibilities, Authorities

Financing SGMA – Why?

- SGMA is the law – "unfunded mandate"
- GSAs are new, local government, **Regulating Agencies**
- GSAs must be funded to operate

If the CGA is unable to comply with SGMA due to a lack of sufficient funding , the State will intervene

- The agencies on the Board of the CGA funded the agency for the first two years (July 2017-June 2019)
- By June, 2019, CGA Member Agencies will have contributed a total of **$616,181, plus staff time, and other resources**
- Leveraging Grant Funding and other programs to keep costs down:
  - $1 million in Proposition 1 grant funding for GSP development in the Colusa Subbasin (shared with Glenn GW Authority)
  - DWR Facilitation Support Services, Technical Support Services

Financing SGMA – How?

- A Proposition 218 Majority Protest
- Similar process starting in the Glenn County portion of the Colusa Subbasin
- A fee study is being developed by a consultant team at Provost and Pritchard
- Per Acre Fee

Financing SGMA – Who?

Who is Subject to Fees?

- **All property owners in the CGA's jurisdiction:**
  - All property owners have an overlying right to groundwater and benefit from compliance with SGMA
- **Community Water Systems**:
  - The **Cities of Colusa and Williams** have a seat on the CGA Board and will continue to pay a fee to the CGA as before to cover the landowners in their jurisdiction. ***Homeowners within the cities' boundaries will not participate in the Proposition 218 process***
  - Homeowners in the communities of Arbuckle, Grimes, Maxwell and Princeton will be covered through their water suppliers, similar to the cities, ***and will not participate in the Proposition 218 process.***
  - This approach will keep costs down – it is not economically feasible to assess these small parcels

Financing SGMA - CGA Budget Forecast

	FY 2017/18	FY 2018/19	FY 2019/20	FY 2020/21	FY 2021/22	FY 2022/23	FY 2023/24
EXPENSES							
Administration	87,456	100,000	150,000	150,000	150,000	150,000	150,000
Legal Services	22,588	100,000	150,000	150,000	150,000	150,000	150,000
Office/Outreach Materials	516	1,000	8,500	8,500	8,500	8,500	8,500
Annual/Biennial Audits	-	9,500	9,750	10,000	-	20,000	-
Bookeeping		10,000	14,000	8,000	2,000	2,000	2,000
JPA Insurance	1,577	1,800	1,800	1,800	1,800	1,800	1,800
Consultant Prop 1 Grant GSP Proposal	6,343	-	-	-	-	-	-
GSP Development			102,175	67,175	79,350	-	-
Prop 218 Engineering Study	-	65,000	-	-	-	-	-
County Tax Collector	-	-	10,000	10,000	10,000	10,000	10,000
GSP Implementation, Monitoring/Reporting					50,000	50,000	50,000
Contingency	-	-	50,000	50,000	50,000	50,000	50,000
Total Expenses	118,480	287,300	496,225	455,475	501,650	442,300	422,300

Financing SGMA – Projected Costs

Initial Fee Estimate: $1.21/Acre

With yearly inflation factor (Consumer Price Index currently 3%):

2020/21 - **$1.25**	2021/22 - **$1.28**	2022/23 - **$1.32**	2023/24 - **$1.36**

Estimated at 3% - could vary

Cannot go above 2023/24 rate without another Prop. 218 effort

- Rate is pending outcome of final fee study
- SGMA is a new program, many unknowns
  - Budget is the most reasonable estimate at this time
  - The fee cannot exceed the reasonable costs of the CGA activities
- Fee is for day to day operations of the CGA
- Additional project-specific fees may also apply in the future

Financing SGMA - Statewide

GSA 1 – in Fresno County
$19.00/acre
entirely dependent on groundwater

GSA 2 – in Kings County
$5.00/acre initially
$3.00/acre in second year

GSA 3 – Salinas Valley
$2.27/non-ag acre to
$4.81 irrigated ag acre

State Intervention – Alternative to Prop. 218 Fee

State Board Intervention actions may include:

- Well Head fees
- Volumetric fees (fee per acre-foot of water pumped)
- Late fees (subject to backdating to 2017)
- Mandatory extraction reporting including monthly pumping data
- May require installation of meters on wells at owner's expense
- Technical reporting and special studies at landowners' expense
- Any corrective actions will likely result in pumping restrictions

Any **fees collected by the State will not benefit local groundwater management, or local projects**. Fees will go to SWRCB staffing.

State intervention will come at a **much greater cost** than SGMA implementation by the CGA.

State intervention will impose **restrictions without any local benefits.**

State Intervention – Alternative to Prop. 218 Fee

SWRCB Fees, 2018

BASE FEE (per well)	**$300**
Volumetric Fee (per AF)	
Unmanaged, metered	**$10/AF**
Unmanaged, unmetered	**$25/AF**
An unmanaged area is a part of a basin not within the management area of a GSA before July 1, 2017	
Probation	**$40/AF**
If locals fail to form a GSA, fail to develop an adequate sustainability plan, or fail to implement the plan successfully, the Board may designate the entire basin probationary. The Board may require the use of a meter to measure extractions and reporting of additional information.	
Interim Plan	**$55/AF**
If local agencies are unable to fix the deficiencies, the Board will develop an interim plan to directly manage groundwater extractions.	
De minimis (less than 2 AF/year)	**$100/well**
Late Fee	**25% per month**

https://www.waterboards.ca.gov/water_issues/programs/gmp/sgma.html

State Intervention – Alternative to Prop. 218 Fee

Sample Fee Comparison

100 acre irrigated parcel with one well, probationary basin

Estimated Max. CGA Fee: $136

100 Acres X $1.36 = $136

→ **Local Control, Local Management Local Benefit**

SWRCB Fees: $12,300

1 well = $300

3 AF/ac = 300 AF X $40 = $12,000

→ **Fees will not benefit local groundwater management, or local projects.**

Corrective actions will equal reduced pumping.

Financing SGMA – Next Steps

1. Continued Public Outreach Meetings
2. Fee Study Completed (within next two weeks)
3. Protest Notice and instructions mailed to property owners **April 19 (tentative)**- election is a written protest.
4. Public Hearing minimum of 45 days after mailing – anticipated **June 5, 2019 (tentative)** also deadline to submit a written protest
5. Absent majority protest, CGA may adopt fees
6. If passed, fee will appear on December 2019 property tax roll, and yearly there after

Upcoming Town Hall Meetings

COLUSA/PRINCETON/GRIMES
March 14, 2019 at 6:00 p.m.
Colusa Veteran's Hall
108 East Main Street, Colusa, CA 95932

MAXWELL/WILLIAMS
March 20, 2019 at 6:00 p.m.
Sites Project Authority Office
122 Old Highway 99 W., Maxwell, CA 95955

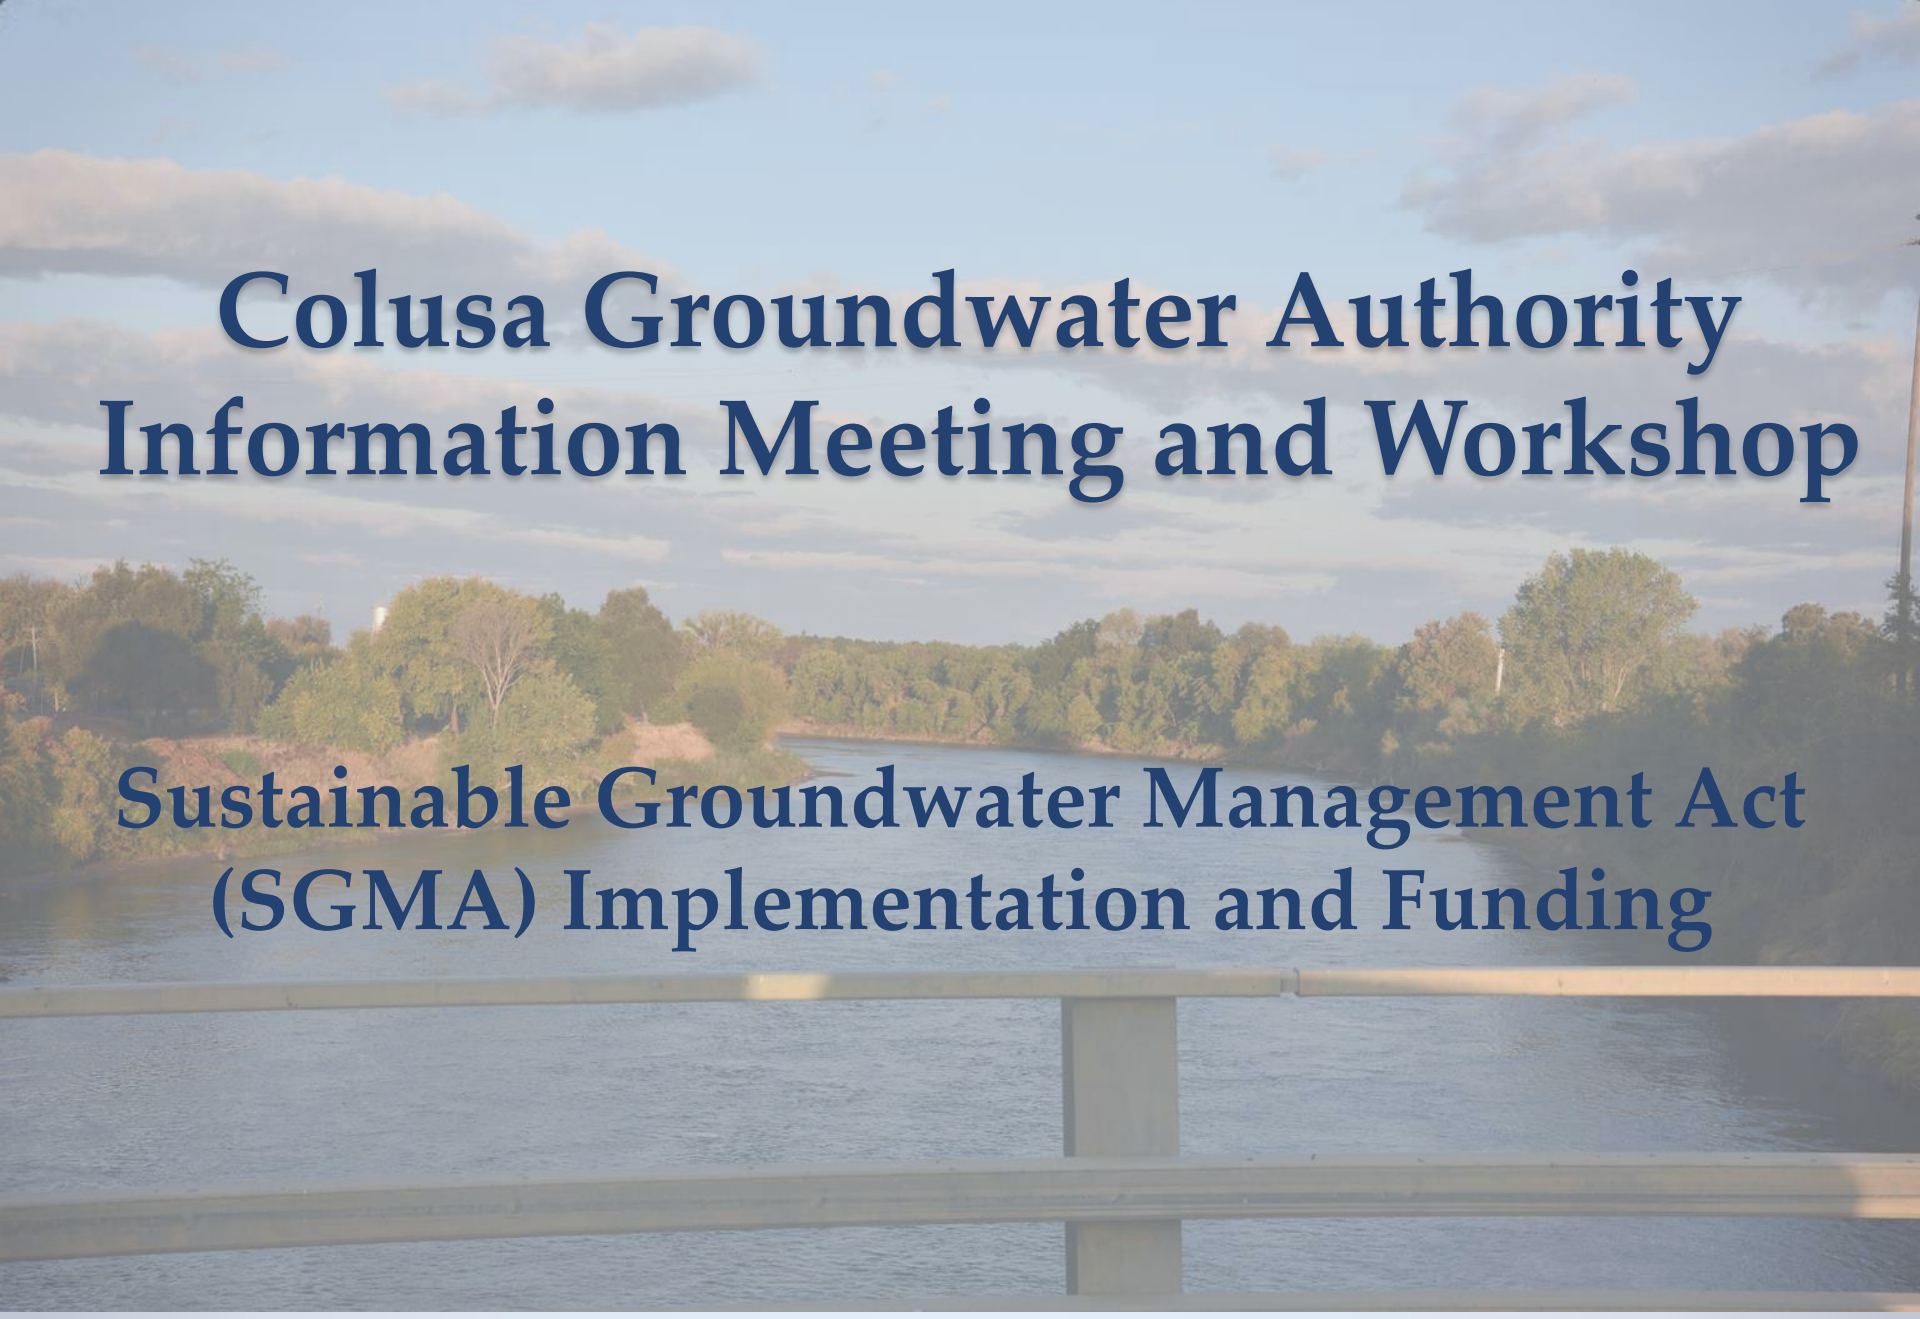
The Colusa Groundwater Authority (CGA)

And

The Colusa County Groundwater Commission

Present:

The Sustainable Groundwater Management Act Town Hall Public Information Meetings



This is an opportunity to learn about the Sustainable Groundwater Management Act (SGMA) and local groundwater management efforts, and have a dialogue with CGA Board Members and Colusa County Groundwater Commissioners. We hope you can join us at one of these meetings:

ARBUCKLE/WILLIAMS/COLLEGE CITY
March 6, 2019 at 6:00 p.m.
Arbuckle I.O.O.F. Building
5th and King Streets, Downtown Arbuckle

COLUSA/PRINCETON/GRIMES
March 14, 2019 at 6:00 p.m.
Colusa Veteran's Hall
108 East Main Street, Colusa, CA 95932

MAXWELL/WILLIAMS
March 20, 2019 at 6:00 p.m.
Sites Project Authority Office
122 Old Highway 99 W., Maxwell, CA 95955

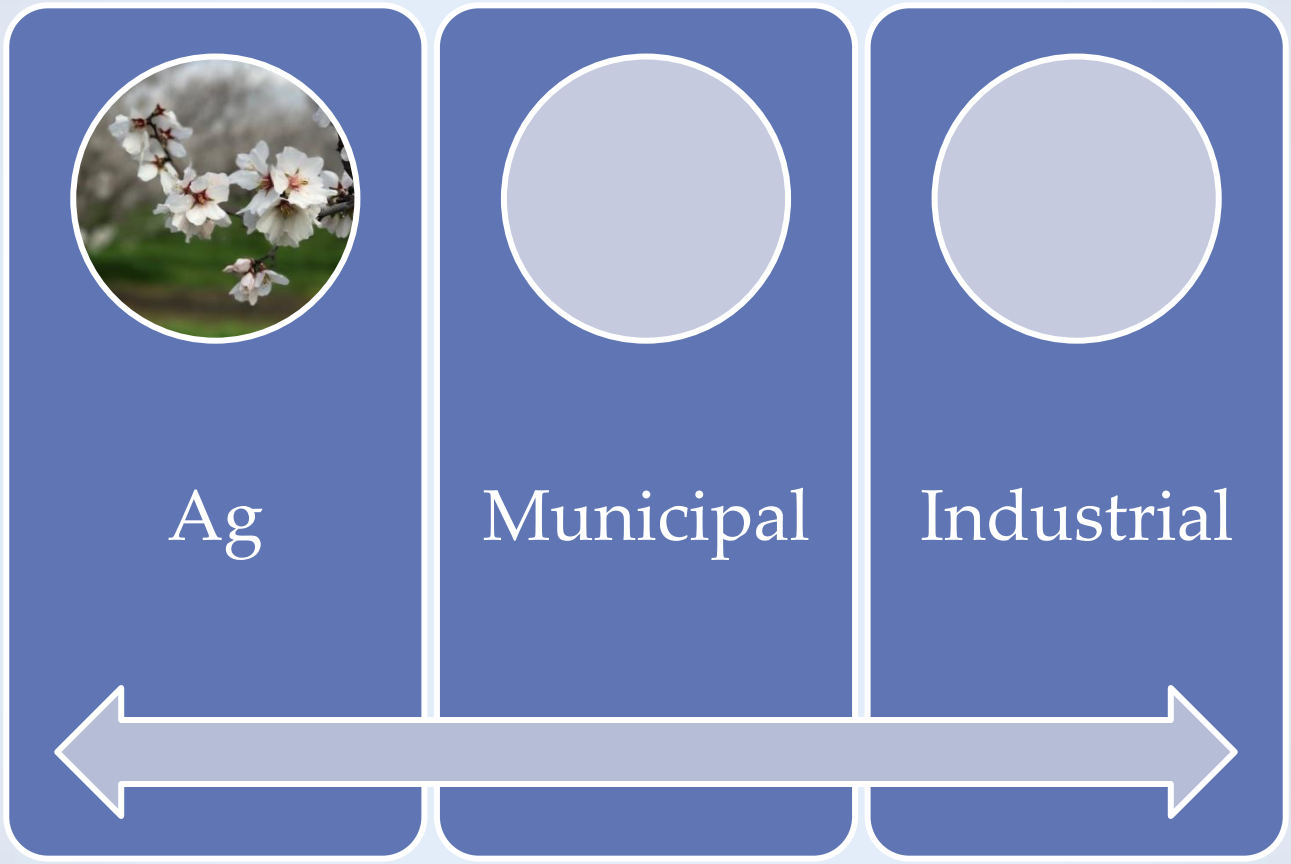
Colusa Groundwater Authority Information Meeting and Workshop



Sustainable Groundwater Management Act (SGMA) Implementation and Funding

January 31, 2019

Program

* 1. Sustainable Groundwater Management Act (SGMA) Overview
* 2. Colusa Groundwater Authority
* 3. Financing SGMA Implementation
  * CGA Activities and the Need for Funding
  * Proposition 218 Majority Protest
* 4. State Intervention
* 5. CGA Panel Questions and Answers

SGMA: Who is Affected

Diminimus (less than 2 A/F pumped per year) are not the focus.

SGMA Foundations

- Sustainable Groundwater Management Act of 2014
- **Groundwater Sustainability Agency(ies) (GSA)** by **June 30, 2017**
- **Groundwater Sustainability Plan(s) (GSP)** by **January 31, 2022**
- Yearly reporting and GSP Update every 5 years, demonstrating progress towards sustainability
- 20 years to achieve Sustainability – 2042
- **SGMA is a completely different program than the Irrigated Lands Regulatory Program!**

SGMA Foundations

Six "**Undesirable Results**"

1. Chronic lowering of groundwater levels
2. Reduction of groundwater storage
3. Degraded water quality
4. Land subsidence
5. Depletions of interconnected groundwater and surface water
6. Seawater intrusion (*not applicable in the Colusa Subbasin*)

GSA Roles and Responsibilities

- **Governance** – Colusa Groundwater Authority
- **Outreach/Engagement (Transparency)** with all beneficial users
- **Compliance** with local ordinances, state and federal laws and regulations, and similar
- **Funding** which may include one or more of the following: regulatory fees, property-related fees or assessments, local taxes, local general obligation bonds, contributions from member agencies, grants from other state or federal agencies

GSA Roles and Responsibilities

- **Authorities**

  General:

  - Do anything 'necessary and proper" to carry out SGMA's purposes
  - Adopt rules, regulations, ordinances and resolutions
  - Use any other authority allowed to the GSA to apply and enforce SGMA requirements

  Information Gathering

  Groundwater Extraction Oversight

  Property Acquisition and Management

  Enforcement:

  - Sue to collect delinquent fees, interest, or penalties or order extraction stopped until delinquent fees are paid
  - Pursue civil penalties for extraction exceedances
  - Pursue civil penalties for violations of SGMA-related rules, regulations, ordinances, or resolutions*

GSA Roles and Responsibilities

- **Coordination** with adjacent subbasins and Counties (if applicable), and between Management Areas (if applicable)
- **Technical** – access technical expertise; conduct/oversee monitoring, data collection and reporting; develop water budget and identify sustainable yield; assess basin history and potential paths to sustainable management; remediate oversee remediation of polluted groundwater.

Colusa Groundwater Authority

- CGA Formation; 2 years, common principles
- CGA formed June 29, 2017 as mandated by SGMA
- CGA is the Groundwater Sustainability Agency (GSA) covering the Colusa County portions of the Subbasins within the county, outside of RD 1004
- CGA is a 12-member Joint Powers Authority Board
- Board includes two Private Pumper representatives

Colusa Groundwater Authority

Board of Directors

County of Colusa
Denise Carter (Chair) / Alternate: Gary Evans

City of Colusa
Tom Reische / Alternate: Dave Markss

City of Williams
Alfred Sellers, Jr. / Alternate: TBD

Colusa County Water District
Knute Myers / Alternate: Shelly Murphy

Glenn-Colusa Irrigation District
Blake Vann / Alternate: Thad Bettner

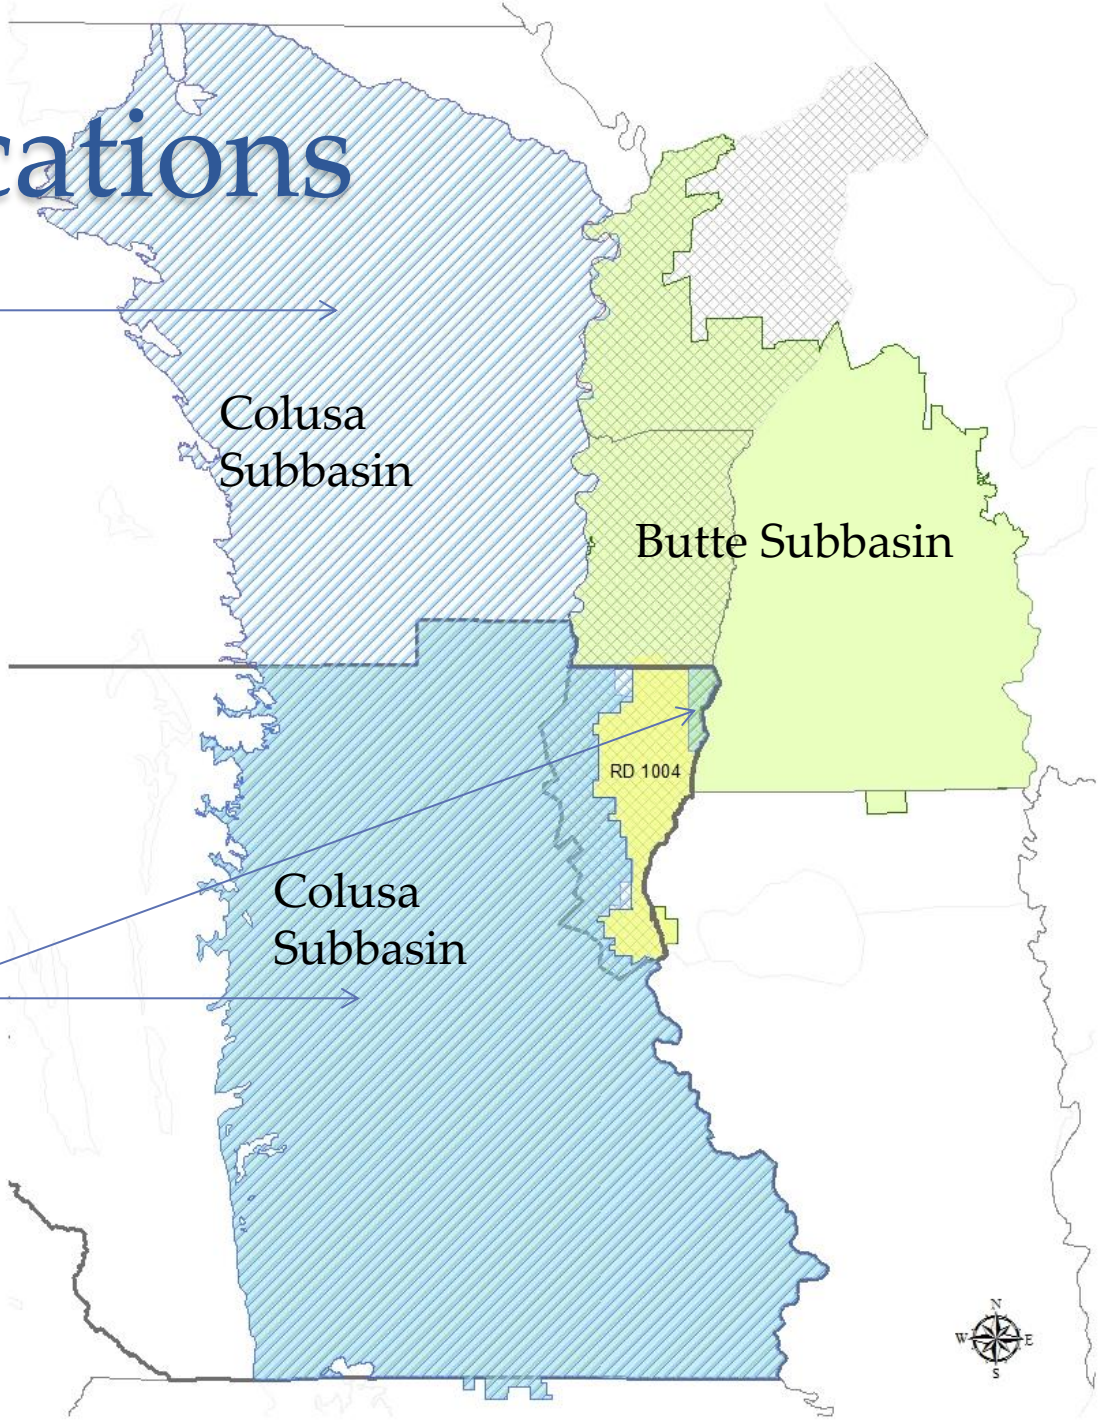
Maxwell I.D. and Westside I.D.
Zachary Dennis / Alternate: Dan Ruiz

Princeton-Codora-Glenn I.D. and Provident I.D.
David Alves / Alternate: Lance Boyd

RD 108
Hilary Reinhard (Vice Chair)
Alternate: Bill Vanderwaal

RD 479
Charles Marsh / Alternate: Derick Strain

Colusa Drain Mutual Water Company
Jim Wallace / Alternate: Lynell Pollock



2 Private Pumper Representatives from the Colusa County Groundwater Commission:
Darrin Williams and Jeff Moresco

Subbasin Locations

Glenn Groundwater Authority (GGA) GSA

Mallory fix map

Colusa Groundwater Authority (CGA) GSA

CGA Activities

- Groundwater Sustainability Plan (GSP) for the Colusa Subbasin (CGA & GGA)
  - Awarded $1 million Proposition 1 grant funding for GSP development
  - Consultant team to developing Basin Setting for GSP
- Installing a new monitoring well in the Arbuckle area (DWR funded)
- Coordinating with Glenn Groundwater Authority (GGA) on GSP development and other activities in the Colusa Subbasin
- Coordinating with GSAs in other surrounding basins/counties
- Organizing ongoing public meetings and public outreach activities
- Developing Long-term Funding strategy for the CGA to maintain local control of Groundwater Management under SGMA

Financing SGMA

- CGA members working together, pooling resources to keep costs to a minimum
- Leveraging grant funding, Facilitation Support and Technical Support services

Need for Long-term funding for day to day operations of the CGA:

- **Technical:** GSP development ($1.5 million), technical studies, monitoring and data management, coordination and outreach efforts, implementation of the GSP, yearly reporting to DWR, Plan updates every five years
- **O&M:** Staff, insurance, legal services, bookkeeping, office needs, etc.

- CGA Member Agencies agreed to fund the JPA for the first two years (July, 2017 – June, 2019) (dollar amount)
- Fees are needed to comply with SGMA and fund the GSP and basin monitoring activities

Financing SGMA

Proposition 218 Option

- Approved by voters in 1996, Prop 218 imposes certain requirements relative to the imposition of certain assessments, fees and charges by local agencies.
- Procedures act to fully inform the Agency's landowners while simultaneously giving them a direct say in the matter.
- Two processes for approval of revenue generation under Proposition 218
  - Land-based assessments (per acre charge)
  - Fees or charges on a unit basis.

Financing SGMA

Proposition 218 Majority Protest Requirements

- Fees must be based on the reasonable cost of providing service
  - CGA's annual operating budget
- Fees must proportionally recover costs from ratepayers (i.e. no subsidies)
  - $/acre fee
- Fees in the Prop 218 notice are the max fees that may be adopted
  - Board may lower fees without conducting another Prop 218 notice and hearing process

Financing SGMA

Proposition 218 Majority Protest: Next Steps

* CGA contracted with Provost and Pritchard Engineering to initiate a Proposition 218 Majority Protest
* Consultants will complete a rate study to determine a fee structure based on CGA budget and acreages in the CGA's jurisdiction
* Amount of fee cannot exceed the reasonable cost of the activity to be funded
* Public information meetings being planned, January – March
* A similar process is beginning in the GGA portion of the Colusa Subbasin

Financing SGMA

Prop 218 procedural requirements

- Mail a protest notice to property owners
- Hold a public hearing minimum of 45 days later – anticipated in March, 2019
- Absent majority protest, CGA may adopt fees
- If the Proposition 218 effort passes, a fee will appear on December 2019 property tax roll

Financing SGMA
Who is Affected?

- All property owners have an overlying right and benefit from a healthy groundwater system
- Small Community Water Systems: homeowners in the Cities of Colusa and Williams and the small communities of Arbuckle, Grimes, Maxwell and Princeton may be charged through their water suppliers.
  - This will save money processing multiple property tax bills on these small parcels

Financing SGMA

Initial Estimate: Proposition 218 Majority Protest Fee Calculation

	Estimates
Budget	$540,000
Acres	402, 541
Fee ($/acre)	$1.34

- Pending outcome of fee study
- Pending CGA Board approval and budget review
- SGMA is a new program, many unknowns
  - Budget is the best estimate at this time
  - The fee cannot exceed the reasonable costs of the CGA activities

Financing SGMA

What if the Prop 218 Effort Fails?

* If the CGA cannot be funded, it will dissolve.
* If a basin is not covered entirely by a GSA(s) and/or approved GSP, the State Water Resources Control Board assumes SGMA responsibilities.
* Lose local control of the groundwater resource.

Financing SGMA

What if the Prop 218 Effort Fails?

- State Board intervention actions can include:
  - Well Head fees
  - Volumetric fees (fee per acre-foot of water pumped)
  - Late fees (back dated to 2017)
  - Mandatory extraction reporting including monthly pumping data
  - May require installation of meters on wells at owner's expense
  - Technical reporting and special studies at landowners' expense
  - Any corrective actions will likely result in pumping restrictions

State Intervention

SWRCB Fees, 2018

BASE FEE (per well)	**$300**	
Volumetric Fee (per AF)		
Unmanaged, metered	**$10/AF**	
Unmanaged, unmetered	**$25/AF**	
An unmanaged area is a part of a basin not within the management area of a GSA before July 1, 2017		
Probation	**$40/AF**	
If locals fail to form a GSA, fail to develop an adequate sustainability plan, or fail to implement the plan successfully, the Board may designate the entire basin probationary. The Board may require the use of a meter to measure extractions and reporting of additional information.		
Interim Plan	**$55/AF**	
If local agencies are unable to fix the deficiencies, the Board will develop an interim plan to directly manage groundwater extractions.		
Deminimus (less than 2 AF/year)	**$100/well**	
Late Fee	**25% per month**	

https://www.waterboards.ca.gov/water_issues/programs/gmp/sgma.html

State Intervention

Sample Fee Comparison

100 acre irrigated parcel with one well, probationary basin

* **SWRCB Fees**:
  * 1 well = $300
  * 3.5 AF/ac = 350 AF X $40 = $14,000
  * **TOTAL: $14,300**

* **Estimated CGA Fee:**
  * 100 Acres X $1.34 = $134
  * **TOTAL: $134**

CGA will not know the proposed fee until the Rate Study is completed.

CGA Panel Questions & Answers

Panel Members:

- Denise Carter, CGA Board Chair
- Hilary Reinhard, RD 108
- Darrin Williams, Private Pumper
- City Rep

Thank You

Landowner input is essential to GSP development and SGMA planning and implementation.

Sustainable Groundwater Management Act
Public Workshop

Question / Comment Card

Please write your question / comment on this card and turn it in when requested.

Group Worksheet

Colusa Subbasin
Groundwater Workshop
Small Group Discussions

There are 5 "Sustainability Indicators" that the Groundwater Sustainability Agency potentially must address to comply with the Sustainable Groundwater Management Act. These are:

1. Lowering Groundwater Levels
2. Reduction of Groundwater Storage
3. Subsidence
4. Water Quality
5. Surface Water Depletion

For each of these Sustainability Indicators, Please answer the following questions:

Are any of following, groundwater problems in the Colusa Subbasin right now? If so, where and why?
1 - Lowering Groundwater Levels
2 - Reduction of Groundwater Storage
3- Subsidence
4 - Water Quality
5 - Surface Water Depletion

Do you think any of these could be groundwater problems in the future? If so, where and why?
1 – Lowering Groundwater Levels
2 - Reduction of Groundwater Storage
3- Subsidence
4 - Water Quality
5 - Surface Water Depletion

If you identified current and/or potential problems, can you describe if and how these will affect you?
1 - Lowering Groundwater Levels
2 - Reduction of Groundwater Storage
3- Subsidence
4 - Water Quality
5 - Surface Water Depletion

COLUSA GROUNDWATER AUTHORITY AND GLENN GROUNDWATER AUTHORITY

Colusa Subbasin Groundwater Workshop

September 19 & 23, 2019

Program

- Welcome and Introductions
- Sustainable Groundwater Management Act (SGMA) Overview
- SGMA Basin Setting - Colusa Subbasin
  - Basin Setting Presentation
  - Small Group Discussion – Subbasin Challenges
  - Water Budget Update
  - Modelling Update
- Groundwater Sustainability Planning - Next Steps
- GSA Question and Answer Session (Comment Cards Available)
- Adjourn

Sustainable Groundwater Management Act (SGMA) Overview

Dave Ceppos – Facilitator, Sacramento State University

SGMA: Who is Affected

Agricultural

Municipal

Industrial

Environmental

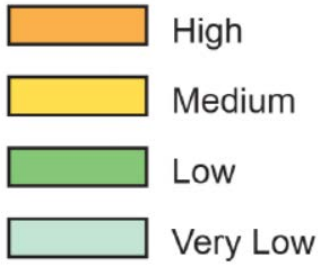
Sustainable Groundwater Management Act SGMA

- Sustainable Groundwater Management Act of 2014
- **Groundwater Sustainability Agency(ies) (GSA)** by **June 30, 2017**
- **Groundwater Sustainability Plan(s) (GSP)** by **January 31, 2022**
- Annual reporting and GSP Update every 5 years, demonstrating progress towards sustainability
- 20 years to achieve Sustainability – 2042
- **SGMA is a completely different program than the Irrigated Lands Regulatory Program (Colusa Glenn Subwatershed Program)**

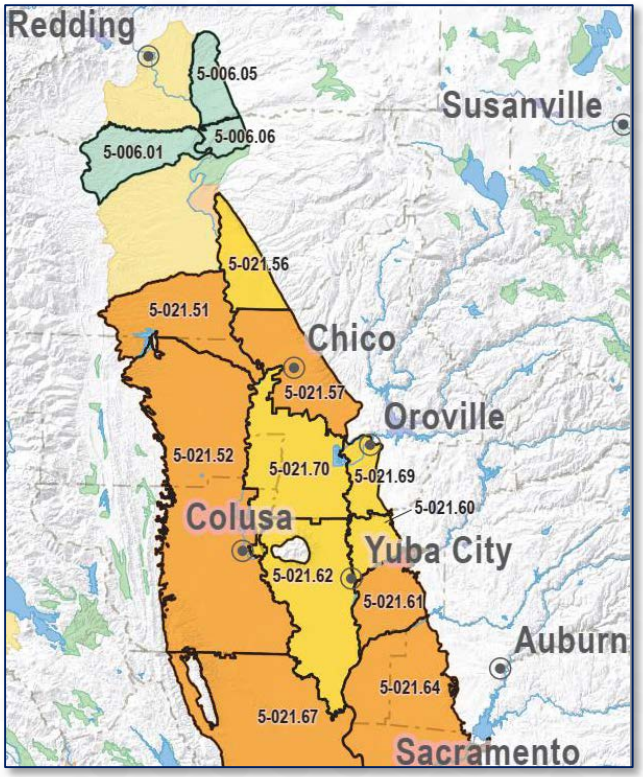
Groundwater Sustainability Agency Eligibility Requirements

- Local Public Agencies Responsible for:
  - Water Management
  - Water Supply
  - Land Use Authority
    - *For Example: Cities, Counties, Irrigation Districts*

- One or more GSAs must be formed per Basin / Subbasin
- Formed by a single eligible agency or by legal agreement between two or more
- Counties represent / manage all groundwater conditions outside another managed area (Water Code §10724)



GSA Roles and Responsibilities

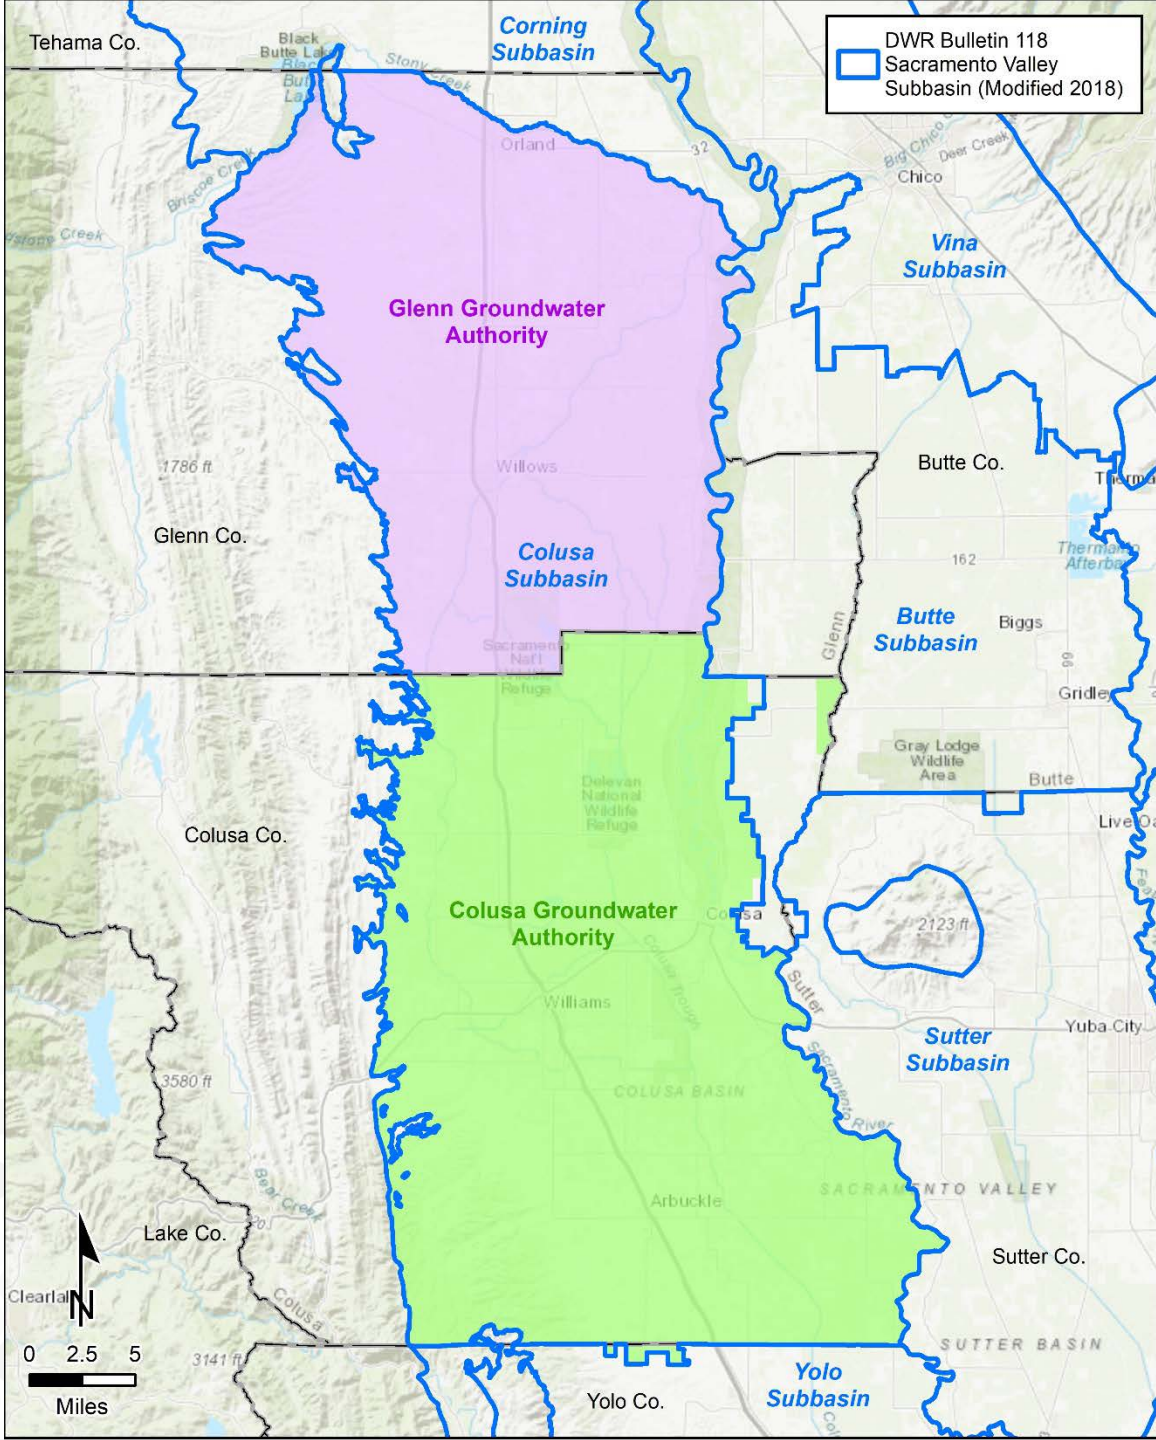


- Governance
- Outreach and Engagement
- Funding
- Information Gathering
- Plan Development and Reporting
- Projects (e.g. Groundwater Recharge)
- Groundwater Regulation and Enforcement
- Groundwater Extraction Oversight
- Property Acquisition and Management

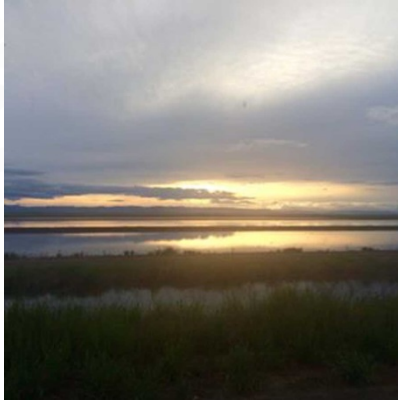
SGMA Foundations

- 515 Groundwater Basins / Subbasins Statewide
- 98 Basins / Subbasins required to comply with SGMA*
- Compliance based on basin prioritization as mandated by State Legislature in 2009.
- Prioritization variables include (but not limited to):
  - Population
  - Socioeconomics
  - Number of wells
  - Groundwater elevations
  - Irrigated acres

*Draft Prioritization Results as of September 2019



SGMA Foundations



Beneficial Users (Water Code §10723.2)

- All Groundwater Users
- Holders of Overlying Rights (agricultural and domestic)
- Municipal Well Operators
- Public Water Systems
- Tribes
- Local Land Use Planning Agencies
- Counties
- Local Landowners
- Disadvantaged Communities
- Businesses
- Federal Government
- Environmental Users
- Surface Water Users (*if connection between surface and groundwater*)

Sustainability Indicators

Example GSP Section Requirements

1. **Administrative Information**
2. **Basin Setting**
3. **Sustainable Management Criteria**
4. **Monitoring Networks**
5. Projects and Management Actions
6. Technical & Reporting Standards
7. Interagency Agreements

Example GSP Section Requirements

- Administrative Information
  - General Description of Area
    - Location, Land Uses, Well Information, Maps, etc.
  - Notice and Communication
  - Public Outreach
  - Beneficial User Information and Input
  - GSA Decision-Making

Example GSP Section Requirements

- Basin Setting
  - –Hydrogeologic Conceptual Model (HCM)
  - –Groundwater Conditions
  - –Water Budget
  - –Management Areas (if applicable and selected by the GSA)

Example GSP Section Requirements

- Sustainable Management Criteria
  - –Sustainability Goal
  - –Undesirable Results
  - –Minimum Thresholds
  - –Interim Milestones
  - –Measurable Objectives

Example GSP Section Requirements

- Monitoring Networks
  - Network Objectives for each Sustainability Indicator
  - Scientific Rationale
  - Monitoring Protocols
  - Locations and Type
  - Data and Reporting Standards
  - Assessment and Improvement Methods

GSP Iterative Process

Thank You

Beneficial User input is essential to GSP development and SGMA planning and implementation.

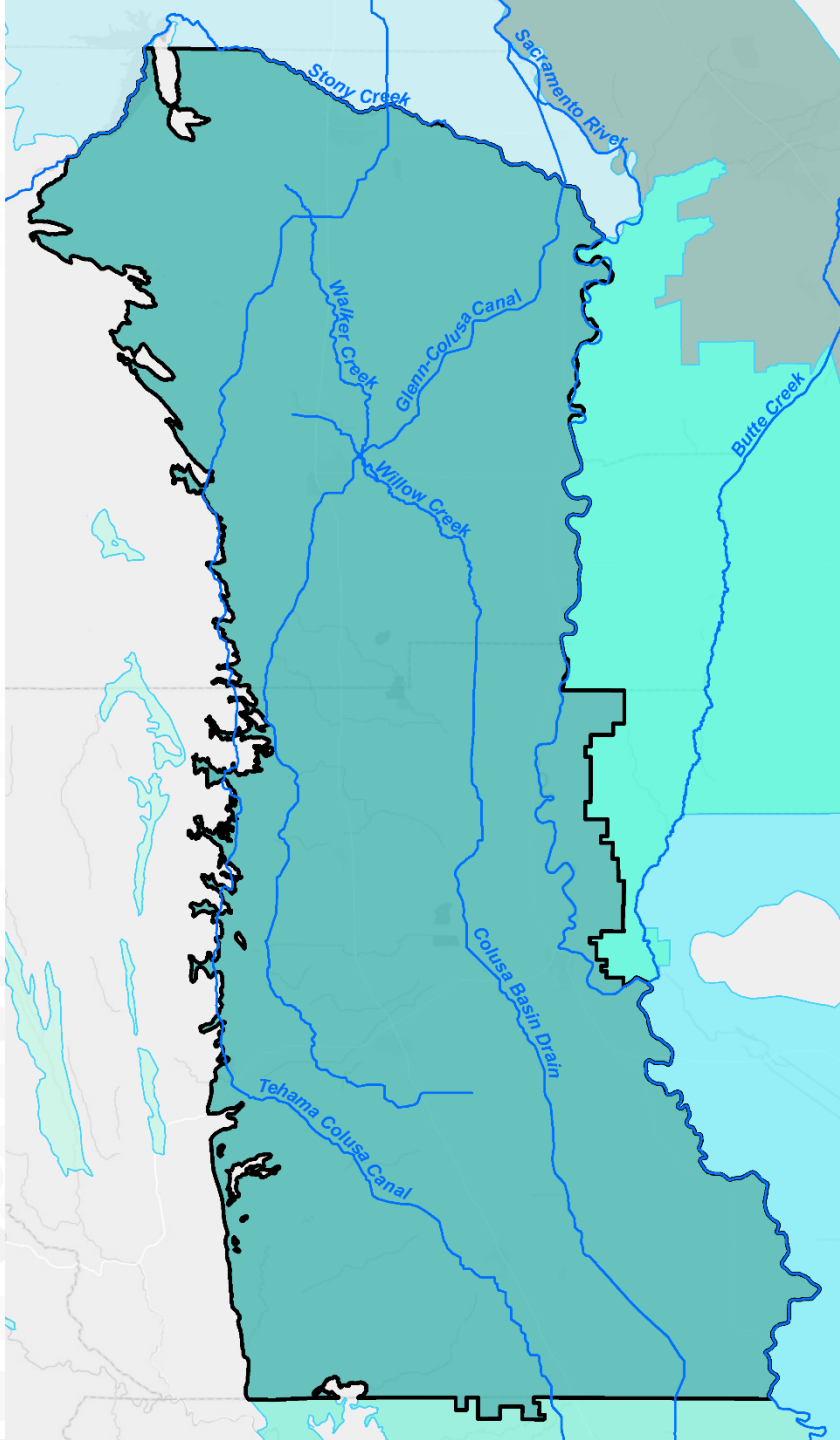
SGMA Basin Setting
Colusa Subbasin



Ken Loy, CHG – West Yost Associates

Dave Ceppos – Facilitator, Sacramento State University

Byron Clark, PE – Davids Engineering

Session Agenda

- Basin Setting Presentation
  - SGMA Definitions
  - Colusa Subbasin Overview
  - Groundwater Flow in Alluvial Basins
  - Stream-Aquifer Interactions
  - Colusa Subbasin HCM
  - Colusa Subbasin Groundwater Conditions
- Small Group Discussions
- Water Budget Update
- Modelling Update

Basin Setting

"Basin Setting"

Definition

(23 CCR § 354.12)

"… physical setting ... characteristics ... and current conditions of the basin … including … **data gaps** and **levels of uncertainty** … that serve as the basis for defining and assessing reasonable **sustainable management criteria** and projects and management actions."

Includes

- Hydrogeologic Conceptual Model (HCM)
- Groundwater Conditions
- Water Budget
- Management Areas (if applicable)

Logical Progression of Basin Activities Needed to Increase Basin Sustainability

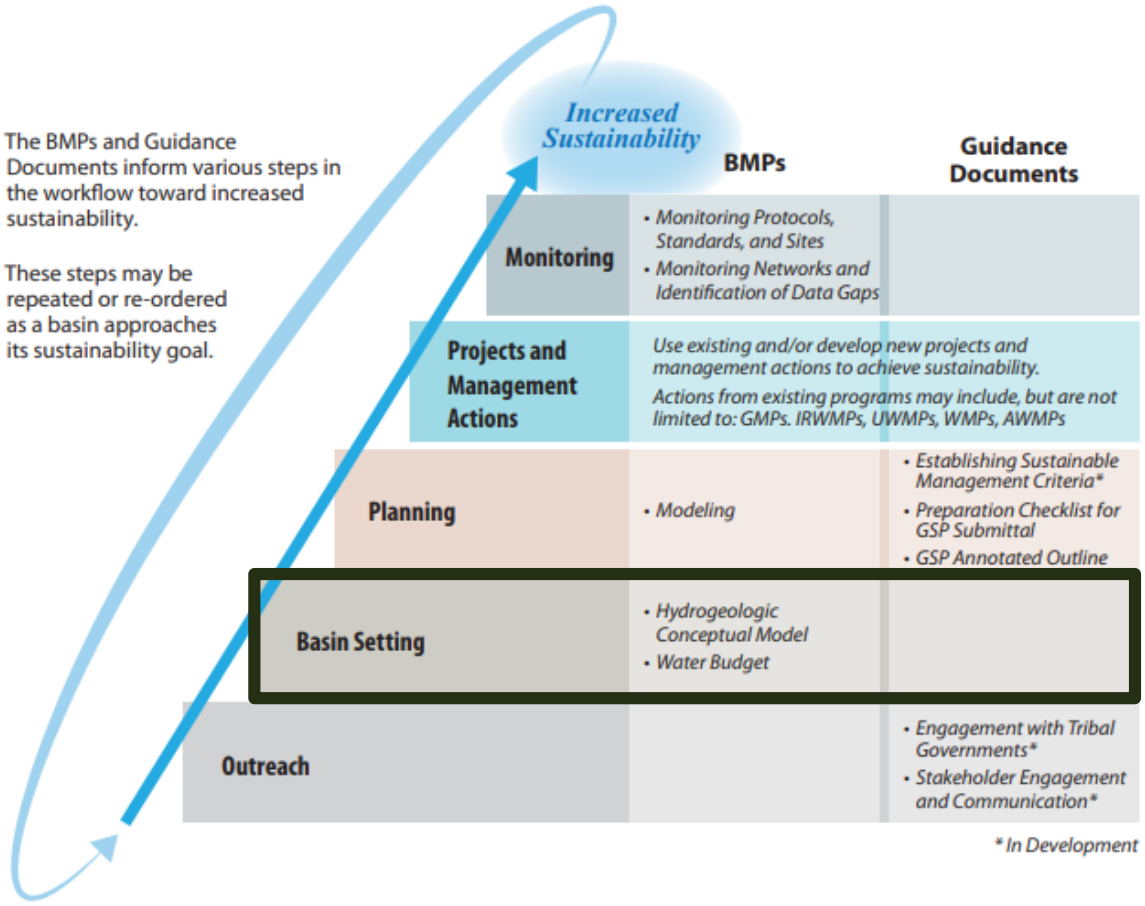


Image Source: DWR, Framework BMP, December 2016.

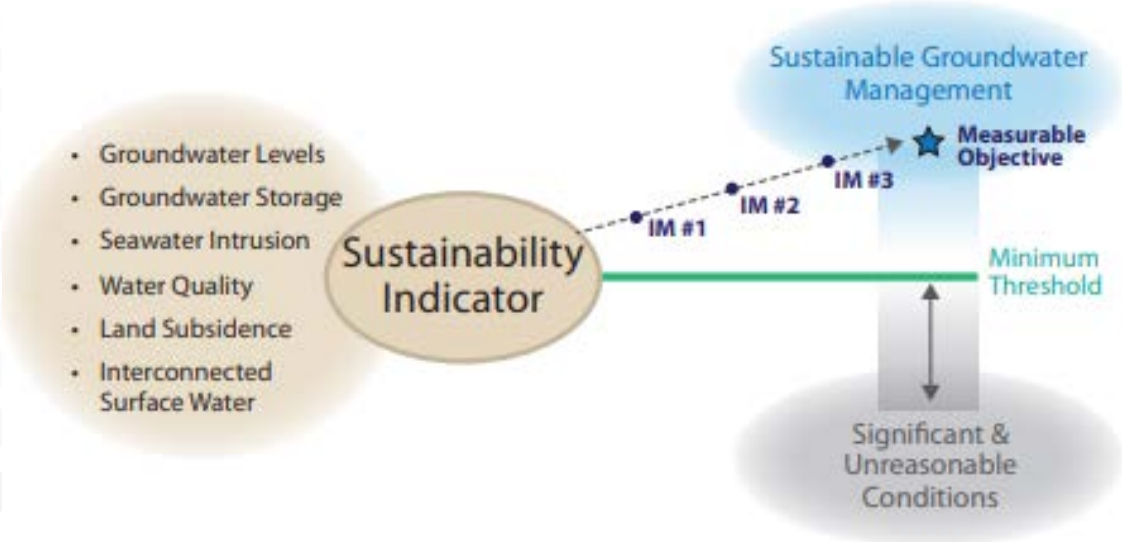
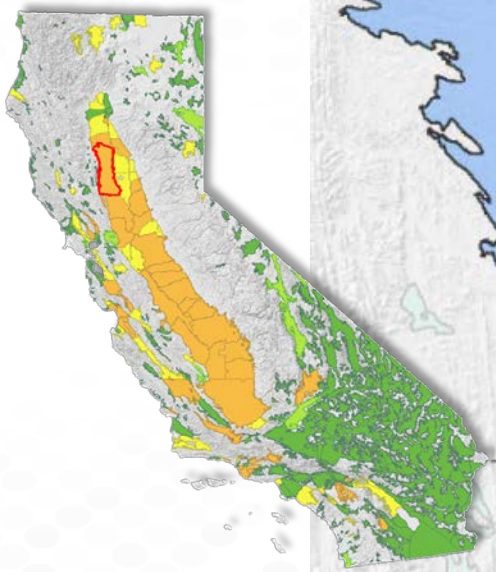
“Data Gaps” and “Uncertainty”

- **Data Gaps** refer to a lack of information that significantly affects the understanding of the basin setting.
- **Uncertainty** refers to a lack of understanding of the basin setting that affects an Agency's ability to develop sustainable management criteria, appropriate projects, and management actions in a Plan.
- **Data Gaps** and **Uncertainty** may limit the ability to evaluate the efficacy of Plan implementation and to assess whether a basin is being sustainably managed.

"Sustainability Indicators" and Sustainable Management Criteria

- **<u>Sustainability Indicators</u>** refer to any of the effects caused by groundwater conditions that can cause undesirable results with regard to:
  - Groundwater levels
  - Groundwater storage
  - Seawater intrusion
  - Water quality
  - Land subsidence
  - Interconnected surface water





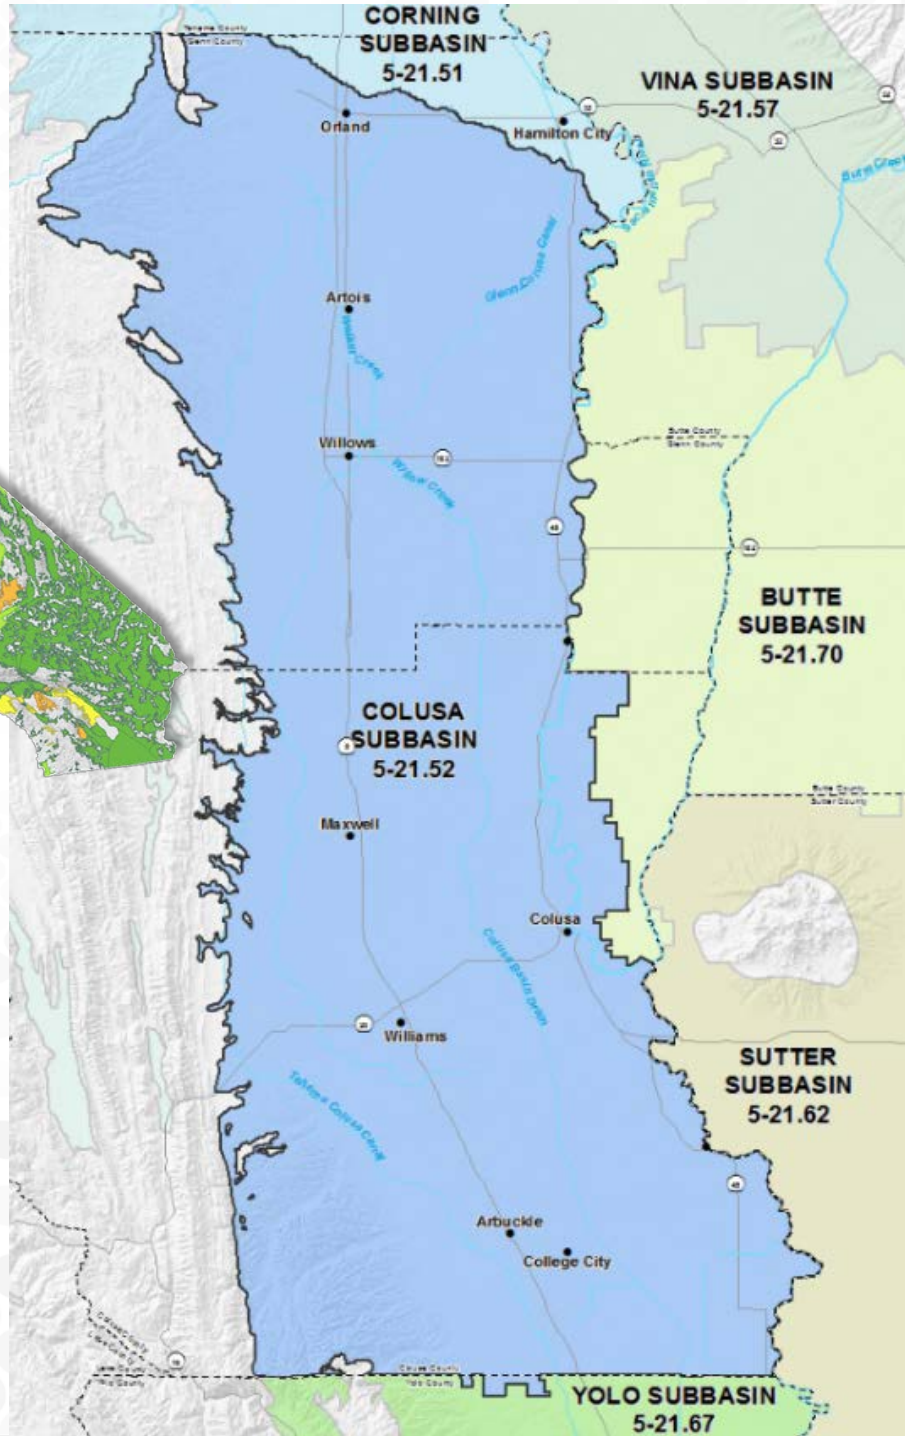


Image Sources: DWR, GSP Emergency Regulations Guide, July 2016.

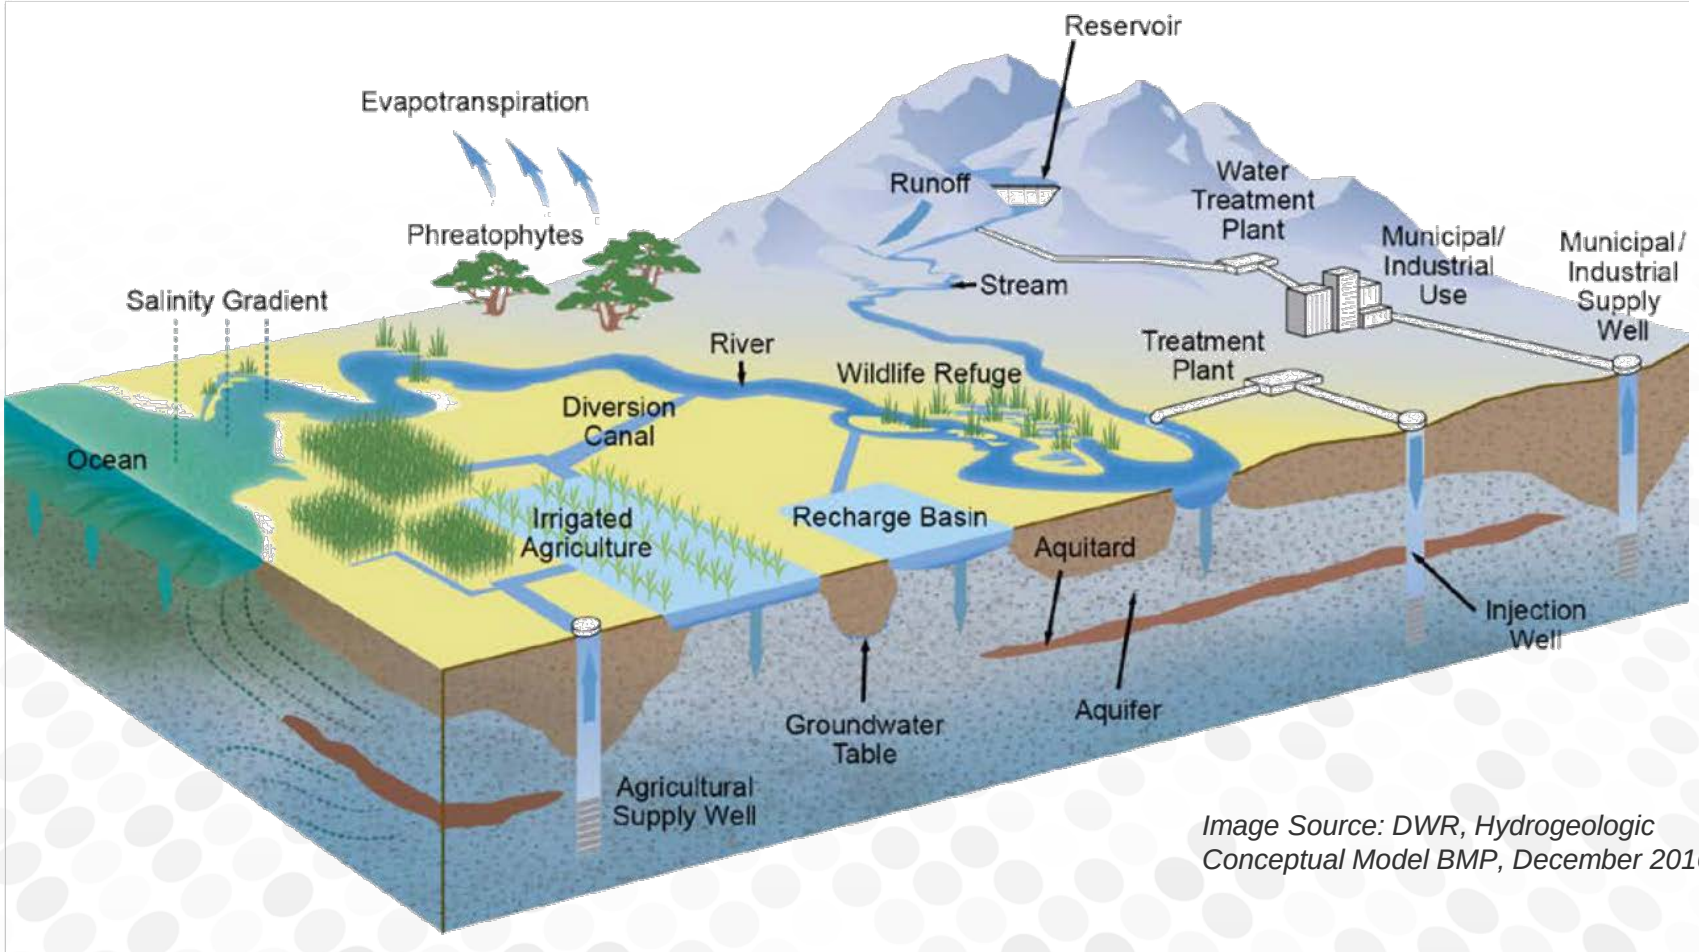
Colusa Subbasin

- Largest Subbasin in the Sacramento Valley
- 724,000-acre Area
- 60 miles North-South
- 20 miles East-West
- 1,500 ft Thickness

Groundwater Flow in Alluvial Basins



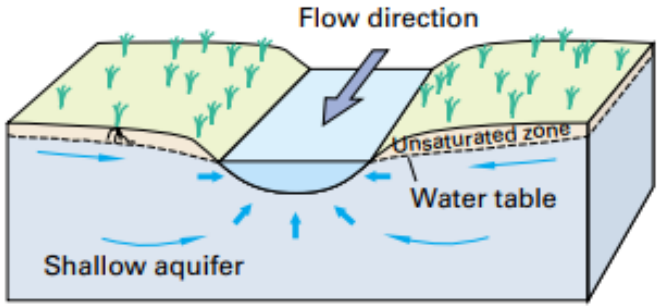


Image Source: DWR, Hydrogeologic Conceptual Model BMP, December 2016.

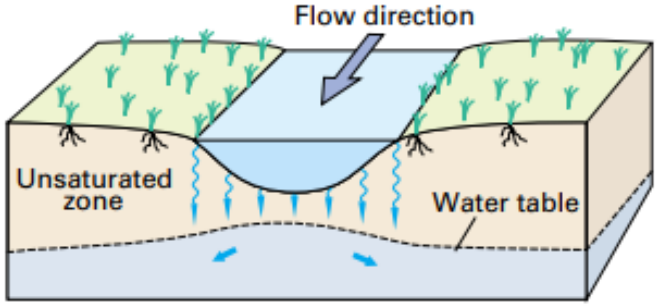
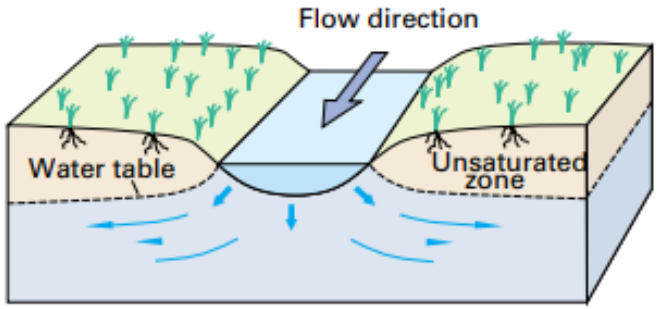


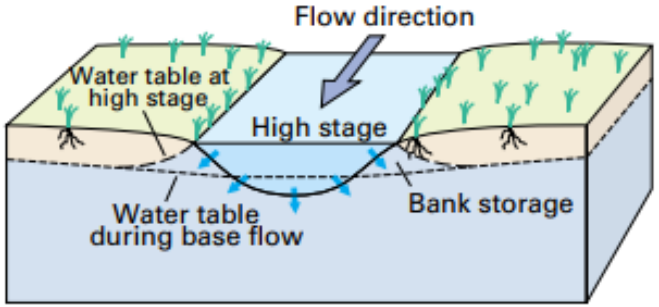
Stream – Aquifer Interactions

GAINING STREAM



Gaining streams receive water from the groundwater system.

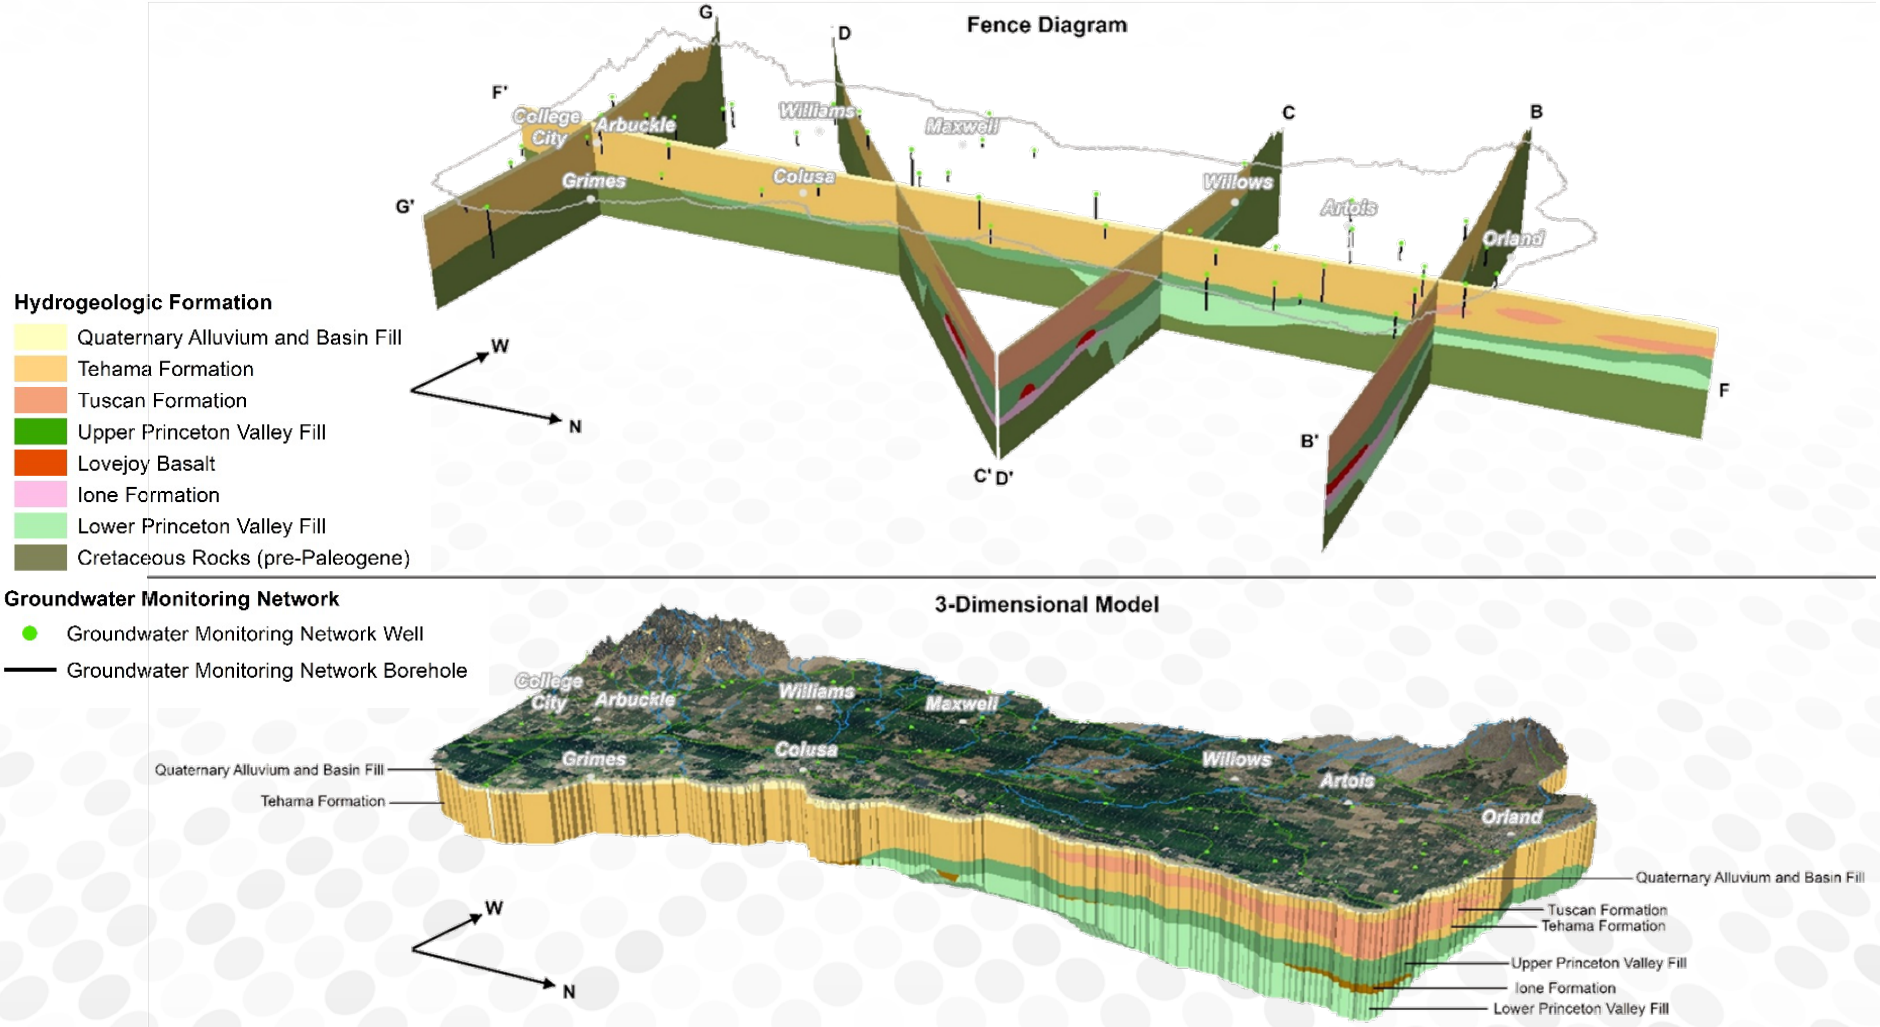
DISCONNECTED STREAM



Disconnected streams are separated from the ground water system by an unsaturated zone. For disconnect-ed streams, losses are independent of the groundwater level.

LOSING STREAM

Losing streams lose water to the groundwater system.

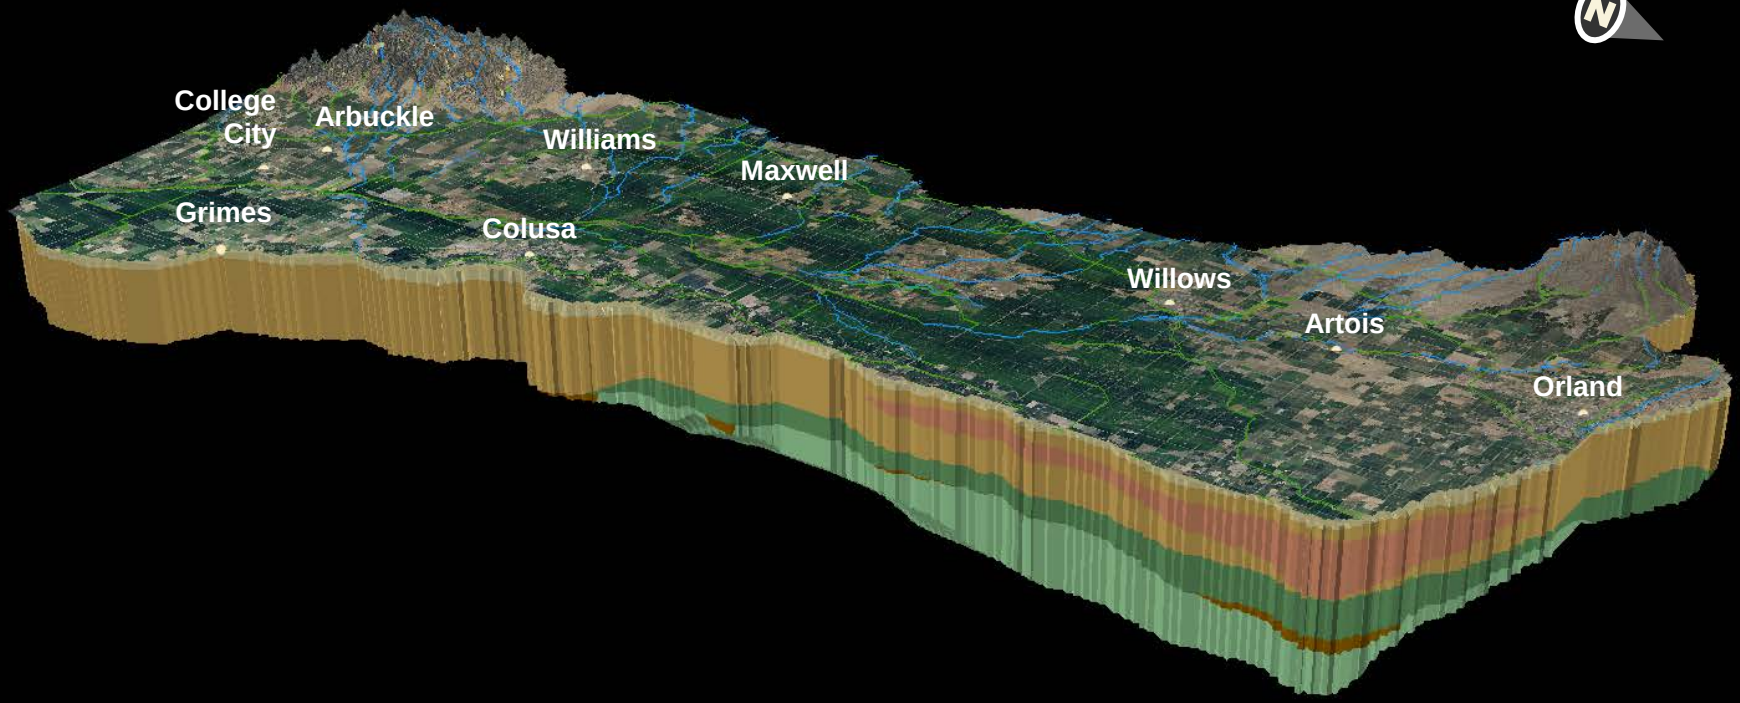


BANK STORAGE

If stream levels ride higher than adjacent groundwater levels, stream water moves into the streambanks as bank storage.

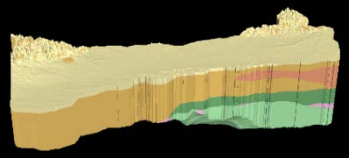
Image Source: Sacramento Valley Groundwater Assessment, prepared for Northern California Water Association, June 2014.

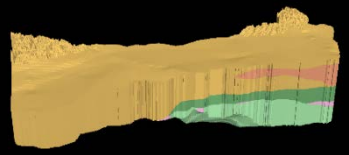
Hydrogeologic Conceptual Model

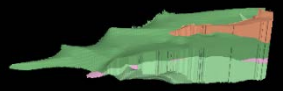


Vertical Exaggeration=10x

Image Source: Hydrogeologic Conceptual Model Report, May 2018.



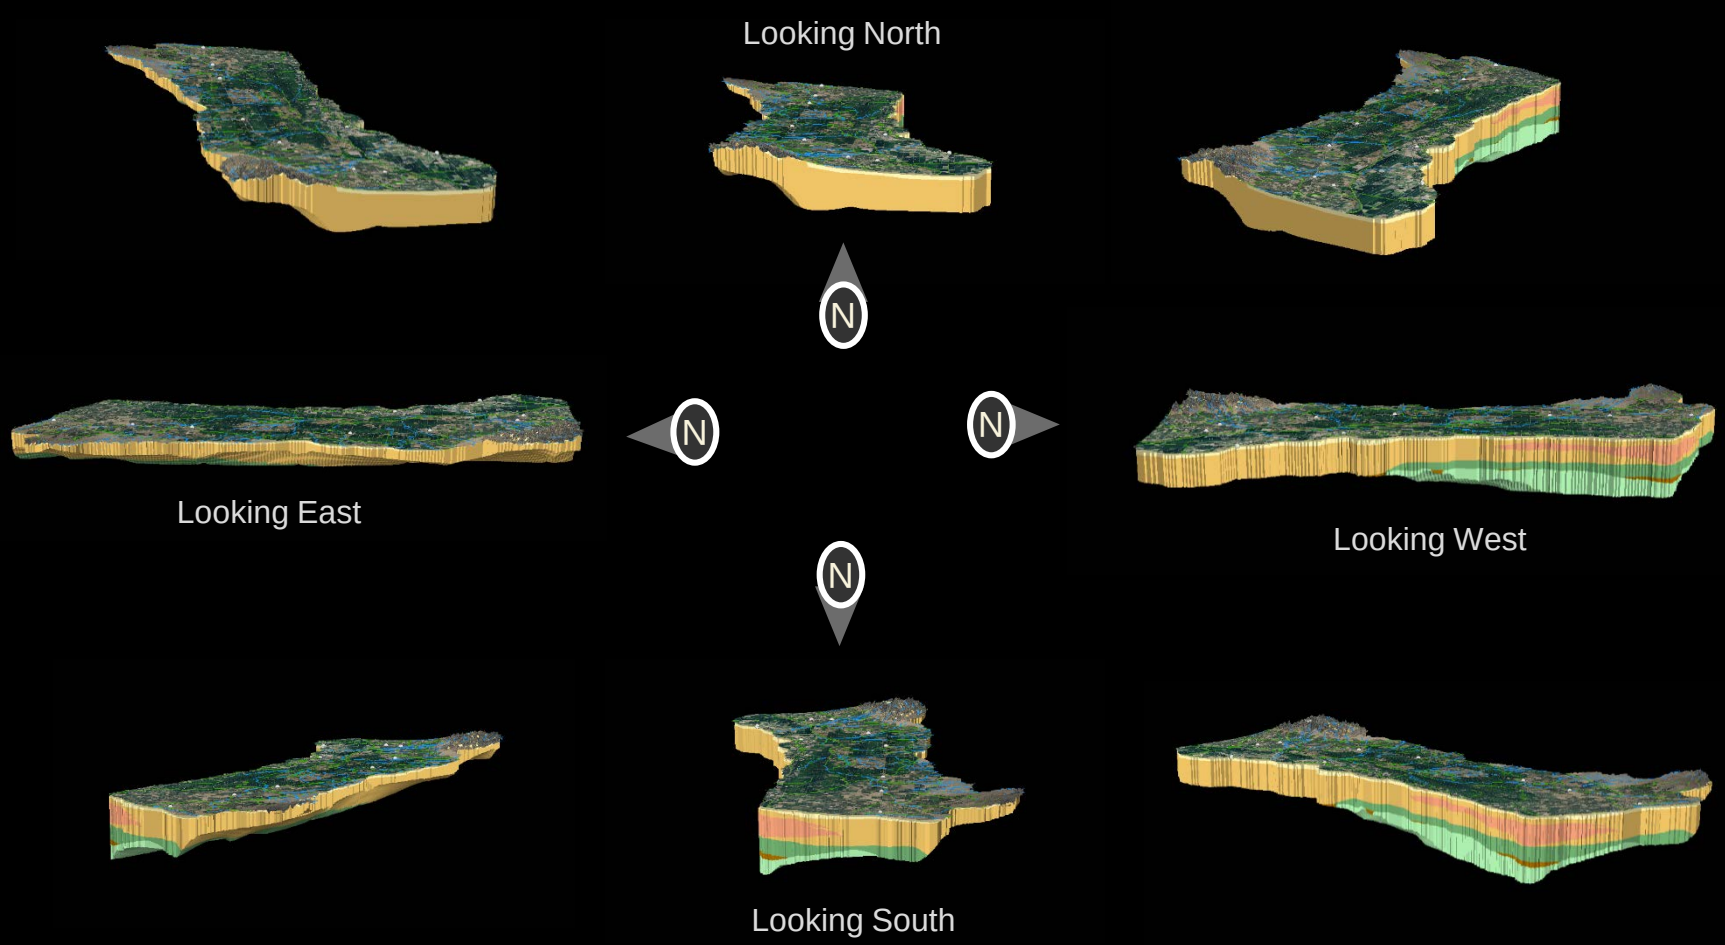




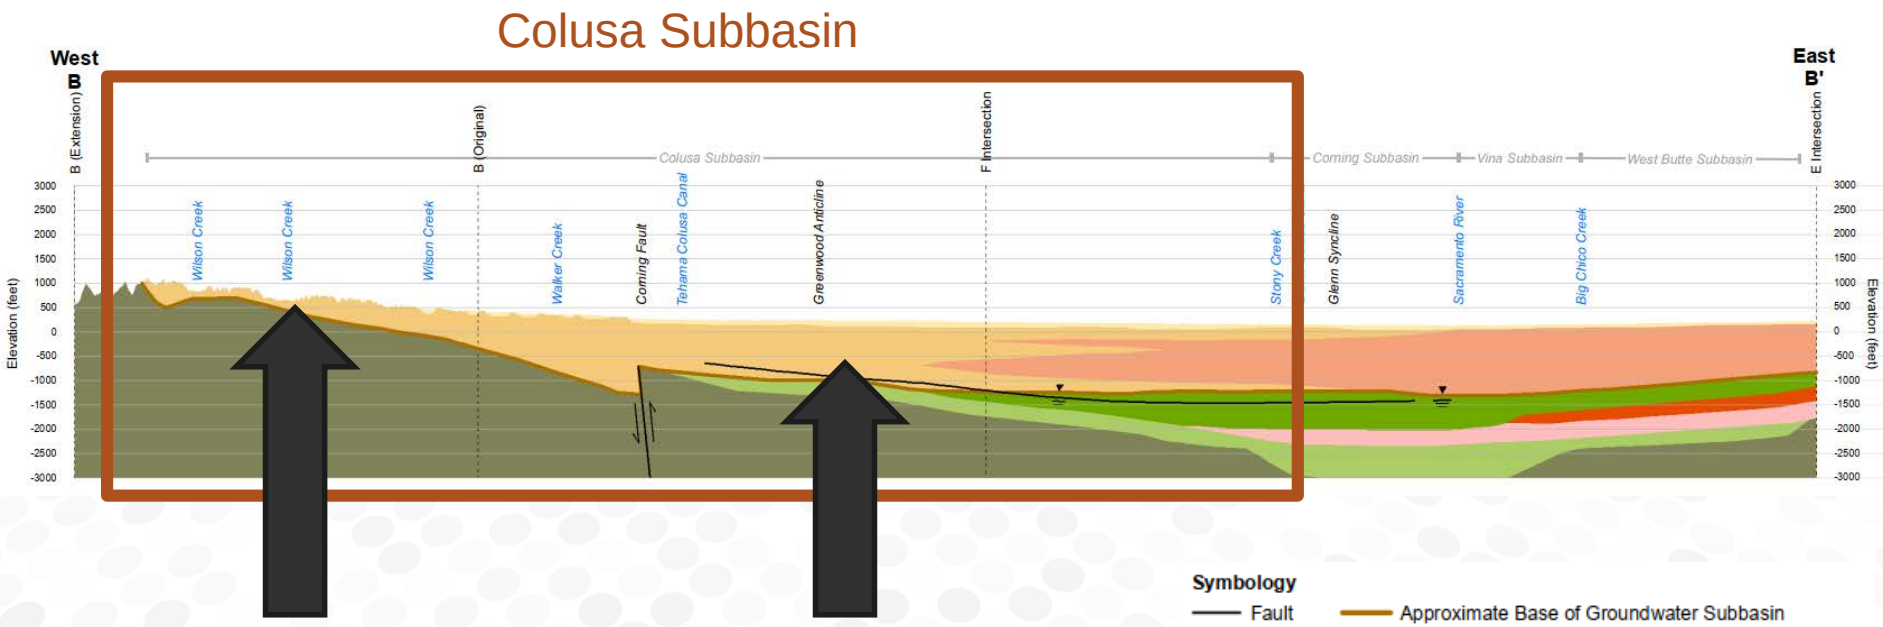
Hydrogeologic Conceptual Model

Hydrogeologic Conceptual Model

Improved Understanding of Principal Aquifers



Stacked Formations	Principal Aquifers	Geologic Formation
		Young Alluvium
		Tehama Formation
		Tuscan Formation
Below Geologic Base of Freshwater		
		Upper Princeton Valley Fill Ione Formation Lower Princeton Valley Fill



Vertical Exaggeration=10x

Colusa Subbasin Groundwater Storage

Colusa County

Glenn County

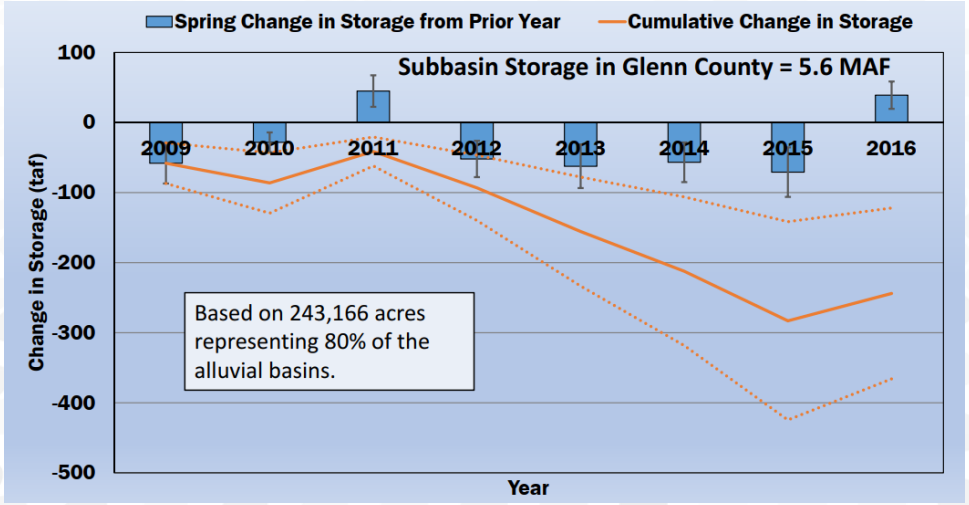

Image Sources:
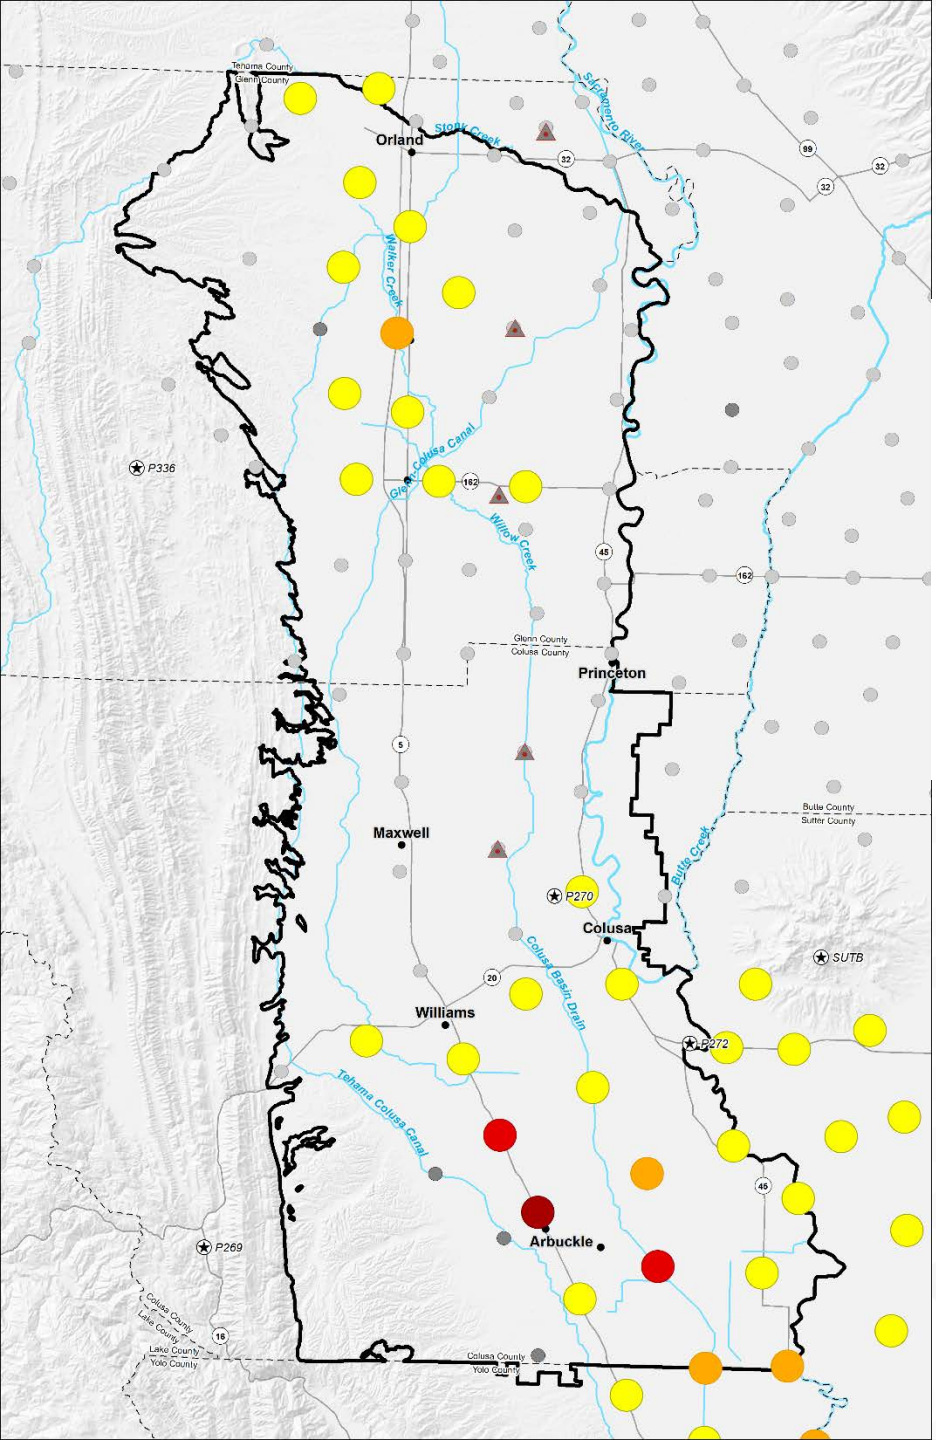
Groundwater Conditions in Colusa County Relative to Final Groundwater Sustainability Plan Regulations, July 2016.
Glenn County Reconnaissance-Level Groundwater Sustainability Risk Assessment, May 2017.

Groundwater Storage

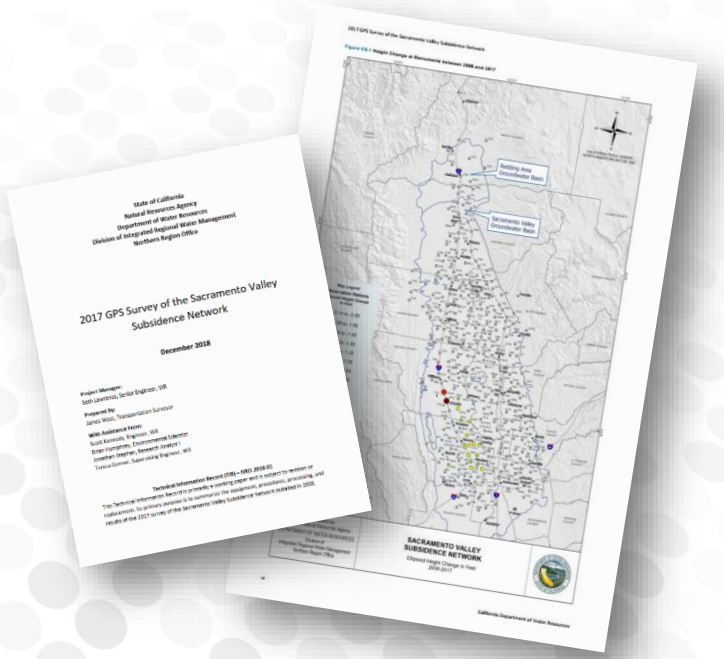


- Storage reduced during multiple-year drought but early analysis indicates recovery.

Groundwater Quality

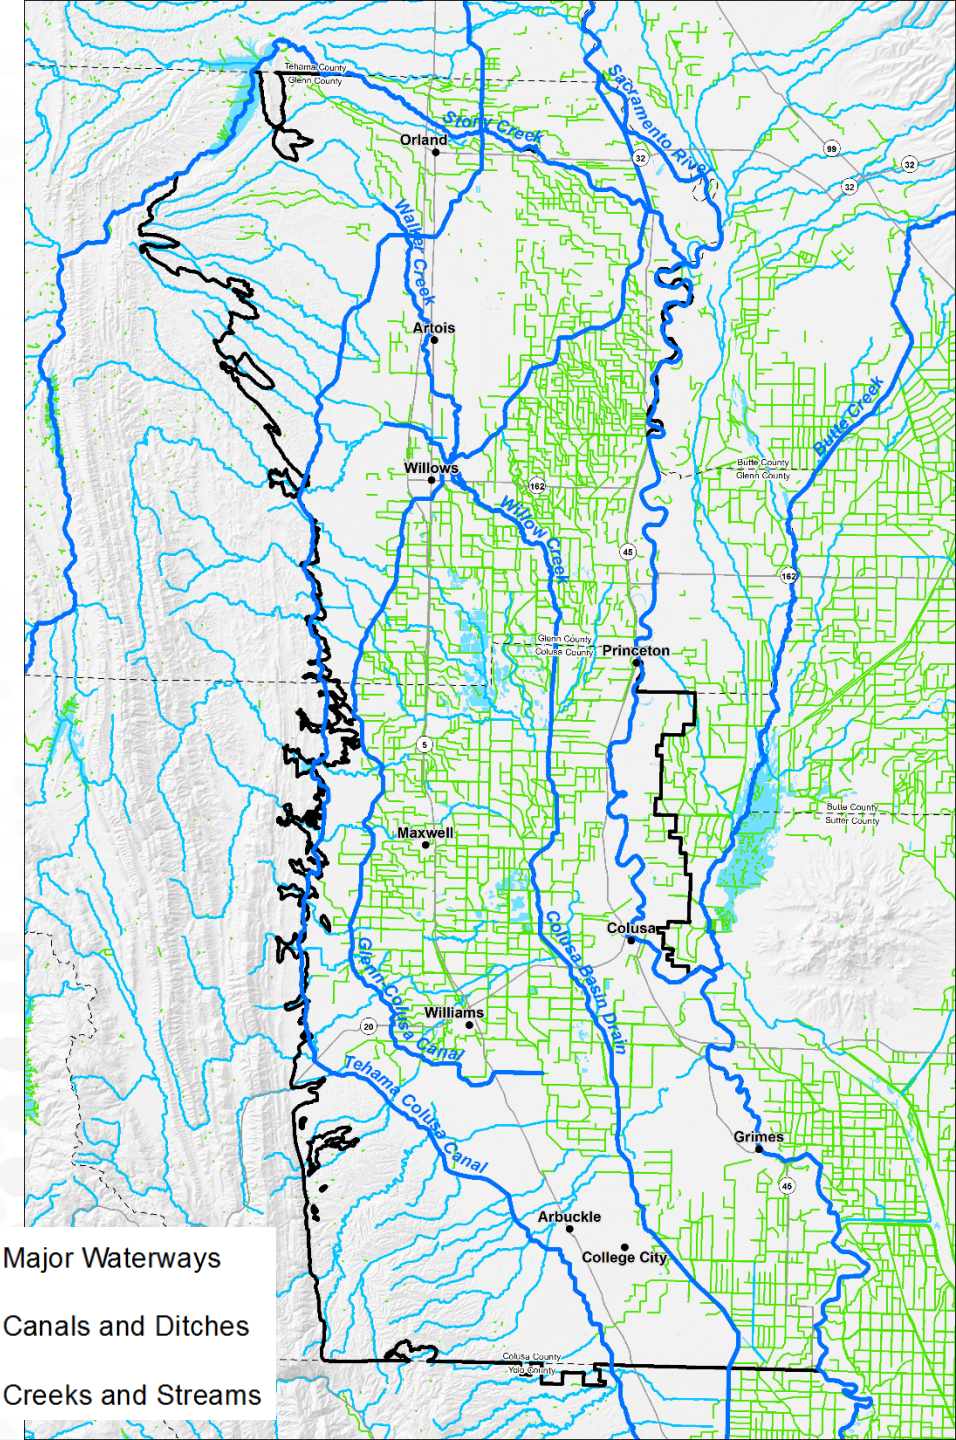
- Current groundwater quality is generally “good” with potential for some isolated issues.
- Focus will be on impacts to groundwater quality due to activities after implementation of Colusa Subbasin GSP.
- Existing water quality monitoring programs are sufficient and not expected to change due to GSP implementation.

Land Subsidence Survey



- Continuous GPS Station
- Extensometer

Sacramento Valley Subsidence Benchmarks with 2008 to 2017 Height Difference



- ≥2 feet
- 1 - <2 feet
- 0.5 - <1 foot
- 2 - <6 inches
- < 2 inches
- New Benchmark or Not Surveyed

2017 GPS Survey Sacramento Valley Subsidence Network, December 2018

Interconnected Surface Waters

- Interconnected surface waters exist within Colusa Subbasin.
- There is uncertainty regarding how groundwater use under the Colusa Subbasin GSP would impact these surface waters.
- Numerical modelling will be used to evaluate impacts to interconnected surface waters.

Small Group Discussions – Subbasin Challenges

Water Budget Update

Water Budget Overview

- Explicitly required for inclusion in the GSP (§354.18)
- Complete accounting of inflows, outflows, and change in storage
- Just like a checking account:
  - Deposits – Withdrawals = Balance Change, or
  - Inflows – Outflows = Change in Storage
- Grounded in data
- Must be developed for historical, current, and potential future conditions
- Supported by development of an Integrated Hydrologic Model

PUBLIC WORKSHOP ON LOCAL GROUNDWATER CONDITIONS

The Colusa Groundwater Authority (CGA) and Glenn Groundwater Authority (GGA) (Agencies) will host a pair of public workshops about local groundwater conditions and areas of concern in portions of Colusa and Glenn Counties. Both workshops will cover the same material. Groundwater in the two counties is regulated by the CGA and GGA respectively as per the Sustainable Groundwater Management Act (SGMA). The entire area managed by the Agencies is titled the "Colusa Subbasin" by the California Department of Water Resources, and the Agencies are required to work together to address groundwater problems in the Subbasin. Groundwater conditions that are not sustainable will be subject to a range of future solutions and if these local Agencies are not successful addressing these challenges, the State of California can take over groundwater management in the Subbasin. The Boards of the Agencies are committed to maintain local control of groundwater and regularly update stakeholders about Subbasin conditions and future Agency decisions.

The workshops will provide a brief overview of SGMA and Groundwater Sustainability Plan requirements. Each will then focus on up-to-date, technical information about groundwater conditions and related topics with a focus on sustainability issues in the Colusa Subbasin. Stakeholders will have time to ask questions to Agency Directors, staff, and the technical consulting team. The public is encouraged to attend to learn more about SGMA and the Agencies' next steps. The public will also learn about the importance of Stakeholder participation during Groundwater Sustainability Plan development, and how they can be involved in the process.

"We will have some tough decisions to make in the future" said Supervisor Denise Carter, Chair of the CGA. "We are committed to share everything we know about this Subbasin's groundwater and then develop a program to protect this critical resource".

Similarly, Leslie Nerli representing Glide Water District on the GGA said "We have to hear from our neighbors. This is a big deal. We're going to make decisions soon that will affect groundwater management for the next 20 years. We may not like it but we have some tough challenges in this basin and we need folks to come to the meeting and help provide information to make some of these decisions".

Meeting Dates, Times and Locations:

September 19, 2019
6:00 p.m. – 8:30 p.m.
Colusa VFW Hall
108 East Main Street
Colusa, CA

Well Monitoring Pilot Program Public Workshop

The Colusa Groundwater Authority (CGA) and Glenn Groundwater Authority (GGA) will host an evening online workshop on January 25, 2021. The purpose is to engage and inform growers and landowners who may want to in participate in a Well Monitoring Pilot Program (Pilot Program). This voluntary, non-regulatory program will support gather information about groundwater use in the Colusa Subbasin. It will provide participants near-real time access to information on production and groundwater levels at their wells as a way to support their irrigation management. Interested growers and landowners will work with the CGA and GGA to continuously monitor groundwater use and water levels at participating wells. Funding comes from the *Water Quality, Supply, and Infrastructure Improvement Act of 2014* and the *California Drought, Water, Parks, Climate, Coastal Protection, and Outdoor Access For All Act of 2018 (Proposition 68),* and through an agreement with the California Department of Water Resources

During this workshop, the CGA and GGA will:

- Provide an overview of the Pilot Program
- Describe incentives and responsibilities for interested participants
- Review the application process
- Describe selection criteria for applications received, and
- Answer questions about the Pilot Program

"This is really a win-win for us" said Colusa County Supervisor Denise Carter, Chair of the CGA. "We're required to have the best information to ensure our Groundwater Sustainability Plan is approved and that we can manage our resources locally and avoid State intervention. Many of our neighbors could also really benefit from new technologies to better manage their irrigation sources. This Program gets us both of these."

PUBLIC MEETINGS
GROUNDWATER SUSTAINABILITY PLAN DRAFT CHAPTERS

The Colusa Groundwater Authority (CGA) and Glenn Groundwater Authority (GGA) (Agencies) will host an in-person meeting on July 28 and a virtual meeting on July 29 to discuss the Sustainable Groundwater Management Act (SGMA). The content of these meeting will be the same. Against the backdrop of the critical drought, these meetings will engage the public about future groundwater management to improve long range local sustainable conditions. Under SGMA, the Agencies are required to prepare a Groundwater Sustainability Plan (GSP) for the Colusa Subbasin. Draft Chapters 5 and 6 of the GSP discuss sustainability conditions and potential projects and actions that might be pursued by the Agencies. These chapters will be released on July 16 and the Agencies seek public feedback on these important topics. Agency representatives will provide an overview of the information in these chapters and will outline methods to provide feedback in the near future. The meetings will also include a review of previously released draft chapters and a discussion of next steps in the GSP completion process.

Glenn County Supervisor Grant Carmon said "As a relatively new member of the Glenn Groundwater Authority Board, I can attest that SGMA is a challenging topic. The decisions we will make soon will affect the lives of many people in Glenn and Colusa Counties and the information we will present at these meetings is critically important for stakeholders to consider. I can't stress enough how important it is that our constituents attend one of these meetings".

"We've been at this process a long time and the planning is nearing its end" said CGA Board Member Darrin Williams. "As a Private Well Owner representing similar water users on the CGA Board, we're getting to crunch time for stakeholders to get up-to-speed on SGMA and how it will affect us in the long run. People really need to come to these meetings."

PUBLIC MEETINGS
GROUNDWATER SUSTAINABILITY PLAN – PUBLIC DRAFT REVIEW

The Colusa Groundwater Authority (CGA) and Glenn Groundwater Authority (GGA) (Agencies) will host a virtual meeting on October 13 and an in-person meeting on October 15 to discuss the Agencies' release of the Public Draft Groundwater Sustainability Plan (GSP) for the Colusa Subbasin. The content of these meetings will be the same.

Against the backdrop of the last and current critical drought, the California Legislature passed and has required implementation of the Sustainable Groundwater Management Act (SGMA). Under SGMA, the Agencies are required to prepare a GSP for the Colusa Subbasin. The GSP defines what the Agencies will do for the next 20 years to protect the subbasins and ensure groundwater is sustainable. The Agencies have opted to prepare a single, joint GSP for the entire Colusa Subbasin. Prior public events have provided stakeholders the opportunity to learn about and comment on SGMA and the draft GSP chapters. These upcoming meetings will engage the public about the entire draft GSP. Agency representatives will provide an overview of the information in each chapter of the GSP, will outline methods for the public to provide focused input and will provide the public time to ask questions about GSP content.

Colusa County Supervisor and CGA Board Chair Denise Carter said "We're at the culmination of a long process and on the cusp of implementing projects that will better monitor and enhance our groundwater. These meetings and the public comment period are a critical opportunity for stakeholders to give their input to the CGA and GGA before we approve the GSP and submit it to the State. I encourage every affected groundwater user in the subbasin to attend one of these meetings, review the plan and give us your feedback."

Similarly, City of Willows Vice Mayor and GGA Vice Chair Gary Hansen said "As the CGA and GGA Chairpersons noted in their recent Op-Ed, our aquifers provide an essential safety net for our water availability but that safety net is only as good as the tools we create to support it. Our GSP does that and we need public input to confirm if we've done it the right way".

COLUSA SUBBASIN

Colusa Subbasin Well Monitoring Pilot Program

Participant Information Form

BACKGROUND

The Colusa Subbasin Groundwater Sustainability Agencies (GSAs) are implementing an incentive-based pilot program to work with interested growers and landowners to continuously monitor groundwater use and water levels at participating wells. This voluntary, non-regulatory program is intended to support the GSAs in gathering information regarding groundwater use in the subbasin while providing participants with near-real time access to information on well production and groundwater levels at their wells to support irrigation management.

PROGRAM DESCRIPTION

Activities

Interested parties are invited to submit a brief application describing contact information, location, cropping, and other information related to the proposed groundwater well. Following the receipt of applications, participants will be selected considering certain criteria. Participants agree that the well location and information collected may be made publicly available. Participants also agree that GSA representatives may make site visits to inspect wells, verify installation, and collect manual measurements as needed.

Incentives

The program will cover the purchase cost of a flowmeter or upgrades to an existing flow meter (up to $2,500), if needed, purchase and installation of a pressure transducer (to monitor groundwater levels), datalogger, solar panel, cellular modem, and a 3-year subscription for web and mobile access to data gathered. Program participation may be extended beyond 3 years, as mutually agreed.

Participants will be responsible for:

- Installation of flow meter per manufacturer specifications
- Installation of access tube for pressure transducer in well casing
- Monthly cellular modem costs (approx. $15 per month)
- Manual reporting of pumping data, in the event of device failure

Timeline

- **January 2021:** Applications Accepted
- **February – March 2021:** Participants Selected, Agreements Executed, Wells Inspected, and Equipment Installed
- **April 2021 – October 2023:** Wells Monitored

Funding for this project has been provided in full or in part from the Water Quality, Supply, and Infrastructure Improvement Act of 2014 and the California Drought, Water, Parks, Climate, Coastal Protection, and Outdoor Access For All Act of 2018 (Proposition 68), and through an agreement with the State Department of Water Resources.

Article for the Colusa County Farm Bureau "Sodbuster," February, 2016
Sustainable Groundwater Management Act Update from Colusa County
Mary Fahey, Colusa County Water Resources Coordinator

SGMA Background
The Sustainable Groundwater Management Act (SGMA) is a new law that affects all citizens of Colusa County. It offers beneficial opportunities to achieve sustainable groundwater conditions in a manner that will support our vital agricultural economy, as well as other industry, and domestic and public water uses. The law provides for local management of groundwater resources, with the State as an enforcement "backstop" if locals do not successfully implement planning approaches.

The law dictates that Groundwater Sustainability Agencies (GSAs) must be formed to locally implement the law in all high and medium priority groundwater basins (as defined by the California Statewide Groundwater Elevation Monitoring [CASGEM] program). Public agencies with Land or Water Use Authority are eligible to be a GSA. This includes County and City governments, irrigation and reclamation districts, and public water suppliers. A GSA can be made up of one or more local public agencies, and there can be a single GSA or multiple GSAs per groundwater basin. If multiple GSAs exist, they must coordinate planning efforts. GSA(s) must be in place by June 30, 2017, or the State will enforce management responsibilities on all local groundwater users including fees for SGMA implementation.

GSAs are responsible to develop and implement Groundwater Sustainability Plans (GSPs). If there are multiple GSPs in a basin, they must be coordinated, utilize the same data and methodologies, and a Coordination Agreement is required. GSPs must be developed by Jan. 31, 2022, or, again, the state will take on groundwater management responsibilities for the basin.

In Colusa County, we have one high priority CASGEM subbasin (West Butte) and one medium priority CASGEM subbasin (Colusa), both of which are subject to SGMA. Locally, we must reach sustainability by 2042 – 20 years after the GSPs are in place. Measureable objectives must be included in the GSPs, as well as 5-year milestones.

Local Effort
Locally, we are focusing SGMA planning efforts within Colusa County boundaries, while communicating and coordinating with surrounding counties (Glenn, Yolo, Butte, Tehama). The County anticipates being part of a groundwater management partnership that implements SGMA the right way, ensures that we are regional and statewide leaders, and keeps our citizens ahead of the curve on groundwater management policies. We feel we are moving in a positive direction to implement SGMA, as the County has already taken several positive steps, including: acquired professional facilitation services through funding from the Department of Water Resources (to be provided by Sacramento State, Center for Collaborative Policy [CCP]), initiated a county-wide groundwater assessment, and pursued a recent groundwater planning grant through the Water Bond. The County is committed to share these resources with SGMA partners and affected citizens while working with agencies, landowners and other affected parties on GSA and GSP development, and SGMA implementation.

Over the next several months, CCP will coordinate and facilitate several public meetings, including GSA group meetings to determine local GSA structure. CCP will act as a neutral third party at these meetings to ensure that all of the GSA-eligible agencies have an equal voice at the table. Through these meetings, we hope to have a good idea of what our local governance structure will look like by June, 2016. Other efforts will include informational public meetings to ensure that Colusa County citizens are informed and engaged in local groundwater management planning.

Stay Informed

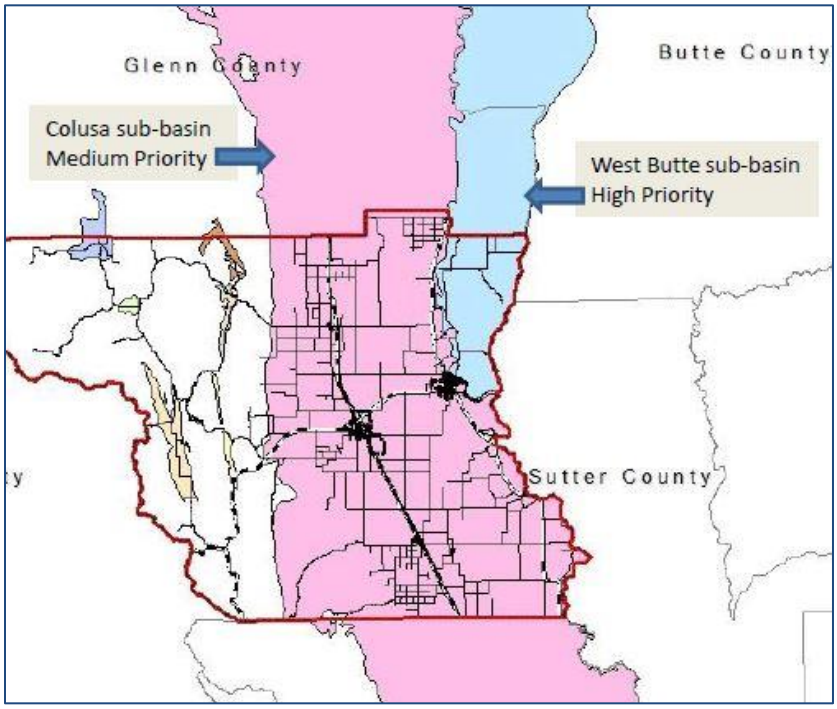
Colusa County and all of its residents need to work together and commit to manage this valuable resource so that we may continue to live here and farm for many generations to come. Here are a few ways you can stay informed:

- Sign up for the Water Resources Mailing List to receive meeting announcements and current news: email mfahey@countyofcolusa.org; or call: 530.458.7709
- Visit the DWR SGMA Website: www.water.ca.gov/groundwater
- Visit the Water Resources Website: www.countyofcolusa.org, under *Departments > Agricultural Administrative Services*

July 11, 2016

Sustainable Groundwater Management Act (SGMA); Introduction, Part 1 of 4

For immediate release
Contact: Mary Fahey, Colusa County Water Resources Coordinator
mfahey@countyofcolusa.com
530-458-7709



This is the first article in a four-part series to inform groundwater users in Colusa County about new groundwater legislation and the local efforts that are taking place to implement these new laws.

Part 1: The Sustainable Groundwater Management Act (SGMA) – An Overview

What is the Sustainable Groundwater Management Act (SGMA)?

SGMA is comprehensive statewide groundwater legislation that went into effect January 1, 2015. SGMA affects all groundwater users in California. The purpose of the legislation is to achieve sustainable groundwater conditions statewide. Sustainable conditions will support Colusa County's vital agricultural economy, industry, and domestic and public water uses.

SGMA mandates that all high and medium priority groundwater basins in California must be managed sustainably over a 20-year implementation period**.** In Colusa County we have two groundwater basins subject to SGMA: the Colusa subbasin and the West Butte subbasin. Both basins span multiple counties and SGMA implementation efforts must be coordinated basin-wide.

Who Will Be In Charge?

SGMA requires that a local agency, or combination of local agencies, implement SGMA at the local level, with the state as a backstop if necessary. These local agencies are called Groundwater Sustainability Agencies (GSA), and they will be responsible for developing Groundwater Sustainability Plans and ensuring that groundwater is being managed sustainably. GSAs will have many authorities and responsibilities.

According to SGMA, "Any local public agency or combination of local public agencies overlying a groundwater basin may decide to become a groundwater sustainability agency for that basin." "Local agency" means a local public agency that has water supply, water management or land use responsibilities within a groundwater basin. These agencies include counties, cities, irrigation and reclamation districts, and public utility districts, or similar. "Efforts are underway now in Colusa County to determine a local GSA structure, including which agencies will participate in SGMA implementation," said Mary Fahey, Colusa County Water Resources Coordinator. Fahey went on to say, "now is the time for folks to become engaged in local SGMA planning efforts. All of our meetings are open to the public."

What is Sustainability?

Sustainable groundwater management is defined as the management and use of groundwater without causing undesirable results. The California Department of Water Resources has developed Groundwater Sustainability Plan Regulations which define six "Sustainability Indicators" for undesirable results. These conditions must be avoided for a basin to be considered sustainable:

1. Significant and Unreasonable reductions in Groundwater Levels
2. Significant and Unreasonable reductions in Groundwater Storage
3. Significant and Unreasonable Land Subsidence
4. Significant and Unreasonable reductions in Groundwater Quality
5. Significant and Unreasonable reductions in Groundwater-Surface Water Interaction
6. Significant and Unreasonable Seawater Intrusion (we do not have to address this criteria in Colusa County)

Since groundwater conditions vary greatly throughout the state, undesirable results are defined at the basin level (what is undesirable for one area may be acceptable in another area). The bottom line is that the amount of groundwater pumped cannot exceed the amount of water recharged. Cooperation and coordination among agencies and landowners is crucial to successful SGMA implementation, and to maintaining local control over our groundwater resources.

The county would like to remind its citizens that SGMA affects every well owner in California, which is why it is so important for the general public to be informed. Colusa County Supervisor, Denise Carter said, "SGMA planning efforts have been taking place in Colusa County over the past year and a half, and important governance decisions will be made over the next few months. I highly encourage landowners to participate in this process by attending our public meetings and staying informed."

In the next article, we will discuss Groundwater Sustainability Agencies (GSA) and Groundwater Sustainability Plans (GSP) in more detail, and we will also discuss Colusa County's efforts to include private groundwater pumpers in local SGMA planning efforts.

Here's how you can stay informed:

Upcoming Colusa County SGMA Meetings:

July 15, 2016
GSA Working Group Meeting #5
9:00 a.m. – noon
Colusa County Farm Bureau Board Room; 520 Market Street, Colusa, CA 95932
This is the fifth in a series of facilitated working meetings for GSA-eligible agencies to coordinate local governance planning. There will be a presentation on local groundwater conditions and how they relate to the GSP Regulations and sustainability indicators. This presentation will help local agencies determine how they want to participate in local governance. These meetings are open to the public.

SGMA - How to Stay Informed:

- ✓ Get on the Colusa County Water Resources email notification list for updates and meeting announcements - call or email Water Resources Staff: **530.458.7709**; email: mfahey@countyofcolusa.com
- ✓ Visit the Colusa County Water Resources website where you can find meeting announcements, agendas, meeting summaries and presentations as well as information on SGMA: Countyofcolusa.org
- ✓ Visit us on Facebook – Colusa County Groundwater
- ✓ Visit DWR's Groundwater Information Center website for extensive information on SGMA: http://www.water.ca.gov/groundwater/gwinfo/index.cfm

July 25, 2016

Sustainable Groundwater Management Act (SGMA); Groundwater Sustainability Agencies and Groundwater Sustainability Plans, Part 2 of 4

For immediate release
Contact: Mary Fahey, Colusa County Water Resources Coordinator
mfahey@countyofcolusa.com
530-458-7709

This is the second article in a four-part series to inform groundwater users in Colusa County about new groundwater legislation, the Sustainable Groundwater Management Act (SGMA), and the local efforts that are taking place to implement these new laws.

Part 2: Groundwater Sustainability Agencies (GSAs), Private Pumper Advisory Committee (PPAC), and Groundwater Sustainability Plans (GSPs)

What is a Groundwater Sustainability Agency?

As discussed in a previous article, the Sustainable Groundwater Management Act (SGMA) requires that a local agency, or combination of local agencies, implement the legislation at the local level, with the state as a backstop if necessary. These local agencies are called Groundwater Sustainability Agencies (GSA). Any local public agency with water supply, water management and/or land use responsibilities is eligible to be a GSA. Eligible agencies include counties, cities, water districts, reclamation districts, public utility districts and similar.

A GSA is responsible for enforcing all of the requirements of SGMA. GSAs have certain responsibilities and authorities under SGMA. Responsibilities include developing and implementing a Groundwater Sustainability Plan (GSP), conducting studies, providing extensive outreach, monitoring groundwater conditions, and reporting to the state. Authorities that GSAs may use include adopting regulations, levying fees, requiring metering on wells, and regulating groundwater extractions, among others. These authorities are available to GSAs as tools to utilize, if necessary to achieve sustainability.

In Colusa County, we have 28 agencies that are eligible to be a GSA. SGMA allows the local agencies to decide the best governance structure for their basins. Agencies can be a stand-alone GSA covering just their service area, or part of a multi-agency GSA that covers an entire basin or portion of a basin. There can be one or more GSAs in a groundwater basin, but if there are multiple GSAs, they all must work together and coordinate efforts.

GSAs must be established in all of the high and medium priority groundwater basins in the state by June 30, 2017. The GSA-eligible agencies in Colusa County have participated in five governance planning meetings over the last several months. These meetings have been productive and the group continues to make progress in determining a local SGMA governance structure. These meetings are open to the

public and run by professional facilitators from the Center for Collaborative Policy, Sacramento State University.

SGMA and Private Pumpers; Colusa County Private Pumper Advisory Committee (PPAC)

Under SGMA, private landowners are not eligible to be a GSA. Counties are presumed to be the GSA over the "white areas," or "private pumper" areas, which are areas of the county that are not covered by another GSA-eligible agency. This can be seen as problematic because landowners in the private pumper areas rely on groundwater as their sole source of irrigation, making them key players in successful SGMA implementation.

Colusa County has given our private pumpers a greater voice in SGMA planning and implementation by forming a Private Pumper Advisory Committee (PPAC). The PPAC is made up of 7 members and 3 alternates. Members of the PPAC are private pumper individuals from throughout the County, chosen by the Colusa County Groundwater Commission.

PPAC responsibilities include two main tasks; they are advisory to the County on the concerns and issues of the private pumpers, and they are also responsible to provide SGMA outreach to their neighbors. The PPAC is also very engaged in Colusa County's governance planning.

What is a Groundwater Sustainability Plan (GSP)?

SGMA requires one or more Groundwater Sustainability Plans (GSP) be prepared for all high and medium priority groundwater basins in the state. Local GSAs will be responsible for developing GSPs by January 31, 2022 (January 31, 2020 for basins in overdraft). If there are multiple GSPs in a basin, they must be coordinated and must utilize the same data and methodologies.

The GSPs will be the road map to achieving sustainable groundwater management. GSPs must include, among other elements: a description of the plan area, sustainability goals for each of the six Sustainability Indicators (see below), measurable objectives and milestones, a monitoring and data management program, projects and management actions to achieve/maintain sustainability, a water budget detailing projected water supplies and demands, a description of how the Plan will affect other surrounding plans, and many more details. SGMA requires yearly reporting and every-five-year Plan evaluation to ensure that progress is being made.

The Groundwater Sustainability Plan Regulations define six "Sustainability Indicators" for undesirable results. These conditions must be avoided for a basin to be considered sustainable:

- Significant and Unreasonable reductions in Groundwater Levels
- Significant and Unreasonable reductions in Groundwater Storage
- Significant and Unreasonable Land Subsidence
- Significant and Unreasonable reductions in Groundwater Quality
- Significant and Unreasonable reductions in Groundwater-Surface Water Interaction
- Significant and Unreasonable Seawater Intrusion (we do not have to address this criteria in Colusa County)

The California Department of Water Resources (DWR) developed GSP Regulations which were adopted June 1, 2016. You can find these on their website at:
http://www.water.ca.gov/groundwater/sgm/gsp.cfm

Upcoming Colusa County SGMA Meetings:

August 26, 2016
Private Pumper Advisory Committee Meeting
10:00-noon
Colusa Industrial Properties Conference Room
100 Sunrise Blvd., Colusa, CA 95932

SGMA - How to Stay Informed:

- ✓ Visit the Colusa County Water Resources website where you can find meeting announcements, agendas, meeting summaries and presentations as well as information on SGMA: countyofcolusa.org
- ✓ Visit DWR's Groundwater Information Center website for extensive information on SGMA: http://www.water.ca.gov/groundwater/gwinfo/index.cfm
- ✓ Do you have questions? Call or email Colusa County Water Resources Staff

August 1, 2016

Sustainable Groundwater Management Act (SGMA); Implementing SGMA in Colusa County, Part 3 of 4

For immediate release
Contact: Mary Fahey, Colusa County Water Resources Coordinator
mfahey@countyofcolusa.com
530-458-7709

This is the third article in a four-part series to inform groundwater users in Colusa County about new groundwater legislation, called the Sustainable Groundwater Management Act (SGMA), and the local efforts that are taking place to implement these new laws.

Part 3 – Implementing SGMA in Colusa County

Forming Governance

The County of Colusa and other local agencies and stakeholders have been working cooperatively on a proactive approach to SGMA implementation since early 2015. The County wants to be part of a partnership that implements SGMA the right way, ensures that we are regional and statewide leaders, and keeps our citizens ahead of the curve on groundwater management policies.

Formation of local Groundwater Sustainability Agencies (GSAs) is the first major task required by local agencies. GSAs are the governing bodies that will be responsible for developing a Groundwater Sustainability plan (GSP) and implementing SGMA locally. GSA-eligible agencies in Colusa County have formed a Governance Workgroup that has been meeting regularly to determine the best approach to form one or more GSAs in the county. The Governance Workgroup includes various water management districts, and public water suppliers. Groundwater users from the County's Private Pumper Advisory Committee are also participating in these meetings.

GSA-eligible agencies will have to make very important decisions regarding their level of participation in governance. Implementing SGMA will will require significant resources from GSAs. Some agencies may not have the necessary resources, yet they don't want to be left out of the process. Other agencies may not want to participate and prefer to leave decision making to other agencies. The Governance Workgroup is discussing options to include different levels of engagement from agencies.

Recognizing the delicate nature of bringing agencies together to form a new political governing body, the Department of Water Resources (DWR) developed a program to provide facilitation support services to counties. Colusa County acquired these services and the Center for Collaborative Policy (CCP) at California State University, Sacramento, has been facilitating the Governance Workgroup meetings. The facilitators act as a neutral third party so that each agency has an equal voice at the table. They also work closely with DWR to ensure that accurate and current information regarding SGMA is shared with the group.

DRAFT

Five facilitated Governance Workgroup meetings have taken place in Colusa County with a sixth meeting being scheduled in August. The group continues to make progress at the county leve. Plans for the near future include coordinating with Glenn and Butte Counties who share subbasins with Colusa County. These meetings are open to the public and are noticed at the project website (see web links below).

Next Steps

The Colusa SGMA Governance Workgroup will continue to convene regular planning meetings over the next year. In the next few months, the group will begin to coordinate with Glenn and Butte Counties on basin-wide governance planning. By the end of 2016, and possibly sooner, we anticipate that the Colusa County portions of the Colusa Subbasin and West Butte Subbasin will have a defined governance structure. Once that structure is agreed upon, legal agreements, such as Joint Powers Authority (JPA) Agreements and Coordination Agreements will be drawn up.

Important Dates:

12/30/2016	Governance Structure defined in Colusa County
Jan. 2017-June, 2017	Legal Agreements are developed
6/30/2017	GSAs must be in place for all high and medium priority groundwater basins that are not in critical overdraft
1/31/2022	GSPs must be completed for all high and medium priority groundwater basins that are not in critical overdraft

SGMA - How to Stay Informed:

- ✓ Get on the Colusa County Water Resources email notification list for updates and meeting announcements - call or email Water Resources Staff: 530.458.7709; email: mfahey@countyofcolusa.com
- ✓ Visit the Colusa County Water Resources website where you can find meeting announcements, agendas, meeting summaries and presentations as well as information on SGMA: countyofcolusa.org
- ✓ Visit DWR's Groundwater Information Center website for extensive information on SGMA: http://www.water.ca.gov/groundwater/gwinfo/index.cfm

Date: April 27, 2018

Sustainable Groundwater Management Act (SGMA) Groundwater Sustainability Planning

ATTENTION ALL USERS OF GROUNDWATER WELLS IN COLUSA, AND/OR GLENN COUNTY:
The State of California under the Sustainable Groundwater Management Act (SGMA) law requires all groundwater well users to live under a Groundwater Sustainability Plan developed by Groundwater Sustainability Agencies that must be completed by January 31, 2022. This Plan will require all groundwater well use to be sustainable for all parts of the basins throughout California, and will potentially require meters and records on groundwater use. Also required will be a plan for recharging the aquifers if groundwater falls into an overdraft situation.

Development of the Groundwater Sustainability Plans by Groundwater Sustainability Agencies is just getting underway in Colusa and Glenn Counties. Each groundwater user has the opportunity to help develop these Plans which all users will have to live by. It would behoove all groundwater users to get involved in this process.

Please attend Groundwater Sustainability Agency meetings and other local water management meetings including the Colusa Groundwater Authority, Glenn Groundwater Authority, and Colusa County Groundwater Commission meetings, and add your name to email notification lists. You can find more information and sign up for the email lists on the websites at:

Colusa Groundwater Authority:
www.colusagroundwater.org
Contact the office: 530-458-0719 or email: mfahey@countyofcolusa.com

Glenn Groundwater Authority:
http://www.countyofglenn.net/dept/ag-commissioner/water-resources/glenn-groundwater-authority
Contact the office: 530-934-6501 or email: lhunter@countyofglenn.net

Other Groundwater Sustainability Agencies within Colusa and Glenn County include the Corning Sub-basin GSA, Glenn County, Reclamation District 1004, Reclamation District 2106, and Western Canal Water District.
More information can also be found on the Department of Water Resources website at:
https://www.water.ca.gov/Programs/Groundwater-Management/SGMA-Groundwater-Management

Next County Committee Meeting: TBD

Elections for the 2018 County Committee

Elections for USDA's Farm Service Agency's (FSA) Colusa County Committee is underway.

It is important that every eligible producer participate in these elections because FSA county committees are a link between the agricultural community and the USDA. The 2018 election in Colusa County will be conducted for the representative Local Administrative Area (LAA) 3 located west of Interstate 5.

County committee members are a critical component of FSA operations. Committees should be comprised of members who reflect the diversity of producers involved in production agriculture in Colusa County. This means that producers representing underserved groups or communities should be on the committee to speak on behalf of their constituency.

Underserved producers are beginning, women and other minority farmers and ranchers and land owners and/or operators who have limited resources. Other minority groups including Native American and Alaska Natives; persons under the poverty level, and persons that have disabilities are also considered underserved.

County committee election ballots will be mailed to eligible voters on Nov. 5, 2018. The last day to return completed ballots to the Colusa County USDA service center is Dec. 3, 2018.

For more information on eligibility to serve on FSA county committees, visit: **www.fsa.usda.gov/elections**.

Heading 2 HereSustainable Groundwater Management Act

(SGMA) Groundwater Sustainability Planning

ATTENTION ALL USERS OF GROUNDWATER WELLS IN COLUSA, AND/OR GLENN COUNTY

The State of California under the Sustainable Groundwater Management Act (SGMA) law requires all groundwater well users to live under a Groundwater Sustainability Plan developed by Groundwater Sustainability Agencies that must be completed by January 31, 2022. This Plan will require all groundwater well use to be sustainable for all parts of the basins throughout California, and will potentially require meters and records on groundwater use. Also required will be a plan for recharging the aquifers if groundwater falls into an overdraft situation.

Development of the Groundwater Sustainability Plans by Groundwater Sustainability Agencies is just getting underway in Colusa and Glenn Counties. Each groundwater user has the opportunity to help develop these Plans which all users will have to live by. It would behoove all groundwater users to get involved in this process.

Please attend Groundwater Sustainability Agency meetings and other local water management meetings including the Colusa Groundwater Authority, Glenn Groundwater Authority, and Colusa County Groundwater Commission meetings, and add your name to email notification lists. You can find more information and sign up for the email lists on the websites at:

www.colusagroundwater.org

SEPTEMBER 4, 2018 SPECIAL BASIN BOUNDARY MODIFICATION (BBM) EDITION NEWSLETTER

The purpose of this newsletter is to inform the public about the basin boundary modification proposals being considered in the Colusa and West Butte groundwater subbasins in Colusa County.

BASIN BOUNDARY MODIFICATIONS (BBM)

The Sustainable Groundwater Management Act (SGMA) established a process for local Groundwater Sustainability Agencies (GSAs) to request that the California Department of Water Resources (DWR) revise the boundaries of Bulletin 118 groundwater basins or subbasins in order to promote sustainable groundwater management. DWR completed the first round of Basin Boundary Modifications (BBMs) under SGMA in 2016. On January 1, 2018, DWR opened the second and current round of BBM modifications. Proposals are due September 28, 2018. Once a BBM request is submitted and deemed complete by DWR, a 30-day public comment period is opened. It is anticipated that DWR will release the initial results of round two BBMs in late 2018, after which another 30-day public comment period will open.

The purpose of this newsletter is to describe two basin boundary modification proposals being considered in the basins that lie in, and adjacent to, Colusa County:

1. The Colusa Groundwater Authority is proposing modifications to the West Butte and Colusa Subbasins.

2. The County of Butte is proposing modifications to the Vina, West Butte and East Butte Subbasins.

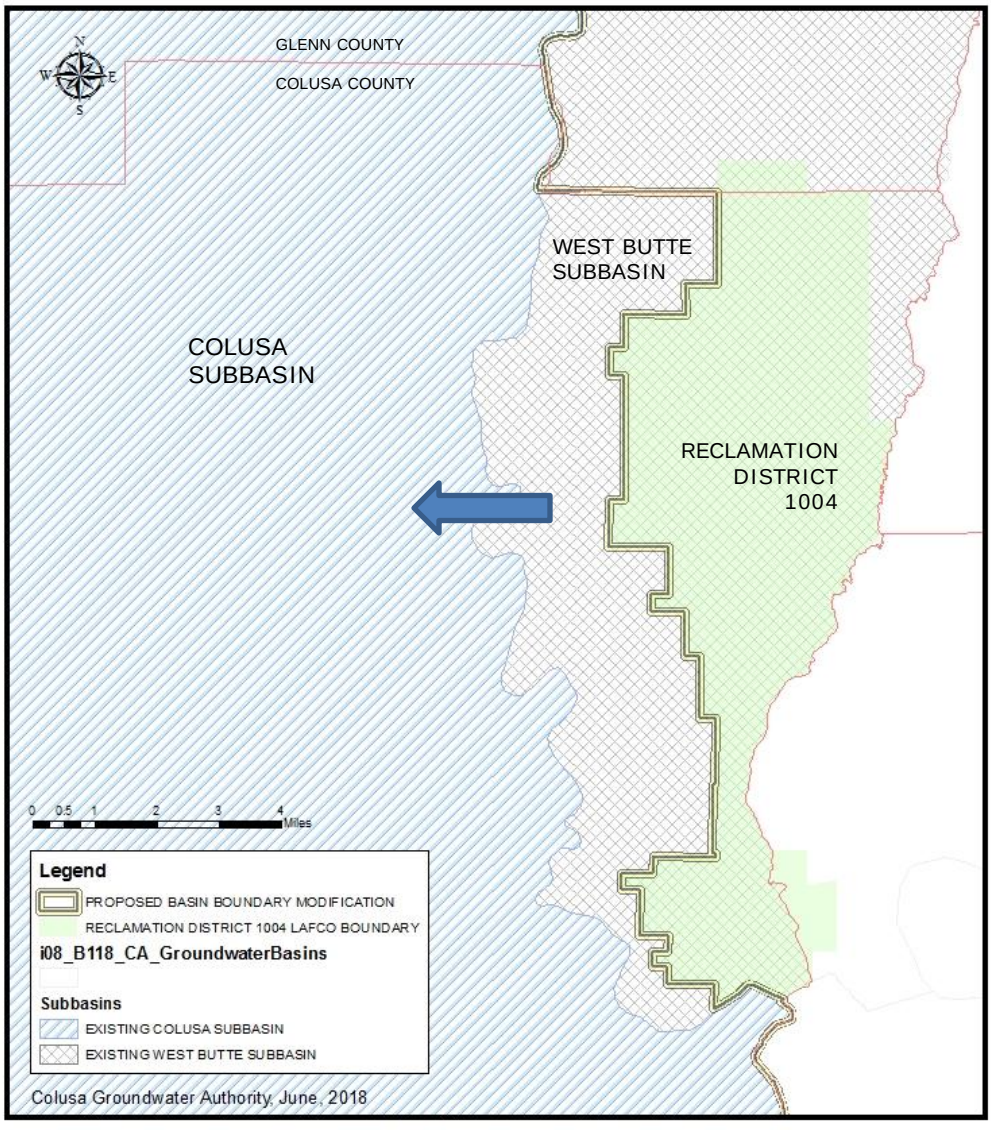
These proposed modifications are discussed in detail on the following pages.

More information on BBMs

You can find a map of statewide groundwater basins by accessing DWR's online Basin Boundary Assessment tool: https://gis.water.ca.gov/app/bbat/

You can find more information about Basin Boundary Modifications, including a list of proposed modifications and submitted BBM proposals by accessing DWRs online SGMA Portal: https://sgma.water.ca.gov/basinmod/

More information on BBMs can be found on DWR's website: https://water.ca.gov/Programs/Groundwater-Management/Basin-Boundary-Modifications



LOCAL BASIN BOUNDARY MODIFICATION (BBM) PROPOSALS

Colusa Groundwater Authority Proposed Basin Boundary Modification (BBM)

In May, 2018, the Colusa Groundwater Authority (CGA) submitted an initial notification to DWR of a proposed jurisdictional Basin Boundary Modification that would consolidate a portion of the West Butte Subbasin (5-21.58) with the Colusa subbasin (5-21.52). This jurisdictional consolidation would bring the Colusa County portion of the West Butte Subbasin that lies on the west side of the legal service area boundary of Reclamation District 1004 into the Colusa Subbasin.

A **Jurisdictional Basin Boundary Modification** involves the addition, deletion, or relocation of a basin or subbasin boundary that is not a scientific modification but promotes sustainable groundwater management.

COLUSA GROUNDWATER AUTHORITY
PROPOSED BASIN BOUNDARY MODIFICATION 2018
Colusa Subbasin (5-21.52); West Butte Subbasin (5-21.58)

Data Sources:
1. Groundwater Basins from DWR's final 2016 Bulletin 118 Groundwater Basin Boundaries, downloaded
2. GSA Boundaries from DWR SGMA GSA Map Viewer, downloaded
3. California Counties from DWR SGMA GSA Map Viewer, downloaded
4. Reclamation District 1004 Boundaries from Colusa County LAFCO

A **Management Area** is defined in the GSP Regulations as:

"… an area within a basin for which the Plan may identify different minimum thresholds, measureable objectives, monitoring or projects and management actions based on water use sector, water source type, geology, aquifer characteristics, or other factors."
§ 351 (r)

"Each Agency may define one or more management areas within a basin if the Agency has determined that creation of management areas will facilitate implementation of the plan."

The Colusa Groundwater Authority identified that this proposed jurisdictional basin boundary modification would improve the efficiency and cost-effectiveness of sustainable groundwater management within these basins. The current Bulletin 118-defined basin boundaries split the CGA into two subbasins, which will require the CGA to participate in the development and implementation of two separate Groundwater Sustainability Plans. The majority of the CGA's jurisdiction lies in the Colusa Subbasin, where we have achieved very effective sustainable groundwater management planning, in close coordination with the Glenn Groundwater Authority. Consolidation of the CGA's jurisdiction would allow this coordinated effort to continue seamlessly through GSP development.

The CGA intends, through development of the Groundwater Sustainability Plan, to delineate **Management Areas** in the Colusa Subbasin. Management Areas are tools that GSAs can use to define areas in the basin where more localized groundwater management can take place. Management Areas can be defined by unique hydrological conditions, or other parameters. It is anticipated that the area in the West Butte Subbasin proposed to be consolidated into the Colusa Subbasin would become its own Management Area in the Colusa Subbasin GSP.

The proposed Basin Boundary Modification does not alter any landowner's water rights - the CGA does not have that authority. Additionally, the proposed BBM does not have any bearing on groundwater transfers - Colusa County's Groundwater Ordinance remains in place and the GSA cannot override any County Ordinance.

Opportunities to Provide Input

The CGA is interested in receiving feedback regarding the proposed BBM from local agencies and landowners in the Colusa and West Butte Subbasins. In May, 2018, a notification of the proposed BBM was distributed to the CGA's email distribution list and a notification was posted on the DWR SGMA Portal website. The proposed modification has been discussed at several public CGA Board meetings, Colusa County Farm Bureau Board meetings, Northern Sacramento Valley IRWMP meetings, RD 1004 Board meetings, West Butte Subbasin Workgroup meetings, and other various public meetings. Information is also posted on the CGA website.

A presentation and discussion regarding the CGA's proposed Basin Boundary Modification will be held at the next **Colusa Groundwater Authority Board Meeting:**

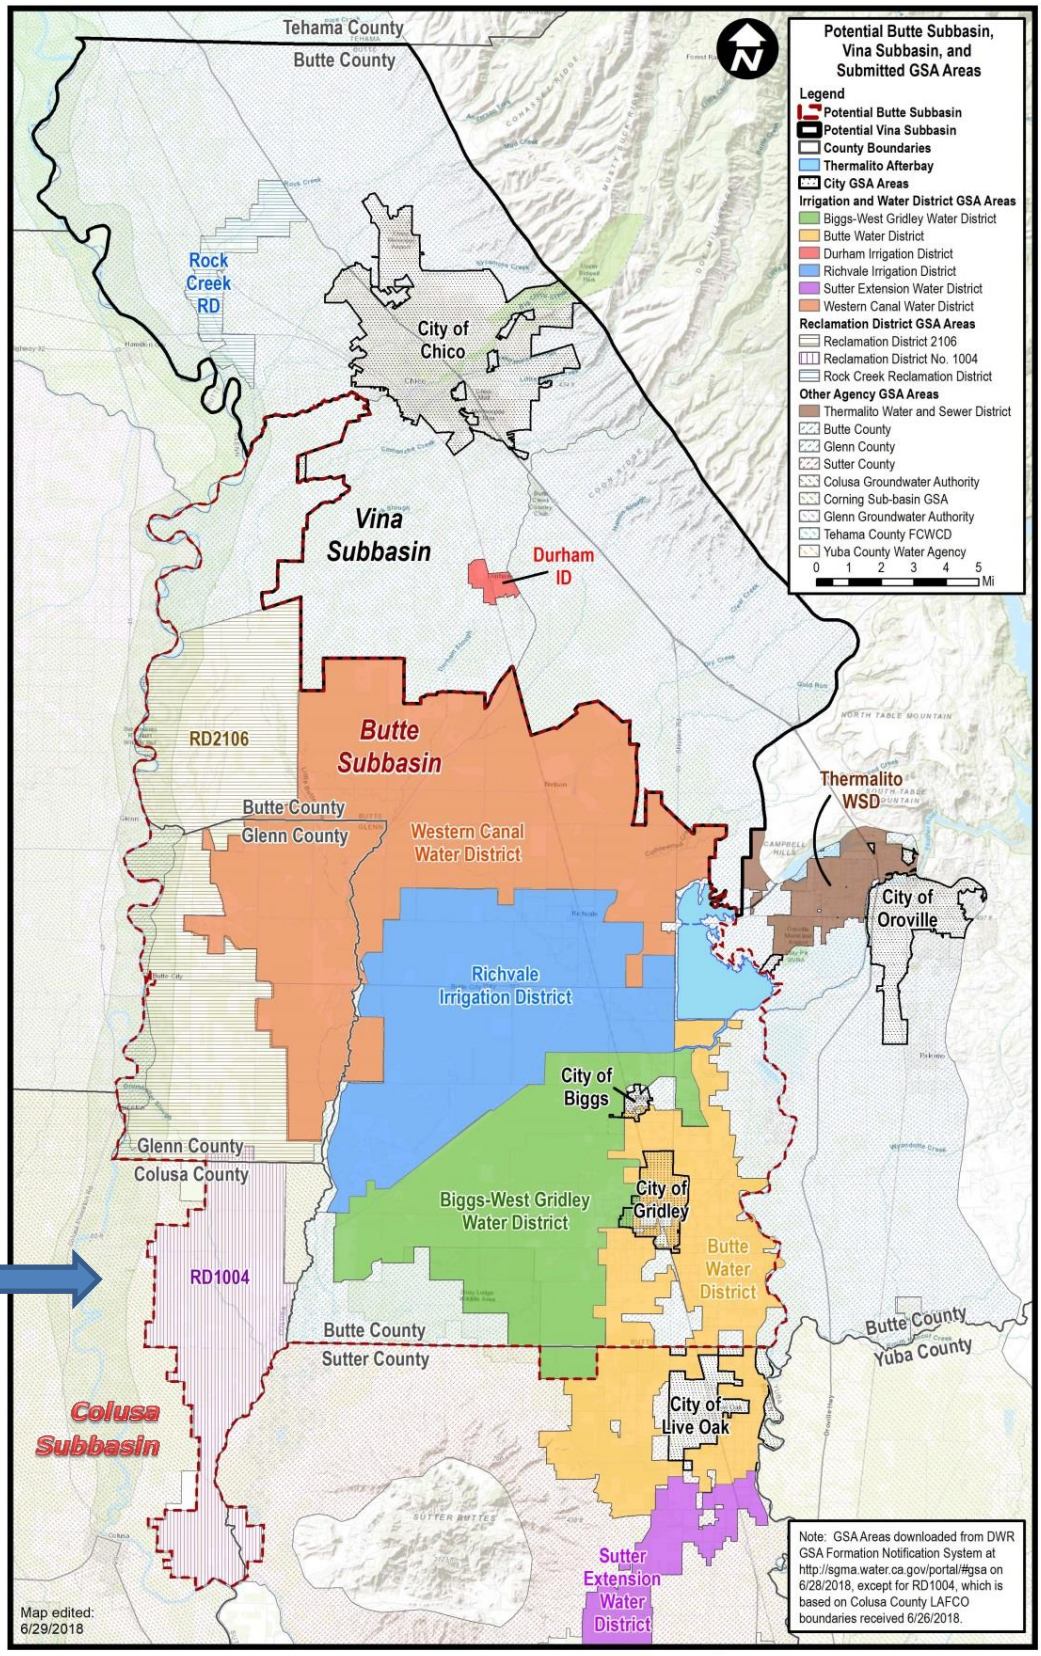
September 25, 2018
1:00 p.m. – 3:00 p.m.
Colusa Industrial Properties Conference Room
100 Sunrise Blvd., Colusa, CA 95932

Members of the public that wish to learn more are encouraged to attend this meeting. Additionally, comments and questions can be sent to CGA Staff via email to Mary Fahey at mfahey@countyofcolusa.com, mail: **100 Sunrise Blvd., Suite A, Colusa, CA 95932**, or by phone: **530-458-0719**.

Colusa Groundwater Authority Staff and Butte County Staff communicate regularly and share information related to SGMA implementation. There is a high level of coordination between all of the GSAs in the local groundwater basins.

Butte County's Proposed Basin Boundary Modification

Butte County is working toward submitting a BBM request to DWR in coordination with the Feather River Water Districts (Western Canal Water District, Richvale Irrigation District, Biggs West Gridley Water district, and Butte Water District) and other GSAs to modify the Vina, West Butte, and East Butte Subbasins. The proposed modification would create a new "Butte Subbasin" by consolidating large portions of the West Butte and East Butte Subbasins. The "Butte Subbasin" would include Butte County GSA areas, RD 2106, RD 1004, the Feather River Districts, the City of Biggs, the City of Gridley and small portions of the Glenn County GSA and Colusa Groundwater Authority. The southern boundary would mostly align with the Butte-Sutter County line. As a result of these modifications, the Vina Subbasin expands to the south to include Butte County GSA areas and Durham Irrigation District.



This modification, combined with the CGA's proposed modification would remove the West Butte Subbasin, and reduce the number of subbasins in Butte County from four down to three. Similar to the CGA's proposed BBM, Butte County's proposal provides greater efficiency and will reduce costs for long-term governance of groundwater in these subbasins and for development and implementation of Groundwater Sustainability Plans.

See map of the proposed "Butte Subbasin" on Page 5.

For questions or additional information regarding Butte County's Basin Boundary Modification, please contact Christina Buck at (530) 552-3593 or cbuck@buttecounty.net

Butte County Proposed Basin Boundary Modification in the West Butte, East Butte and Vina Subbasins

The area outlined in the dashed red line is the proposed Butte Subbasin BBM.

The CGA's proposed BBM aligns with the proposed Butte Subbasin boundary in Colusa County.

DWR's BBM Public Comment Opportunity

Once the Basin Boundary Modification proposals are posted to the California Department of Water Resources' (DWR) online Basin Boundary Modification Request System, public comments can be submitted pursuant to Article 4, Section 343.12 of the Basin Boundary Modification Emergency Regulations (see below). Public comments will be accepted by DWR for 30 days after the BBM request is posted.

Written comments regarding any Basin Boundary Modification proposal can be submitted to DWR within 30 days of the BBM proposal being posted on DWR's website.

§ 343.12. Public Input

(a) Any person may provide information to support or oppose a proposed boundary modification request as follows:

(1) Public input must be submitted by written notice to the California Department of Water Resources within 30 days after the Department posts a notice that the request is complete pursuant to Section 343.10(c), and provide the requesting agency a duplicate copy of that information the same day.

(2) Public input must include the name, address, and electronic mail address of the person or entity providing that input.

(3) Public input must include a clear statement of the basis for the support of or opposition to the proposed boundary modification.

(4) The level of detail provided by public input need not be as comprehensive as that contained in the request, but must rely on similar scientific and technical information as the particular boundary modification request to which it is addressed, and will be evaluated by the Department using the same criteria.

(b) The Department shall post all public input on the Department's Internet Web site.

(c) The Department is not required to respond to comments received through public input, but will consider such comments as part of its evaluation of a boundary modification request.

(d) The Department shall give the requesting agency a reasonable opportunity to respond to public input, including the opportunity to modify the boundary modification request.

Note: Authority cited: Section 10722.2, Water Code. Reference: Section 10722.2, Water Code.

A **Groundwater Sustainability Agency (GSA)** is responsible for performing the duties and exercising the necessary powers to implement the Sustainable Groundwater Management Act at the local level. A single agency can be a GSA, or a combination of local agencies can form a GSA through a Joint Powers Agreement or other legal Agreement. SGMA law required GSAs to be in place by June 30, 2017.

Any "unmanaged areas" (areas not covered by a GSA) in a groundwater basin that is subject to SGMA will come under management of the State Water Resources Control Board.

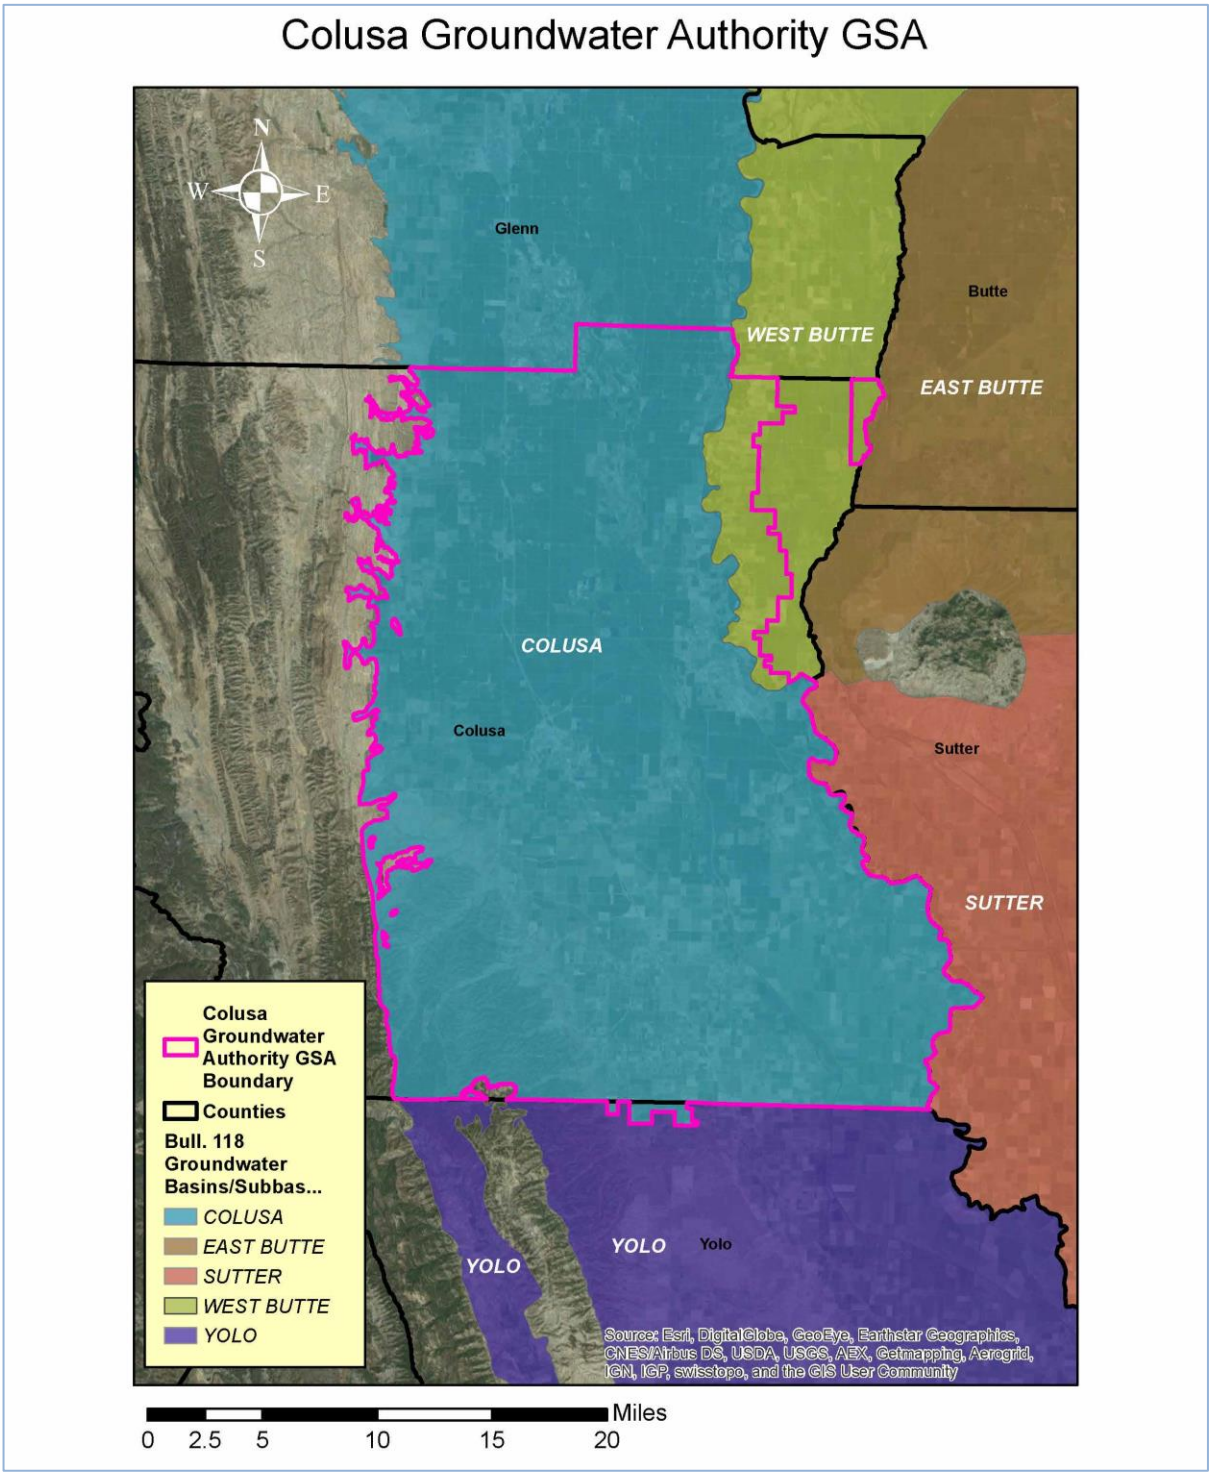
The Colusa Groundwater Authority was formed to ensure that the groundwater resources in Colusa County are managed locally and State intervention is avoided.

ABOUT THE COLUSA GROUNDWATER AUTHORITY

The Colusa Groundwater Authority (CGA) was formed on June 29, 2017 to comply with the Sustainable Groundwater Management Act (SGMA) regulations and ensure that groundwater is managed locally. The CGA is a Joint Powers Authority and is recognized by DWR as the Groundwater Sustainability Agency (GSA) for the Colusa County portion of the Colusa Subbasin, and portions of the West Butte Subbasin outside of Reclamation District 1004. (see map, page 8).

Members of the Colusa Groundwater Authority Board:

1. County of Colusa
2. City of Colusa
3. City of Williams
4. Glenn Colusa Irrigation District
5. Maxwell Irrigation District and Westside Water District (1 seat)
6. Princeton-Codora-Glenn Irrigation District and Provident Irrigation District (1 seat)
7. Colusa County Water District
8. Reclamation District 108
9. Reclamation District 479
10. Colusa Drain Mutual Water Company
11. Private Pumper Representative from Colusa County Groundwater Commission
12. Private Pumper Representative from Colusa County Groundwater Commission



Get to know the Colusa Groundwater Authority, and keep up with the latest SGMA news.

Visit the website:

Colusagroundwater.org

Colusa Groundwater Authority Jurisdiction

The Colusa Groundwater Authority covers the areas outlined in pink on this map. The Blue area is the Colusa Subbasin and the green area is the West Butte Subbasin. A map of statewide GSAs can be found on the DWR GSA Map Viewer.

STAY INFORMED!
All beneficial uses and users of groundwater (Water Code Section 10723.2) must be taken into consideration during SGMA planning and implementation. There will continue to be ample opportunities for public engagement during GSP development. If you are not on the CGA's email list, please contact Water Resources staff to ensure you receive meeting notices and other relevant information, and please share this information with your friends and neighbors.

SGMA – STAY INFORMED:

Between now and January 31, 2022, the CGA will be developing the Groundwater Sustainability Plan for the Colusa Subbasin. **If you have not been involved in local SGMA planning, now is the time!**

There are many opportunities to be engaged and informed about local groundwater management planning:

- ✓ Get on the CGA email notification list for updates and meeting announcements - call or email Staff (see contact info below), or sign up on the website: https://colusagroundwater.org/contact-us/
- ✓ Visit the CGA Website regularly: http://colusagroundwater.org
- ✓ Attend Colusa Groundwater Authority Board meetings
- ✓ Visit DWR's Groundwater Information Center website: https://water.ca.gov/Programs/Groundwater-Management/SGMA-Groundwater-Management
- ✓ Visit the DWR SGMA Portal: https://sgma.water.ca.gov/portal/#intro

The next meeting of the CGA Board is **September 25, 2018** at 1:00 p.m. at Colusa Industrial Properties. The full Board meeting schedule can be found on the CGA website: https://colusagroundwater.org/meetings/

All CGA Board meetings are open to the public.

Colusa Groundwater Authority, Article for October, 2018 Family Water Alliance "Green Ribbon" Newsletter

Submitted by Mary Fahey, Program Manager, Colusa Groundwater Authority / 530-458-7709

The Sustainable Groundwater Management Act – Time for Landowners to Get Involved!

With a myriad of water-related issues dominating the headlines these days, it's difficult for landowners to know where to focus and when to get involved. While all of the issues are important, now is definitely the time to get up to speed and involved with local Sustainable Groundwater Management Act (SGMA) efforts.

As the Colusa Groundwater Authority (CGA) moves into its second year of operations, the Board is working on important projects that all landowners in Colusa County should be aware of, including development of the Groundwater Sustainability Plans that will dictate the future of groundwater management in the local basins. Development of these plans is just getting underway in the basins in Colusa County, and surrounding counties, and Stakeholder input is critical to development of these plans. The Plans must be completed by January 31, 2022.

The Colusa Groundwater Authority is also working on a Long-term Funding plan to maintain its day to day operations. The Agencies that make up the Board of the CGA agreed to fund the effort for the first two years, through June 30, 2019. The CGA is beginning a Proposition 218 Assessment process for long-term funding. Similar processes are taking place in other basins throughout the State, including the Glenn County portion of the Colusa Subbasin.

And finally, the CGA has submitted a request to the California Department of Water Resources (DWR) for a Basin Boundary Modification. This modification would bring the Colusa County portion of the West Butte Subbasin that lies on the west side of the legal service area of Reclamation District 1004 into the Colusa Subbasin. This proposed modification will create greater efficiency and will reduce costs for long-term governance of groundwater in these subbasins, and for development and implementation of Groundwater Sustainability Plans. The proposal is posted on DWR's online Basin Boundary Modification Request System: https://sgma.water.ca.gov/basinmod/init/preview/162. Public comments can be submitted on the DWR online Portal: https://sgma.water.ca.gov/basinmod/modrequest/comments/243 pursuant to Article 4, Section 343.12 of the Basin Boundary Modification Emergency Regulations. The Deadline for public comment is 11:59 p.m. October 28, 2018.

All of this information and more can be found on the **Colusa Groundwater Authority website: http://colusagroundwater.org**

You can also sign up on the CGA email notification list for updates and meeting announcements:

- Sign up on the website: https://colusagroundwater.org/contact-us/
- Or call or email Staff: Mary Fahey, Program Manager, 530-458-0719; email: mfhahey@countyofcolusa.com

If you have not been involved in local SGMA planning, now is the time!

If you have not been involved in local SGMA planning, now is the time!

Colusa Farm Bureau

Sodbuster December 2020

Sustainable Groundwater Management Act Update in the Colusa Subbasin

The big news in local groundwater management right now is Groundwater Sustainability Plan (GSP) development to comply with the Sustainable Groundwater Management Act (SGMA). Local GSPs are due January 31, 2022 and groundwater agencies throughout the region are working hard to achieve that milestone.

The Colusa Groundwater Authority (CGA) and Glenn Groundwater Authority (GGA) are jointly launching a focused "*SGMA –Series*" of GSP-related events, starting with two online public meetings in December. The meetings will be identical and will cover the status of the GSP for the Colusa Subbasin. Stakeholders will learn about work completed, work in progress, and next steps as the agencies continue their mandate to regulate groundwater use through implementation of SGMA. The meetings will be an opportunity for stakeholders to give the CGA and GGA Boards and their consultant team critically important feedback on how groundwater should be managed in the future. Stakeholders will also learn about future *SGMA-Series* opportunities and how to be involved in GSP development over the next year.

The CGA and GGA Boards hope you can participate in one of these public meetings in December:

- **Wednesday, December 9 at 5:30 p.m.**
- **Thursday, December 10 at 1:00 p.m.**

Over the next several months, CGA and GGA will release the Colusa Subbasin GSP in draft sections for public review and comment. The entire Public Draft GSP will be released for a final round of public comments in August, 2021. The *SGMA-Series* meetings will occur at strategic intervals between now and August to provide information on GSP development and to solicit Stakeholder input. Additionally, both the CGA and GGA Boards of Directors and Technical Advisory Committees hold monthly meetings that are open to the public and everyone is welcome to attend.

For more information about local SGMA planning, please visit:

- Colusa Groundwater Authority website: https://colusagroundwater.org
- Glenn Groundwater Authority website: https://www.countyofglenn.net/dept/planning-community-development-services/water-resources/glenn-groundwater-authority

COLUSA SUBBASIN

Drought has returned. Severe. Unrelenting. Undiscriminating.

As we face a long, frustrating summer and fall in the Sacramento Valley, everyone…farmer, homeowner, rancher, environmental advocate, businessperson, water deliverer, etc. will be profoundly affected by our current and pending drought conditions. In the immediate, there are no easy answers. Scarce resources inevitably create conflict. However, such conditions can also create uncommon partnerships and with the right tools, powerful solutions. In 2014, the State Legislature passed the Sustainable Groundwater Management Act (SGMA); a sweeping law that foundationally changes how groundwater is and will be managed. Our part of California is unique and we need groundwater management methods that will work for us and for our communities. We have answered the call and the requirements of SGMA and are finalizing a locally driven, locally focused Groundwater Sustainability Plan for the Colusa Groundwater Subbasin (covering most of Colusa and Glenn Counties).

SGMA is hard. It is cumbersome, expensive, complicated, intrusive and far reaching. Few people, regardless of where they sit on the ideological spectrum, like it when legislation is created that dramatically affects them. As water users in this region we are no exception. But it is undeniable that SGMA was written for just this circumstance. It forces us to build local solutions and partnerships to achieve and maintain sustainable groundwater conditions for the future, particularly during droughts. In an era of water uncertainty, it is an uncomfortable reality that being forced to be more resilient to drought may not be what we wanted; but it is what we need.

Think about why we live in this region. Why our relatives settled here and put down roots. Why we stayed or came, raising families, building homes, businesses and futures. Whether it is the productivity of the soils, the charm of our communities, the beauty of our natural resources, we hope to pass these attributes on to the next generations. Then think about this region without a resilient water supply.

We need to think about “sustainability” not as a title forced on us from people in Sacramento but instead, as a way of life that protects what we hold dear. Like it or not, SGMA helps or will help us do what we have not been able to do on our own across the State. It created new, regulating groundwater agencies, vested with powerful authorities to guarantee that groundwater is protected. It gives us the ability to manage these resources locally and to bring a diverse collection of affected parties together to make this happen. In our case, SGMA led us to create the Glenn Groundwater Authority (GGA) and Colusa Groundwater Authority (CGA). Multi-organization, multi-person public agencies represented by your neighbors, colleagues and friends. We shop in the same stores, send our kids to the same schools, and love the same communities and natural resources that you do. And we are dedicated to building the necessary solutions that in time, can help protect us from drought.

We have a robust surface water supply in the Sacramento Valley. One that has historically supported water needs and the groundwater beneath us. But we know all too well that some of these sources are being challenged and have proved legally uncertain and beyond our control to protect. Within the groundwater aquifers lies a safety net. That safety net however, is only as good as the tools we create to support it. In the case of SGMA, this comes in the form of the aforementioned Groundwater Sustainability Plan that the GGA and CGA are jointly preparing. The Plan defines our current

groundwater situation, and describes what we will do in the future to better understand and protect these resources. The Plan describes the conditions we are obligated to address. Important factors like preserving and enhancing groundwater levels, minimizing potentially damaging subsidence, avoiding adverse water quality impacts and protecting natural resources that depend on the connection between groundwater and surface water. Once the Plan is adopted and submitted to the State, the GSAs will then have the authority to implement the actions in the Plan.

By State law, we are nearing the end of the period to prepare the Plan. In the coming weeks and months, the CGA and GGA will host and encourage you to attend, public meetings to discuss the draft Plan and provide written comments to us. The CGA and GGA will consider comments received and then finalize and adopt the Plan by January 2022. The projects and management actions described in the Plan won't be easy to achieve. They may require new investments, an unfailing commitment to collaboration, uncomfortable options we haven't wanted to discuss in the past, and potential sacrifice in the future. They will reflect a continued commitment to work collaboratively for the common good of our region, rather than as individual water users and organizations competing for limited resources. The Plan will not be ready in time to help us through the current drought. We won't even be able to begin to implement aspects of the Plan until February 2022 at the earliest. But we will learn from the current and recent water crises and that will inform our Plan and actions. Over time, SGMA will live up to its promise, warts and all, to support resilience as best we can locally and to ensure that we work together to achieve successful outcomes.

In closing, on July 28 and 29 from 6 – 8 p.m, the CGA and GGA will hold the next round of public meetings in our "SGMA-Series".

The meeting on the 28th will be held virtually. See the following websites for more information:

- https://colusagroundwater.org
- https://www.countyofglenn.net/dept/planning-community-development-services/water-resources/glenn-groundwater-authority/gga

The meeting on the 29th will be held at:

- Sites Project Authority Office - 122 Old Highway 99W, Maxwell, CA 95955.

These meetings will focus on the sustainability conditions we have been studying for the Plan, and the potential projects and management actions that we refer to above. We encourage you to attend these meetings and to visit our websites and related social media to learn more about SGMA and the GGA and CGA. We need you to participate in upcoming meetings, to embrace the need for these collaborative changes and to work with us to forge a new resilient groundwater future in the Sacramento Valley.

On behalf of the Colusa Groundwater Authority Board and Glenn Groundwater Authority Board

Signed,

Ms. Denise Carter
Chair
Colusa Groundwater Authority

Mr. John Amaro
Chair

once the purchase closes and the repairs are completed, Tyler said. ■

Groundwater Sustainability Plan meetings scheduled

PIONEER REVIEW
news@colusacountynews.com

The Colusa Groundwater Authority and Glenn Groundwater Authority will host two meetings this month to discuss the recently-released Draft Groundwater Sustainability Plan for the Colusa Subbasin.

The content of the two meetings will be the same, although one will be held "virtually" and the other, in person, officials said.

The virtual meeting will be held from 1-3:30 PM on Wednesday, Oct. 13, via Zoom. The in-person meeting will be held from 5:30-8 PM at the Sites Project Authority Office, 122 Old Highway 99W, in Maxwell.

Against the backdrop of the last drought, the California Legislature passed the Sustainable Groundwater Management Act, which requires local groundwater agencies to define and implement measures that ensure groundwater is sustainable for the next 20 years, officials said.

Glenn and Colusa authorities have worked together to prepare a single joint plan for the Colusa Subbasin.

CGA Chair Denise Carter said the agency representative will provide an overview of each chapter of the plan at the two meetings, allowing members of the public to ask questions and provide focused input about the sustainability methods that will be used.

"We're at the culmination of a long process and on the cusp of implementing projects that will better monitor and enhance our groundwater," Carter said in a joint press release.

GGA Vice-Chair Gary Hansen said the Colusa Subbasin aquifers provide an essential safety net for water availability, but that safety net is only as good as the tools that can be created to support it.

"Our GSP does that and we need public input to confirm if we've done it the right way," Hansen said.

The draft Groundwater Sustainability Plan and online meeting instructions can be viewed on the CGA's website at colusagroundwater.org. ■

Tri-County News

In one of the final steps to complete a Groundwater Sustainability Plan (GSP) for the Colusa Subbasin, the Colusa Groundwater Authority (CGA) and the Glenn Groundwater Authority (GGA) hosted a virtual public meeting on Wednesday to review the plan and gather community input.

The GSP is a roadmap for how groundwater will be managed over the next two decades, according to meeting facilitator Dave Ceppos, and is being prepared by the CGA and GGA in response

ng Scenario at Richfield lementary School (when tudents are not in atten-ance) during which all irst responders in the ounty attend.

"It is a sad fact that such training has to take place," Fears said. "But in today's atmosphere, it is essential to protecting our children."

municipal, tribal, agricultural, industrial and environmental uses," said Ceppos.

According to Ceppos, avoiding adverse impacts is based on the evaluation of six sustainability indicators, including surface water depletion, reduction of storage, regraded quality, land subsidence and lowering groundwater levels. The final indicator, seawater intrusion, was determined to not be applicable in the Colusa Subbasin.

The development of the Colusa Subbasin GSP, like many others throughout California, has coincided with one of the most severe and extensive droughts that has ever gripped the western United States, with drought conditions throughout most of California, including the area in and around the Colusa Subbasin, classified as "exceptional" – the most extreme classification, according to the U.S. Drought Monitor.

During the meeting John Amaro, chairperson of the GGA, said at this point in time it is likely too late to make any major and immediate changes to the way aquifers are managed within the Colusa Subbasin and the entire Sacramento Valley region to mitigate the effects of the current drought.

"We will have to work collaboratively together through this current water emergency and then prepare for the next drought with the lessons we learned and the tools we've built as a result of our new, almost completed, groundwater sustainability plan," said Amaro.

According to the draft, technical work and related public involvement processes supporting development of the Colusa Subbasin GSP began in earnest in May 2020 and is now nearing completion.

"Development of the GSP has utilized the best available science and tools, with the most sufficient and credible information and data available for the decisions being made and the time frame available for making those decisions," read the draft. "Current and historical groundwater conditions and water budgets have been evaluated for the subbasin in alignment with the GSP regulations. The technical work is based primarily on historical records of surface water and groundwater conditions from 1966 through 2015, which includes the prior 2014-2015 drought, but not the current 2020- 2021 drought."

The Colusa Subbasin has been designated by the Department of Water Resources as a high priority subbasin, which means Colusa Subbasin GSAs must develop, adopt, and submit a GSP covering the entire subbasin to DWR by January 31, 2022.

Another public meeting to discuss the Public Draft Colusa Subbasin Groundwater Sustainability Plan will be held in person today (Friday) at the Sites Project Authority office, 122 Old Highway 99W, Maxwell, from 5:30-8 p.m.

"Your participation today andover the past few years has been incredibly important to guide our approach as we prepare the GSP in a way that reflects your needs, " said Amaro. "Of many things we are proud of, one and most particular is the unprecedented opportunities we have had for you to participate in this process."

According to Amaro, the GCA and the GGA have collectively sponsored, publicized and conducted 236 separate meetings in various formats since Jan. 2016 to give the community the opportunity to learn about this "challenging law and the steps to comply with it."

The Draft GSP is available for public review and comment through Oct. 31.

Those located in the Glenn Groundwater Authority can get more information by contacting Lisa Hunter, program manager for the Glenn Groundwa-

Colusa Subbasin
Final Stakeholder Communication and Engagement Plan

Version: August 2019

Purpose

The purpose of this Stakeholder Communication and Engagement Plan is to assist Colusa Subbasin Groundwater Sustainability Agencies (GSAs) (respectively the Colusa Groundwater Authority [CGA] and the Glenn Groundwater Authority [GGA]) in their efforts to develop general and strategic communications to engage stakeholders in groundwater management activities.

Overview and Background

California's Sustainable Groundwater Management Act (SGMA) of 2014 requires broad and diverse stakeholder involvement in GSA activities, and the development and implementation of Groundwater Sustainability Plans (GSPs) for groundwater basins around the state, including the Colusa Subbasin. The intent of SGMA is to ensure successful, sustainable management of groundwater resources at the local level. Success will require cooperation by all stakeholders, and cooperation is far more likely if stakeholders have consistent messaging of valid information and are provided with opportunities to help shape the path forward. Further, to ensure trust and cooperation from stakeholders, all activities of the GSA's should be conducted in as transparent a manner as possible. The California Department of Water Resources (DWR) has designated the Colusa Subbasin as a high priority basin (2019), and subject to SGMA.

To that end, the intention of the Plan is to:

- Provide the GSAs, community leaders, and other beneficial users a roadmap to follow to ensure consistent messaging of SGMA requirements and related Colusa Subbasin information and data.
- Provide a roadmap for the GSAs and community leaders to ensure stakeholders have meaningful input into GSA decision-making, including GSP development.
- Ensure the roadmap demonstrates a process that is widely seen by stakeholders as fair, transparent and respectful to the range of interested parties.
- Provide a transparent and easily-accessible process for stakeholders to contribute to the development of a GSP that can effectively address groundwater management within the Colusa Subbasin.
- Ensure that information reaches all beneficial users who have an interest in the Subbasin.

Communication Plan Goals

The Plan supports the following goals:

1. Educate stakeholders about:

A. SGMA and its requirements,

B. The CGA and GGA,

C. Groundwater resources in the Colusa Subbasin and the benefits of sustainable groundwater management

D. Potential changes to current groundwater management under SGMA

E. How stakeholders will be represented in their GSAs, and

F. How stakeholders can participate in SGMA planning and decision-making efforts.

2. Communicate important SGMA deadlines and dates.
3. Coordinate outreach and engagement activities between the GSAs to ensure efficiency and to support stakeholders in GSP development.
4. Support individual GSA outreach and engagement activities.
5. Articulate strategies and channels for obtaining ongoing stakeholder input and feedback to inform GSP design and development.
6. Provide a roadmap to the GSAs on ways to effectively and efficiently reach all beneficial users.
7. Encourage stakeholder engagement (e.g., by establishing dedicated SGMA outreach strategies and channels, communicating information about meeting and workshop dates and content, and highlighting all opportunities for stakeholders to provide input in the GSA decision-making process and GSP planning process).

Major Audiences

A Colusa Subbasin stakeholder is a "beneficial user" as described by SGMA. Under the requirements of SGMA, all beneficial uses and users of groundwater must be considered in the development of GSPs, and GSAs must encourage the active involvement of diverse social, cultural, and economic elements of the population. Beneficial users, therefore, are any stakeholders who have an interest in groundwater use and management in the Colusa Subbasin. Their interest may be related to GSA activities, GSP development and implementation, and/or water access and management in general.

To assist in determining who the specific SGMA stakeholders and beneficial users are, DWR has created a Stakeholder Engagement Chart for GSP development in their 2017 *GSP Stakeholder Communication and Engagement Guidance Document*. The following table (Table 1) is based on the DWR chart, modified to fit the circumstances and stakeholders of the Colusa Subbasin. It will continue to be updated during the GSP planning process.

Table 1. Stakeholder Engagement Chart for GSP Development

Category of Interest	Examples of Stakeholder Groups	Engagement Purpose
General Public	• Citizens groups • Community leaders • Interested individuals • Universities/Academia	Inform to improve public awareness of sustainable groundwater management
Land Use	• Municipalities • Local land use agencies • Regional land use agencies • Community Service Districts	Consult and involve to ensure land use policies are supporting GSPs and there are no conflicting policies between the GSAs / GSP and said local government agencies
Private Users	• Private pumpers (domestic and agricultural) • Schools and colleges • Hospitals	Inform and involve in assessing impacts to groundwater users
Urban/ Agricultural Users	• Water agencies • Irrigation districts • Municipal water companies • Mutual water companies • Resource conservation districts • Farmers/Farm Bureaus • Water Districts • Water users associations • Irrigated Lands Regulatory Program Coalition	Collaborate to ensure sustainable management of groundwater
Industrial Users	• Commercial and industrial self-suppliers • Local trade associations or groups	Inform and involve in assessing impacts to users
Environmental and Ecosystem Uses	• Federal and State agencies • Wetland managers • Environmental groups	Inform and involve to consider/incorporate potential ecosystem impacts to GSP process
Surface Water Users	• Irrigation Districts • Water Districts • Water users associations • Agricultural users	Inform and involve to collaborate to ensure sustainable water supplies
Economic Development	• Chambers of commerce • Business groups/associations • Elected officials • State Assembly members • State Senators • Economic Development Team	Inform and involve to support a stable economy
Human Right to Water	• Disadvantaged communities • Small water systems • Environmental justice groups/community-based organizations	Inform and involve to provide safe and secure groundwater supplies to all communities reliant on groundwater

Category of Interest	Examples of Stakeholder Groups	Engagement Purpose
	• De minimis well owners	
Tribes	• Federally Recognized Tribes • Non-Federally Recognized Tribes	Inform, involve and consult with tribal government
Federal Lands	• U.S. Fish and Wildlife Service • U.S. Bureau of Reclamation • U.S. Army Corps of Engineers	Inform, involve and collaborate to ensure basin sustainability
Integrated Water Management	• Regional water management groups (IRWM regions) • Flood agencies	Inform, involve and collaborate to improve regional sustainability

Key Messages

Beneficial users have been engaged in Subbasin-scale SGMA activities since shortly after enactment of the Act through the convening of governance work groups in each county to define governance in the Subbasin and establish GSAs. Each work group publicized all meetings and held initial SGMA information public meetings. As the GSAs expand the process of reaching out to stakeholders to inform and engage them in GSP development, and to conduct general communication about groundwater management issues and items, it is critical that GSAs share clear and consistent key messages to avoid confusion and misunderstanding. Key messages include:

1. The CGA and GGA are the exclusive GSAs in the Colusa Subbasin
2. Management responsibilities of the CGA and GGA include GSP preparation and approval, funding, SGMA implementation, and SGMA enforcement.
3. The CGA and GGA have committed to prepare a single GSP for the Colusa Subbasin.
4. The Colusa Subbasin GSP will inform and regulate groundwater usage. It will account for groundwater use and impacts on diverse groups of beneficial users, including, disadvantaged communities, agricultural users, residential users, municipal users, Tribes, and environmental water uses.
5. The CGA and GGA will proactively and sustainably managing groundwater in the Colusa Subbasin, and shall ensure compliance with SGMA to prevent State intervention.
6. The CGA and GGA will coordinate efforts with surrounding GSAs and subbasins in managing their respective portions of the Subbasin to achieve compliance with SGMA.
7. The CGA and GGA are committed to proactive and transparent outreach and engagement with all beneficial users during the GSP preparation process, and future SGMA implementation.
8. All beneficial users have an equal opportunity, either directly or through appropriate representation on the governing boards of the GSAs, to participate in GSP development and SGMA implementation.
9. Extensive outreach is a priority of both GSAs, to inform beneficial users about

implementation and potential effects of SGMA, and to ensure beneficial users are involved in the process.

10. Sustainable groundwater conditions in the Colusa Subbasin are critical to support, preserve, and enhance the economic viability, social well-being and culture of all beneficial uses and users, including tribal, domestic, municipal, agricultural, and industrial users.
11. Implementation and enforcement of the GSP should take place at the most local level possible and should allow each GSA member maximum input to any GSP chapter or section applicable to the Member and the beneficial uses and users that exist or will exist in a Member's service area or jurisdiction, and should reflect the Member's authority and desire to manage the water resources available to its constituents or customers, provided such management is consistent with sustainability requirements of SGMA and the GSP.
12. The Members agree that the GSP should encourage board members of each GSA to act on behalf of and represent all beneficial users within their service areas to ensure collective compliance with the Act.

Decision-Making

The CGA and GGA operate under respective Joint Powers Agreements (JPA). The JPAs can be found respectively at the following weblinks:

- https://colusagroundwater.org/mdocs-posts/cga-joint-powers-agreement-v1/
- https://www.countyofglenn.net/dept/agriculture/water-resources/glenn-groundwater-authority

Regarding decision-making, each GSA has identified in their respective JPA, the following text regarding decision-making:

> *"Except as to actions identified in Section 4.7, the Board of Directors will conduct all business by vote of a majority of the Directors present, if a quorum shall be established, and each Director shall have one (1) vote. Prior to voting, Board members shall endeavor in good faith to reach consensus on the matters to be determined such that any subsequent vote shall be to confirm the consensus of the Board. If any Board member or Member strongly objects to a consensus-based decision prior to a vote being cast, the Board shall work in good faith to reasonably resolve such strong objection, and, if the same is not resolved collaboratively, then the matter will proceed to a vote for final resolution under this Article 4.6 or Article 4.7 below, as applicable."*

Furthermore, each GSA JPA includes an attached Memorandum of Agreement (MOA) that represents negotiated guiding principles adopted by the respective GSA members during the development of their respective governance. These MOAs include the following stated principle regarding decision-making and engagement with beneficial users.

> *"A partnered approach should be fostered for sustainable groundwater management in the Colusa Subbasin that, among other things, supports the Act;*

achieves sustainable conditions in the Subbasin; reflects mutual respect for each Party's discretion, governmental authority, expertise, knowledge of groundwater conditions, rights, needs and concerns; and ensures appropriate representation of all Beneficial Uses and Users."

Regarding advisory and coordinating committees, the CGA and GGA have each created a Technical Advisory Committee that meets periodically and is expected to have a significant role during the GSP development period as a venue for key technical discussions and subsequent recommendations to technical consultants, and to the respective GSA Boards. The CGA TAC and the GGA TAC generally meet jointly to facilitate basin-wide technical discussions and recommendations. These meetings are open to the public.

Each GSA has also formed other committees such as Executive Committees, Long-Term Funding Committees, and Public Engagement Committees. Some committees, such as standing committees are Brown Act compliant while ad hoc committees are generally formed for a limited time and purpose and do not require Brown Act compliance, although open meetings are commonly encouraged.

Recommended Communication Strategies and Mechanisms

This Plan is designed to meet the needs of the Subbasin as a whole. To maximize efficiency and support consistent messaging, it is appropriate that some outreach activities be conducted on a basin-wide level. However, it is also important to recognize that under SGMA each GSA has its own responsibility for engagement of the beneficial users within its boundaries, and individual GSA representatives and staff will need to engage with their own stakeholders and will be responsible for tracking the needs of their local communities. GSAs will consider stakeholder input gathered from outreach efforts as they move through GSP development and implementation processes. Three sets of strategies are important to consider when planning outreach and engagement activities, included in the following categories:

1. SGMA-required activities: The law requires GSAs to undertake specific types of outreach and engagement activities.
2. Essential strategies centrally communicated at the Subbasin and GSA service area level: Activities proven to successfully engage stakeholders.
3. Secondary strategies locally communicated at the GSA service area and beneficial user level: Activities that will enhance engagement efforts on a local and as-needed basis. These strategies are recommended for engaging specific stakeholder groups.

SGMA-Required Strategies

SGMA strongly encourages broad stakeholder engagement in development and implementation of GSPs. According to SGMA:

- *"The groundwater sustainability agency shall encourage the active involvement of diverse social, cultural, and economic elements of the population within the groundwater basin prior to and during the development and implementation of the groundwater sustainability plan."* [CA Water Code Sec. 10727.8(a)]

- "*The groundwater sustainability agency shall consider the interests of all beneficial uses and users of groundwater."* [CA Water Code Sec. 10723.2]

GSAs are given broad discretion in the methods and processes utilized to meet engagement requirements. DWR has provided recommended phasing of engagement activities from the start of SGMA governance through long-term SGMA implementation however these recommendations are not prescriptive and are subject to GSA-specific discretion as to the timing and sequence of activities. (See Appendix 3 for graphical descriptions of generalized, sequential engagement strategies, phases and statutory and regulatory citations)

Centralized Outreach and Engagement Strategies

In the interest of collaboration as well as efficiency, the two GSAs in the Subbasin are conducting and will continue to conduct various joint outreach and engagement activities (as also stated above), including:

- Joint public outreach and education meetings and workshops
- Joint CGA/GGA Board meetings and workshops
- Joint CGA/GGA Executive Committee meetings
- Joint CGA/GGA Technical Advisory Committee meetings
- Potentially other joint CGA/GGA committees as developed
- Development of outreach materials

Localized Outreach and Engagement Strategies

1. Develop and Maintain Lists of Interested Parties

A list of stakeholders and beneficial users (interested parties) has been developed by each GSA and will be updated throughout the GSP planning, implementation and enforcement processes. Each GSA will maintain its own list.

Timely notification of opportunities for interested parties to participate in the development and implementation of the GSP will be given via the channels and strategies described in detail throughout this document.

Additional options for engagement will be considered during specific engagement opportunities and include: (and in some cases are described further below)

- GSA Websites
- Flyers
- Direct mailers
- Newsletters
- Fact Sheets
- Print Media (Newspaper notifications and SGMA articles)
- Social Media

- Surveys
- Articles in agency newsletters/websites (e.g. Farm Bureau, RCDs, Farm Service Agency, Cooperative Extension, etc.)
- Notifications on GSA Member Agency websites/newsletters
- Engagement Partner events (e.g. community workshops, community meetings, etc.)
- Educational tours/field trips

To assist in determining the topics, types, and sequencing of outreach vis-à-vis specific stakeholder interests, DWR has recommended conducting a "Lay of the Land" exercise. In the Colusa Subbasin, although many of the major interests are represented on the GSA boards or advisory committees, there are still some interests (e.g., de minimis- users, small agriculturally-allied businesses) that need to be engaged. Table 2, below, presents this "lay of the land" analysis as recommended by DWR.

Table 2. SGMA GSA/GSP Stakeholder Constituency "Lay of the Land" Exercise

Organization or Individual	Type of Stakeholder	Key Interests	Key Issues	Expected GSP Sections of Interest	Rationale
Small urban/domestic (non-agricultural) water users	Domestic well users/Municipal well operators	Access to safe and affordable drinking water	Encourage active participation in the process	• Basin Setting • Projects and Management Actions (PMA)	Not represented directly on GSA board
De minimis users	Private well users	Access to safe and affordable drinking water	Encourage active participation in the process Financial impacts from SGMA implementation	• Basin Setting • Sustainable Management Criteria (SMC) • Monitoring Networks • PMA	Not represented directly on GSA board
Agricultural workers	Disadvantaged communities	Water availability, quality, fees, fallowing	Difficult to reach. Transient and housing insecure population	• Basin Setting • SMC • Monitoring Networks • PMA	Extensive and potentially underrepresented community of beneficial users
Businesses	Private users	Water availability, quality, fees	Economic and financial impacts from SGMA implementation	• Basin Setting • PMA	Not commonly associated or active with water policy issues
Ag-allied users (e.g. tractor	Private users	Access to safe and affordable drinking	Economic and financial impacts	• Basin Setting • PMA	Direct economic benefits and impacts

Organization or Individual	Type of Stakeholder	Key Interests	Key Issues	Expected GSP Sections of Interest	Rationale
leasing and maintenance)		water	from SGMA implementation		associated with water availability
Tribes	California Native American Tribes	Equitable use and availability of groundwater resources. Avoidance of negative redirected effects from groundwater extraction	Respect of cultural backgrounds, norms and needs	• Basin Setting • SMC • Monitoring Networks • PMA	Underrepresented community of beneficial users.
Environmental interests	Environmental users of groundwater	Water availability for environmental purposes	Ecological health of tributaries and groundwater dependent ecosystems. Equitable and balanced use of groundwater	• Basin Setting • SMC • Monitoring Networks • PMA	
Small surface water diverters (including private wetlands	Agricultural users, and environmental users of	Water availability, quality, fees, fallowing	Water resource availability Financial impacts from SGMA	• Basin Setting • SMC • Monitoring Networks	Direct economic benefits and impacts associated with water availability

Organization or Individual	Type of Stakeholder	Key Interests	Key Issues	Expected GSP Sections of Interest	Rationale
managers)	groundwater		implementation	• PMA	
Surface Water Suppliers and Diverters	Agricultural water suppliers and irrigators	Opportunities for conjunctive use and groundwater recharge projects,	Protecting surface water rights. Acknowledgement for additional groundwater recharge created from agricultural irrigation and MAR projects	• Basin Setting • SMC • Monitoring Networks PMA	GW and Surface water are connected
Sites Reservoir JPA	Surface water users	Opportunities for conjunctive uses	Conjunctive use	• Basin Setting • SMC • Monitoring Networks • PMA	New and potentially influential agency of local and statewide interests

2. Provide Regular Public Notices and Updates; Ensure Brown Act Compliance

The GSAs will provide public notices about their open meetings to ensure all stakeholders are informed and all Brown Act noticing requirements are fulfilled. The GSAs will also coordinate consistent messaging and outreach regarding basin-wide SGMA information and updates as they relate to the Colusa Subbasin.

A. Topics to be noticed include and are not limited to:
    i. GSP development and planning updates
    ii. GSP implementation and enforcement updates
        - GSP work plan and timeline
        - Funding/financing plans
    iii. General GSA updates, including:
        - GSA Board meetings
        - Executive Committee meetings
        - Technical Advisory Committee meetings
        - Public outreach and education meetings and workshops
        - GSA annual reports
        - Other SGMA related updates

B. Schedule notices to be sent on a regular schedule, for example bi-monthly, monthly, or as needed
    i. Meetings subject to the Brown Act, such as GSA Board meetings, must provide public notice and agendas must be posted 72 hours in advance of each regularly scheduled meeting (special meetings require 24-hour advance notice)

C. Develop content appropriate to audiences and their interests, ensuring information is articulated in a way that is easily understood
    i. Communication to beneficial users with less SGMA or technical experience should be easily understood, with streamlined, relatable, and repetitive information
    ii. Updates and messages should be condensed to one page when possible, providing a succinct summary of the issues discussed, and including links for further or additional information
    iii. As applicable, specific items should have an estimated timeline and a designated point of contact, including the person's position, email and telephone number
    iv. Updates and information should be provided in both English and Spanish if possible

D. Designate responsible staff and appropriate resources for ongoing inter-agency coordination regarding joint messaging, consistent outreach, and communication with stakeholders

E. Determine appropriate dissemination channels by considering the following:
    i. Utilize Constant Contact or a similar email marketing platform for management of interested party stakeholder lists or utilize GSA interested parties lists for email communications

ii. Utilize member agency listservs delivered via standard email and/or U.S. Mail, e.g., inclusion in water bills, tax assessor documents, etc.

iii. Utilize updated interested party stakeholder list for the Colusa Subbasin, including organizations and agencies such as Farm Bureaus, RCDs, DAC groups, Tribes, schools, hospitals, utilities, mutual water companies, neighborhood groups, and local non-profits

3. Provide Notices and Updates in Local Newspapers and Periodicals

Notices can take the form of public notices, op-ed articles, letters to the editor, advertisements or earned media.

A. Send information and/or media releases to regional and local media outlets and contacts

i. Print Media
ii. Organization and community newsletters and periodicals
iii. Identify trusted bi-lingual and/or Spanish speaking media outlets

B. Provide follow-up or wrap-up articles written by staff when appropriate

C. Include notices for appropriate public meetings (as described throughout this Plan):

4. Create and Manage Social Media Content

Social media is not considered to be a primary mode for beneficial users to get information in the Subbasin (when compared to other more traditional means). However, recognizing changing trends in information access and exchange, the GSAs will consider expanding their outreach to include some of the more common social media platforms as long as said engagement proves beneficial (in terms of verifiable uses) and does not create an undo impact on staff time and GSA resources.

5. Institute Regular Stakeholder Outreach and Engagement Opportunities

It is critical that stakeholders and beneficial users are provided regular opportunities for their input to be incorporated into GSA decision-making processes, and that they understand exactly how they are able to contribute to the GSP planning and implementation processes.

Stakeholder engagement opportunities include but are not limited to:

A. Standing Operations Meetings

i. GSA Board meetings
ii. Advisory Committee meetings

B. Public Workshops and Stakeholder meetings

The following should be considered when planning workshops and stakeholder meetings:

i. Schedule workshops in evenings, or times that work well for the target audience, and/or near easily-accessible community areas as feasible and avoid busy seasons (i.e. planting and harvest)

ii. Provide translation and facilitation services in English and Spanish (when feasible)

iii. Public workshop (or similar) content includes but is not limited to:

a) Updates on GSA coordination activities
b) SGMA information
c) Updates on GSP development and planning activities
d) Opportunities for interested parties to participate in the development and implementation of the GSP (e.g. technical workshops on specific GSP components)
e) Notice of GSA intent to adopt or amend a GSP
f) Updates on groundwater management activities in the Subbasin, including projects
g) Notice to impose fees
h) Updates on SGMA activities in surrounding basins
i) Information on legislative activities related to SGMA, and groundwater and surface water management

6. Develop Consistent, Coordinated Messages and Talking Points

Define the key messages needed to effectively convey SGMA-related information to various audiences, and ensure consistency in a coordinated and meaningful outreach effort to all stakeholders.

A. For each topic being discussed (see work plan), develop a set of talking points that can be used by GSA members when speaking to specific stakeholder groups or audiences. Talking points and messaging may be customized to specific stakeholder groups as appropriate.
B. Develop tools, such as a glossary and a SGMA information piece, that contain easy-to-understand information as well as responses to anticipated questions from stakeholder groups. Consider developing simple brochures, infographics, and short videos.
C. Identify and communicate opportunities for public engagement and/or public comment during meetings on GSP development.
D. Provide clear messaging that GSAs retain legal responsibility for final GSA- and GSP-related decisions.

Additional Outreach and Engagement Strategies

While engagement opportunities can be created by GSAs, there are also opportunities for engagement that already exists in the Subbasin community.

The most effective way to inform and engage many stakeholders and beneficial users regarding SGMA requirements and soliciting feedback is through trusted local agencies and community organizations with standing meetings and established communication channels.

A. Support local agencies and community organizations in disseminating information and engaging stakeholders in the following ways:

i. During standing board and/or community meetings
ii. Through monthly information pieces in newsletters or included in mailings

iii. By disseminating information in both English and Spanish when appropriate

B. Local trusted agencies and community organizations include but are not limited to:
   i. Boards of Supervisors
   ii. City Councils
   iii. Environmental conservation groups
   iv. Farm Bureaus
   v. Growers associations and industry organizations
   vi. Irrigation Districts
   vii. Leaders in DAC communities
   viii. Local hospitals and schools
   ix. Local non-profits
   x. Mutual Water Companies
   xi. RCDs
   xii. Tribal Council meetings
   xiii. Water Districts

C. Leverage local, trusted resources for community meetings, such as fairgrounds, firehouses, schools, churches, and community centers

D. Organize public meetings around concrete impacts to specific stakeholders, including:
   i. SGMA informational workshop(s) to inform stakeholders of important changes in groundwater management and how it will impact them
   ii. Meetings that detail when and how opportunities to provide input to the GSA decision-making and GSP development processes will occur
   iii. Public meetings regarding fee structures to help stakeholders understand how to interpret the impacts on them

E. Make information and meetings accessible to various stakeholder groups
   i. Provide information in easy-to-understand and streamlined terms
   ii. Provide information and facilitation in both English and Spanish, when appropriate and as feasible
   iii. Hold meetings during hours that do not conflict with regular work schedules (i.e., nights and weekends), or during prime planting and harvesting seasons

Recommended Milestones for Engaging Stakeholders

To employ the Stakeholder Communication and Engagement Plan effectively, Colusa Subbasin GSAs will need to develop a schedule for outreach and engagement activities. The below table (Table 3) identifies milestones required by SGMA, as well as centralized and localized engagement strategies that will be considered during each timeframe. This schedule, or similar, is expected to be updated into a task-oriented work plan and timeline as communication and engagement tasks are allocated and a more specific workplan for GSP development is prepared.

Table 3. Summary of Engagement Opportunities and Milestones

Timeframe	Milestone or Stage	Required Community Engagement Under SGMA	Centralized & Localized Communication Strategies
Shortly after GSA formation	After identification of outreach responsibilities among GSA member agencies	Notification of GSA formation	• Provide notice of GSA outreach resources: website, email listserv, calendar of GSA Board and subcommittee meetings • Develop and continue to update list of interested parties
Before GSP Planning Activities	Prior to beginning GSP development	Provide to the public and State, notice of intent to begin GSP planning and description of opportunities for interested parties to participate in GSP development and implementation	• Public workshop (s) • GSA Board meetings • Email notices and updates • Newspaper notice of public workshop(s)
Between Notice of GSP Planning and January 31, 2022	During GSP development	Public workshops, public meetings, TAC meetings, GSA Board meetings and other opportunities providing stakeholder avenues to participate in GSP development	*Centralized:* • Public workshops and/or public meetings on GSP development. • Email notice of public workshops / meetings • Newspaper notices of public workshops / meetings *Localized:* • Updates and information on GSP development at standing meetings • Disseminate updates via newsletter, websites and social media
	During GSP development	Active involvement of diverse social, cultural, and economic	*Centralized:* • Provide monthly email notices and updates

Timeframe	Milestone or Stage	Required Community Engagement Under SGMA	Centralized & Localized Communication Strategies
		elements of the population within the Subbasin	• Update website regularly • Convene monthly or bimonthly meetings of GSA Coordination Committee and Technical Advisory Committee • Convene quarterly or monthly meetings of GSA Board • Identify and communicate opportunities for public engagement on GSP development, (providing clear messages that GSAs retain legal responsibility for final GSA and GSP related decisions) • Develop consistent, coordinated messages and talking points • Arrange for technical support to stakeholder groups through presentations or workshops conducted by GSA representatives/staff • Develop content appropriate to the audience and their interests, ensuring information can be easily understood • Update area legislative bodies at strategic mileposts (and any other groups upon request) • Utilize updated interested party stakeholder list, member agency listservs delivered via email and/or U.S. Mail, and other media outlets such as newspaper and radio to provide notices • Strategically engage local, special SGMA identified groups *Localized:* • Utilize local channels and meetings to identify and

Timeframe	Milestone or Stage	Required Community Engagement Under SGMA	Centralized & Localized Communication Strategies
			communicate opportunities for public engagement and/or public comment during meetings on GSP development • Leverage and support local agencies and community organizations in disseminating information and engaging stakeholders, including through existing community meetings, newsletters, websites, and social media • Organize public meetings around concrete impacts to specific stakeholders • Develop additional, locally-targeted communication strategies to engage difficult-to-reach communities and community members
GSP adoption no later than January 31, 2022	Prior to GSP adoption or amendment	○ Provide notice to cities and counties within Plan area ○ Consider comments provided by the cities and counties ○ Accommodate requests for consultation received from the cities and counties within 30 days	SEE ABOVE
GSP adoption no later than January 31, 2022	Prior to GSP adoption or amendment	No sooner than 90 days following public notice, hold public hearing/ public workshop	SEE ABOVE

Evaluation and Assessment

Any communication strategy should include opportunities to check in at various points during implementation to ensure that it is meeting the communication and engagement goals and complying with SGMA law. These check-ins can include:

- What worked well
- What didn't work as planned
- Meeting recaps with next steps
- Listing lessons learned and developing mid-course corrections
- (As relevant) Communications budget analysis

Educational Materials

DWR and the State Water Resources Control Board have developed various educational materials about SGMA and GSA/GSP development. In addition to State materials, academic institutions and foundations have published useful reports about SGMA implementation. While not comprehensive, Table 4 lists some essential SGMA educational and reference materials.

Table 4. Educational and Reference Documents for SGMA Implementation

Educational/Reference Document Titles	Publishing Entity	Date/Year of Publication
Groundwater Sustainability Agency Frequently Asked Questions http://www.water.ca.gov/groundwater/sgm/pdfs/DWR_GSA_FAQ_2016-01-07.pdf	DWR	January 7, 2016
Groundwater Sustainability Plan (GSP) Emergency Regulations Guide http://www.water.ca.gov/groundwater/sgm/pdfs/GSP_Final_Regs_Guidebook.pdf	DWR	July 2016
Collaborating for Success: Stakeholder Engagement for Sustainable Groundwater Management Act Implementation http://www.cleanwateraction.org/files/publications/ca/SGMA_Stakeholder_Engagement_White_Paper.pdf	Community Water Center Clean Water Fund Union of Concerned Scientists	July 2015

Educational/Reference Document Titles	Publishing Entity	Date/Year of Publication
The 2014 Sustainable Groundwater Management Act: A Handbook to Understanding and Implementing the Law http://www.watereducation.org/sites/main/files/file-attachments/groundwatermgthandbook_oct2015.pdf	Water Education Foundation	October 2015
SGMA Engagement With Tribal Governments https://www.water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/GD_Tribal_Final_2017-06-28.pdf	DWR	June 2017
California's Sustainable Groundwater Management Act (SGMA): Understanding the Law https://www.cfbf.com/storage/app/media/documents/Issues/SGMA_Brochure.pdf	California Farm Bureau Federation	2018

Appendix 1: Opportunities for Engagement

The following table is a template for the regularly updated schedule of meetings that provide opportunities for engagement. This table (or similar) should be isolated as a standalone portion of the GSAs' respective administrative records for GSP preparation and SGMA implementation to ensure accurate comprehensive memorialization of engagement events.

Table A. Scheduled Meetings and Workshops

Date	Meeting Purpose/Topics	Time & Location	Meeting Type

Appendix 2: Tribal Engagement

There are two Tribes in the Colusa Subbasin: The Colusa Indian Community and the Cortina Rancheria. Both Tribes have been engaged and active in SGMA planning and implementation activities from the beginning, and they have been welcomed into the process. The GSAs will continue to engage with these entities throughout GSP development and beyond.

Relevant DWR Information

SGMA Section 10720.3. …any federally recognized Indian Tribe, appreciating the shared interest in assuring the sustainability of groundwater resources, may voluntarily agree to participate in the preparation or administration of a groundwater sustainability plan or groundwater management plan under this part through a joint powers authority or other agreement with local agencies in the basin. A participating Tribe shall be eligible to participate fully in planning, financing, and management under this part, including eligibility for grants and technical assistance, if any exercise of regulatory authority, enforcement, or imposition and collection of fees is pursuant to the Tribe's independent authority and not pursuant to authority granted to a groundwater sustainability agency under this part.
Draft Discussion Paper Tribal Participation with Groundwater Sustainability Agencies http://www.water.ca.gov/groundwater/sgm/pdfs/SGMA_Tribal_GSAs.pdf
Must a local agency exclude federal and tribal lands from its service area when forming a GSA? No, federal lands and tribal lands need not be excluded from a local agency's GSA area if a local agency has jurisdiction in those areas; however, those areas are not subject to SGMA. But, a local agency in its GSA formation notice shall explain how it will consider the interests of the federal government and California Native American tribes when forming a GSA and developing a GSP. DWR strongly recommends that local agencies communicate with federal and tribal representatives prior to deciding to become a GSA. As stated in Water Code §10720.3, the federal government or any federally recognized Indian tribe, appreciating the shared interest in assuring the sustainability of groundwater resources, may voluntarily agree to participate in the preparation or administration of a GSP or groundwater management plan through a JPA or other agreement with local agencies in the basin. Water Code References: §10720.3, §10723.2, §10723.8

Tribal Outreach Resources

The following are links to agency Tribal outreach resources and considerations, each of which captures important principles and resources for Tribal outreach. A short summary of key outreach principles can be found below.

- Draft Discussion Paper Tribal Participation with Groundwater Sustainability Agencies

- CalEPA Tribal Consultation Policy Memo (August 2015)
- DWR Tribal Engagement Policy (May 2016)
- CA Natural Resources Agency Tribal Consultation Policy (November 2012)
- SWRCB Proposed Tribal Beneficial Uses
- Butte County Associate of Governments: Policy For Government-To-Government Consultation With Federally Recognized Native American Tribal Governments *(a model from the transportation sector)*
- CA Court Tribal Outreach and Engagement Strategies
- Traditional Ecological Knowledge resources
- Water Education Foundation Tribal Water Issues

Key Outreach Principles

- Engage early and often
- Consider tribal beneficial uses in decision-making (identified by region here); identify and seek to protect tribal cultural resources
- Share relevant documentation with tribal officials
- Conduct meetings at times convenient for tribal participation with ample notification
- Request relevant process input/data/information from tribes
- Empower tribes to act as tribal cultural resources caretakers
- Designate a tribal liaison(s) where appropriate
- Share resources for tribal involvement as is feasible
- Develop MOUs where relevant
- Be mindful of the traditions and cultural norms of tribes in your area

Appendix 3: DWR Guidance: General Engagement Phases and Requirements

Phase 1: 2015 - 2017

Phase 1 Engagement Requirements

- **Establish and Maintain List of Interested Parties** §10723.4
- **GSA Formation Public Notice** §10723(b)
- **GSA Formation Public Hearing** §10723(b)
- **GSA Formation (due 6/30/17)** §10723(b)
  Notify DWR:
  - Include list of interested parties
  - Explain how parties' interests will be considered
- **Pre-GSP Development** §10727.8
  Provide a written statement describing how interested parties may participate to:
  - DWR
  - Cities within the GSA boundary
  - Counties within the GSA boundary

Relevant DWR Information

Phase 2: 2017 - 2022

Phase 2 Engagement Requirements

- **GSP Initial Notification** §353.6*
  - GSAs are required to submit GSP Initial Notifications through the SGMA Portal - GSP Initial Notification System at http://sgma.water.ca.gov/portal/#gsp
  - Public can comment on the submitted GSP notification
- **GSP Preparation** §10727.8 and §10723.2
  - Encourage active involvement
  - Consider beneficial uses and users of groundwater when describing *Undesirable Results, Minimum Thresholds, and Projects & Actions*
- **GSP Communications Section** §354.10*
  - GSA decision-making process
  - Opportunities for engagement and how public input is used
  - How GSA encourages active involvement
  - Method of informing the public
- **Public Notice of Proposed Adoption** §10728.4
- **GSP Adoption Public Hearing** §10728.4
- **GSP Submittal** §354.10*
  - Include a summary of communications: description of beneficial uses/users, list of public meetings, comments received/responses

Phase 3: 2018

Phase 3 Engagement Requirements

- **60 Day Comment Period** §353.8*
  - Any person may provide comments to DWR regarding a proposed or adopted GSP via the SGMA Portal at http://sgma.water.ca.gov/portal/
  - Comments will be posted to DWR's website

Phase 4: 2022+

Phase 4 Engagement Requirements

- **Public Notices and Meetings** §10730
  - Before amending a GSP
  - Prior to imposing or increasing a fee
- **Encourage Active Involvement** §10727.8

Engagement Requirements Applicable to ALL PHASES

- **Beneficial Uses and Users** §10723.2
  Consider interests of all beneficial uses and users of groundwater
- **Advisory Committee** §10727.8
  GSA may appoint and consult with an advisory committee
- **Public Notices and Meetings** §10730
  - Before electing to be a GSA
  - Before adopting or amending a GSP
  - Prior to imposing or increasing a fee
- **Encourage Active Involvement** §10727.8
  Encourage the active involvement of diverse social, cultural, and economic elements of the population within the groundwater basin
- **Native American Tribes** §10720.3
  - May voluntarily agree to participate
  - See Engagement with Tribal Government Guidance Document
- **Federal Government** §10720.3
  - May voluntarily agree to participate

1. INTRODUCTION

This technical memorandum documents the development and calibration of the C2VSimFG-Colusa model, an integrated hydrologic flow model for the Colusa Subbasin (Subbasin) that is used to support development of the Subbasin Groundwater Sustainability Plan (GSP). The C2VSimFG-Colusa model was adapted from the Fine Grid California Central Valley Groundwater-Surface Water Simulation Model (C2VSimFG).

Specifically, this technical memorandum focuses on model enhancements and calibrations that were made to characterize the historical water budget in the Colusa Subbasin. Other model runs for current and projected water budget scenarios were adapted from the historical C2VSimFG-Colusa model inputs described in this technical memorandum. Those water budget inputs, assumptions, and results are described in the Colusa Subbasin GSP.

The C2VSimFG-Colusa model is based on the C2VSimFG Beta2 model released May 2019, with updates and enhancements to better represent local conditions in the Colusa Subbasin. C2VSimFG-Colusa runs the entire C2VSimFG model; however, data updates and calibration efforts are focused only on the area within and immediately surrounding the Colusa Subbasin. The Subbasin plus a five-mile buffer was chosen as the calibration area for C2VSimFG-Colusa (Figure 1).

The following sections describe specific enhancements to the C2VSimFG Beta2 inputs that were made to better reflect local water supply and water use characteristics; specific calibrations of model inputs to match available streamflow data, groundwater level data, and local water budget results; sensitivity analyses of the C2VSimFG-Colusa model; and a summary of the historical water budget results from the refined and calibrated historical model.

2. REFINEMENTS AND ENHANCEMENTS TO C2VSIMFG BETA2

The C2VSimFG-Colusa model was refined from C2VSimFG Beta2 through enhancements to specific model inputs, assumptions, and parameters related to the surface water and groundwater systems. Davids Engineering and Woodard & Curran refined and calibrated the surface and groundwater system water budgets for the portion of the model domain within and five miles surrounding the Colusa Subbasin.

The C2VSimFG-Colusa model inputs have been updated using the best available data and science, including information from publicly available data sources, past water and groundwater management planning documents, and other local water budgets computed for areas of the Colusa Subbasin. Data and information about specific water agencies was used to quantify water supply and water use within the agency's service area, to the extent permitted by the resolution of the C2VSimFG-Colusa model element grid.

Specific enhancements made to C2VSimFG Beta2 include changes to the simulation period, initial groundwater elevation, groundwater pumping, land use, evapotranspiration, soil properties, irrigation operations and efficiency, urban demand, surface water diversions, streambed elevation, and aquifer parameters. These changes are described in the sections below. Other changes made to calibrate specific root zone, stream, and aquifer characteristics are discussed further in Section 3. Unless otherwise noted, other inputs to the C2VSimFG Beta2 model were generally used directly in the C2VSimFG-Colusa model.

2.1 Historical Simulation Period

C2VSimFG Beta2 operates on a monthly time step and was initialized to simulate the period of October 1973 through September 2015, corresponding to water years (WY) 1974-2015. Time series data is provided in the C2VSimFG Beta2 input files for WY 1921-2015.

The C2VSimFG-Colusa model historical simulation period was updated to begin in October 1985 (WY 1986), simulating WY 1986-2015. The revised historical simulation period was selected based on the availability of local data for the Colusa Subbasin, and to allow sufficient time for the initial model conditions to stabilize prior to the start of the historical water budget analysis period (WY 1990-2015). Selection of the historical water budget period is described in the GSP.

2.2 Initial Groundwater Elevation

Initial groundwater elevations in C2VSimFG-Colusa were updated to reflect the new historical simulation start date in Fall 1985. Groundwater elevations for Fall 1985 for each model node and each layer were first extracted from C2VSimFG-Beta2 and then portions of the Subbasin were updated with elevations developed using the DWR's WDL database. A raster was developed using 202 observations from Fall 1985, supplemented with Fall 1984 and Fall 1986 readings. The difference between this observed data and simulated Layer 1 groundwater levels was calculated. For those areas with differences greater than 25 feet, initial groundwater heads were adjusted to reflect historical data. The groundwater level initial conditions for C2VSimFG-Colusa representing October 1985 are shown in Figure 2.

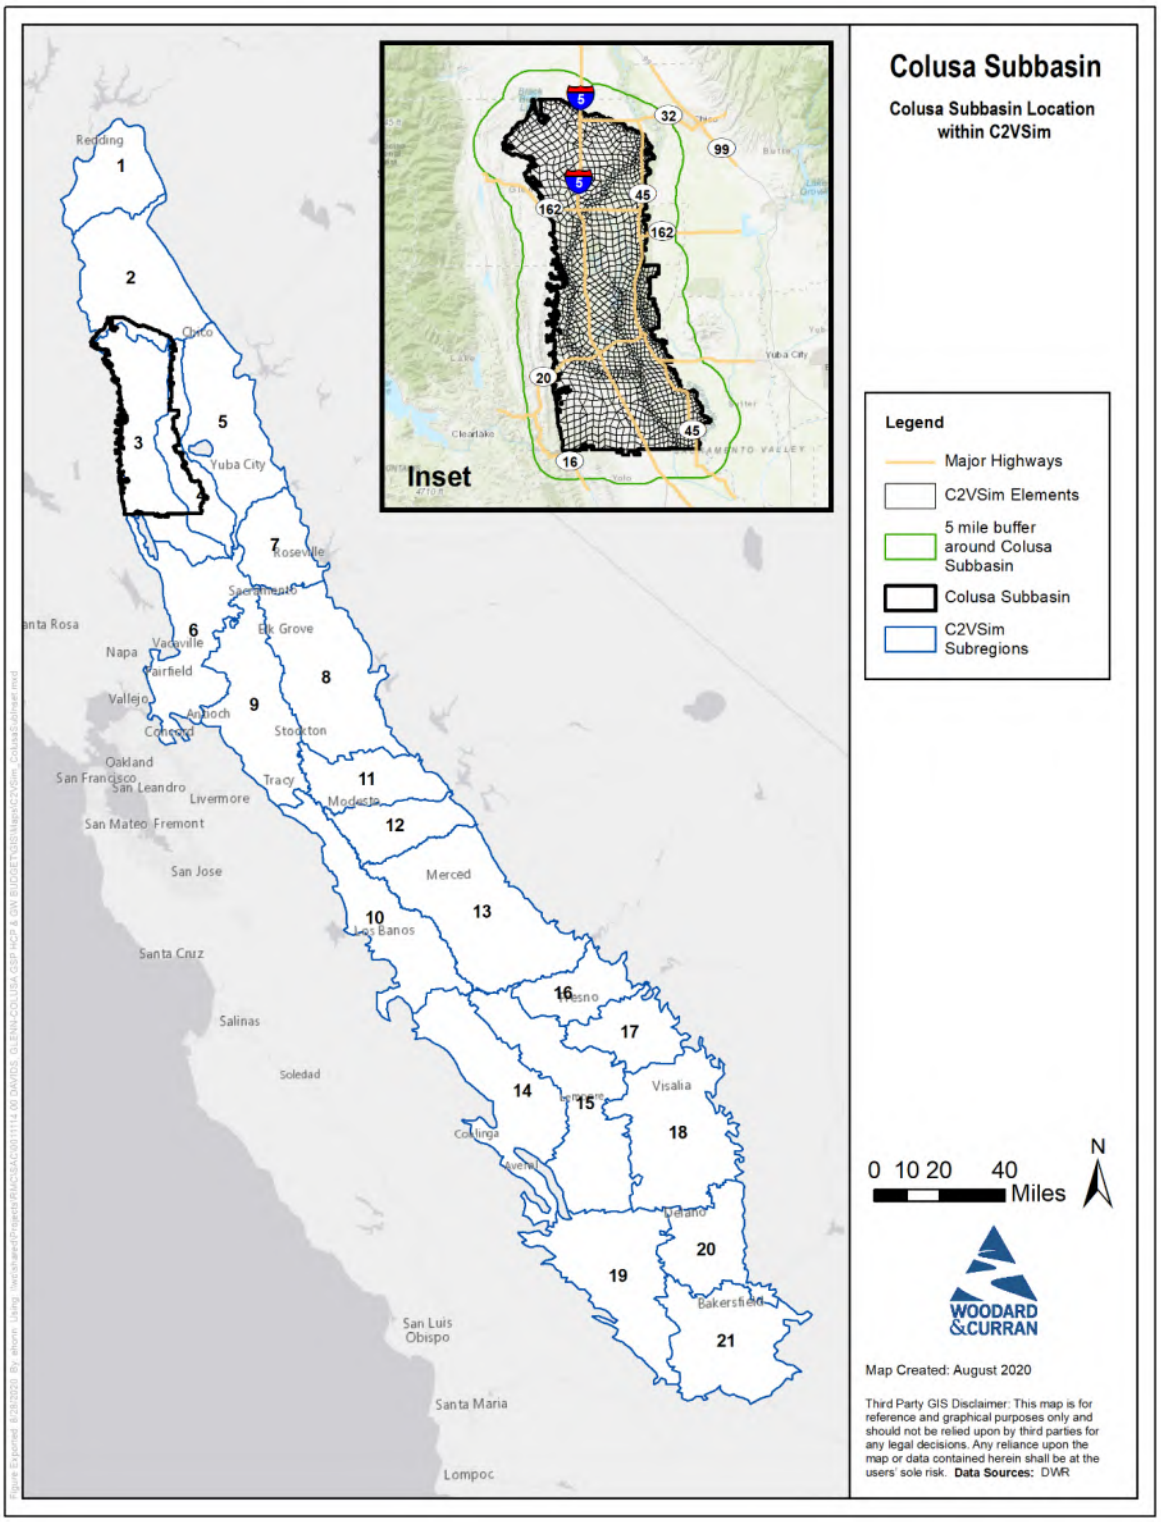

Figure 1: C2VSimFG and Location of Colusa Subbasin

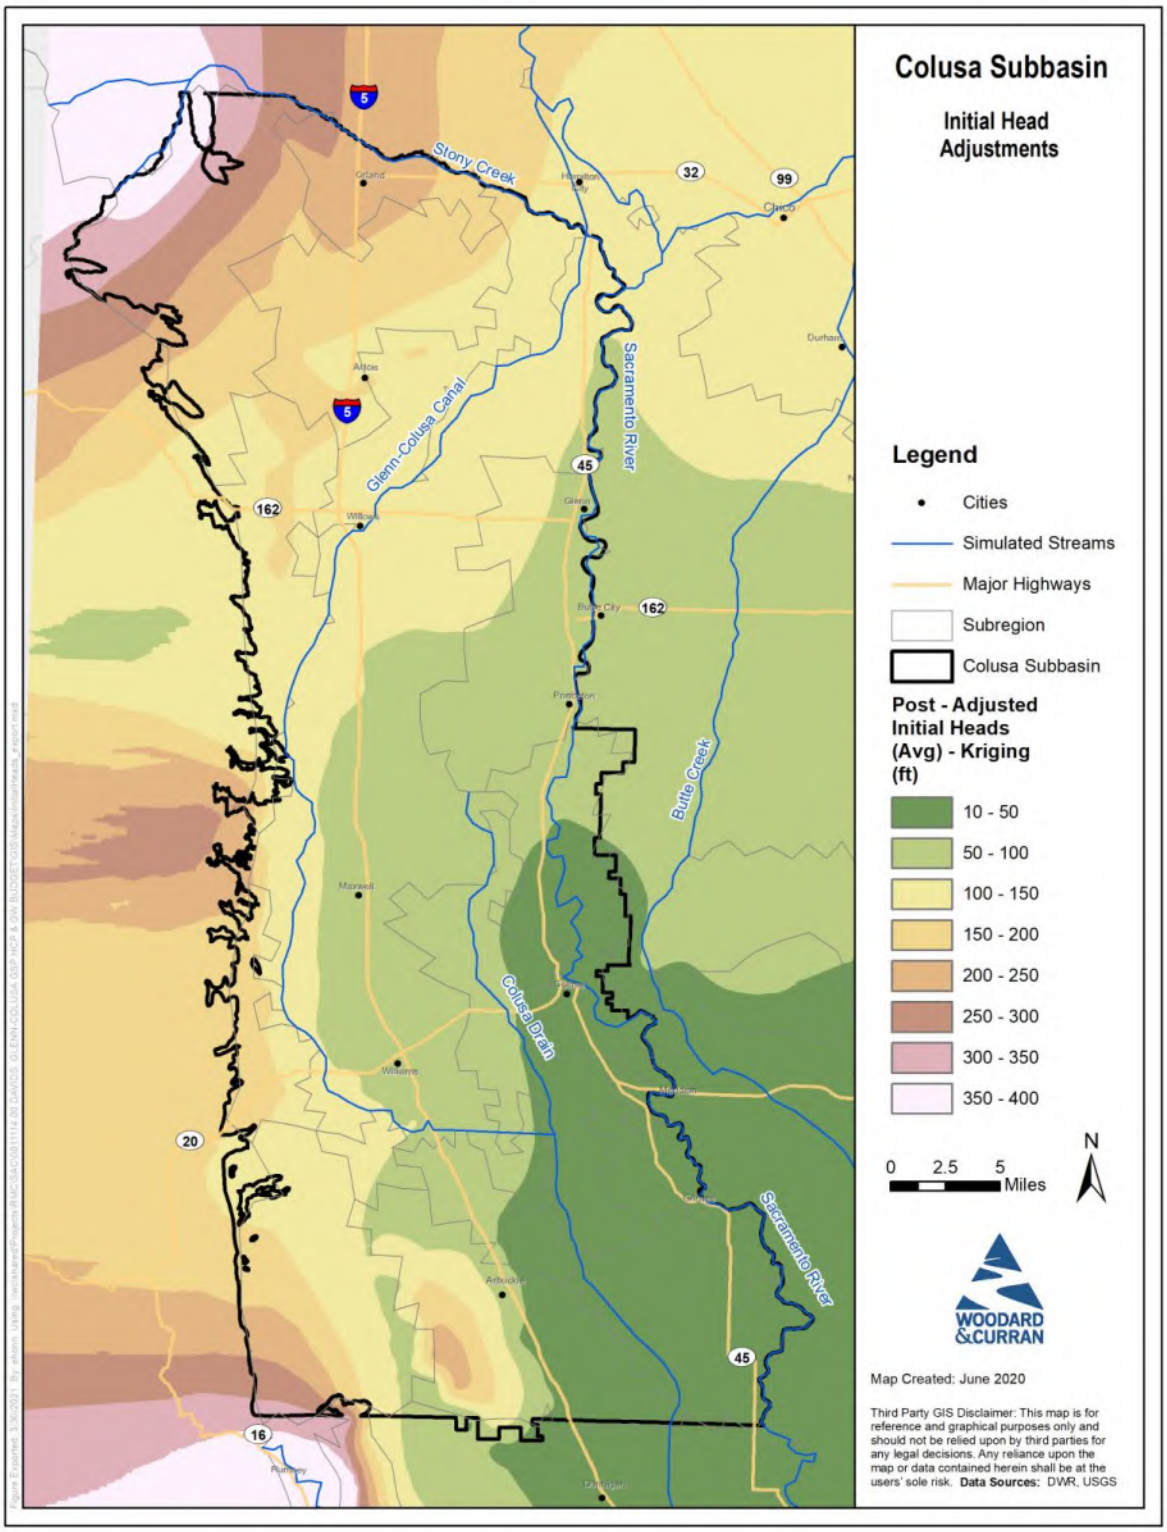

Figure 2: Initial Groundwater Elevation (Average of Layers 1-4)

2.3 Groundwater Pumping

Groundwater pumping in C2VSimFG-Colusa was refined by (1) specifying or refining groundwater pumping volumes in areas where data or other information on pumping was available, and by (2) assigning and refining virtual wells to simulate private groundwater pumping by agricultural and rural domestic well users based on demand in the model. The data sources and methods used to make these refinements are described below.

2.3.1 Specified or Refined Pumping

Groundwater pumping volumes in C2VSimFG-Colusa were specified or refined where possible based on groundwater pumping data reported by local water suppliers and based on other local information related to historical groundwater pumping.

Agricultural groundwater pumping previously enabled in C2VSimFG Beta2 for areas within the Sacramento, Delevan, and Colusa National Wildlife Refuges was turned off in C2VSimFG-Colusa, based on local information indicating that agricultural pumping does not occur within the bounds of these areas.

Urban groundwater pumping was refined for urban demand areas in the Colusa Subbasin based on pumping data reported by specific urban suppliers and public water systems (Table 2-1). Groundwater pumping by public water systems was summarized from Small Supplier Conservation Reports available through the California State Water Resources Control Board (SWRCB). Reports were available for the Cities of Colusa, Orland, and Williams and the Arbuckle and Maxwell Public Utility Districts. Groundwater pumping for use within the City of Willows was summarized from Urban Water Supplier Reports, also available through the SWRCB. . Available groundwater pumping data were combined with population data to refine the model inputs that define per capita water use. As a result, the groundwater pumping calculated by the C2VSimFG-Colusa model was refined to match pumping data in years when these data were available. Additional information about these procedures and urban inputs are described further in Section 2.7.

Table 2-1. Groundwater Pumping Data for Urban Suppliers and Public Water Systems

Supplier Name	Data Source	Reported Years (Partial or Complete)
Arbuckle Public Utility District	SWRCB Small Supplier Conservation Report (ID CA0610001)	2013, 2015, 2016
City Of Colusa	SWRCB Small Supplier Conservation Report (ID CA0610002)	2013, 2015, 2016
City Of Orland	SWRCB Small Supplier Conservation Report (ID CA1110001)	2013, 2015, 2016
City Of Williams	SWRCB Small Supplier Conservation Report (ID CA0610004)	2013, 2015, 2016
Maxwell Public Utility District	SWRCB Small Supplier Conservation Report (ID CA0610003)	2013, 2015, 2016
California Water Service Company Willows	SWRCB Urban Water Supplier Report (ID CA1110003)	2014-2019

2.3.2 Private Groundwater Pumping

Private groundwater pumping quantities on an individual well basis are largely unknown, though aggregate estimates for private pumping are often included in planning documents (e.g., AWMPs, UWMPs, groundwater management plans). Private pumping in C2VSimFG-Colusa was estimated on an element basis by assigning two virtual wells at the

centroid of each model element. One well represents private agricultural pumping and one well represents rural residential pumping. The estimated pumping at these wells was calculated within C2VSimFG-Colusa as the additional volume of water necessary to meet agricultural and urban demand within that element, after distributing any other specified groundwater pumping and surface water deliveries. Figure 3 shows the total groundwater pumping in feet in each element in WY 2015.

The well screening interval or well depth was used to assign the model layers from which each simulated well extracts water. These assignments were made separately for the agricultural and rural residential wells in each element. Rural residential wells used a statistical analysis of typical perforation intervals developed for C2VSimFG. Agricultural wells were initially mainly assigned to pump from Layer 1, C2VSimFG's unconfined layer. Data provided by DWR and extracted from well completion reports was processed by Davids Engineering for updating agricultural pumping (Characterization of Groundwater Development in Colusa County and Evaluation of Potential Future Groundwater Demands TM by Davids Engineering, 2018). These data included information on well depths of irrigation wells drilled since 1970. These wells were mapped and assigned to C2VSimFG layers based on the total well depth (Figure 4 and Figure 5). Analysis of the north-western and south-western areas of the Subbasin revealed that most agricultural wells were pumping mainly from Layers 2 and 3. As a result, pumping in the majority of elements in these areas was edited so that 30% of groundwater pumping was from Layer 2 and 70% from Layer 3.

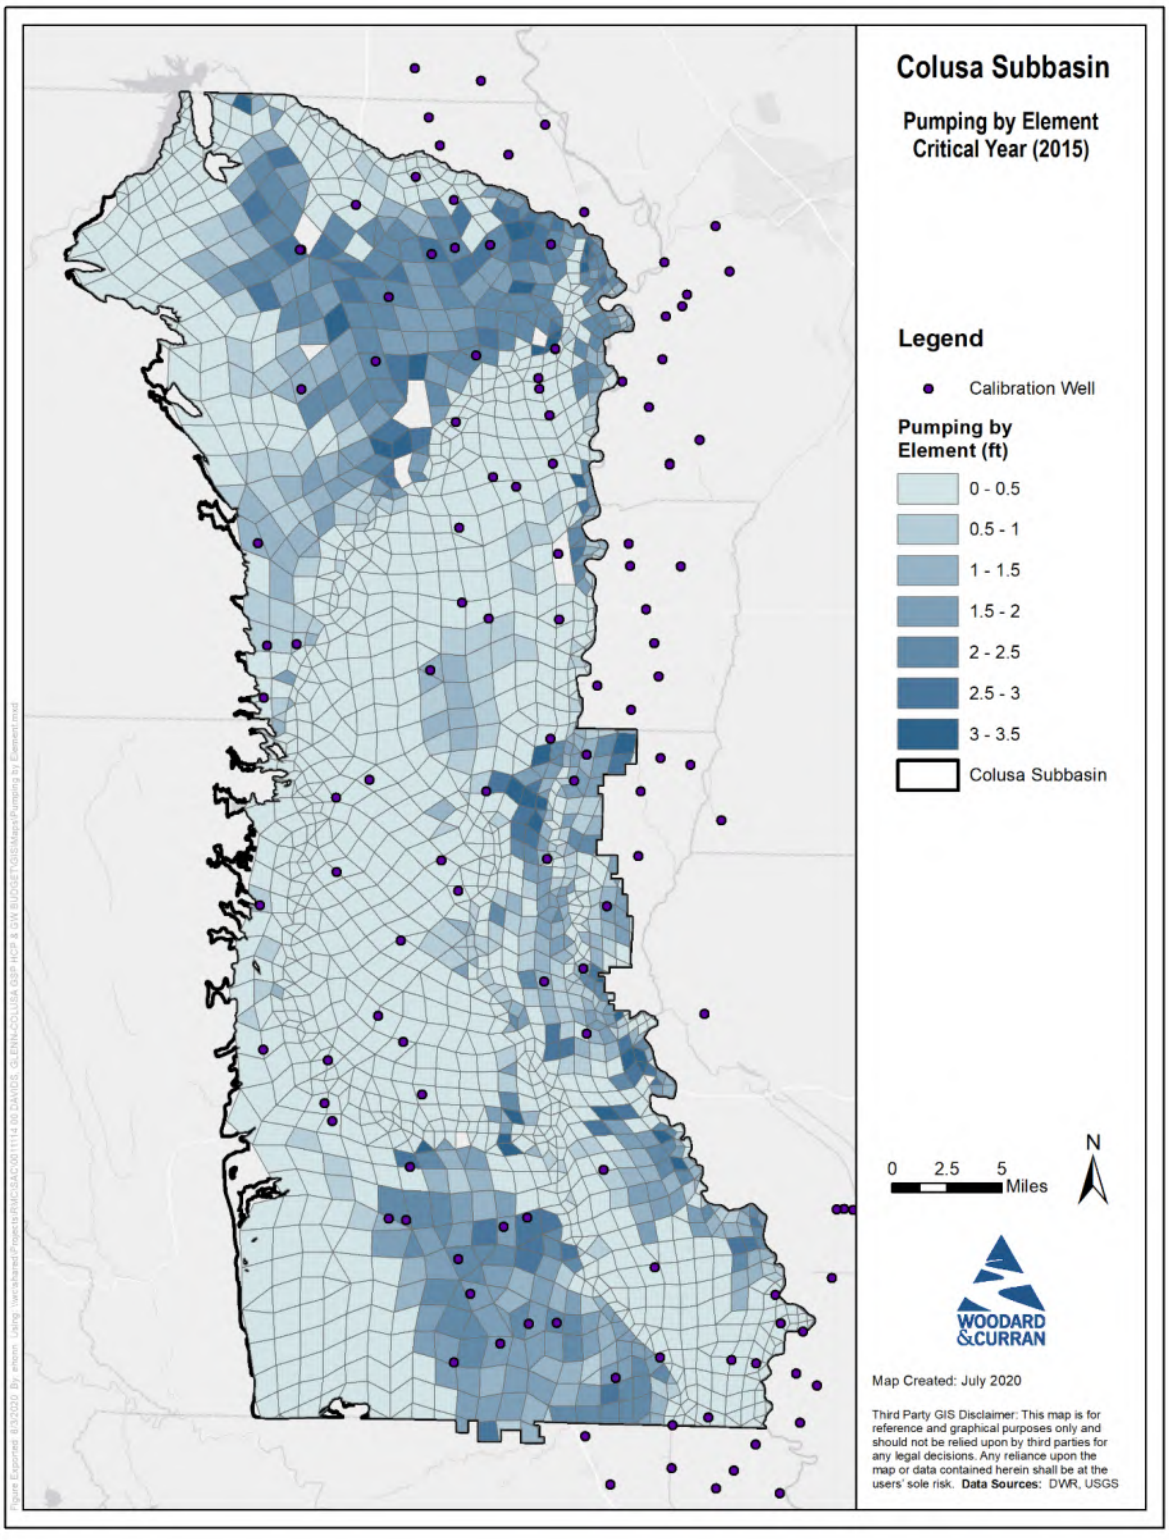

Figure 3: Element Pumping in Colusa Subbasin for WY 2015

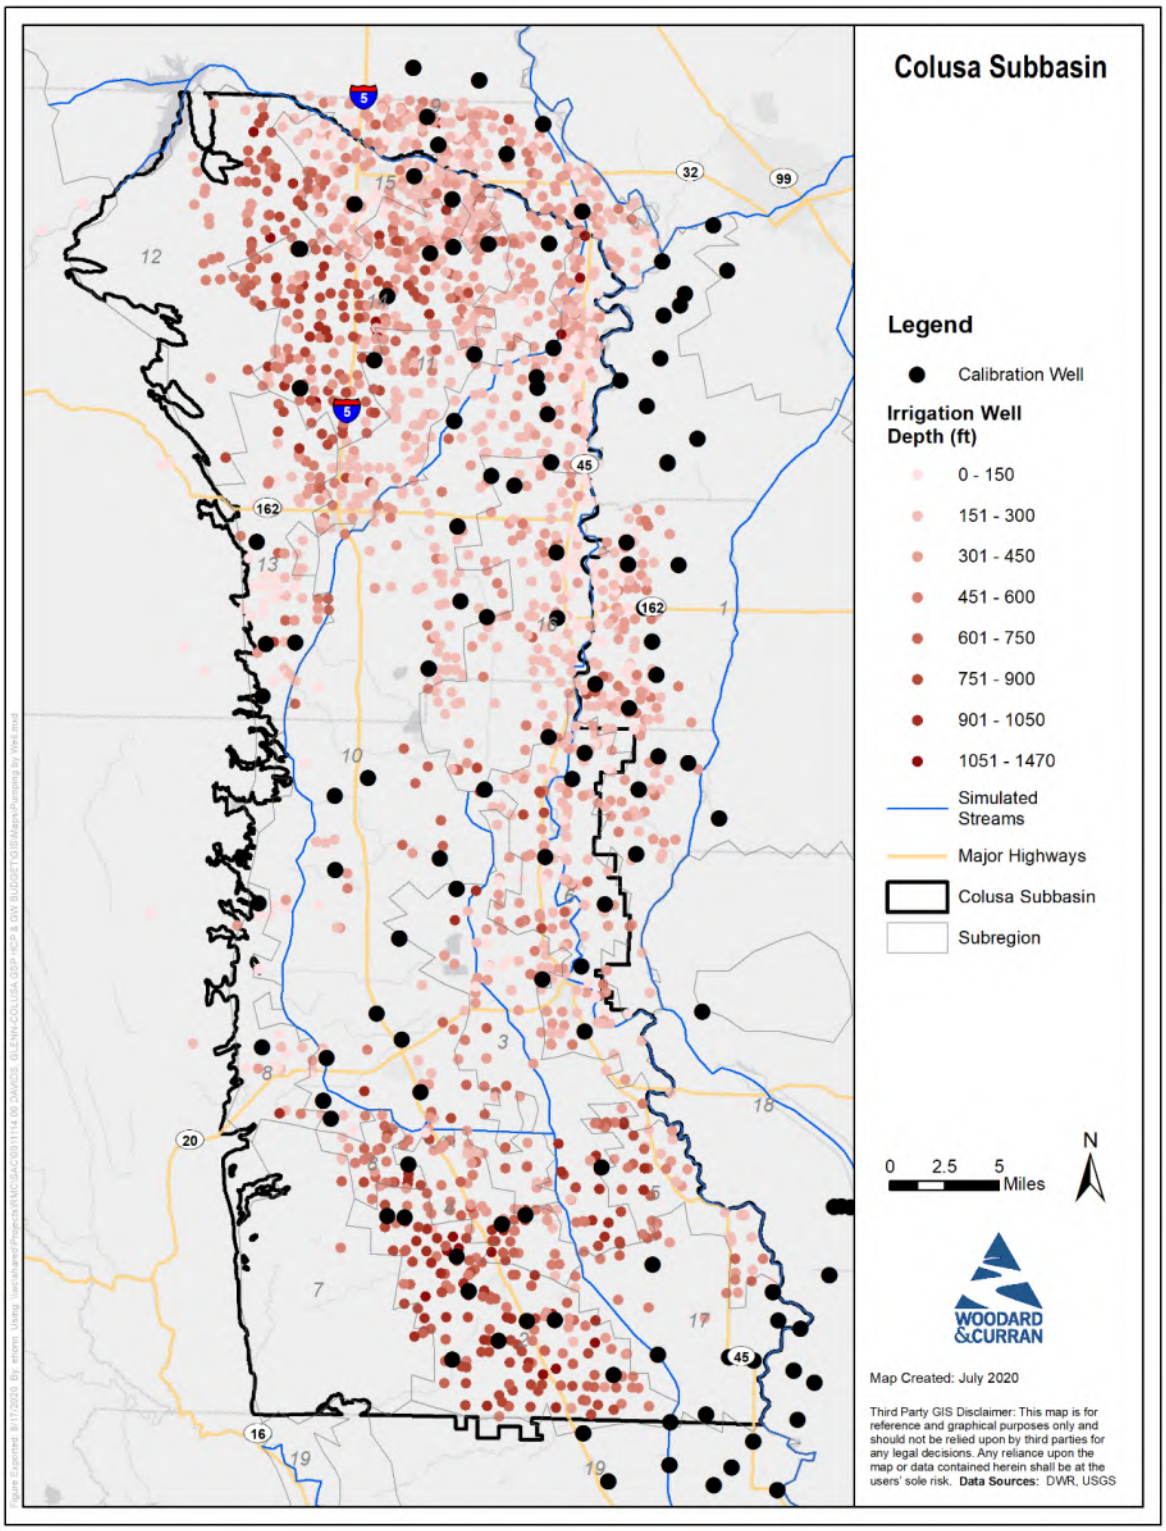

Figure 4: Irrigation Well Depths in Colusa Subbasin

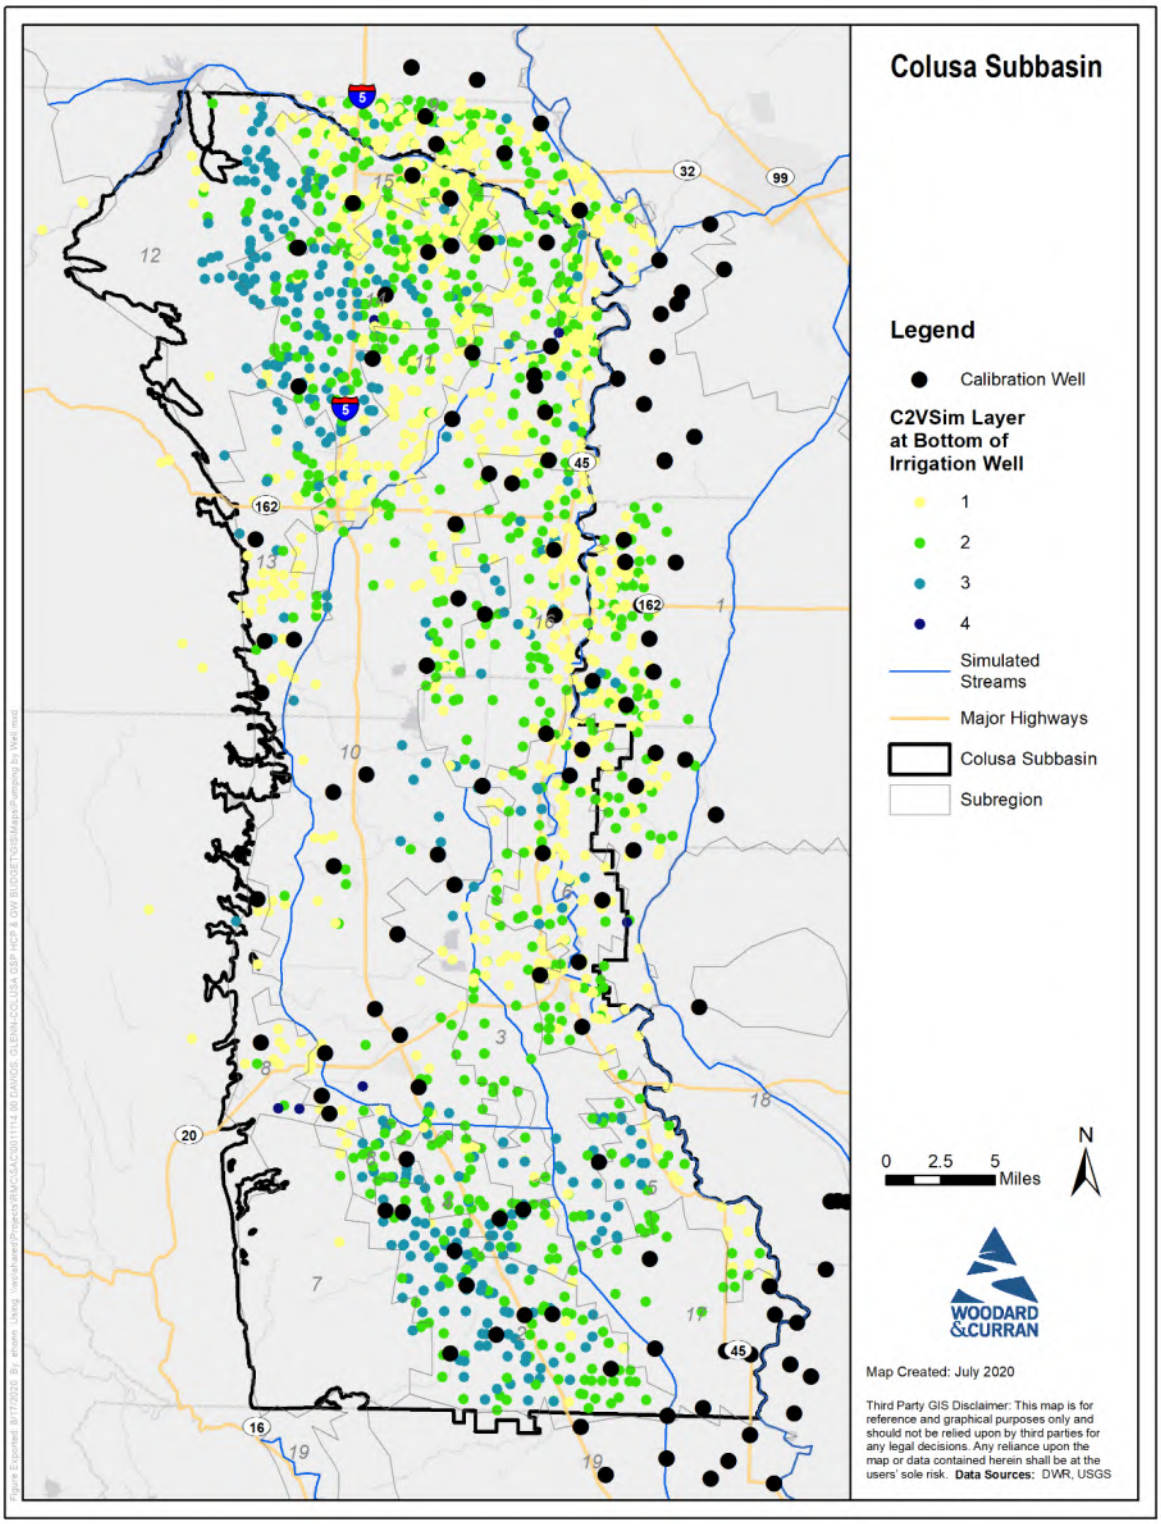

Figure 5: Irrigation Well Depths in Colusa Subbasin by Model Layer

2.4 Land Use

Annual land use in the Colusa Subbasin was estimated primarily based on spatially distributed land use information from DWR Land Use surveys in 1993, 1998, 2004, and 2009 and Land IQ[1] remote sensing-based land use identification in 2014. County Agricultural Commission land use areas were used to interpolate between years with available spatial land use information. The DWR LUEXINT Land Use Adjustment Preprocessor interpolation tool was implemented to create annual spatial cropping data sets in all years, compiling spatial land use data and creating estimates of spatial land use assignments in years when spatial data was unavailable. The spatial land use refinements were compared to the land use inputs to C2VSimFG Beta2, and were also reviewed by GSA representatives, Boards, and other local agencies to confirm the accuracy of annual patterns in crop acreage.

Land areas in the Colusa Subbasin were assigned to one of 29 land uses, and summarized under 22 land use classes. These land use classes are summarized by water use sector in Table 2-2. The area of each land use class was spatially assigned according to the percent area represented in each model element. Complete land use areas for the entire Colusa Subbasin are provided in the GSP.

Table 2-2. Land Use Classes by Water Use Sector.

Water Use Sector	C2VSimFG Land Use Class	C2VSimFG Land Use Code	Land Uses Included in Land Use Class
Agricultural (Nonponded and Ponded)	Alfalfa	AL	Alfalfa
	Almonds & Pistachios	AP	Almonds, Pistachios
	Citrus & Subtropical	CS	Citrus, Olives
	Corn	CN	Corn

Urban	Urban	UR	Urban, Semiagricultural

[1] Land IQ is a firm that was contracted by DWR to use remote sensing methodologies to identify crops in fields.

2.5 Evapotranspiration

Crop evapotranspiration (ET_c), or crop consumptive use, represents the volume of water that is lost to the atmosphere through both evaporation from the soil and transpiration from crop surfaces. A portion of the total water that crops and vegetation consume originates from precipitation (referred to as evapotranspiration of precipitation, or ET_{pr}) while other portions of ET_c may originate from applied water (referred to as evapotranspiration of applied water, or ET_{aw}).

C2VSimFG-Colusa computes a monthly root zone water budget, utilizing inputs of monthly ET_c together with other parameters that describe soil and land use characteristics in order to quantify all inflows and outflows through the root zone.[1] A root zone water budget is a generally accepted and widely used method to accurately and consistently track the portions of ET_c attributed to precipitation and applied water, respectively, as well as other water that is transmitted through the soil and plant surfaces (ASCE, 2016 and ASABE, 2007).

Monthly ET_c inputs for each crop and land use class in the Colusa Subbasin were adapted from the C2VSimFG Beta2 standard ET_c inputs. The C2VSimFG Beta2 inputs were first quality controlled and then adjusted to reflect local crop water use characteristics more accurately. Adjustments were determined through comparisons with local ET_c data and through discussion and consultation with selected local growers. Three main local ET_c data sources were compared to the C2VSimFG Beta2 inputs:

- METRIC Results (METRIC): Actual ET (ET_a) estimates were calculated using satellite imagery and the Mapping Evapotranspiration at High Resolution using Internalized Calibration (METRIC) (Allen, et al. 2007a) remotely-sensed surface energy balance model. METRIC ET_a estimates account for actual, observed conditions in the Colusa Subbasin that affect crop consumptive use, such as salinity, deficit irrigation, disease, fertilization, immature permanent crops, and crop canopy structure, and other factors. Studies by Bastiaanssen et al. (2005), Allen et al. (2007b, 2011), Thoreson et al. (2009), and others have found that when performed by an expert analyst, seasonal ET_a estimates by remotely-sensed surface energy balance models are expected to be within five percent of actual ET determined using other reliable methods. METRIC ET_a results are available for 2017 in the Sacramento Valley. Notably, METRIC results represent ET_a in a single, wet year (2017), rather than a multi-year average.

- Cal-SIMETAW Results (DWR): ET_c is computed in the California Simulation of Evapotranspiration of Applied Water (Cal-SIMETAW) model, and is publicly reported by the California Department of Water Resources (DWR) for 132 individual crops, 20 crop categories, and four land-use categories by county for use in the California Water Plan. Cal-SIMETAW is a daily, spatial crop water balance model that utilizes weather data, soil properties, crop coefficients, rooting depths, seepage, and other parameters to calculate ET_c and ET_{aw}. Monthly ET_c values were available from Cal-SIMETAW for 24 land use types in Glenn and Colusa Counties over the period spanning water years 2000-2015. The monthly ET_c values were averaged across both counties and all years for each land use type, and were summarized to average annual values for comparison.

- ITRC Results (Cal Poly): The Irrigation Training & Research Center (ITRC) at California Polytechnic State University, San Luis Obispo has compiled a database of typical ET_c rates for agricultural crop types across the various ETo Zones in California. These rates are publicly available online (http://itrc.org/etdata/index.html), and are offered for water budget and irrigation scheduling and design purposes. The ITRC provides typical

[1] The root zone is defined as "the upper portion of the soil where water extraction by plant roots occurs." (ASCE, 2016)

ET_c rates for various irrigation methods, two of which were considered for analyses in the Colusa Subbasin: surface irrigation systems and drip/micro irrigation systems. Across these irrigation systems, ITRC also summarizes ET_c for various relative precipitation conditions, with 1997 representing a "typical" year, 1998 representing a "wet" year, and 1999 representing a "dry" year.

ET_c values in C2VSimFG-Colusa were refined to provide for similar results among all crops represented in the model and described in the various ET_c data sources above. Sample comparisons of the average annual ET_c for major crops are shown in Figure 6.

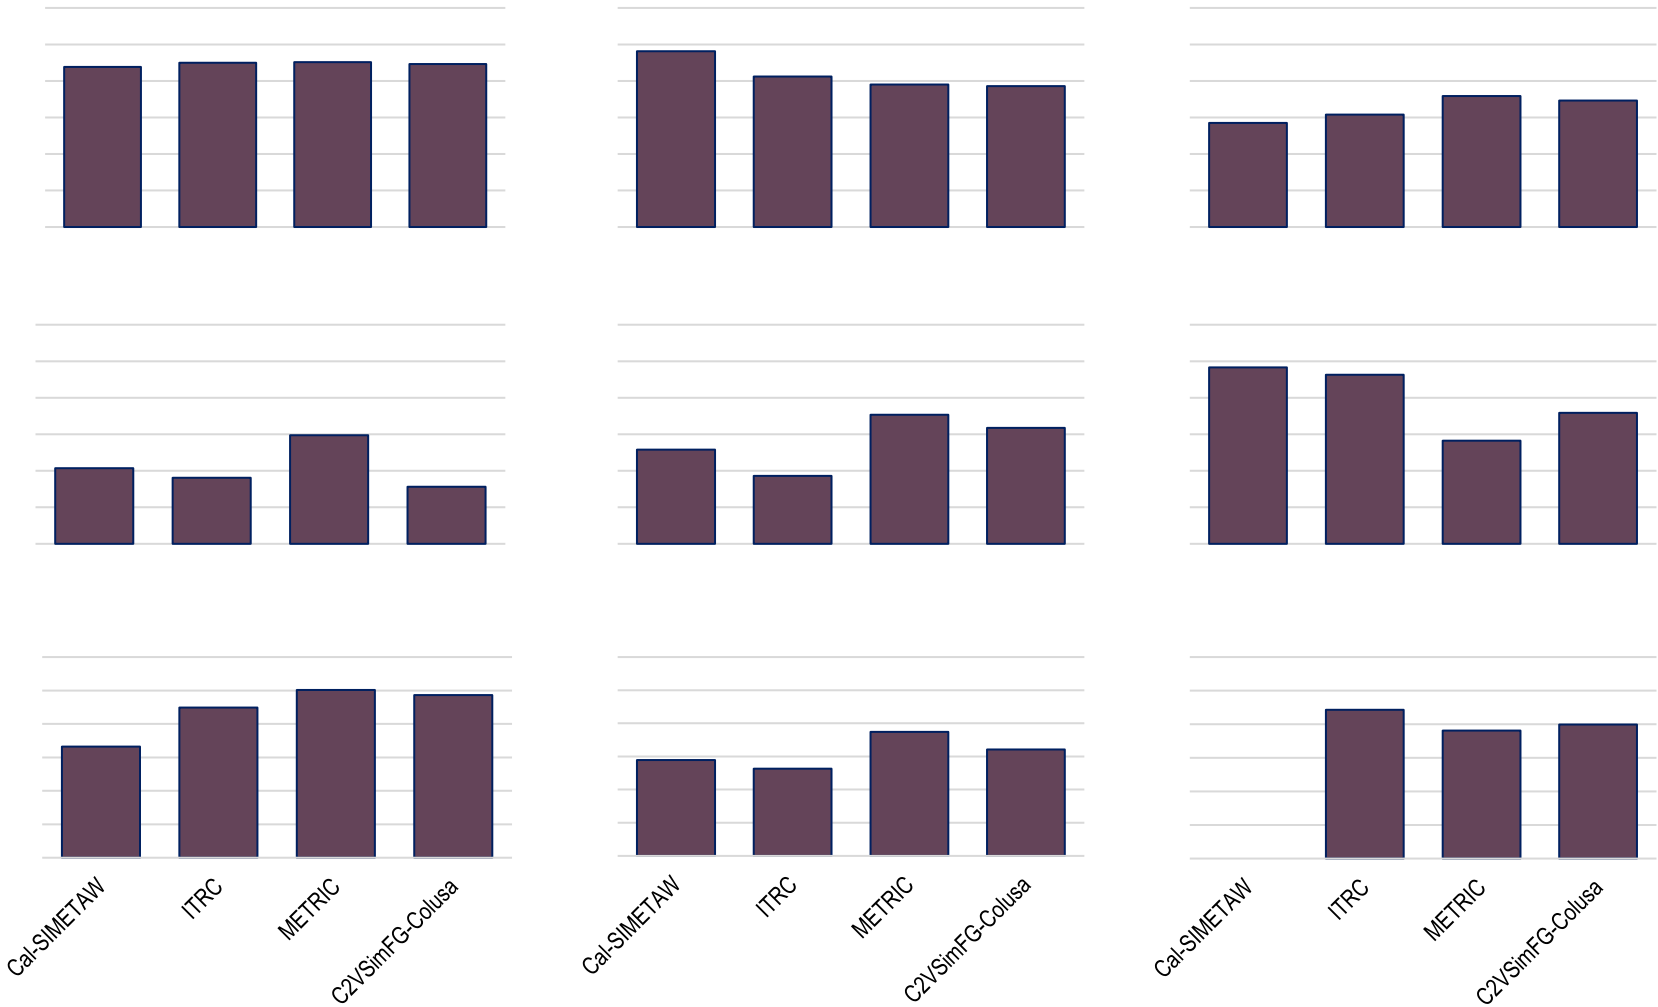

Figure 6. Average Annual* ET_c Comparison between Cal-SIMETAW, ITRC, METRIC, and C2VSimFG-Colusa for Major Irrigated Crops in the Colusa Subbasin (1990-2015 Average Annual Area Greater Than 10,000 acres).

**Average summary years vary, see text for description of years considered.*

2.6 Other Irrigation and Crop Inputs

2.6.1 Irrigation Period

The irrigation period identifies the months during which irrigation is available to a crop or land use class. A value of one designates a month during which IDC calculates applied water demand for the land use class and simulates irrigation events, as needed. A value of zero designates a non-irrigation month during which IDC does not compute applied water and does not simulate irrigation for the land use class. Different monthly designations can be defined for different land use classes, if necessary.

In C2VSimFG-Colusa, the irrigation period was defined through time series inputs corresponding to typical crop irrigation seasons in the Colusa Subbasin. The irrigation period was also refined for rice in select months in order to better match the timing of planting and application of water in the winter months, according to local agricultural practices.

2.6.2 Reuse and Return Flow

The return flow fraction determines the proportion of applied water that can leave the land use area as runoff, while the reuse fraction determines the proportion of applied water that is captured and reused for irrigation. A value of one for each indicates that all applied water can leave as runoff, but that all applied water is captured and reused for irrigation. A value of zero for each indicates that no applied water leaves the land use cell, and that no water is reused for irrigation.

In C2VSimFG-Colusa, irrigation water return flow fractions were converted to timeseries inputs for all crops, with decreasing values that reflect changes in local irrigation practices over time, leading to reductions in runoff (Figure 7). Irrigation reuse fractions were unchanged from C2VSimFG Beta2, with values of 0 set for all crops.

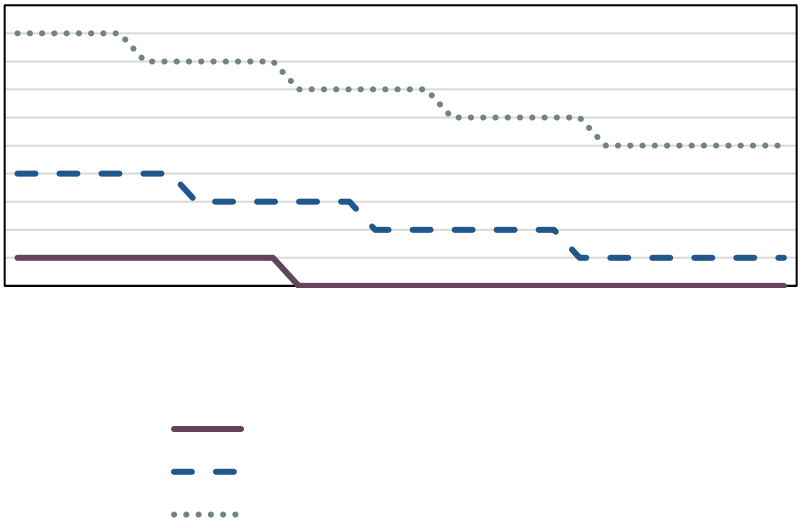

Figure 7. Return Flow Fractions in C2VSimFG-Colusa.

2.6.3 Ponded Crop Inputs

Ponding depth inputs to the model dictate the amount of water that is applied to ponded crops during irrigation. Monthly ponding depths for rice with non-flooded decomposition and rice with no decomposition were refined in C2VSimFG-Colusa to more accurately match early and late-season water application rates in the Colusa Subbasin in recent years (Table 2-3). Other ponding depths were unchanged from the standard C2VSimFG Beta2 inputs.

Table 2-3. Average Monthly Ponding Depths Updated in C2VSimFG-Colusa.

Month	Average Ponding Depth by Crop Type (ft; 1990-2015 Average)	
	Rice with Non-Flooded Decomposition	Rice with No Decomposition
1	0.15	0.00
2	0.02	0.00
3	0.00	0.00
4	0.01	0.02
5	0.34	0.35
6	0.38	0.38
7	0.35	0.35
8	0.25	0.25
9	0.01	0.03
10	0.09	0.00
11	0.32	0.00
12	0.26	0.00

2.7 Other Urban Inputs

Urban inputs to C2VSimFG-Colusa were updated from the standard inputs to C2VSimFG Beta2 to accommodate new, locally-defined urban demand areas. These new urban demand areas in the Colusa Subbasin were specified as subdivisions of larger urban demand areas in C2VSimFG Beta2, corresponding to specific urban subareas for which water supply and water use data were available. The new urban demand areas corresponded to:

- Arbuckle (Public Utility District service area)
- City of Colusa
- City of Orland
- City of Williams
- City of Willows (California Water Service Company Willows service area)
- Unincorporated urban areas in the Colusa Subbasin

Data sources used to describe these new urban demand areas include SWRCB Small Supplier Conservation Reports and Urban Water Supplier Reports, population data and estimates from the California Department of Finance, census data, and the Willows 2015 Urban Water Management Plan.

Key urban inputs that were identified or refined for these new urban demand areas are population, groundwater pumping, per capita water use, urban pervious area fractions, and urban indoor water use fractions. These inputs are described below.

2.7.1 Population

The population in each urban demand area was quantified based on population data and population estimates available from the California Department of Finance or from United States Census Bureau. Annual population estimates were available from the Department of Finance for the Cities of Colusa, Orland, Williams, and Willows, and for Colusa and Glenn Counties in 1989-2015. The population in the Community of Arbuckle was summarized from available Census Bureau data in 1990, 2000, and 2010. The population in Arbuckle in other years was estimated through linear interpolation. The population of unincorporated areas in each county was calculated as the total population in that county (adjusted to the area overlying the Subbasin), minus the population in each city or community overlying the Subbasin.

2.7.2 Groundwater Pumping

Groundwater pumping data for urban suppliers and public water systems in the Colusa Subbasin were available from the SWRCB, as described in Section 2.3.1.

2.7.3 Per Capita Water Use

Per capita water use for the new urban demand areas was estimated based on available urban population and total urban water use from water supplier data, where available. Average per capita water use and data sources for each urban demand area are identified in Table 2-4.

Per capita water use in Willows was calculated in 1995-2015 from California Department of Finance population data and water use data. Per capita water use in 1989-1994 was calculated as the 1999-2008 average, taken to approximate average conditions observed in the early 1990s.

Per capita water use in Colusa, Orland, Williams, Arbuckle, and unincorporated areas in the Colusa Subbasin was calculated from the per capita water use in Willows, adjusted upward to accommodate slight differences in typical water use in these areas.

Average per capita water use values range from 231 gallons per capita per day in Willows and Colusa, to 277 gallons per capita per day in Orland.

Table 2-4. Urban Per Capita Water Use for New Urban Demand Areas in Colusa Subbasin.

Urban Demand Area	Average Per Capita Water Use (Gallons per Capita Per Day, 1990-2015)	Source
Arbuckle	254	Adjusted from Willows per capita water use (annual adjustment factor 1.1)
City Of Colusa	231	Assumed equal to Willows per capita water use (annual adjustment factor 1.0)
City Of Orland	277	Adjusted from Willows per capita water use (annual adjustment factor 1.2)
City Of Williams	242	Adjusted from Willows per capita water use (annual adjustment factor 1.05)

Urban Demand Area	Average Per Capita Water Use (Gallons per Capita Per Day, 1990-2015)	Source
Willows	231	Department of Finance population data; gross water use data (1995-2015); estimated as 199-2008 average (1989-1994)
Unincorporated urban areas in the Colusa Subbasin	254	Adjusted from Willows per capita water use (annual adjustment factor 1.1)

2.7.4 Urban Pervious Area Fractions

The urban pervious area fraction input is used by the C2VSimFG-Colusa model to quantify evapotranspiration (ET) and runoff from urban areas. It is assumed that only pervious areas are available for ET, and that no ET occurs in impervious areas. It is also assumed that all precipitation that falls on impervious areas becomes runoff. The runoff and ET of pervious areas is defined in C2VSimFG Beta2 according to typical conditions in urban areas.

The pervious fractions in the C2VSimFG-Colusa urban demand areas were updated to monthly values ranging from 0.40 to 0.49 in cities and incorporated urban demand areas (indicating less pervious area, and more developed area), and to a value of 0.70 in unincorporated urban demand areas (indicating more pervious area, and less developed area than cities and incorporated urban areas). These values were estimated to reflect the proportion of 'built-up' and undeveloped areas within the respective urban demand areas, and are similar to the pervious fractions specified for other urban areas in C2VSimFG Beta2.

2.7.5 Indoor Use Fractions

C2VSimFG-Colusa parses the total volume of applied water in each urban demand area into the amount of water that is used indoors versus outdoors based on user-defined indoor use fractions. A monthly pattern of indoor use fractions was calculated based on the average monthly average ratio of estimated indoor to outdoor water use in each city or community in the Colusa Subbasin in 2013, compared to total groundwater pumping that year. The year 2013 was taken to be representative of a typical year. The indoor use fractions in Table 2-5 were used for all new urban demand areas.

Table 2-5. Urban Indoor Water Use Fractions for New Urban Demand Areas in Colusa Subbasin.

Month	Fraction of Total Urban Water Used Indoors
January	1.00
February	0.93
March	0.57
April	0.47
May	0.37
June	0.30
July	0.28
August	0.32
September	0.36
October	0.41
November	0.59
December	0.69

2.8 Diversions

Diversions are specified in C2VSimFG-Colusa to quantify the volume of water available for deliveries to specific land use areas in the Colusa Subbasin. The diversion specifications are also used by the model to quantify the volumes of nonrecoverable loss to the atmosphere through evaporation and recoverable loss to the GWS through seepage (infiltration of surface water).

Diversions that are used within the Colusa Subbasin are generally quantified based on outside data sources, including: delivery records reported by the United States Bureau of Reclamation (USBR), groundwater management or water planning documents developed by water agencies, and publicly available records maintained by the California State Water Resources Control Board (SWRCB) in the Electronic Water Rights Information Management System (eWRIMS). Data sources and updates to specific diversion volumes and specifications are described below.

Diversions of supply used outside the Subbasin are generally assumed to be equal to diversions data specified in C2VSimFG Beta2. Deliveries are generally calculated by C2VSimFG-Colusa as the water supply used to meet simulated crop water demands, after accounting for seepage and evaporation of the diverted supply.

Table 2-6 identifies new diversions added to C2VSimFG-Colusa, and Table 2-7 identifies diversions originally in C2VSimFG Beta2 that were changed in C2VSimFG-Colusa. Details about these added diversions and changes are described in the sections below.

Table 2-6. Diversions Added to C2VSimFG-Colusa.

Diversion ID	Description	Data Source	Average Volume in Historical Water Budget (AF per year, 1990-2015)
444	Orland Unit Water Users' Association (OUWUA) (South Canal only)	USBR delivery reports (1989-2015); estimated other years	60,011
445	Colusa County Water District (WD)	USBR delivery reports (1989-2015); estimated other years	50,967

36	Glenn-Colusa Canal to Glenn-Colusa ID (58%) for Ag (08N_SA2)	No longer used (replaced with specified diversions from GCIDWIS and eWRIMS data)	458
37	Glenn-Colusa Canal to Glenn-Colusa ID (42%) for Ag (08S_SA2)	No longer used (replaced with specified diversions from GCIDWIS and eWRIMS data)	458
116	Sacramento River RM 178 to Provident ID, Princeton-Cordua-Glenn ID and miscellaneous diverters for Ag (08N_SA1)	No longer used (replaced with specified USBR diversions)	460-468
117	Sacramento River RB diversions between Butte City and Wilkins Slough to Princeton-Cordora-Glenn ID, Green Valley Corporation (Formerly Cannell, F.), and Maxwell ID (5%) and miscellaneous settlement contractors for Ag (08N_SA1)	No longer used (replaced with specified USBR diversions)	460-468
118	Sacramento River RB diversions between Butte City and Wilkins Slough to Maxwell ID (95%), Odysseus Farms, Robert Ditch Irrigation Company, Colusa Irrigation Company, Mehrhof Susan M. (Formerly Swinford Tract Irrigation Company), and Sycamore Family Trust (Formerly Davis, Olive P. et al) and miscellaneous settlement contractors for Ag (08S_SA1)	No longer used (replaced with specified USBR diversions)	460-468
119	Sacramento River RM 146 miscellaneous non-CVP diversions for Ag (08S_NA1)	No longer used (replaced with specified USBR diversions)	460-468

Diversion ID	Description in C2VSimFG Beta2	Revision in C2VSimFG-Colusa	Diversion ID Replacement
122	Sacramento River RB diversions between Butte City and Wilkins Slough to miscellaneous non-CVP diverters for Ag (08S_NA2)	Revised to account only for River Garden Farms and misc. outside Colusa SB	N/A
124	Sacramento River RB diversions between Butte City and Wilkins Slough to Reclamation District 108 and miscellaneous diverters for Ag (08S_SA3)	No longer used (replaced with specified USBR diversions)	459
126	Sacramento River RB diversions between Wilkins Slough and Knights Landing to RD 108, River Garden Farms and miscellaneous CVP diverters for Ag (08S_SA3)	No longer used (replaced with specified USBR diversions)	459

2.8.1 Diversions by USBR Contractors and Diverters

New diversions were added to C2VSimFG-Colusa to specify the monthly USBR deliveries to individual CVP contractors and diverters within the Colusa Subbasin (Diversion IDs 444-468). While many diversions of CVP supplies were specified in C2VSimFG Beta2, the original model largely aggregated the diversion volumes and element groups across multiple diverters. The new diversions were specified to instead distinguish the diversion volume and distribution area for each of the major diverters.

Diversions data were initially downloaded from USBR for all diverters that receive water from the Tehama-Colusa Canal (TCC), the Sacramento River, and other CVP supplies. Monthly data were quality controlled and reviewed for consistency. Diversion locations were generally identified from eWRIMS, and were used to classify diverters as within, outside, or partly within the Colusa Subbasin.

New diversions were specified in C2VSimFG-Colusa for all diverters within or partly within the Subbasin that receive water from the TCC and other CVP supplies, and for all diverters within or partly within the Subbasin that divert more than 3,000 acre-feet (AF) from the Sacramento River each year. Smaller diverters that divert less than 3,000 AF from the Sacramento River each year were grouped in C2VSimFG-Colusa based on their location along the Sacramento River. A small number of diverters identified in the USBR data diverted from an unknown location. It was assumed that a diversion from the TCC to support “fish facilities” in an unknown location was not within the Subbasin, while thirteen smaller diversions from the Sacramento River were assumed to be located within the Subbasin. These smaller diversions range from less than 100 AF per year to 2,900 AF per year, on average, with a total average volume of approximately 17,000 AF per year.

For diverters entirely within the Colusa Subbasin, the volume of diversions from USBR was taken directly from USBR reports in years when data were available (1989-2015). For diverters partially within the Colusa Subbasin, the volume of diversions from USBR was prorated based on the relative area inside the Subbasin. Any diversions originally specified in C2VSimFG Beta2 that accounted for these same USBR deliveries were used to quantify the diversion volumes in years prior to 1989, either directly or prorated based on area (if the diverter is partly within the Colusa Subbasin). In 1989-2015, these original C2VSimFG Beta2 diversions were either set to zero volume (for diverters within the Colusa Subbasin), or revised to deliver a reduced volume prorated by area to only those the elements located outside the Subbasin.

The diversion specifications were updated for all new and revised USBR deliveries, as needed. Diversion locations were updated to the stream node closest to the point of diversion identified in eWRIMS, where available. Distribution and recharge element groups were revised to match the diverter's service area, if available, as well as all changes in how the diversions are distributed inside and outside the Colusa Subbasin, refined to exclude areas within or outside the subbasin, as needed. The recoverable and nonrecoverable loss fraction of each new USBR diversion was updated based on local water budget information, where available.

2.8.2 Other Diversions

Diversions to Glenn-Colusa Irrigation District (GCID) were updated with diversion data available from GCIDWIS (1989-2015), and with eWRIMS data to account for winter water use.

Diversions to Reclamation District 108 (RD108), Princeton-Codora-Glenn Irrigation District (PCGID), and Provident Irrigation District (PID) were specified with all available data from the Districts between water year 1989-2015. Estimates of winter water used within these Districts were also specified, assuming similarity to the winter water use observed in GCID.

The diversion element groups and recharge element groups were updated for all new diversions, reflecting the service area of each District to the extent permitted by the model element resolution.

3. MODEL CALIBRATION

3.1 Calibration Goals

The goals of model calibration are (1) to achieve a reasonable water budget for each component of the hydrologic cycle modeled (i.e., land and water use, stream flow, and groundwater) and (2) to maximize the agreement between a) simulated and observed groundwater levels at selected well locations and b) simulated and observed streamflow hydrographs at selected gaging stations. These objectives are achieved through verification of the model input data and adjustment of model parameters.

3.2 Calibration Approach

Model calibration begins after data analysis and input data file development are completed. The calibration effort can be broken down into subsets that align with packages within the Integrated Water Flow Model (IWFM) platform. IWFM is used for development of C2VSim-FG Colusa model. As an integrated groundwater model, the results of each part of the simulation are interrelated with the other parts. The model calibration can be considered a systematic process that includes the following activities:

- Calibration of water budgets to other local water budgets through adjustment of root zone parameters
- Calibration of simulated groundwater levels and stream flows to observed data
- Comparison of calibration performance with the calibration targets
- Completion of additional model refinements, as necessary

C2VSimFG-Colusa was calibrated to achieve agreement with other local water budget results, measured stream flows and groundwater elevations, and groundwater elevation contours. The major data sources used to check model results include measured groundwater levels and contours and observed streamflow data. Though the model simulation period is October 1985 through September 2015 (30 years) or water years 1986 through 2015, the model calibration focused on water years 1990 through 2015 (26 years) because land and water use data for the model area is more reliable in those years.

3.3 Water Budget Calibration

Numerous water agencies and organizations use and manage water resources in areas overlying the Colusa Subbasin. For many of these entities, developing local water budgets is an important means of tracking and reporting water supply and water use in their service area. Local water budgets have been developed and are publicly available through various water management planning documents, including Agricultural Water Management Plans (AWMPs), Urban Water Management Plans (UWMPs), USBR Water Management Plans (WMPs), and Groundwater Management Plans.

The historical C2VSimFG-Colusa water budget results were evaluated for consistency with other local water budgets in the Subbasin by reporting and comparing subarea water budgets from the C2VSimFG-Colusa model with these local water budgets. To facilitate these comparisons, the historical C2VSimFG-Colusa model was divided into 38 subareas, several of which represent the service areas of specific water agencies and organizations.

Major flow paths considered in the calibration process included surface water deliveries, groundwater pumping, evapotranspiration, and deep percolation. Sample comparisons of these four parameters are shown in Figure 8 through Figure 10 for GCID, OAWD, and OUWUA. Other flow paths reported in both the local water budgets and the C2VSimFG-Colusa water budget results were also compared, as available. Comparisons were made in subareas and years when local water budget results were available to ensure similarity between major inflows to and outflows from land surfaces. Other comparisons were also made to confirm the accuracy of diversions, and the seepage and evaporation of diversions in the subarea.

Across the entire Subbasin, a key parameter considered during the calibration process was the crop consumptive use fraction (CCUF). CCUF is a ratio of the consumptive use of applied water (also referred to as or evapotranspiration of applied water, or ET_{aw}) to the total volume of applied water. High CCUF values close to 1.0 generally indicate higher irrigation efficiency, while lower CCUF values generally indicate lower irrigation efficiency. Discussion with local water users and review of irrigation methods throughout the Colusa Subbasin over time suggest that irrigation efficiency has generally increased over time, leading to increasing CCUF values over the historical water budget period.

Root zone parameters were refined, as needed, through an iterative process to calibrate the C2VSimFG-Colusa subarea water budget results (1) for agreement with local water budget results, and (2) to provide for typical historical CCUF values and increasing CCUF values over the historical water budget period, reflecting trends toward higher irrigation efficiency in the Colusa Subbasin.

For most areas, calibrations were made by adjusting the target soil moisture (TSM) for each land use class in C2VSimFG-Colusa. The TSM specifies the irrigation target soil moisture as a fraction of field capacity, and is used by C2VSimFG-Colusa to compute irrigation depths for each land use in the model domain. When simulating an irrigation event, C2VSimFG-Colusa will apply water until the soil reaches the specified percent of field capacity. TSM fractions in the C2VSimFG-Colusa were refined through several iterations of adjustment and comparison against local water budgets (Figure 8 through Figure 10) and evaluation of local CCUF values. Average CCUF values for crops in the Colusa Subbasin range from 0.55 for rice, which is typically irrigated with higher volumes of water relative to demand, to values between 0.80 and 0.85 for almonds, pistachios, and grain crops.

TSM fractions in the calibrated model range from 0.9 to 1.0 (i.e., 90 to 100 percent of field capacity) for rice, to values generally between 0.76 and 1.00 (i.e., 76 to 100 percent of field capacity) for other nonponded crops. These values approximate soil moisture resulting from common irrigation practices in the Sacramento Valley.

3.4 Streamflow Calibration

The major streams in the C2VSimFG-Colusa are Stony Creek, Sacramento River, Glenn-Colusa Canal, and Colusa Drain. Streamflow calibration is primarily performed by comparing the simulated streamflow at 6 locations with local data from 9 stream gages (Table 3-1 and Figure 11). Data for these gages came from the United States Geological Survey (USGS) and California Data Exchange Center (CDEC).

Table 3-1: Summary of C2VSimFG-Colusa Streamflow Calibration Gages

Stream	Stream Node	Agency	Gage Name	Period of Record
Stony Creek	3315	USGS	USGS 11388500: Stony Creek Near Hamilton City	January 1941 to September 1973
Sacramento River	3341	CDEC	CDEC ORD: Sacramento River at Ords Ferry	January 1984 to present
Sacramento River	3370	USGS	USGS 11389000: Sacramento River at Butte City, CA	October 1938 to June 1995
		CDEC	CDEC BTC: Sacramento River at Butte City	January 1998 to present
Sacramento River	3502	USGS	USGS 11389500: Sacramento River at Colusa, CA	April 1921 to present
		CDEC	CDEC COL: Sacramento River at Colusa	January 1984 to present
Sacramento River	3502	USGS	USGS 11390500: Sacramento River Below Wilkins Slough Near Grimes, CA	October 1938 to present
		CDEC	CDEC WLK: Sacramento River Below Wilkins Slough	January 1984 to present
Colusa Drain	3764	CDEC	CDEC CDR: Colusa Drain Near Hwy 20	November 1997 to present

Colusa Drain[1], as the major collector of excess irrigation flows or rice field runoff, was analyzed in the central portion of the Subbasin bounded by Glenn-Colusa Canal and Sacramento River. Most of the runoff in this region ends up flowing into Colusa Drain. Groundwater elevations in the vicinity of Colusa Drain are closely influenced by volume of runoff collected by Colusa Drain. It was necessary to increase shallow groundwater flow into the drain to lower the simulated groundwater levels to match the observed groundwater levels. This was achieved by adjusting the streambed conductance and elevation of Colusa Drain nodes in order to increase the capacity of flows into Colusa Drain. Simulated streamflows of Colusa Drain were compared to measured streamflows at CDEC CDR station in Colusa Drain.

Streamflow calibration included analysis of the streambed hydraulic conductivity and stream gain from or loss to the groundwater system. Simulated stream flows were compared with observed records and exceedance charts were also used to check the model performance when simulating high and low flows at each gage location. Calibration results for select stream gages (except Stony Creek due to lack of observation data) are included in Figure 12 through Figure 16.

[1] Also commonly referred to as the Colusa Basin Drain.

3.5 Groundwater Level Calibration

Like streamflow calibration, the goal of groundwater level calibration is to achieve reasonable agreement between the simulated and observed groundwater levels at the calibration wells. Within Colusa Subbasin and a five-mile buffer around the Subbasin, 740 wells were evaluated for developing groundwater observation locations to track calibration at both a regional and local scale. These wells came from DWR's California Statewide Groundwater Elevation Monitoring (CASGEM) Program and the groundwater level monitoring network for Colusa Subbasin. The calibration wells were filtered based on their period of observation records, availability of construction information (e.g., well depth and screen intervals), number of measurements between 1990 and 2015, number of spring measurements (assumed to be March, April, or May), spatial location, and active completions (for nested wells). Checks were also made on whether wells were included in Colusa Subbasin's groundwater level monitoring network, Butte Basin Groundwater Model's (BBGM) calibration wells, and C2VSimFG's calibration wells. An ultimate set of 252 wells were chosen that are representative of the long-term conditions of groundwater levels both at a local and regional scale in the area in and around the Colusa Subbasin. Calibration well locations are shown in Figure 17.

Calibration wells were assigned to a model layer based on the well top/bottom perforations or total well depth. C2VSimFG-Colusa's model layering was not altered and is described in C2VSimFG documentation. Of the 252 calibration wells, 134 were assigned to Layer 1 (unconfined aquifer), 70 to Layer 2, and 48 to Layer 3 which extends to the base of fresh water. Layer 4, which is saline water, extends down to the base of continental deposits and typically does not contain any wells.

Simulated groundwater levels were calibrated to observed levels through adjustments to model aquifer parameters including hydraulic conductivity, specific storage, and specific yield. The goal of groundwater level calibration is to achieve the maximum agreement between simulated and observed groundwater elevations at calibration wells while maintaining reasonable values for aquifer parameters. The groundwater level calibration was performed in two stages:

- The initial calibration effort was focused on the regional scale to verify hydrogeological assumptions made during model data development and confirm the accuracy of general groundwater flow directions. During this iteration, simulated groundwater elevation trends, flow directions, and groundwater gradients were compared to measured data. DWR's groundwater level contours for Fall 2015 and West Yost's draft contours for Spring 2006 and Spring 2015 were used to evaluate C2VSimFG-Colusa groundwater contours from matching time periods. Figure 18 through Figure 20 show the simulated C2VSimFG-Colusa groundwater elevation contours (developed using Layer 1 elevations at model nodes) compared to DWR contours for Fall 2015 and West Yost contours for Spring 2006 and Spring 2015. Fall 2015 also represents the end of simulation groundwater levels.
- The second stage of calibration of groundwater levels was to compare the simulated and observed groundwater levels at each calibration well. This comparison provides information on the overall model performance during the simulation period, focusing on the calibration period of water years 1990 through 2015. To minimize the effects of groundwater pumping on groundwater elevations, only spring groundwater levels (assumed to be March, April, or May) were used to calculate calibration statistics. The simulated groundwater elevations at the 252 calibration wells were compared with corresponding observed values for concurrence in long-term trends as well as spring water levels.

The results of the groundwater level calibration indicate that the C2VSimFG-Colusa reasonably simulates the long-term hydrologic responses under various hydrologic conditions in Colusa Subbasin. Calibration statistics are provided in Section 6. Figure 21 shows a selection of calibration wells with their resulting groundwater level hydrographs. Appendix A shows all calibration groundwater level hydrographs. Appendix B shows all nested well locations with their hydrographs plotted on the same plot.

4. AQUIFER PARAMETERS AND DATA

C2VSimFG-Colusa uses a parametric grid that has been developed based on C2VSim Fine Grid (C2VSimCG) nodes and elements. The parametric grid nodes are spaced approximately 3.5 miles apart. Aquifer parameters are assigned to each parametric node and interpolated to the nearby C2VSimFG-Colusa groundwater nodes. Figure 22 shows the parametric grid nodes used to calibrate Colusa Subbasin. After regional calibration using the parametric grid, local calibration was made by changing aquifer parameters at each C2VSimFG-Colusa model node.

The initial aquifer parameters were from C2VSimFG Beta2 model. Through analysis of subregion water budgets and groundwater level hydrographs at the calibration wells, aquifer parameters were adjusted either model-wide or by node in particular areas. The parameters resulting from the calibration process are listed in Table 4-1.

Table 4-1: Range of Calibrated Aquifer Parameter Values

Layer	Horizontal Hydraulic Conductivity (ft/day)	Specific Storage (1/ft)	Specific Yield (-)	Aquifer Vertical Hydraulic Conductivity (ft/day)
1	1 - 218	1.00E-05 – 1.00E-04	0.06 - 0.11	0.02 – 0.69
2	2 - 215	1.00E-05 – 1.00E-04	0.06 - 0.11	0.02 – 0.67
3	2 - 127	9.00E-6 - 1.00E-04	0.06 - 0.11	0.02 – 0.48
4	5 - 49	1.00E-05 – 1.00E-04	0.06 - 0.11	0.14 – 1.05

The horizontal hydraulic conductivity in the C2VSimFG-Colusa varies across the horizontal direction and across model layers. The fully calibrated values for model layers 1 through 4 range from 1 ft/day to 218 ft/day, and the spatial distribution is represented in Figure 23 through Figure 26.

The aquifer vertical hydraulic conductivity facilitates the separation between the unconfined and confined aquifers within the C2VSimFG-Colusa and controls the flow of groundwater between the materials making up the different modeled aquifer layers. Analysis of the groundwater levels in each layer for calibration wells (i.e., nested calibration wells spanning multiple layers) determined that greater separation between layers was needed in some areas and resulted in a range of 0.02 ft/day to 1.05 ft/day across the model layers.

5. CALIBRATION TARGETS AND STATISTICS

The C2VSim-Colusa simulated groundwater levels were evaluated to meet the American Standard Testing Method (ASTM) standards. The "Standard Guide for Calibrating a Groundwater Flow Model Application" (ASTM D5981) states that "the acceptable residual should be a small fraction of the head difference between the highest and lowest heads across the site." The residual is defined as the simulated head minus the observed head. An analysis of all observed groundwater levels within the model area indicated the presence of 250+ feet of groundwater level changes in Colusa basin. Assuming 10 percent as the small fraction, the acceptable residual level would be about 25 feet. Calibration goals for the groundwater level residuals were set such that no more than 10 percent of the observed groundwater levels would exceed the acceptable residual level of 25 feet.

- 69% of observed groundwater levels are within +/- 10 feet of its respective simulated values
- 81% of observed groundwater levels are within +/- 15 feet of its respective simulated values
- 92% of observed groundwater levels are within +/- 25 feet of its respective simulated values

The residual histogram for the monitoring wells selected to be part of the calibration dataset for C2VSimFG-Colusa is shown in Figure 27. Additionally, a scatter plot of simulated versus observed values is shown in Figure 28.

Note: Statistics calculated using only observed water levels for Spring (March-May) WY 1986-2015

6. SENSITIVITY ANALYSIS

Sensitivity analysis is an important step in the model development process. It is defined as "the study of distribution of dependent variables (e.g., groundwater elevations in a groundwater model) in response to changes in the distribution of independent variables, initial conditions, boundary conditions, and physical parameters" (AWWA, 2001). In general, a sensitivity analysis of an integrated groundwater and surface water model is performed for the following purposes:

- To test the robustness and stability of the model by establishing tolerance within which the model parameters can vary without significantly changing the model results;
- To understand the impact of inaccuracies in input data on model results (e.g., how model results can change because of a 10% error in the estimation of agricultural pumping); and
- To develop an understanding of the relative sensitivity of the components of the hydrologic cycle and data, so that an effective data collection and monitoring plan can be developed.

A sensitivity analysis was performed using the C2VSimFG-Colusa to assess the sensitivity of model results to specific model parameters. Adjustments of aquifer parameters, and analyses of the resulting calibration well residuals, was performed across all calibration wells for various model runs. Analysis performed on parameters indicated that the model was fairly sensitive to horizontal hydraulic conductivity, specific yield, and less sensitive to the other parameters (Figure 29).

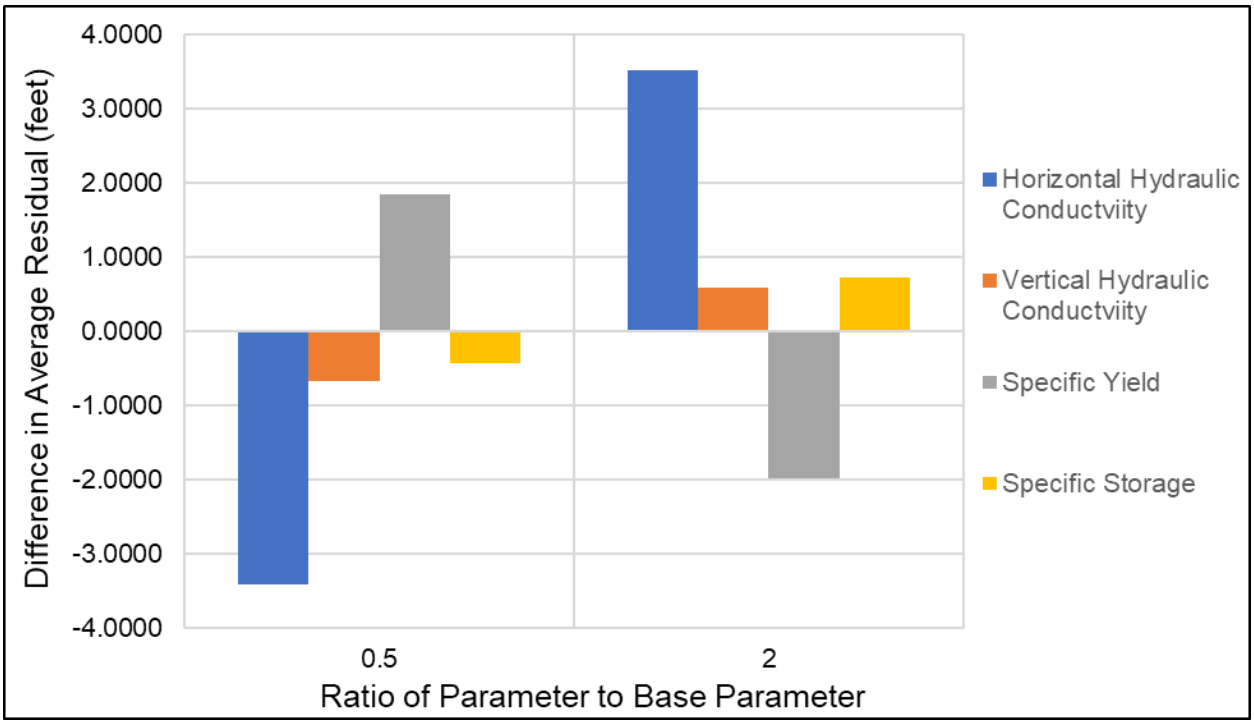

Figure 29: Difference in Calibration Well Residuals due to Changes in Aquifer Parameters

7. HISTORICAL WATER BUDGET RESULTS

Following all refinements, enhancements, and calibration procedures described in this technical memorandum, the C2VSimFG-Colusa model was used to quantify the historical water budget for the Colusa Subbasin. The historical water budget provides a foundation for understanding how the Subbasin has behaved historically, as well as insight into historical groundwater conditions (e.g. observed water levels) and insight into the sustainability of past groundwater management. In accordance with the GSP Regulations, the historical water budget covers a period of at least ten years (26-year period from 1990 to 2015).

A summary of the historical water budget results are presented below for the Subbasin land and surface water system (SWS), and for the Subbasin groundwater system (GWS). Additional information and discussion of the historical water budget is provided in the GSP, including an evaluation of the availability and reliability of historical surface water supplies per the GSP regulations. It is anticipated that the water budgets will be refined and updated over time as part of GSP implementation in the basin.

7.1 Historical Water Budget: Land and Surface Water System

Average annual inflows and outflows to and from the Colusa Subbasin land and surface water system were estimated to be nearly 13.83 million acre-feet (MAF) per year. Average annual values are shown in Figure 30 and Table 7-1.

Primary inflows to the land and SWS include surface water inflows (11,747 TAF/yr), precipitation (1,210 TAF/yr), groundwater pumping (502 TAF/yr), and stream gains from groundwater (i.e., stream accretions) (366 TAF/yr). Surface water inflows predominantly enter the Colusa Subbasin along the Sacramento River, where the river is wholly contained within the subbasin, flowing into the Subbasin south of the town of Princeton and out near of the City of Colusa. Additional surface water inflows occur through diversions from outside the Subbasin to land within the Subbasin (1,168 TAF/yr), and through overland runoff of precipitation from upslope small watersheds to the Subbasin (78 TAF/yr).

Primary outflows from the land and SWS include surface water outflows (11,302 TAF/yr), evapotranspiration (1,740 TAF/yr), deep percolation from land surfaces and small watersheds (441 TAF/yr), and seepage from streams, canals, and drains (345 TAF/yr). Surface water outflows include outflows along the Sacramento River, outflows to Sutter Bypass at Colusa Weir, drainage from the Colusa Basin Drain, overland runoff of precipitation and applied water to downslope lands, and other outflows to boundary streams. Evapotranspiration is primarily from agricultural lands, but also from managed wetlands, canal evaporation, native vegetation, and urban and industrial lands.

The average annual change in SWS storage is negligible compared to other inflows and outflows due to similar soil moisture content in the root zone, on average, across water years.

Figure 31 and Table 7-2 summarize the applied water computed by the C2VSimFG-Colusa model for the historical water budget period, according to the data sources and refinements describe in this technical memorandum. The total applied water includes surface water deliveries and groundwater pumping applied to all water use sectors in the Colusa Subbasin (agricultural, managed wetlands, and urban and industrial lands). Total surface water deliveries are computed based on the refined diversions data described above, averaging just over 1,260 TAF/yr (approximately 72 percent of the total applied water). Total groundwater pumping averages just over 500 TAF/yr (approximately 28 percent of the total applied water).

Figure 32 and Table 7-3 summarize the total groundwater recharge from the surface water system in the Colusa Subbasin. More than half of all groundwater recharge comes from deep percolation of applied water and precipitation on land surfaces, averaging 439 TAF/yr over the 1990-2015 historical water budget period (56 percent of total groundwater recharge). Other major contributors to groundwater recharge are stream seepage, and canal seepage. Stream seepage averaged 206 TAF/yr in 1990-2015 (26 percent of total groundwater recharge), while canal seepage averaged 139 TAF/yr over the same period (18 percent of total groundwater recharge). Percolation of runoff from small watersheds has contributed another 2 TAF/yr (less than one percent of total groundwater recharge).

Additional details describing the historical land and surface water system water budget are provided in the Colusa Subbasin GSP Appendix A.

7.2 Historical Water Budget: Groundwater System

Average annual inflows and outflows to and from the Colusa Subbasin groundwater system are shown in Figure 33 and Table 7-4.

Primary inflows to the GWS include deep percolation from land surfaces and small watersheds (441 TAF/yr), seepage from streams, canals, and drains (345 TAF/yr), and subsurface inflows from adjacent subbasins (200 TAF/yr).

Primary outflows from the GWS include groundwater pumping (502 TAF/yr), stream gains from groundwater (i.e., stream accretions) (366 TAF/yr), and subsurface outflows to adjacent subbasins (146 TAF/yr). On average, subsurface outflows of groundwater from the Colusa Subbasin exceed subsurface gains of groundwater to the Colusa Subbasin.

The average annual change in storage is -28 TAF/yr over the 1990-2015 historical water budget period. This indicates that on average more groundwater leaves the Colusa Subbasin than enters, resulting in an average net reduction in groundwater stored in the Subbasin. The majority of groundwater inflows and outflows are exchanged directly with the land and SWS overlying the Colusa Subbasin GWS. Figure 34 summarizes the annual change in storage and the cumulative change in storage in the Colusa Subbasin GWS over the historical water budget period.

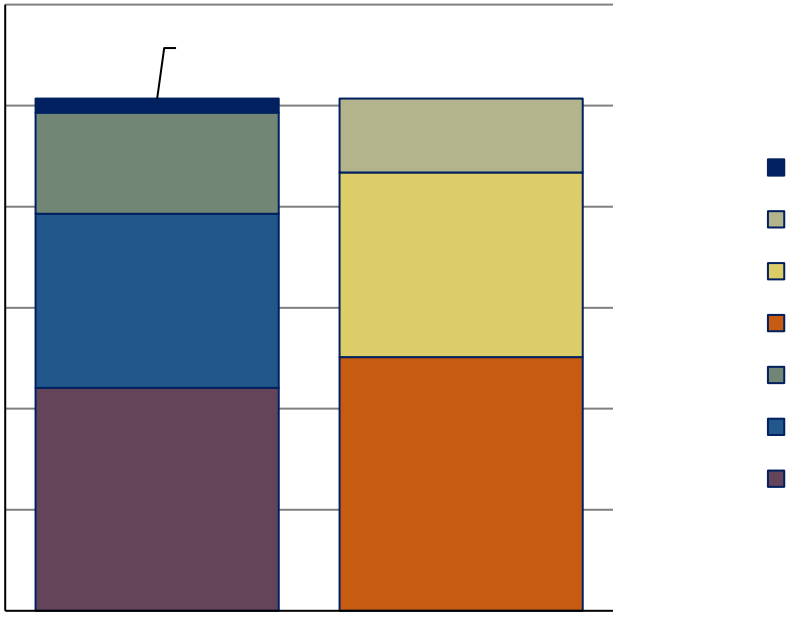

Figure 33. Historical Water Budget: Groundwater System Summary.

Table 7-4. Historical Water Budget: Groundwater System Summary.

Groundwater System Flow Direction	Water Budget Component	Average Volume (TAF per year, 1990-2015)[1]

Total Outflows		***1,014***
Change in Storage (Inflows – Outflows)		***-28***

[1] Volumes rounded to 1,000 AF.
[2] Deep percolation includes deep percolation of applied water, deep percolation of precipitation, and small watershed percolation.
[3] Seepage includes stream, canal, and drain seepage to groundwater.

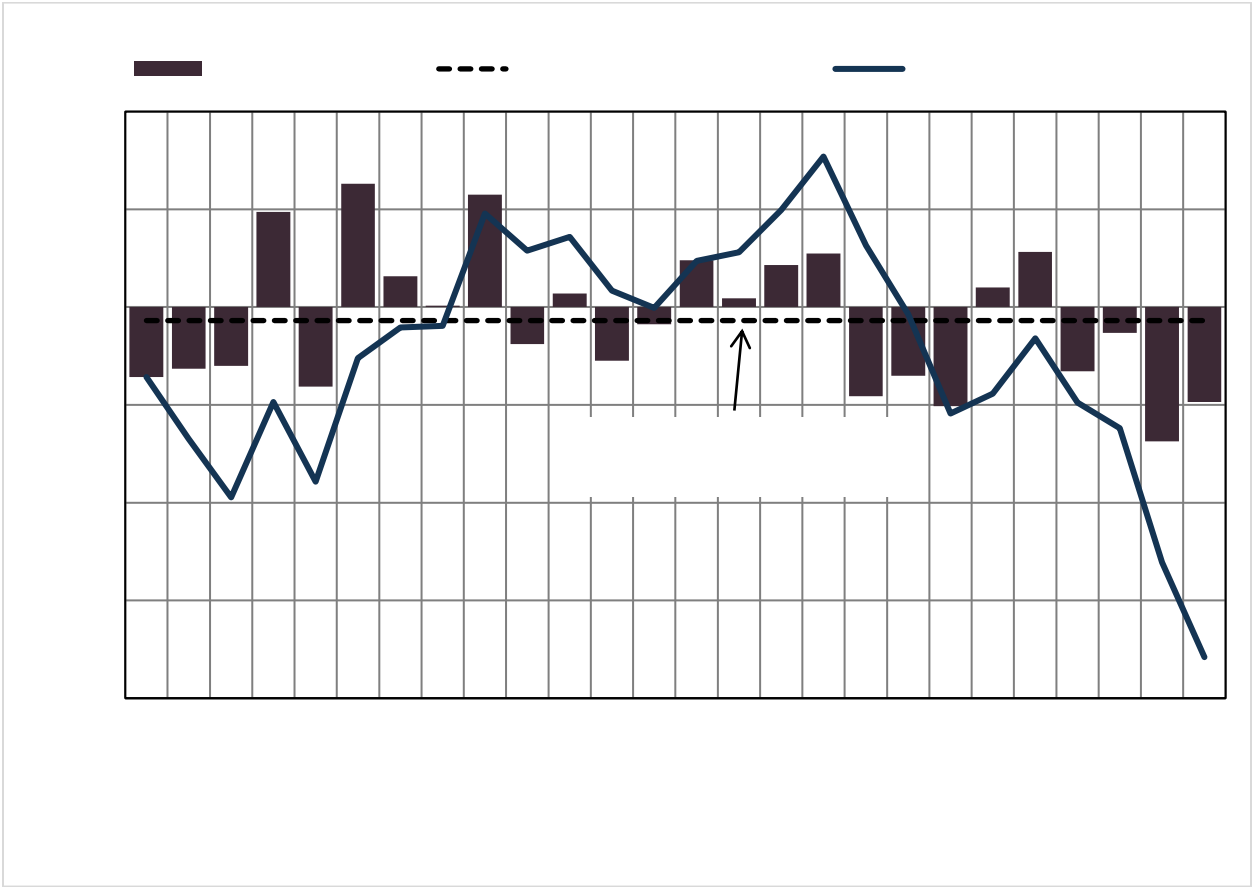

Figure 34. Historical Water Budget: Groundwater System Change in Storage.

8. SUMMARY AND FUTURE REFINEMENTS

The C2VSimFG-Colusa model is a well-calibrated regional integrated surface water and groundwater model that can be used effectively to analyze surface and groundwater conditions of the Colusa Subbasin. This model could be used adequately for evaluation of effectiveness and impacts of groundwater sustainability projects and management actions that are being developed as part of Groundwater Sustainability Plan (GSP) of the Colusa Basin.

C2VSimFG-Colusa model was developed based on DWR's C2VSimFG model for the entire Central Valley of California for a simulation period ending in 2015. The simulation period and model grid resolution and layers thicknesses of C2VSimFG were not changed in development of C2VSimFG-Colusa model. However, many local features and data such as land use and surface water delivery were updated for C2VSimFG-Colusa model. During development and calibration of C2VSimFG-Colusa model, several potential refinements were identified to may be included in future refinements to the model. These refinements may include:

- **Extension of time series data past WY 2015**. With the calibrated model, extending time series data (e.g., precipitation, land use, stream inflows, evapotranspiration, surface water diversions, urban demand, groundwater pumping) allows for use of more recent data and improved accuracy of the model for predicting near-term and future conditions in the Colusa groundwater subbasin.

- **Model layering**. Model layer thicknesses may be adjusted locally, primarily in the southwest and northwest areas of the model, to better represent local geologic conditions and potential faults in these areas.

- **Distribution of groundwater pumping between layers**. Model layer thicknesses may be refined such that distribution of groundwater pumping between model layers better matches groundwater extraction from different depth and layers of the aquifer.

- **Small watersheds**. The water coming from the foothills is simulated using small watersheds representing small streams and groundwater flowing into the western side of the Colusa Subbasin. These streams, mostly ephemeral, may need explicit representation and simulation in the model to better control recharge and flows from the foothills as some observed groundwater levels near the foothills show signs of recharge from nearby small streams.

- **Interbasin flows**. C2VSimFG-Colusa model is well calibrated along the eastern boundary of the basin and the five mile zone on the eastern side of this boundary. Quantification of Sacramento River recharge along the eastern boundary of the basin and subsurface groundwater underflow across this boundary into and out of Colusa, Butte and Vina basins will be useful in building consensus for management of groundwater by these neighboring basins.

- **Model Grid Resolution**. The observed groundwater level data show high spatial gradients in the northwestern and southwestern areas of the model. Model grid may be refined in these areas the simulate these local high groundwater gradients.

Colusa Subbasin Subarea Water Budgets

(THIS PAGE LEFT BLANK INTENTIONALLY)

Specialists in Agricultural Water Management
Serving Stewards of Western Water since 1993

Technical Memorandum

To: Colusa Groundwater Authority, Glenn Groundwater Authority

From: Davids Engineering

Date: August 2021

Subject: **Colusa Subbasin Subarea Water Budgets**

Overview

Water budgets have been developed for the Colusa Subbasin using the C2VSimFG-Colusa model, an integrated hydrologic flow model for the Colusa Subbasin (Subbasin) that is used to support development of the Subbasin Groundwater Sustainability Plan (GSP). The C2VSimFG-Colusa model is an element adapted from DWR's Fine Grid California Central Valley Groundwater – Surface Water Simulation Model (C2VSimFG). The development and calibration of the C2VSimFG-Colusa model is documented in Appendix 3D of the GSP.

This technical memorandum (TM) presents water budget results from the C2VSimFG-Colusa model for 32 distinct subareas defined within the Colusa Subbasin. Each subarea approximately represents a region of the Subbasin that shares a common water supplier (e.g., irrigation or water district), a common governing agency (e.g., county or city), and a common primary water supply source (e.g., areas with access to surface water or areas with access to only groundwater, i.e., "groundwater" areas).

Subareas were delineated within the C2VSimFG-Colusa model element grid to support development of model inputs and to support quality control and calibration of model outputs. Data and information corresponding to specific subareas were used to quantify water supply and water use within the subarea, to the extent permitted by the resolution of the model element grid. Specific data and information used to create model inputs are summarized in Appendix 3D of the GSP.

Local refinements were generally made to the following model inputs and attributes:

- Land use areas and characteristics for:
  - Non-ponded agriculture (17 crop types, including idle)
  - Ponded crops and managed wetlands
  - Native vegetation
  - Urban/Rural residential
- Water use characteristics, including:
  - Evapotranspiration (ET)
  - Irrigation efficiency
  - Return flows and reuse
  - Irrigation timing (all crops) and pond depths (rice and wetlands)
  - Population and per capita water use

- Surface Water Diversions, including:
    - Surface water diversion volumes (applied to corresponding subareas)
    - Seepage (recoverable loss)
    - Evaporation (non-recoverable loss)
- Aquifer and stream parameters

The following sections briefly describe the water budget components evaluated and reported in this TM, the unique subareas defined within the Colusa Subbasin, and the historical water budget results summarized from the C2VSimFG-Colusa model outputs for these subareas.

Water Budget Components

The general structure of the Colusa Subbasin water budget is shown in Figure 1. The structure contains two interacting systems: the surface water system and the groundwater system. The water budget results for these two systems may be reported separately to describe conditions at/near the land surface or in the underlying aquifer, or the results may be combined to describe the overall Subbasin water budget. The surface water budget comprises all inflows and outflows of water at the land surface within the spatial extent of the Subbasin, and all exchanges of water to and from the underlying groundwater system. The groundwater budget comprises these same exchanges with the surface water system in addition to subsurface inflows and outflows across the Subbasin boundary.

The C2VSimFG-Colusa model computes the complete surface water and groundwater budgets for each element within the model grid. Water budget results reported in Chapter 3 of the GSP are summarized for all elements that approximately represent the entire Colusa Subbasin. Water budget results reported in this TM are summarized for all subsets of elements that represent the water budget subareas described in the following section.

This section describes the water budget components that are reported in the surface water budgets and groundwater budgets for each subarea. Land uses simulated in the C2VSimFG-Colusa model are also described because of their significant effect on both the surface water and groundwater systems. Additional information about specific data sources and model inputs for land use and all water budget components are provided in Appendix 3D of the GSP.

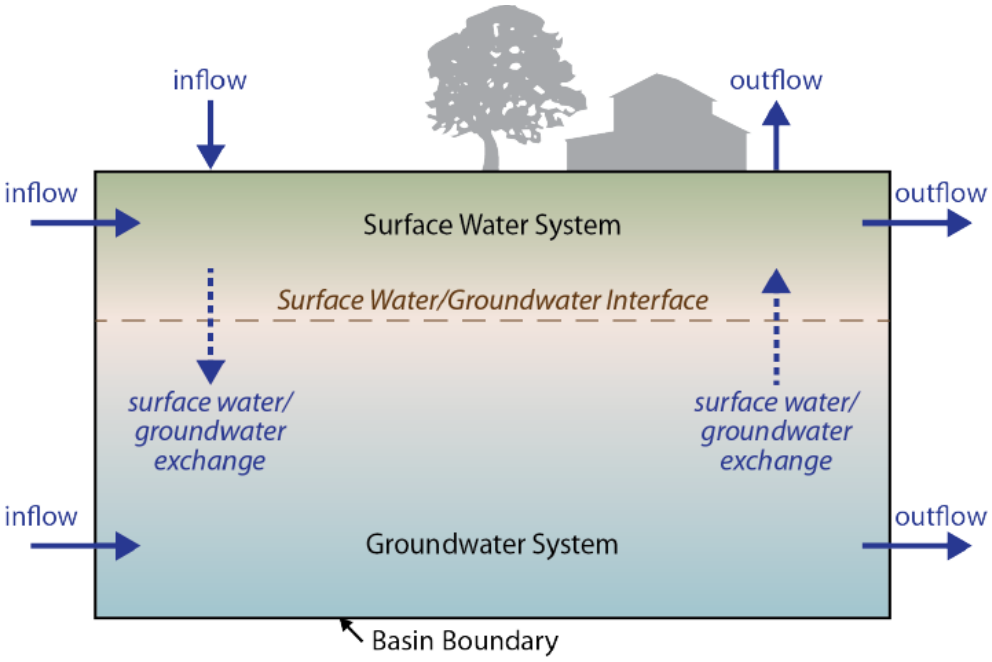

Figure 1. Generalized Water Budget Structure (Source: DWR).

Land Use

Table 1 identifies the general land use types and land use classes simulated in the C2VSimFG-Colusa model. Four general land use types are simulated: non-ponded agriculture, ponded crops and managed wetlands, native vegetation, and urban/rural residential. Land use characteristics are provided as inputs to the C2VSimFG-Colusa model and are used to simulate many of the water budget components that relate to land use, from crop irrigation demand and pumping requirements to percolation through the root zone and runoff from the land surface. Land use areas are also used to compute the volume of all water budget components in each model element. Water budget components are initially calculated on a unitized depth basis and are then converted to a volume by multiplying the unitized depth across the area represented by that land use class in the element.

Non-ponded agriculture land uses include 17 distinct land use classes, of which 16 represent specific crop types and one represents idle land. The model evaluates the water budget for each of these land use classes separately, considering differences in crop consumptive use (i.e., ET), rooting depth, irrigation practices, and other factors that affect how much water is applied to and used by the crop.

Ponded crops and managed wetlands in the model include all rice crops and managed wetlands – land uses that are periodically flooded and ponded. Like non-ponded crop land use classes, the model also evaluates the water budget for each of these land use classes separately.

Native vegetation includes native and riparian land use classes. Native land use represents undeveloped and uncultivated areas, while riparian land use represents undeveloped areas along waterways. Like crop land use classes, the model evaluates the water budget for each of these land use classes separately.

Urban/rural residential land is represented by a single “urban” land use class that includes all urban, rural residential, industrial, and semi-agricultural lands (e.g. dairies and farmsteads) as well as roads. Model inputs and results are specified for the combined urban land use class.

Table 1. Land Use Classes in the Colusa Subbasin.

General Land Use Type	Land Use Class
Non-Ponded Agriculture	Includes 16 crop types and idle land. The water budget for each is evaluated individually within the model based on differences in consumptive use, rooting depth, irrigation practices, etc.
Ponded Crops and Managed Wetlands	Rice and Managed Wetlands
Native Vegetation	Native and Riparian
Urban/Rural Residential	Urban land use class includes urban, rural residential, industrial, and semi-agricultural lands (e.g. dairies and farmsteads) as well as roads.

Surface Water Budget

Table 2 describes the surface water budget components reported from the C2VSimFG-Colusa model results, as well as the corresponding section of the GSP regulations that requires reporting of that component. Each of these components is reported in the surface water budget for each subarea.

Table 2. Surface Water Budget Components

Surface Water Budget Component[1]	Category	Description	GSP Regulation Section[2]
Surface Water (SW) Diversions	Inflow	Diversions of surface water supply for irrigation in the subregion.	§354.18(b)(1)
Groundwater (GW) Pumping	Inflow	Groundwater pumping to meet water demands not met by surface water. Simulated for all land uses except native vegetation.	§354.18(b)(3)
Precipitation	Inflow	Direct precipitation on the land surface.	Implied
Evapotranspiration	Outflow	Consumptive use of applied water and precipitation through the processes of evaporation and transpiration. Includes evaporation from canals and drains.	§354.18(b)(3)
Percolation *(from Land Surface)*	Outflow	Percolation (i.e., vertical movement) of applied water and precipitation below the root zone to the groundwater system. Does not include percolation from upslope small watersheds.	§354.18(b)(2)
Seepage *(from Canals and Drains)*	Outflow	Seepage (i.e., vertical movement) to the groundwater system from canals and drains. Does not include seepage from rivers and streams.	§354.18(b)(2)

Surface Water Budget Component[1]	Category	Description	GSP Regulation Section[2]
Return Flow	Inflow	Surface outflow from irrigation tailwater and drainage of rice and wetlands ponds.	§354.18(b)(1)
Runoff	Outflow	Surface outflow from precipitation.	§354.18(b)(1)
Change in Storage	Storage	Change in root zone soil moisture storage. Does not represent change in groundwater storage.	§354.18(a)
Net Recharge[3]	Recharge	Seepage + Percolation - Groundwater Pumping.	N/A

[1] Inflows to and outflows from the rivers and streams system in the Colusa Subbasin (i.e., stream gains and seepage from rivers and streams) are excluded from the subarea surface water budget summary.

[2] California Code of Regulations, Title 23, Division 2, Chapter 1.5, Subchapter 2 Groundwater Sustainability Plans, Article 5 Plan Contents.

[3] Net vertical movement of water from the land surface to the groundwater system (excluding rivers and streams).

Groundwater Budget

Table 3 describes the groundwater budget components reported from the C2VSimFG-Colusa model results, as well as the corresponding section of the GSP regulations that requires reporting of that component. Each of these components is reported in the groundwater budget for each subarea.

Table 3. Groundwater Budget Components.

Groundwater Budget Component	Category	Description	GSP Regulation Section[1]
Percolation *(from Land Surface and Small Watersheds)*	Inflow	Percolation (i.e., vertical movement) of applied water, precipitation, and drainage from upslope small watersheds below the root zone to the groundwater system.	§354.18(b)(2)
Seepage *(Seepage from rivers, streams, canals, and drains)*	Inflow	Seepage (i.e., vertical movement) to the groundwater system from rivers, streams, canals, and drains.	§354.18(b)(2)
Subsurface Inflows (net)	Inflow	Net subsurface groundwater inflow from adjacent groundwater basins or from the Coast Range foothills on the west side of the Subbasin.	§354.18(b)(2)
Groundwater (GW) Pumping	Outflow	Groundwater pumping to meet water demands not met by surface water. Simulated for all land uses except native vegetation.	§354.18(b)(3)
Stream Gains	Outflow	Groundwater flowing into rivers and streams, resulting in gaining streamflows (e.g. accretions).	§354.18(b)(2)
Change in Storage	Storage	Change in groundwater storage throughout the year; does not represent change in root zone soil moisture.	§354.18(b)(4)
Cumulative Change in Storage	Storage	Change in groundwater storage accumulated annually.	§354.18(b)(4)

Water Budget Subareas

Water budget subareas in the Colusa Subbasin are listed in Table 4 and shown in Figure 2. As described previously, these subareas were delineated within the C2VSimFG-Colusa model element grid to support development of model refinements, and to support quality control and calibration of model outputs. Historical summaries of land use, surface water budgets, and groundwater budgets for each of these subareas are reported below.

Table 4. Water Budget Subareas.

Subarea Number	Subarea Name	County	Description[1]	Acres
1	4MWD	Colusa	4M W.D., Colusa County	2,070
2	CCWD	Colusa	Colusa County W.D., Colusa County	49,335
3	CDMWC	Colusa	Colusa Drain M.W.C, Colusa County	30,943
4	ColGWE	Colusa	Colusa Groundwater East	42,360

			Total[3]	**714,507**

[1] Abbreviations: I.D.: Irrigation District
M.W.C: Mutual Water Company
W.D.: Water District
W.U.A.: Water Users Association

[2] Substantial portions of the GCID, PCGID, and PID service areas are located within Colusa and Glenn County. Separate subareas have been evaluated for the portions of each district in each county. The subarea boundaries shown in Figure 2 indicate the boundary line between the Colusa and Glenn County subareas; however, the subarea labels describe only the name of each district.

[3] Total acreage across all subareas differs from the total acreage of the Colusa Subbasin primarily because of slight differences between subarea and subbasin boundaries, particularly along the western edge of the Colusa Subbasin.

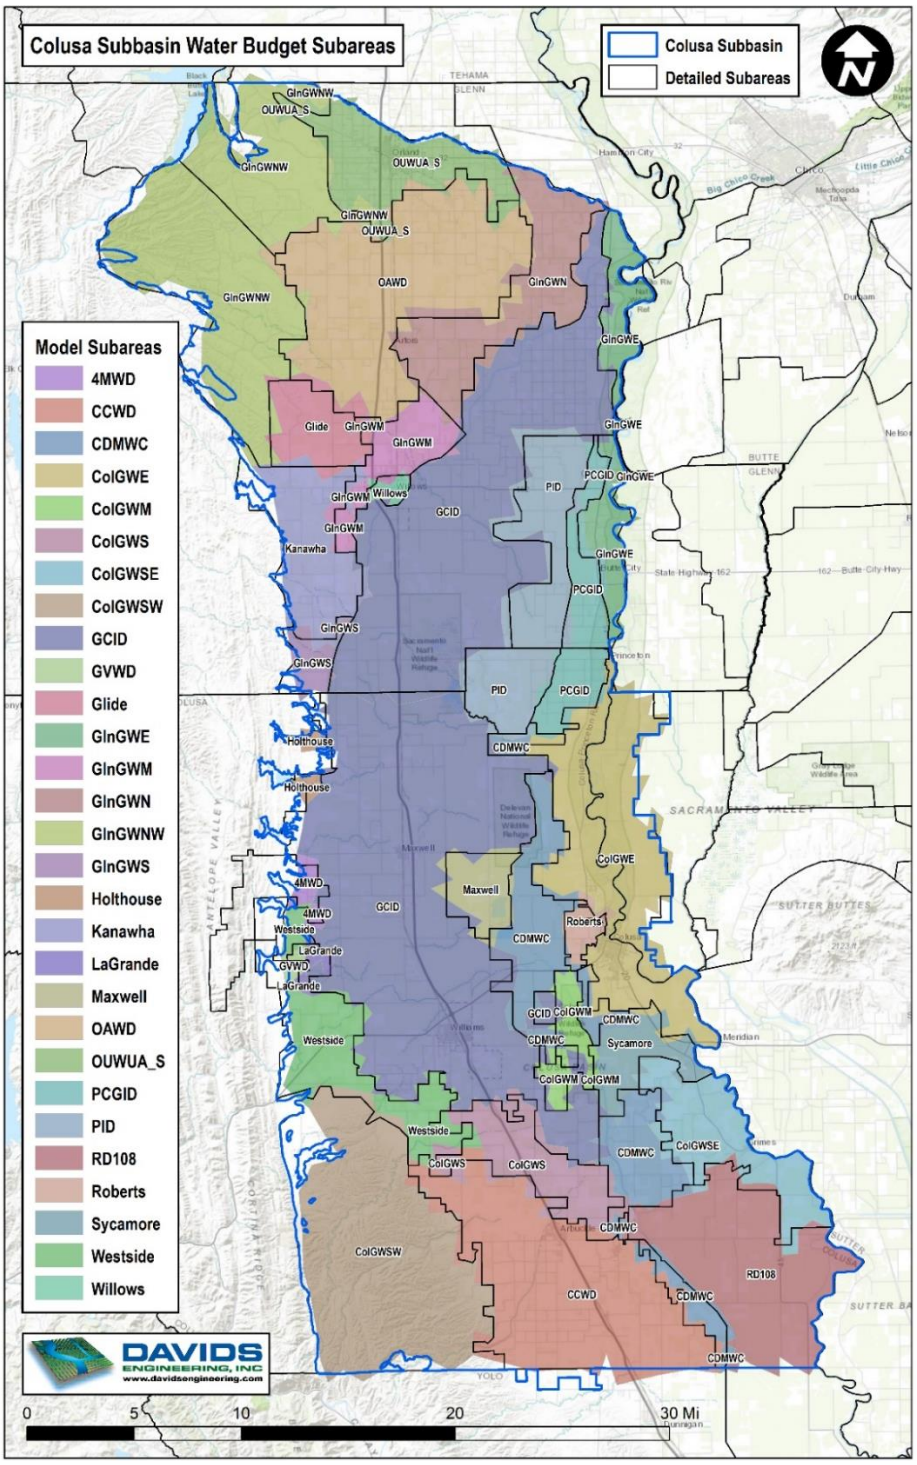

Figure 2. Water Budget Subareas.[1]

[1] Substantial portions of the GCID, PCGID, and PID service areas are located within Colusa and Glenn County. Separate subareas have been evaluated for the portions of each district in each county. The subarea boundaries shown in Figure 2 indicate the boundary line between the Colusa and Glenn County subareas; however, the subarea labels describe only the name of each district.

Uncertainties and Limitations

All estimates of water budget components are subject to uncertainty. These uncertainties arise from potential inaccuracies of input data, errors in assumptions, limitations of model processes used to simulate the physical world, and other factors. The basin-wide and subarea water budgets developed for the Colusa Subbasin for planning purposes to support GSP development have been assembled using the best available science and data. Uncertainties in the water budget are described with the subbasin water budget results in Chapter 3 of the Colusa Subbasin GSP.

Summary of Historical Water Budgets

This section summarizes the historical water budget results across all subareas in the Colusa Subbasin. Results presented in this section are generally extracted from the C2VSimFG-Colusa model outputs and summarized as average annual values over the historical water budget period (water years 1990-2015). Annual results for all water years during the 1990-2015 period are presented for each subarea in the final section of this TM.

Land Use Summary

Table 5 provides a summary of the total acreage simulated in each subarea and the average percent of the total area represented by each of the four general land use types over the 1990-2015 period. The total acreage of each subarea ranges from less than 1,000 acres (GVWD) to more than 100,000 acres (GCID subarea in Colusa County).

Across all subareas, non-ponded agriculture represents approximately 41 percent of the total area simulated in the C2VSimFG-Colusa model during the 1990-2015 period, while ponded-crops and managed wetlands represent approximately 30 percent of the total area. Across most subareas, non-ponded agriculture represents at least 20 percent of the total area. Ponded crops and managed wetlands represent a wider range of areas, from less than 5 percent in several water districts and subregions largely comprised of urban areas or undeveloped native vegetation, to more than 70 percent of the total area in Maxwell W.D., PID, and the PCGID subarea in Colusa County.

Native vegetation represents approximately 24 percent of the total acreage across all subareas. Urban/rural residential areas represent less than 10 percent of the total acreage in most subareas except those representing cities, such as Willows, or regions with higher urban or residential populations.

Table 5. Total Area and Average Percent of Total Area by General Land Use Type for all Subareas, 1990-2015.

Subarea Name	Total Area (acres)	Average Percent Total Area by General Land Use Type, 1990-2015 (percent)

Surface Water Budget Summary

This section summarizes average results of key components in the subarea surface water budgets. Average results are summarized from the C2VSimFG-Colusa model outputs over the 1990-2015 period. The complete annual surface water budget results for each subarea over the entire 1990-2015 period are summarized in the final section of this TM.

Total Inflows

Table 6 summarizes the average annual total inflows to the surface water budget for all subareas. Total inflows include surface water (SW) diversions into the subarea, groundwater (GW) pumping, and total precipitation that falls within the subarea. Across all subareas, average total inflows are estimated to be more than 3.11 million acre-feet (maf), or approximately 4.4 acre-feet per acre (af/ac). On average, approximately 45 percent of this total (1.42 maf) is comprised of SW diversions, approximately 16 percent (0.50 maf) is comprised of GW pumping, and the remaining 38 percent (1.20 maf) is precipitation.

In individual subareas, average total inflow volumes range from less than 10 thousand acre-feet (taf) in smaller water districts and subareas to more than 600,000 acre-feet in the GCID subarea in Colusa County, the largest of all subareas. Adjusted for area, average total inflows are typically between 2 and 6 af/ac, with typically higher values in subareas with greater access to SW diversions. In both the Colusa and Glenn County subareas of PCGID, average total inflows exceed 9 af/ac, of which approximately 80 percent is supplied by SW diversions.

The portion of total inflows supplied by GW pumping varies among subareas, but is generally higher in "groundwater" subareas outside the service areas of surface water suppliers. In these "groundwater" subareas, SW diversions are generally unavailable or limited to individual water rights users.

The portion of total inflows supplied by precipitation is approximately 30 percent or more in most subareas. While only a portion of the total precipitation is consumed within each subarea, precipitation is the primary water supply for much of the native vegetation in the Colusa Subbasin, and also supplies valuable soil moisture to support winter crops and other crops in the early spring months.

Table 6. Average Annual Total Inflows to the Surface Water Budget for all Subareas, 1990-2015.

Subarea Name	Average Annual Total Inflows, 1990-2015		Percent Average Total Inflows by Water Source, 1990-2015

Net Recharge

Table 7 summarizes the simulated average net recharge from the surface water system for each subarea over the 1990-2015 period. Net recharge from the subarea water budgets is defined as the sum of groundwater recharge from the surface water system caused by water use and water management within the subarea (percolation from the land surface plus seepage from canals and drains) minus the sum of groundwater extraction from the groundwater system within the subarea (GW pumping).

Net recharge is a useful metric for understanding and analyzing the combined effects of land surface processes on the underlying groundwater system. When calculated from the historical water budget, average net recharge represents the average additional recharge that exceeds pumping (when positive) or the average additional groundwater pumping in excess of recharge (when negative) that occurs in the surface water system based on historical cropping, land use practices, and average hydrologic conditions.

Notably, the calculation of net recharge does not consider the net seepage or stream gains exchanged between the groundwater system and rivers and streams on the land surface. Stream seepage and stream gains also impact the groundwater budget (see Table 3); however, stream seepage and stream gains are driven by many factors that are not all directly related to or caused by water use and water management within a given subarea. The calculation of net recharge is also not meant to connote change in groundwater storage because it does not include subsurface inflows and outflows. Change in groundwater storage is reported in the groundwater budget results in the following section.

Over all subareas, the total average annual net recharge is approximately 76.8 taf per year, indicating that across all subareas the simulated groundwater recharge exceeds the simulated groundwater extraction, on average, during the 1990-2015 period. On a per-acre basis, the average annual net recharge across all subareas is approximately 0.11 af/ac. Within individual subareas, average net recharge ranges from more than 1.0 af/ac (indicating that recharge exceeds pumping) within subareas that have access to substantial surface water supplies, to less than -1.0 af/ac (indicating that pumping exceeds recharge) within many of the “groundwater” subareas located outside the service areas of surface water suppliers. In-lieu groundwater recharge projects that provide surface water supplies to irrigated lands in “groundwater” subareas would help to offset some of these localized shortages, and would help to increase net recharge subbasin-wide if additional surface water could be imported into the Colusa Subbasin.

Percolation across all subareas contributes approximately 438 taf per year to the groundwater system, and seepage from canals and drains contributes approximately 139 taf per year. During the 1990-2015 period, nearly 85 taf of seepage was contributed each year by the GCID distribution system, including the district’s 65-mile Main Canal and nearly 1,000 miles of other canals, laterals, and drains. Groundwater pumping across all subareas totals nearly 500 taf per year, on average, with higher volumes generally in “groundwater” subareas without access to significant volumes of surface water.

Table 7. Average Annual Net Recharge for all Subareas, 1990-2015.

Subarea Name	Average Annual Net Recharge (a+b-c), 1990-2015		Average Volume, 1990-2015 (acre-feet, rounded)

[1] Percolation from the land surface within the subarea. Does not include simulated percolation from upslope small watersheds originating from outside the subarea.

[2] Seepage from canals and drains within the subarea. Does not include seepage from rivers and streams.

Groundwater Budget Summary

Table 8 summarizes the average simulated change in storage and cumulative change in storage from the subarea groundwater budgets. These results are summarized from the C2VSimFG-Colusa model outputs over the 1990-2015 period. The complete annual groundwater budget results for each subarea over the entire 1990-2015 period are summarized in the final section of this TM.

Across all subareas, the average simulated change in storage in the groundwater system is approximately -27.5 taf per year over the 1990-2015 period, or approximately -0.04 af/ac, indicating a net decrease in groundwater storage across all subareas. This change in storage equates to a change in groundwater storage of less than 0.5 inches over the aggregate area of all subareas. The cumulative change in groundwater storage across all subareas over the 1990-2015 period is approximately -717 taf per year, or approximately -1.0 af/ac in total.

In individual subareas, the average change in groundwater storage varies between approximately 1 taf and -6 taf per year, and between approximately 0.01 af/ac (less than 0.2 inches) to approximately -0.12 af/ac -1.3 inches) per year.

It is noted that change in groundwater storage is strongly affected by modeled estimates of subsurface groundwater flows. Subsurface groundwater flows are in turn strongly affected by the model calibration and the variable quality and timing of available groundwater level data that may be used to create and calibrate model inputs. Inaccuracies or inadequacies in the historical model calibration have the potential to strongly bias subsurface lateral flow calculations. Likewise, groundwater level data represent only discrete snapshots of groundwater levels, and may not adequately represent all spatial and temporal changes in groundwater flows. Thus, the change in storage and cumulative change in storage calculations for all subareas, especially small subareas, are reported only for general and relative understanding of the groundwater budget simulation results for regions within the Colusa Subbasin. Firm conclusions cannot be drawn from individual subarea groundwater budget results.

Table 8. Average Change in Storage and Cumulative Change in Storage for all Subareas, 1990-2015.

Subarea Name	Average Change in Storage, 1990-2015		Cumulative Change in Storage, 1990-2015

Historical Water Budgets by Subarea

Historical water budgets for each subarea are presented on the following pages. Information for each subarea is listed in numerical order based on the subarea number listed in Table 4.

For all subareas, annual values are provided for the 1990-2015 historical water budget period in both tabular and graphical form, summarizing the following information:

- **Land use**: Annual acreage and average acreage, presented for each general land use type listed in Table 1 (ponded crops and managed wetlands separated into rice and managed wetlands)
- **Surface Water Budget**: Annual volumes and average annual volumes (in acre-feet) for all components listed in Table 2, summarized by water year type according to the Sacramento Valley Water Year Index[2]
- **Groundwater Budget**: Annual volumes and average annual volumes (in acre-feet) for all components listed in Table 3, summarized by water year type according to the Sacramento Valley Water Year Index

Inflows to the surface water budget and groundwater budgets are presented as positive values in each figure, while outflows are presented as negative values. Net recharge (in the surface water budget) and cumulative change in groundwater storage (in the groundwater budget) are presented as line graphs.

In general, surface water diversions and groundwater pumping represent the greatest combined inflows to the surface water budget, with greater surface water diversions generally in subareas representing the service areas of surface water suppliers and greater groundwater pumping in "groundwater" subareas outside those service areas. The greatest outflows from the surface water budget are generally evapotranspiration and percolation in some subareas. Higher volumes of runoff occur in wet years when greater precipitation occurs, and higher volumes of seepage occur within surface water supplier service areas.

Inflows and outflows to and from the groundwater system vary significantly between subareas. In many of the primarily agricultural subareas, percolation of irrigation water is a major inflow and groundwater pumping is a major outflow from the groundwater system. In subareas adjacent to gaining reaches of the Colusa Basin Drain and the Sacramento River, stream gains also represent a major outflow from the groundwater budget and inflow to the surface water budget. In adjoining subareas with significantly different water supplies and demands, such as surface water supplier service areas adjacent to "groundwater" areas, net subsurface inflows between those subareas also represent a major water budget component. Generally, greater subsurface inflows enter "groundwater" areas, and greater subsurface outflows (negative net subsurface inflows) leave surface water supplier service areas or other subareas where significant seepage occurs. However, as described previously, the change in storage and cumulative change in storage calculations for all subareas, especially small subareas, are reported only for general and relative understanding of the groundwater budget simulation results for regions within the Colusa Subbasin. Firm conclusions cannot be drawn from the individual subarea groundwater budget results.

Specific water budget results vary between subareas, as shown in the results that follow.

[2] The Sacramento Valley Water Year Index classifies water years as wet, above normal, below normal, dry, or critical based on Sacramento River unimpaired flows. Additional details describing the Sacramento Valley Water Year Index are available from the California Data Exchange Center.

Evaluation of Depletions of Interconnected Surface Water in the Colusa Subbasin

(THIS PAGE LEFT BLANK INTENTIONALLY)

Specialists in Agricultural Water Management
Serving Stewards of Western Water since 1993

Technical Memorandum

To: Colusa Groundwater Authority and Glenn Groundwater Authority

From: Davids Engineering

Date: July 12, 2021

Subject: **Evaluation of Depletions of Interconnected Surface Water in the Colusa Subbasin**

Introduction

The Groundwater Sustainability Plan (GSP) emergency regulations (emergency regulations), described in 23 CCR §354.28[1], stipulate that Groundwater Sustainability Agencies (GSAs) shall establish minimum thresholds that quantify groundwater conditions for each applicable sustainability indicator that, if exceeded, may cause undesirable results. One of the applicable sustainability indicators in the Colusa Subbasin (Subbasin) is "Depletions of Interconnected Surface Water," referred to in this memorandum as streamflow depletion. The emergency regulations require that the minimum threshold for streamflow depletion be determined based on "the rate or volume of surface water depletions caused by groundwater use that has adverse impacts on beneficial uses of the surface water and may lead to undesirable results" (23 CCR §354.28(c)(6)). The regulations also allow that groundwater levels can be used as a proxy for setting minimum thresholds for streamflow depletion, provided that adequate evidence is given to demonstrate that groundwater levels are a reasonable proxy for those minimum thresholds (§354.28(d)).

Direct quantification of streamflow depletion is a challenge in the Colusa Subbasin because of the substantial distance between streamflow measurement sites and the Subbasin boundaries, and also because the volume of streamflow depletion is small relative to the total volume of streamflow, resulting in measurement accuracy issues. Given these challenges, the two GSAs in the Colusa Subbasin (the Colusa Groundwater Authority GSA and the Glenn Groundwater Authority GSA) elected to use near-stream groundwater levels as a proxy for setting streamflow depletion minimum thresholds. Chapter 4 of the Colusa Subbasin GSP, *Monitoring Networks,* shows the location of representative monitoring wells in the interconnected surface water representative monitoring network. Groundwater levels in the vicinity of a stream or river are considered to be a reasonable proxy for monitoring depletions of surface water (EDF, 2018).

[1] California Code of Regulations, Title 23, Division 2, Chapter 1.5, Subchapter 2 Groundwater Sustainability Plans, Article 5, Section 354.28 Minimum Thresholds.

This memorandum presents and discusses results of the C2VSimFG-Colusa model (model) used to evaluate stream-aquifer interactions in the Colusa Subbasin. This memorandum provides a foundation to support the Colusa Subbasin GSP development with respect to streamflow depletion. The results reflect the simulated groundwater elevations and stream water surface elevations that, together with streambed and aquifer properties, determine the simulated streamflow accretions and depletions over time. This memorandum does not directly address quantitative minimum thresholds for streamflow depletion. Minimum thresholds for streamflow depletion are identified and discussed in the Colusa Subbasin GSP.

The Colusa Subbasin underlies approximately 724,000 acres in California and experiences significant variability in groundwater conditions in certain areas. Due to the large size and variability in conditions, the groundwater model is not currently well calibrated. This leads to greater uncertainty in simulated groundwater levels and streamflow depletions in some areas. Potential future refinements to the C2VSimFG-Colusa Model are noted at the end of this TM and are described in Appendix 3D of the GSP. However, at the time of GSP development the model is considered to provide the best available information on groundwater conditions in the Subbasin, and the accuracy of this information is generally sufficient to support GSP preparation, including description of streamflow depletion and related groundwater levels. For simplicity, hereinafter stream accretions are referred to as “gains” and depletions as “losses.”

Analytic Approach

Modeling Approach

Streamflow depletion in the Colusa Subbasin was evaluated using the C2VSimFG-Colusa model (model), an integrated hydrologic flow model for the Colusa Subbasin. Development and refinement of this model to support GSP development is described in Appendix 3D. The model was adapted from the Fine Grid California Central Valley Groundwater-Surface Water Simulation Model (C2VSimFG).

The model simulates inflows and outflows between the Subbasin surface water system and groundwater system in a grid of land elements, stream nodes, and groundwater nodes that span and surround the Colusa Subbasin. The model calculates a water budget for each element and node on a monthly timestep for different historical, current, and future scenarios described in the GSP. Results of these element and node-level water budgets are aggregated to quantify the historical, current, and future water budgets for the entire Colusa Subbasin, as required in the GSP regulations.

Stream gains (flows from groundwater into the stream) and stream losses (flows from the stream to groundwater) are quantified as components of the element and node-level water budgets along streams explicitly simulated in the Subbasin. Groundwater levels are also quantified within this model. Additional information about how the model operates, its inputs, and assumptions are provided in the model documentation and Appendix 3D.

Modeled Streams and Stream Reaches

There are four surface waterways that are explicitly represented in the model and that can be directly simulated to evaluate streamflow depletion in the Colusa Subbasin under different model scenarios:

1) The Sacramento River, which borders the Colusa Subbasin along most of its eastern boundary and runs through a portion of the Subbasin where the subbasin boundary lies east of the river,
2) Stony Creek, which borders the northern edge of the Subbasin,
3) The Colusa Basin Drain (Colusa Drain), which originates within, flows southward through, and exits the Subbasin at the Colusa-Yolo Subbasin boundary, and
4) The Glenn-Colusa Irrigation District Main Canal (GCID Canal), which originates at its point of diversion from the Sacramento River north of Hamilton City in the Corning Subbasin.

This analysis addresses all of the waterways listed above except the GCID Canal. The GCID Canal is excluded because it lies mostly within the subbasin, is fed by regulated surface water supplies, and does not have sensitive habitat along it.[2] In contrast, the Sacramento River, Stony Creek, and the Colusa Drain support riparian habitat and are also connected to the larger Sacramento River system with its many downstream users.

Water budget calculations are made for each model element for each monthly timestep, including the elements that adjoin the four streams named above[3]. The stream-adjoining elements were assigned to stream reaches for analysis, with each stream separated into two reaches as follows:

- Sacramento River
    - Glenn (Glenn County reach)—the portion of the Sacramento River adjoining the subbasin north of the Glenn-Colusa County line
    - Colusa (Colusa County reach)—the portion of the Sacramento River adjoining the subbasin south of the Glenn-Colusa County line. (Note that a portion of this reach runs through the subbasin rather than bounding it.)
- Stony Creek
    - Upper Stony Creek—the portion of the creek that is less likely to be connected to groundwater (based on separate analysis[4])
    - Lower Stony Creek—the portion of the creek that is more likely to be connected to groundwater
- Colusa Drain
    - Colusa Drain Above GCID Canal Confluence—the portion of the drain upstream of the Glenn Colusa Canal end-spill into the drain
    - Colusa Drain Below GCID Canal Confluence —the portion of the drain downstream of the Glenn Colusa Canal end-spill into the drain

[2] An analysis of groundwater dependent ecosystems in the Colusa Subbasin is described in Section 3.2.8 of the GSP.

[3] Additional information on the C2VSimFG-Colusa model is provided in Appendix 3D.

[4] An analysis of groundwater levels relative to the Stony Creek streambed is described in Section 3.2 of the GSP.

These reaches and their associated model elements are illustrated in ***Figure 1***. Note that for streams that bound the Colusa Subbasin, only the model elements along the Colusa Subbasin side of the stream were selected for analysis. In contrast, for streams or reaches flowing within the subbasin, elements on both sides of the stream were selected for analysis.

Model Scenarios

Stream gains and losses were extracted from the model results for the elements selected along each reach (***Figure 1***) and summed to get an aggregate gain or loss for each monthly timestep. This analysis was done for three model scenarios:

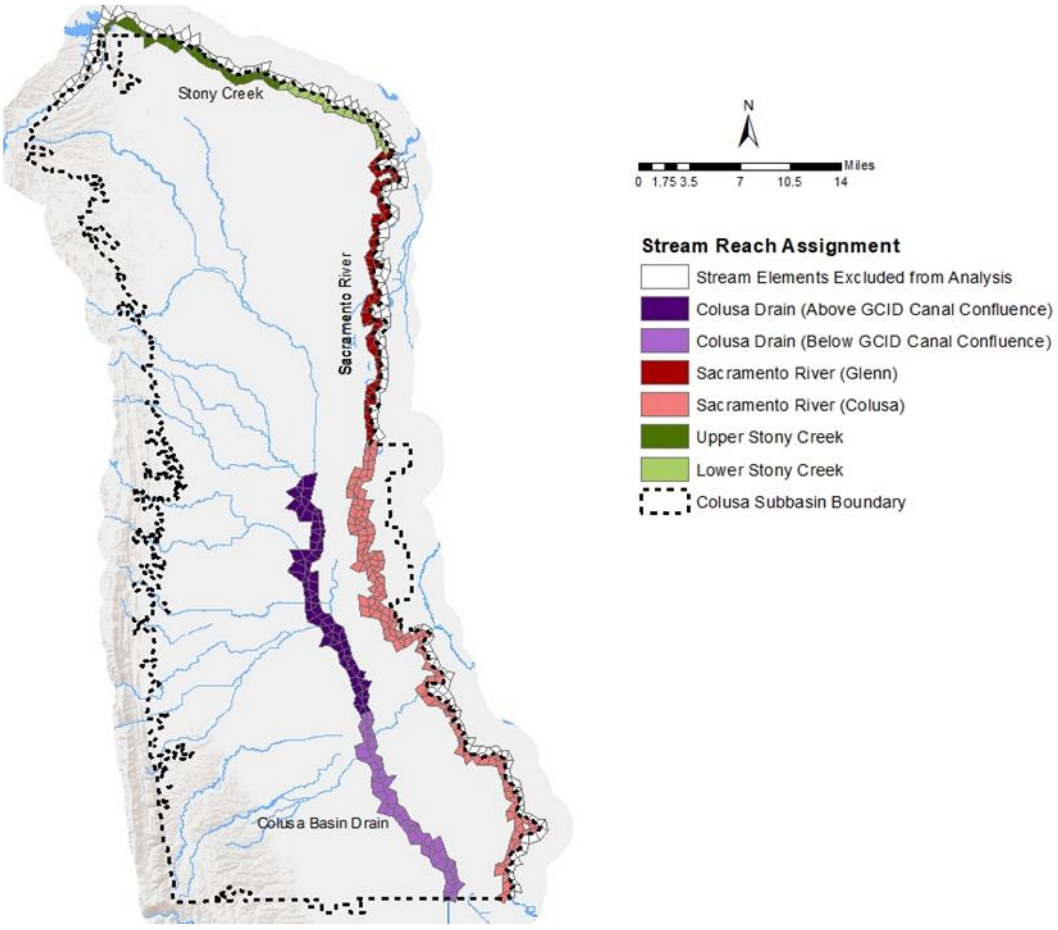

Figure 1. Modeled Streams and Stream Reaches Evaluated for Stream-Aquifer Interactions

- Scenario 1—Projected Future Conditions without Climate Change and without Projects. This is the baseline projection of future conditions over the 50-year period from 2016 through 2065, assuming no climate change and no groundwater recharge or other types of projects are implemented.

- Scenario 2—Projected Future Conditions with 2070 Climate Change and without Projects. This is the same as the Scenario 1 baseline, except that precipitation, evapotranspiration, and surface water supplies were adjusted in the model inputs to reflect the estimated effects of climate change based on the 2070 Central Tendency climate change datasets provided by DWR to support GSP development.[5] The main effect of these adjustments is an estimated increase in future crop water requirements, which result in the need for increased groundwater pumping. It is further assumed that a no groundwater recharge or other types of projects are implemented. Thus, differences in model results between this scenario and Scenario 1 are due entirely to the effects of climate change.
- Scenario 3—Projected Future Conditions with 2070 Climate Change and with Projects. This is the same as the Scenario 2 except that it is assumed that three recharge projects are in operation for the full duration of the 50-year simulation. Thus, differences in model results between this scenario and Scenario 2 are due entirely to the effects of the projects.

Hereinafter, for convenience, these model scenarios are referred to as Scenarios 1, 2, and 3, respectively.

The analysis period and assumptions about hydrology, land use, and water supplies associated with each of the three model scenarios are summarized in. Projected future water supplies and land use are expected to vary depending on Shasta watershed hydrologic conditions, which are monitored and reported by the Bureau of Reclamation (Reclamation). Water supplies and flows through the Colusa Subbasin may be reduced in hydrologic years designated by Reclamation as "Shasta Critical"[6], such as 2015, resulting in reduced cropped acreage in those years. In "Shasta Non-Critical" years, water supplies and land use are expected to be similar to current conditions in recent non-drought years, such as 2013. Additional information on Scenarios 1 and 2 is provided in Chapter 3, Section 3.3, of the Colusa Subbasin GSP. The projects modeled in Scenario 3 are described in the next section.

[5] Climatological, hydrological, and water operations datasets, change factors, and the DWR Climate Change Resource Guide are available at: https://data.cnra.ca.gov/dataset/sgma-climate-change-resources.

[6] In general, "Shasta Critical" conditions are declared when the forecast inflow to Lake Shasta for a particular water year is equal to or less than 3.2 million acre-feet. Conversely, Shasta Non-Critical conditions are declared when the forecast inflow to Lake Shasta for a particular water year exceeds 3.2 million acre-feet. Between 1966-2015, five years were "Shasta Critical," or approximately 1 in 10 years.

Table 1. Summary of Water Budget Assumptions Used for Future Conditions without Projects, Future Conditions with 2070 Climate Change without Projects, and Future Conditions with 2070 Climate Change with Projects

Model Scenario	Analysis Period[1]	Hydrology	Land Use	Water Supplies
Scenario 1: Projected Future Conditions, without Climate Change and without Projects (Baseline)	2016-2065	Historical (1966-2015)	Current (2013 and 2015) used for Shasta Non-Critical and Shasta Critical, respectively	Current (2013 and 2015) used for Shasta Non-Critical and Shasta Critical, respectively, for water diversions; 2006-2015 average for urban demands
Scenario 2: Projected Future Conditions, with 2070 Climate Change and without Projects (Baseline)	2016-2065	Historical (1966-2015), adjusted based on 2070 Central Tendency climate change datasets	Current (2013 and 2015) used for Shasta Non-Critical and Shasta Critical, respectively	Same as Current (see above), adjusted for 2070 Central Tendency climate change
Scenario 3: Projected Future Conditions with 2070 Climate Change with Projects	2016-2065	Historical (1966-2015), adjusted based on 2070 Central Tendency climate change datasets	Current (2013 and 2015) used for Shasta Non-Critical and Shasta Critical, respectively	Same as Current (see above), adjusted for 2070 Central Tendency climate change

[1] Results over analysis period are summarized by water year (October 1 through September 30)

Groundwater Recharge Projects Modeled in Scenario 3

There are five recharge projects described in the Colusa Subbasin GSP that are on track for implementation. Three of those projects were selected for simulation in the model Scenario 3 because they are substantial recharge projects that could have large effects on groundwater conditions relative to other projects and management actions. The three modeled projects are described below.

Colusa County Water District In-Lieu Groundwater Recharge

Colusa County Water District (CCWD) has a total service area of approximately 46,000 acres, of which 39,875 acres are currently irrigable with existing District infrastructure. This area is predominantly planted to permanent crops. CCWD delivers surface water to approximately 35,000 acres, with the remaining acres being idle or irrigated with privately pumped groundwater. CCWD has a Central Valley Project (CVP) water supply contract that provides a maximum of 62,200 acre-feet (af) annually. CCWD also holds a CVP contract water supply for 5,666 af that was part of a Colusa County subcontract assigned to CCWD in 2006. Both contracts are subject to curtailments determined by Reclamation each year based on Shasta watershed hydrologic conditions.

Additionally, CCWD typically transfers in CVP water supplies purchased from others to augment water available under its CVP contract. Historical transfers have been primarily from Westside Water District and, more recently, from Reclamation District 108 (RD108) under a five-year pilot transfer agreement that ends in 2022. Despite the availability of surface water, some CCWD growers choose to pump

groundwater because it is less expensive than surface water and because groundwater requires less screening and filtering compared to surface water.

Under the CCWD In-Lieu Groundwater recharge project, CCWD will acquire additional surface water and incentives will be put in place to make the cost of surface water the same or less than the cost of pumping groundwater, thereby incentivizing growers who would otherwise use groundwater to use surface water. The additional surface water is expected to be acquired under long-term water transfer agreements with other CVP contractors, including Sacramento River Settlement Contractors (settlement contractors), and potentially other sources. The plan is to acquire and deliver 30,000 acre-feet per year (AF/yr) except in Shasta Critical years (approximately one in 10 years[7]) when groundwater stored through in-lieu recharge in prior years would be used. For modeling, it was assumed that 30,000 AF/yr will be delivered to irrigated agricultural land in model elements that approximately represent the CCWD service area during Shasta Non-Critical years in the 2016-2065 analysis period. Based on the model results, the average additional surface water use, and thus the average in-lieu groundwater recharge benefit, over the 2016-2065 analysis period is estimated to be approximately 27,000 AF/yr.

Orland-Artois Water District Land Annexation and Groundwater Recharge

Orland-Artois WD (OAWD) has an existing service area of about 29,000 acres and delivers water to district landowners through 110 miles of pipelines and 300 metered deliveries. Surface water delivered by OAWD is available under a CVP water supply contract with Reclamation and through short- and long-term transfer agreements with other CVP water contractors and settlement contractors. OAWD's water supply contract provides a maximum of 53,000 AF/yr, subject to curtailments determined by Reclamation each year based on Shasta watershed hydrologic conditions. Historically, water transfers have been from Maxwell Irrigation District, Princeton-Codora-Glenn Irrigation District, and others.

OAWD is working with a group of neighboring non-district landowners to annex approximately 12,000 acres of groundwater-dependent agriculture into the district. Additional surface water for the annexed lands would be secured through multi-year purchase or transfer agreements with willing sellers, conveyed through the existing Tehama-Colusa (TC) Canal[8], and distributed to the annexed lands through new distribution facilities. Potential transferors include CVP water supply contractors and settlement contractors. The plan is to acquire and deliver 25,000 AF/yr of surface water to the annexed lands except in Shasta Critical years (approximately one in 10 years) when groundwater banked through in-lieu recharge in prior years would be used. For modeling, it was assumed that 25,000 AF/yr will be added to OAWD available supplies and delivered to irrigated agricultural land in model elements that represent existing OAWD lands and the 12,000 acres that OAWD plans to annex. The additional 25,000 AF/yr is available in only in Shasta Non-Critical years in the 2016-2065 analysis period. Based on the model results, the average additional surface water use, and thus the average in-lieu groundwater recharge benefit, over the 2016-2065 analysis period is estimated to be approximately 22,500 AF/yr.

[7] Over the 50-year period from 1966-2015, five years were classified as "Shasta Critical."

[8] The Tehama-Colusa Canal has a maximum capacity of approximately 2,530 cubic feet per second at the canal inlet (Stene, 1994), and a capacity of approximately 1,700 cubic feet per second at the southern end of the canal. Considering historical canal operations, it is likely that conveyance capacity is available to facilitate such a program, subject to certain conditions (see Appendix A).

Colusa Subbasin Multi-Benefit Groundwater Recharge

The Colusa Groundwater Authority and The Nature Conservancy (TNC) collaborated on a multi-benefit pilot project from 2018 through 2020 to demonstrate direct groundwater recharge and creation of habitat for migrating shorebirds. The pilot project concluded that multi-benefit recharge is feasible and does generate the intended recharge and habitat benefits, serving as an example of how a Colusa Subbasin-wide program could work. For purposes of modeling, the following assumptions and approach were used. Lands with the following characteristics were assumed to enroll in the program:

- Location
    - Within a surface water supplier service area
    - Within 6 miles of the Sacramento River (to have maximum mitigating effects on streamflow depletion, which would not necessarily be a factor in a subbasin-wide program)
- Desirable recharge characteristics (Soil Agricultural Groundwater Banking Index [SAGBI] of moderately good or better
- Minimum size 25 acres

A total of 4,122 acres in 46 model elements satisfy the above criteria. For this analysis, it was assumed, as a maximum "bookend" scenario, that all lands that satisfy the above criteria would be flooded for 30 days (during the month of September) each year, except in Shasta Critical years due to likely water shortages in those years.

Based on the model results, the average additional groundwater recharge (i.e., deep percolation) attributable to the Colusa Subbasin multi-benefit groundwater recharge project is estimated to be approximately 5,200 AF/yr over the 2016-2065 analysis period (including Shasta Critical years when no flooding was done), or 1.25 acre-feet per acre (AF/ac) of additional groundwater recharge.

Results

The results of the streamflow depletion analysis developed using the model outputs are summarized below. The summary is focused primarily on simulated streamflow "net gains," calculated as simulated stream gains minus simulated stream losses from elements along the modeled stream reaches (***Figure 1***). Results are presented in both annual and monthly summaries for the modeled stream reaches to help characterize the quantity and timing of streamflow depletion (23 CCR §354.16(f)). Tables and figures summarizing these results are presented at the end of this TM.

Simulated average annual gains, losses, and net gains are presented for each of the two reaches defined for each stream and for the two reaches combined. Simulated annual gains, losses, and streamflow net gains, and simulated average monthly gains are presented only for the two reaches combined. As described above, there is significant uncertainty in simulated groundwater levels and streamflow depletions in some areas of the Subbasin resulting from issues with calibration of the groundwater model. However, at the time of GSP development the model is considered to provide the best available information on groundwater conditions in the Subbasin, and the accuracy of this information is generally sufficient to support GSP preparation, including description of streamflow depletion and related groundwater levels. Potential future refinements to the C2VSimFG-Colusa Model are noted at the end of this TM.

In the following discussion, simulated gain and loss water volumes are expressed in terms of thousand acre-feet per year (TAF/yr) rounded to the nearest tenth TAF/yr, while in the supporting tables, the volumes are presented in AF/yr. Annual and average annual volumes are summarized by water year (October 1 – September 30).

Sacramento River

Simulated Average Annual Gains and Losses by Reach

Simulated average annual stream gains, losses, net gains, and net gain as a percentage of average reach flow are presented in **Table 2** for the previously defined Glenn and Colusa reaches of the Sacramento River, and for the two reaches combined.

Glenn Reach

For the Glenn reach under Scenario 1, simulated average gains are 72.4 TAF/yr and losses are 25.3 TAF/yr, resulting in a simulated net gain of 47.1 TAF/yr. The simulated net gain is 0.4 percent of the simulated average reach flow of approximately 11.2 million acre-feet per year (MAF/yr). Under Scenario 2, simulated average gains along the Glenn reach are 66.2 TAF/yr and losses are 28.8 TAF/yr resulting in a simulated net gain of 37.4 TAF/yr, or 0.3 percent of the simulated average reach flow of 11.3 MAF/yr. The decreased gains and increased losses relative to Scenario 1 generally result from the increased groundwater pumping needed to meet simulated irrigation demands. Irrigation demands are expected to increase because crop evapotranspiration rates are expected to generally increase with climate change. The slightly increased simulated average reach stream flow between Scenarios 1 and 2 is due to increased precipitation and runoff estimated to occur due to climate change.

Under the "with projects" Scenario 3, the Glenn reach gains increase slightly relative to Scenario 2, but do not recover to Scenario 1 levels. Similarly, the Glenn reach losses are reduced relative to Scenario 2 but are not reduced to the levels of Scenario 1. As shown in **Table 2**, these relative differences are very small and expected to be within the uncertainty of the model results. Analysis of near-stream groundwater levels in relation to stream stages is needed to better understand whether these relative differences are significant.

Colusa Reach

In contrast with the Glenn reach, simulated losses exceed gains in the Colusa reach of the Sacramento River, resulting in a simulated net loss under all three scenarios (**Table 2**). Under Scenario 1, simulated average gains are 148.1 TAF/yr and losses are 161.4 TAF/yr, resulting in a simulated net loss (negative net gain) of 13.2 TAF/yr. The simulated net gain is 0.1 percent of the simulated average reach flow of approximately 10.9 MAF/yr. Under Scenario 2, simulated average Colusa reach gains are 142.6 TAF/yr and losses 171.4 TAF/yr resulting in a simulated net loss of 28.8 TAF/yr, or 0.3 percent of the simulated average reach flow of 11.0 MAF/yr. Differences between Scenarios 1 and 2 are generally related to the same factors discussed above for the Glenn reach.

Under the "with projects" Scenario 3, Colusa reach gains increase slightly relative to Scenario 2, but do not recover to Scenario 1 levels. Similarly, Colusa reach losses are reduced relative to Scenario 2 but are not reduced to the levels of Scenario 1. Similar to the Glenn reach, analysis of near-stream groundwater

levels in relation to stream stages along the Colusa reach is needed to better understand whether these relative differences are significant.

Glenn and Colusa Reaches Combined

The combined effect of simulated groundwater conditions in the Colusa Subbasin on Sacramento River simulated streamflow is modest stream gains ranging between 8.7 TAF/yr and 33.9 TAF/yr, depending on the scenario. These simulated gains correspond to a range of 0.1 to 0.3 percent of the average annual reach flow. The year-to-year variation is much greater than the variation between scenarios.

Simulated Annual Gains and Losses for Combined Reaches

Simulated annual gains, losses, and net gains for the entire portion of the Sacramento River adjoining or running through the Colusa Subbasin are listed in **Table 3** for each of the three scenarios, with water year type indicated based on the Sacramento Valley Water Year Index.[9] Over the 50-year projected future simulation period, simulated stream gains in Scenario 1 range between 167.4 TAF/yr (2016, a below normal year) and 266.8 TAF/yr (2034, a wet year). Simulated stream losses range between 110.0 TAF/yr (2026, a critical year) to 260.3 TAF/yr (2023, an above normal year). Simulated annual net gain varies over a wide range of volumes, from a low of -87.6 TAF/yr (2016, a below normal year), indicating net loss, to a high of 123.1 TAF/yr (2026, a critical year). It is noted that the lowest simulated annual net gain occurs in the year with the lowest simulated stream gains (2016) while the highest simulated annual net gain occurs in the year with the lowest simulated stream losses (2026). General patterns of stream gain and loss are similar across all scenarios.

Simulated average annual gains, losses, and net gains by year type are also presented in **Table 3**. The lowest simulated average net gain occurs in below normal year types and the highest simulated average net gain occurs in dry year types. There does not appear to be a clear correlation between year type and simulated average annual net gain, possibly due to potential lagged responses of groundwater levels to varying hydrology, and the occurrence of different year type sequences over time. There are likely many other physical and operational factors influencing Sacramento River gains and losses that are beyond the scope of this analysis.

Simulated annual net gain is graphed in **Figure 2**, illustrating a highly variable pattern across years and the relatively small differences among the model scenarios. As expected based on the time dependency of groundwater flow from recharge areas to discharge areas, there is a general, lagged correlation between simulated annual net gain and sequences of generally wet or dry year types. For example, the high simulated net gains in 2025-2026 (corresponding to historical hydrology in 1974-1975) follow a series of mostly wet years that occurred from 1968-1974. Similarly, the relatively high simulated net gains in 2048-2051 (corresponding to 1997-2000 historical hydrology) occur following a wet sequence from 1994-1999. Downward spikes in simulated annual net gains appear to be related to dry sequences in some cases but not others. For example, the downward spike in 2027 maps to 1976 historical

[9] The Sacramento Valley Water Year Index is calculated as specified in the 1995 California State Water Resources Control Board Water Quality Control Plan, and is used to determine the Sacramento Valley water year type as implemented in SWRCB D-1641. Additional information is available at: https://cdec.water.ca.gov/reportapp/javareports?name=WSIHIST.
The methodology for assigning Sacramento Valley Water Year Indices to projected water years is described in the GSP.

hydrology, with that year being the second of two back-to-back critical years. Likewise, the sharp declines in 2064 and 2065 map to 2013 and 2014, also back-to-back critical years. Other downward spikes are harder to interpret.

Simulated Average Monthly Net Gains for Combined Reaches

Simulated average monthly net gains for the entire portion of the Sacramento River adjoining or running through the Colusa Subbasin are summarized in **Table 4** and **Figure 3** for each of the three scenarios. As noted previously, the C2VSimFG-Colusa model is not currently well calibrated in some areas, causing greater uncertainty in these precise volumes. However, at the time of GSP development the C2VSimFG-Colusa model is considered to provide the best available data on groundwater conditions in the Subbasin. These results are thus provided mainly as a relative summary of the average temporal exchanges between surface water and groundwater, though the actual volumes and timing may vary.

Over the 50-year projected future simulation period, simulated average monthly net gains vary from net negative values in the winter months to net positive values in the spring, summer, and fall. Similar trends are observed across all three scenarios. These results suggest that, on average, surface water in the Sacramento River recharges the groundwater system through seepage in the winter months, and the groundwater system discharges water, on average, to the river at other times of year. Simulated net gains are estimated to decline under the effects of climate change alone (Scenario 2 minus Scenario 1), but are estimated to increase from those levels following implementation of the simulated projects (Scenario 3 minus Scenario 2). Simulated changes in net gains are greatest in December and January when seepage (negative net gain) is expected to increase under the effects of climate change. Simulated net gains are also expected to decrease in mid-summer under the effects of climate change, though projects and management actions are expected to increase net gains most during the summer months. Further analysis of near-stream groundwater levels in relation to stream stages is needed to better understand whether these simulated relative differences are significant to verify the characteristics of stream-aquifer interactions.

Stony Creek

Simulated Average Annual Gains and Losses by Reach

Simulated average annual stream gains, losses, net gains, and net gain as a percentage of average reach flow are presented in **Table 5** for the previously defined reaches along Upper Stony Creek and Lower Stony Creek, and for the two reaches combined.

Upper Reach

Simulated losses exceed gains in Upper Stony Creek, resulting in a simulated net loss (a negative net gain) under all three scenarios. For the upper reach under Scenario 1, simulated average gains are 4.2 TAF/yr and losses are 12.2 TAF/yr, resulting in a simulated net loss of -8.0 TAF/yr, indicating a net loss. The simulated net gain is -4.8 percent of the simulated average reach flow, totaling approximately 166.2 TAF/yr. Under Scenario 2, simulated average upper reach gains are 3.1 TAF/yr and losses are 14.5 TAF/yr, resulting in a simulated net loss of 11.4 TAF/yr, or 6.9 percent of the simulated average reach flow of 164 TAF/yr. The decreased gains and increased losses relative to Scenario 1 generally result from the increased groundwater pumping needed to meet higher evapotranspiration rates and irrigation

demands resulting from climate change. Between Scenarios 1 and 2, simulated average reach flows decrease slightly, potentially as a result of the decreased gains and increased losses.

Under the "with projects" Scenario 3, the upper reach gains increase slightly relative to Scenario 2, but do not recover to Scenario 1 levels. Similarly, upper reach losses are reduced relative to Scenario 2 but are not reduced to the levels of Scenario 1. As discussed for the Sacramento River, analysis of near-stream groundwater levels in relation to stream stages is needed to better understand whether these relative differences are significant to verify the characteristics of stream-aquifer interactions.

Lower Reach

Like the upper reach, simulated losses exceed gains in Lower Stony Creek, resulting in a simulated net loss (a negative net gain) under all three scenarios. Under Scenario 1, simulated average gains are 0.7 TAF/yr and average losses are 9.9 TAF/yr, resulting in a simulated net gain of -9.3 TAF/yr. The simulated net gain is -2.9 percent of the simulated average reach flow of approximately 319.4 TAF/yr. Under Scenario 2, average lower reach gains slightly decrease to 0.4 TAF/yr and losses increase to 11.7 TAF/yr, resulting in a simulated net loss of 11.2 TAF/yr, or 3.6 percent of the simulated average reach flow of 313.6 TAF/yr. Differences between Scenarios 1 and 2 are generally related to the same factors discussed above for the upper reach.

Under the "with projects" Scenario 3, lower reach gains increase slightly relative to Scenario 2, but do not recover to Scenario 1 levels. Similarly, lower reach losses are reduced relative to Scenario 2 but are not reduced to the levels of Scenario 1. Similar to the upper reach, analysis of near-stream groundwater levels in relation to stream stages is needed to better understand whether these relative differences are significant.

Upper and Lower Reaches Combined

The combined effect of simulated groundwater conditions in the Colusa Subbasin on Stony Creek simulated streamflow is net losses ranging between 17.2 TAF/yr and 22.6 TAF/yr, depending on the scenario. These losses represent a range of 7.1 to 9.5 percent of the average annual reach flow. The year-to-year variation is much greater than the variation between scenarios.

Simulated Annual Gains and Losses for Combined Reaches

Simulated annual gains, losses, and net gains for the entire portion of Stony Creek adjoining or running through the Colusa Subbasin are listed in **Table 6**, with water year type indicated based on the Sacramento Valley Water Year Index. Over the 50-year projected future simulation period for Scenario 1, simulated stream gains range between approximately 0 TAF/yr (2026 and 2040, both critical years, and 2039, a below-normal year) and 11.4 TAF/yr (2033, a wet year). Simulated stream losses range between 3.3 TAF/yr (in 2026) and 51.1 TAF/yr (in 2027), occurring in two sequential critical years. Overall, Stony Creek has a simulated net loss (negative net gain) in all years, ranging from a loss of 50.6 TAF/yr (2027, a critical year) to a loss of 2.6 TAF/yr (2034, a wet year). General patterns of stream gain and loss are similar across all scenarios.

Simulated average annual gains, losses, and net gains by year type are also presented in **Table 6**. The greatest volume of simulated net loss generally occurs in critical years. Lesser volumes of simulated net loss generally occur in progressively wetter water year types, with the exception of below normal years. However, patterns vary due to the lagged responses of groundwater levels to varying hydrology, and the

occurrence of different year type sequences over time. Other factors may also contribute to Stony Creek losses that are beyond the scope of this analysis.

Simulated annual net gain is graphed in **Figure 4**, illustrating a variable pattern of net loss across all years, and a relatively small differences among the model scenarios. The simulated volume of net loss is generally greatest (i.e., more negative net gain) in Scenario 2, when affected only by climate change, and is generally least in Scenario 1, when unaffected by climate change. Like the Sacramento River, there is a general, lagged correlation between simulated annual net loss and sequences of generally wet or dry year types. For example, the relatively higher (i.e., less negative) net gains in 2025-2026 are simulated based on historical hydrology in 1974-1975, which followed a series of mostly wet years that occurred from 1968 through 1974. In 2027, the significant decline in net gain (significant increase in net loss) corresponds to 1976 historical hydrology, the second of two sequential critical years.

Simulated Average Monthly Net Gains for Combined Reaches

Simulated average monthly net gains for the entire portion of Stony Creek adjoining the Colusa Subbasin are summarized in **Table 7** and **Figure 5** for each of the three scenarios. As noted previously, the C2VSimFG-Colusa model is not currently well calibrated in some areas, causing greater uncertainty in these precise volumes. However, at the time of GSP development the C2VSimFG-Colusa model is considered to provide the best available data on groundwater conditions in the Subbasin. These results are thus provided mainly as a relative summary of the average temporal exchanges between surface water and groundwater, though the actual volumes and timing may vary.

Over the 50-year projected future simulation period, simulated average monthly net gains are negative in all months, indicating net loss (seepage) from the streams to groundwater, with fluctuations between seasons. Seepage is comparatively highest in the winter, and comparatively lowest in spring and mid-fall. Similar trends are observed across all three scenarios. Simulated net gains are estimated to decline further under the effects of climate change alone (Scenario 2 minus Scenario 1), but are estimated to increase from those levels following implementation of the simulated projects (Scenario 3 minus Scenario 2). Further analysis of near-stream groundwater levels in relation to stream stages is needed to better understand whether these simulated relative differences are significant to verify the characteristics of stream-aquifer interactions.

Colusa Drain

Simulated Average Annual Gains and Losses by Reach

Simulated average annual stream gains, losses, net gains, and net gain as a percentage of average reach flow are presented in **Table 8** for the previously defined reaches along Colusa Drain above and below the GCID Canal confluence, and for the two reaches combined.

Colusa Drain Above GCID Canal Confluence

Under all scenarios, the upper reach of the Colusa Drain above the GCID Canal confluence is a significantly gaining reach. In Scenario 1, simulated average gains are 104.9 TAF/yr and losses are only 1 TAF/yr, resulting in a simulated net gain of 103.9 TAF/yr, or 28.5 percent of the simulated average reach flow. In Scenario 2, simulated average gains along Colusa Drain above the GCID Canal confluence

are 95.1 TAF/yr and losses are 1.4 TAF/yr, for a simulated net gain of 93.6 TAF/yr, or 25.4 percent of the simulated average reach flow. While simulated net gains slightly decrease under the effects of climate change, the net gain remains a significant fraction of the reach flow.

Under the "with projects" Scenario 3, simulated net gains along the Colusa Drain above the GCID Canal confluence increase slightly relative to Scenario 2, but do not recover to Scenario 1 levels. Like the Sacramento River and Stony Creek, analysis of near-stream groundwater levels in relation to stream stages is needed to better understand whether these relative differences are significant.

Colusa Drain Below GCID Canal Confluence

In contrast with the upper reach of Colusa Drain, Colusa Drain below the GCID Canal is only a slightly gaining reach in Scenarios 1 and 3, and is a slightly losing reach under the effects of climate change in Scenario 2. In Scenario 1, simulated average gains are 13.5 TAF/yr and average losses are 8.9 TAF/yr, resulting in a simulated net gain of 4.6 TAF/yr. This simulated net gain is just 0.6 percent of the simulated average reach flow of approximately 749 TAF/yr. In Scenario 2, simulated average reach gains decrease to 10.6 TAF/yr and simulated average losses increase to 13.1 TAF/yr, resulting in a net loss of 2.5 TAF/yr, or 0.3 percent of the simulated average reach flow. Differences between Scenarios 1 and 2 are expected to be generally related to the same factors discussed above for the other reaches.

Under the "with projects" Scenario 3, average reach gains increase to 14.2 TAF/yr, above the levels observed in Scenarios 1 and 2. However, losses are reduced relative to Scenario 2 but are not reduced to the levels of Scenario 1, resulting in a slight decrease in net gains relative to Scenario 1, totaling just 4.4 TAF/yr.

Upper and Lower Reaches Combined

Altogether, the Colusa Drain is a significantly gaining stream, with simulated net gains ranging between 91.1 and 108.5 TAF/yr, depending on the scenario. These simulated gains correspond to a range of 16.1 to 19.5 percent of the simulated average annual flow.

Simulated Annual Gains and Losses for Combined Reaches

Simulated annual gains, losses, and net gains for the entire portion of the Colusa Drain running through the Colusa Subbasin are listed in **Table 9**, with water year type indicated based on the Sacramento Valley Water Year Index. Over the 50-year projected future simulation period for Scenario 1, simulated net gains range from 80.8 TAF/yr (2042, a critical year) to 138.3 TAF/yr (2049, a wet year). In general, patterns of stream gain and loss are similar across all scenarios, with the highest gain in Scenario 1 (except 2026) and the lowest gain in Scenario 2.

Simulated average annual gains, losses, and net gains by year type are also presented in **Table 9**. On average, the greatest simulated net gains occur in wet years. Across other water year types, simulated average net gains are generally similar within each scenario, ranging within 2 to 5 TAF/yr. Like the Sacramento River and Stony Creek, patterns of net gain vary due to the lagged responses of groundwater levels to varying hydrology, and the occurrence of different year type sequences over time. Other factors may also contribute to net gains in the Colusa Drain that are beyond the scope of this analysis.

Annual net gain is graphed in **Figure 6**, illustrating a variable pattern of net gain across all years. The year-to-year variation exceeds the variation between scenarios. Simulated net gains are generally greatest in

Scenario 1, when unaffected by climate change, and are generally least in Scenario 2, when affected by climate change and without the benefits of projects. The difference in simulated net gains between these scenarios is generally 10 to 20 TAF/yr. Like the Sacramento River and Stony Creek, there is a general, lagged correlation between annual net loss and sequences of generally wet or dry year types.

Simulated Average Monthly Net Gains for Combined Reaches

Simulated average monthly net gains for the entire portion of Colusa Drain running through the Colusa Subbasin are summarized in **Table 10** and **Figure 7** for each of the three scenarios. As noted previously, the C2VSimFG-Colusa model is not currently well calibrated in some areas, causing greater uncertainty in these precise volumes. However, at the time of GSP development the C2VSimFG-Colusa model is considered to provide the best available data on groundwater conditions in the Subbasin. These results are thus provided mainly as a relative summary of the average temporal exchanges between surface water and groundwater, though the actual volumes and timing may vary.

Over the 50-year projected future simulation period, simulated average monthly net gains are positive in all months, but fluctuate from month to month. Net gains are comparatively lower in the winter and in May and October, and peak in mid spring, late summer, and in November. These seasonal patterns are believed to be related to rainfall runoff from westside streams and rice water management practices including winter flooding of fields for rice straw decomposition. Similar trends are observed across all three scenarios. Simulated net gains are estimated to decline under the effects of climate change alone (Scenario 2 minus Scenario 1), but are estimated to increase from those levels nearly back to the pre-climate change estimates following implementation of the simulated projects (Scenario 3 minus Scenario 2). Further analysis of near-stream groundwater levels in relation to stream stages is needed to better understand whether these simulated relative differences are significant to verify the characteristics of stream-aquifer interactions.

Provisional Observations and Conclusions

The results of this analysis are uncertain, resulting primarily from the C2VSimFG-Colusa model not being well calibrated at this time. The GSAs further recognize that there are data gaps in current understanding of stream-aquifer interactions in the Colusa Subbasin. Therefore, firm conclusions cannot be made regarding the nature and patterns of stream-aquifer interaction in relation to groundwater management activities in the Colusa Subbasin. The following provisional observations and conclusions are made for each of the three streams analyzed, pending refinement of the model and additional data collection and analysis, particularly data describing near-stream, shallow groundwater levels and groundwater gradients. To close data gaps and improve future understanding of streamflow depletion in the Colusa Subbasin, the GSAs have proposed GSP implementation studies to update and enhance the C2VSimFG-Colusa model, expand near-stream, shallow groundwater monitoring, and complete other activities to address data gaps. These proposed studies are described in GSP Chapter 7, Plan Implementation. Future refinements to the C2VSimFG-Colusa model are further described below. Finally, because gains and losses in the Sacramento River and Stony Creek are likely affected by groundwater management in adjoining and upstream subbasins, the GSAs in the Colusa Subbasin will seek opportunities to improve understanding of stream accretion and depletion in these water bodies through interbasin coordination.

Sacramento River

The Sacramento River is a very modestly gaining stream as related to groundwater conditions in the Colusa Subbasin, with simulated net gains representing just 0.1 percent to 0.3 percent of the relatively large flows in the river. It is noted that these simulated net gains are less than the typical ±2.5% accuracy of annual volume measurements when calculated from current meter-based stage-discharge functions (Clemmens and Wahlin, 2006). Consequently, these simulated net gains are not considered to be significantly different than the uncertainty of average annual streamflows along these reaches, and cannot be measured directly from stream gage measurements with certainty. It does not appear that patterns of simulated gain and loss are strongly affected by increases in groundwater pumping needed to satisfy increased irrigation requirements resulting from potential future climate change, or by recharge projects that could be implemented in the Subbasin. Therefore, it is concluded, on a provisional basis, that the effects of groundwater management in the Colusa Subbasin do not have significant and unreasonable effects on beneficial uses and users of Sacramento River water. However, recognizing that there are data gaps in current understanding and monitoring of streamflow depletion in the Colusa Subbasin, these analyses and provisional conclusions will be revisited and revised, as needed, in future updates to the Colusa Subbasin GSP when more information is known.

Stony Creek

Overall, based on best available data and analysis, Stony Creek is regarded as a losing stream as related to groundwater conditions in the Colusa Subbasin, losing a simulated average net volume of 17.2 to 22.6 TAF/yr over the projected future scenarios. Simulated losses represent between 4.8 and 6.9 percent of simulated average flows in the upper reach, and between 2.9 and 3.6 percent of simulated average flows in the lower reach. The simulated volume of net loss is generally greater in critical water years and lower in wetter water years. Under the potential future effects of climate change, patterns of simulated net loss do not appear to be significantly or consistently affected by increased demand for groundwater pumping, as evidenced by the similarity in patterns and volumes of simulated net loss across all scenarios. Therefore, it is concluded, on a provisional basis, that the effects of groundwater management in the Colusa Subbasin do not have significant and unreasonable effects on beneficial uses and users of Stony Creek water. Recognizing that there are data gaps in current understanding and monitoring of streamflow depletion in the Colusa Subbasin, these analyses and provisional conclusions will be revisited and revised, as needed, in future updates to the Colusa Subbasin GSP when more information is known.

Colusa Drain

Overall, Colusa Drain is considered to be a significantly gaining stream as related to groundwater conditions in the Colusa Subbasin, with simulated net gains between 91.1 and 108.5 TAF/yr over the projected future scenarios. These simulated net gains represent a significant fraction of the total average streamflow, between 16.1 and 19.5 percent overall. On average, simulated net gains are greatest in wet water years, and generally similar in other water year types. The pattern of simulated annual net gains varies over time, but is generally similar between scenarios and does not appear to be significantly or consistently affected by increased demand for groundwater pumping in drier water years. Therefore, it is concluded, on a provisional basis, that the effects of groundwater management in the Colusa Subbasin do not have significant and unreasonable effects on beneficial uses and users of Colusa Drain water. Recognizing that there are data gaps in current understanding and monitoring of

streamflow depletion in the Colusa Subbasin, these analyses and provisional conclusions will be revisited and revised, as needed, in future updates to the Colusa Subbasin GSP when more information is known.

Future Refinements to the C2VSimFG-Colusa Model

As described previously, the C2VSimFG-Colusa model is expected to require future refinements to improve its calibration. Due to the large area and variability in conditions across the Colusa Subbasin, there is significant uncertainty in simulated groundwater levels and resulting streamflow depletions in some areas.

During development and initial calibration of C2VSimFG-Colusa model, several potential future refinements to the model were identified. These refinements are described in Appendix 3D of the GSP, and may include:

- Refine the model grid resolution in areas where observed groundwater level data show high spatial gradients, to better simulate these local high groundwater gradients.
- Use more recent data (e.g. 2016-2021) to improve the accuracy of the model for predicting near-term and future conditions in the Colusa Subbasin.
- Adjust model layer thicknesses to better represent local geologic conditions and potential faults in these areas.
- Adjust model layer thicknesses to distribute groundwater pumping and better match groundwater extraction from different depth and layers of the aquifer.
- Explicitly model small, ephemeral streams flowing into the western side of the Colusa Subbasin to better represent recharge.
- Improve calibration and representation of interbasin flows, including Sacramento River recharge along the eastern boundary of the Colusa Subbasin and subsurface groundwater flows into and out of Colusa, Butte and Vina Subbasins.

Table 2. Simulated Sacramento River Stream-Aquifer Interaction: Average Annual Summary (Water Years 2016-2065, AF/yr)

Sacramento River					
	Glenn County Reach				
Model Scenario	**Average Reach Flow**	**Stream Gains**	**Stream Losses**	**Net Gains**	**Net Stream Gains as a Percent of Average Reach Flow**

Appendix A. Personal Communication with J. Sutton Regarding the Tehama-Colusa Canal Capacity.

From: Jeffrey P. Sutton (Tehama-Colusa Canal Authority)

Sent: Tuesday, August 10, 2021 4:55 PM

To: Grant Davids (Davids Engineering, Inc.)

Cc: Katherine Klug (Davids Engineering, Inc.)

Subject: **RE: TCC Capacity**

Caveated with the following first blush comments (reserve the right to add to this list), I respond:

1. TCCA will not be responsible for providing the subject water rights or water supply that is diverted for this purpose.
2. TCCA will not be responsible for any permits, mitigation, or other regulatory responsibilities associated with such a program.
3. CCWD and OAWD will be responsible for any and all charges, contracting, Warren Act or other fees and/or costs associated with such a program.
4. TCCA will be paid appropriate conveyance charges pursuant to the rates in the TCCA JPA Agreement that CCWD and OAWD currently pay or other rates as agreed.

I respond to your question as follows: Currently, it is my opinion that under most (in fact all that I currently think of) scenarios experienced, there would be plenty of pumping/diversion capacity (currently maxed out at 2000 cfs) and conveyance capacity in the TC Canal (2500 cfs at the top of the canal, 2100 cfs at Funks Reservoir, 1700 cfs at the south end of the canal) to facilitate such a program. However, historical operations are not always a good predictor of future conditions. In a typical year, we typically divert/convey a maximum amount of water of around 1300-1500 cfs. I would also add that I have not yet discussed particulars details of such a program (because I have not been provided such details until this time) with my Board of Directors. Bill Vanderwaal and Emil Cavagnolo did generally outline the recharge concept being explored at my last meeting, which the Board was generally supportive of - notwithstanding the need to hear the details. However, I anticipate that this water would have to somewhat take a second tier position in the atypical case of a conflict over the available diversion/conveyance capacity.

I hope this is helpful Grant, sorry for the long caveated answer. But I don't want to give the misimpression of complete acquiescence or create a reliance on a simple statement of "sure we have capacity" until all of the details are more fully vetted and the necessary terms have been contemplated. I will leave it to your discretion on how you wish to articulate capacity availability in the Colusa GSP based on the foregoing.

HOLE NO. LCB-4
ELEV. 25 (topo) FEET
DEPTH 1020 FEET

PROJECT Lower Colusa Basin Conjunctive Use
DATE DRILLED 6/24-6/25/97
FEATURE Exploratory Boring
ATTITUDE Vertical
LOCATION 12N/01E-06D*
LOGGED BY F. Nasirian
CONTR. Eaton Drilling Co. DRILL RIG Ingersoll-Rand TH-400
DEPTH TO WATER Not Determined

* Near the south east corner of the intersection of County Line Road and the Colusa Basin Drain

DEPTH (ELEV.)	LOG	FIELD CLASSIFICATION AND DESCRIPTION	SAMPLE NO.	MODE	REMARKS
0.0	CL	Holocene/Pleistocene Sediments 0.0-1020'			Drilled mostly with clear water, at times bentonite was added.
	GC	0.0-10.0' Clay (CL): Brown, medium plasticity, moist. 10.0-20.0' Clayey Gravel (GC): Brown, about 5-10% clay, fine to medium, gravel wet.			
20.0	SP	20.0-40.0' Sand (SP): Gray, less than 5% fines, fine to coarse grained sand.			The drill rods were 2-1/2" in diameter with a 4" collar at both ends.
40.0	CL	40.0-70.0' Clay (CL): Brown, about 5-10% fine gravel, about 5-10% sand, moist			The collars would not allow any cuttings larger than 1/2 -3/4" size to come to the surface.
60.0					Soils and geologic contacts were determined from logging the drill cuttings recovered from the shaker.
	CH	70.0-245.0' Clay (CH): Bluish-brown, high plasticity, moist.			
80.0					
100.0					
120.0					
140.0		140.0-160.0' Clay with about 10-15% fine to coarse grained sand.

(8) Water levels:

Depth at which water first encountered 78 ft.

Depth to water before perforating 53 ft.

Depth to water after perforating 53 ft.

Note any change in water level while drilling
None

(9) Well pumping test:

Date of test 6/7/51 By whom Wm. P. Wilson

Depth to water when test started 53 ft.

G.P.M. at beginning of test 550 G.P.M.

Drawdown from standing level 96 ft.

G.P.M. at completion of test 670 G.P.M.

Drawdown at completion of test 83 ft.

Length of time tested Approx. 10 hours

Temperature of water 55 degrees

Was gas present in water? ☐ Yes ☒ No

(10) General:

Was well gravel packed? Yes Size of rock 5/8 inch Thickness of pack 4 inch

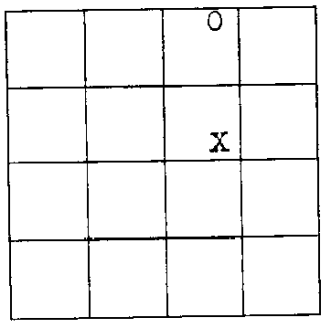
Was a surface sanitary seal provided? None

Were any strata sealed against pollution? ☐ Yes ☒ No If yes, attach detailed description.

Strata sealed

Was analysis made of water? ☐ Yes ☒ No If yes, attach copy.

Was electric log made of well? ☐ Yes ☒ No If yes, attach copy.



If well abandoned, was it plugged and sealed?

Method of plugging and sealing

DEPTH	USCS	FIELD CLASSIFICATION AND DESCRIPTION	SY	REMARKS
0	CL	0ə-10ə GRAVELLY LEAN CLAY w/ SAND: Gray; gravel (>15%) is fine (4 mm); sand >15%	3	General: • Drill bit diameter = 6 1/4əə • Drill rods 22ə long, 2½ə dia. with 4ə collars at both ends, so clasts >1ə prevented from reaching surface • Mud rotary method, so all cuttings are saturated and moisture content not noted. • Log is based on cuttings sampled from shaker about every 10ə, but sampling not consistent, plus lag-time error renders elevations of contacts inaccurate – more so with increasing depth. • USBR 5005 Unified Soil Classification System used. Logging Problem: The rotary drilling method mixes cuttings from thin beds together in a mud slurry with any sluffed materials, and the origination depth of samples from the shaker is uncertain due to irregular collection, lag time and manner cuttings are brought to the surface. Thus, thin beds are often not identifiable, contacts are incorrect or uncertain, and soil classification is obstructed.
	GC	10ə-20ə CLAYEY GRAVEL w/ SAND: Brown; sand is coarse to fine ≥15%).	5	
20	CL	20ə-30ə LEAN CLAY: Brown	3	
40	CL	30ə-65ə GRAVELLY LEAN CLAY w/ SAND: Brown; gravel is fine, angular to sub-angular quartz w/ a few clasts to 1½əə sub-rounded volcanics; sand is coarse (>15%) → Probably thin interbeds	3	
60	GP	65ə-80ə POORLY-GRADED GRAVEL: Gray; most gravel (~90%) is fine, but a few 1əə clasts, all is sub-angular to sub-rounded quartz & volcanics → ***Minor Aquifer*** (70ə-80ə best)	15

WATER WELL DRILLERS REPORT

(Sections 7076, 7077, 7078, Water Code) CONFIDENTIAL Water Code

STATE OF CALIFORNIA

LOCATION NOT CHECKED

Do Not Fill In
No. 40376
State Well No.
Other Well No. 13N/1W-22F

(2) LOCATION OF WELL:

County Colusa Owner's number, if any—

R. F. D. or Street No. Near Southwest Corner of the Southeast 1/4 of the Southwest 1/4 of Section 22, Township 13 North, Range 1 West, M. D. B. & M., and being just off the Mumma Road Right of Way

(3) TYPE OF WORK (*check*):

New well [X] Deepening [ ] Reconditioning [ ] Abandon [ ]

If abandonment, describe material and procedure in Item 11.

(4) PROPOSED USE (*check*):

Domestic [ ] Industrial [ ] Municipal [ ]
Irrigation [X] Test Well [ ] Other [ ]

(5) EQUIPMENT:

Rotary [X]
Cable [ ]
Dug Well [ ]

(6) CASING INSTALLED:

SINGLE [X] DOUBLE [ ]

From ft.	to ft.	Diam.	Gage or Wall
0	236	12"	3/16

If gravel packed

Diameter of Bore	from ft.	to ft.
22"	0	236

Type and size of shoe or well ring: Point
Size of gravel: 5/8"
Describe joint: Collar and all ~~xxxxx~~ welded

(7) PERFORATIONS:

Type of perforator used: Factory Punched
Size of perforations: 1-1/2" in., length, by 3/16" in.

From ft.	to ft.	Perf. per row	Rows per ft.
196	236	4	24

(8) CONSTRUCTION:

Was a surface sanitary seal provided? [ ] Yes [X] No To what depth ft.

Were any strata sealed against pollution? [ ] Yes [X] No If yes, note depth of strata

From ft.	to ft.

Method of Sealing: None

(9) WATER LEVELS:

Depth at which water was first found: 112 ft.
Standing level before perforating: 45 ft.
Standing level after perforating: 45 ft.

(10) WELL TESTS:

Was a pump test made? [X] Yes [ ] No If yes, by whom? W.P.Wilson
Yield: 1950 gal./min. with 79' T.H ft. draw down after 8 hrs.
Temperature of water ? Was a chemical analysis made? [ ] Yes [X] No
Was electric log made of well? [ ] Yes [X] No

(11) WELL LOG:

Total depth 236 ft. Depth of completed well 236 ft.

Formation: *Describe by color, character, size of material, and structure.*

Geologic Log - USCS/ASTM D2488

Depth from Surface Feet to Feet		Soil Class	Soil Color	Soil Description
0	20	SW Well-graded SAND	Dusky yellow 5Y 6/4	Well-graded sand with gravel. About 55% fine sand; about 20% coarse sand; about 20% gravel; about 5% fines with low plasticity; moist, bulk sample dusky yellow 5Y 6/4; coarseness increases with depth
20	40	CL Lean inorganic CLAY with low plasticity	Yellowish brown 10YR 5/4	Lean Clay with Sand. About 75% fines with low to medium plasticity; about 25% medium sand; moist, bulk sample moderate yellowish brown 10YR 5/4
40	90	CL Lean inorganic CLAY with low plasticity	Yellowish brown 10YR 5/4	Lean Clay. Fines with medium plasticity; trace fine sand; moderate yellowish brown 10YR 5/4, dark gray streaks increase with depth
90	110	GC Clayey GRAVEL	Light olive gray 5Y	Clayey Gravel. 60% hard, subangular gravel; about 40% low to non-plastic clay; moist, bulk sample multi-colored dark gray N3 and light olive gray 5Y 6/1; gravel increases and clay decreases with depth
110	160	CH Fat inorganic clay with moderate to high plasticity	Moderate yellowish brown 10YR 5/4	Fat Clay. Fines with medium to high plasticity; trace fine sand; moist, moderate yellowish brown 10 YR 5/4
160	170	GW Well-graded GRAVEL	Light olive gray 5Y 6/1	Well-graded gravel with Sand. About 70% hard, subangular, multi-colored and dark gray N3 gravel; about 15% coarse sand; about 15% fine sand; dry, bulk sample light olive gray 5Y 6/1
170	280	CH Fat inorganic clay with moderate to high plasticity	Moderate yellowish brown 10YR 5/4	Fat Clay. Fines with high plasticity; moist, moderate yellowish brown 10 YR 5/4

280	300	GW Well-graded GRAVEL	Dark gray N3 and Medium dark gray N4	Well-Graded Gravel w/Sand.75% hard, subangular, multi-colored gray and white gravel; about 15% coarse sand; about 10% medium sand; dry, bulk sample multi-colored, dark gray N3, and medium dark gray N4
300	380	CH Fat inorganic clay with moderate to high plasticity	Light olive gray 5Y 5/2	Fat Clay. Fines with high plasticity; intermittent trace fine sand; moist to saturated, light olive gray 5Y 5/2
380	400	CH Fat inorganic clay with moderate to high plasticity	Dusky yellow green 5GY 5/2	Fat Clay w/Sand. 80% fines with high plasticity; about 10% coarse sand; about 10% medium sand; moist, bulk sample dusky yellow green 5GY 5/2
400	570	CH Fat inorganic clay with moderate to high plasticity	streaks of grayish blue green 5BG 5/2 and dusky yellow green 5GY 5/2	Fat Clay. Fines with high plasticity; moist, grayish olive 10Y 4/2; trace silt from about 500-520'; trace sand from about 550-580'; streaks of grayish blue green 5BG 5/2 and dusky yellow green 5GY 5/2
570	640	SW Well-graded SAND	multi-colored, gray and white	Well-Graded Sand w/gravel. 45% subrounded coarse sand; 35% medium sand;15% hard, subrounded gravel; about 5% fine sand; bulk sample multi-colored, gray and white; coarseness increases with depth
640	780	CH Fat inorganic clay with moderate to high plasticity	light olive gray 5Y 6/1, color change at 730-780' to dark greenish gray 5GY 4/1	Fat Clay. Fines with high plasticity, light olive gray 5Y 6/1, color change at 730-780' to dark greenish gray 5GY 4/1; trace fine sand; moist
780	890	SW Well-graded SAND	Multi-colored, white, gray, and light brown	Well-Graded Sand with Gravel. About 50% medium sand; about 25% coarse sand; about 15% hard, subrounded gravel, multi-colored, white and gray; about 10% fine sand; bulk sample multi-colored, white, gra
890	920	CL Lean inorganic CLAY with low plasticity	Light olive gray 5Y 6/1 and yellowish gray 5Y 8/1	Lean Clay. Fines with medium plasticity; moist, light olive gray 5Y 6/1 and yellowish gray 5Y 8/1; trace sand.
920	950	SW Well-graded SAND	multi-colored, gray and white	Well-Graded Sand w/Gravel. About 35% coarse sand, multi-colored gray and white; about 35% medium sand; about 20% hard, subangular gravel, multi-colored, gray and white; about 10% fine sand; dry
950	1000	CL Lean inorganic CLAY with low plasticity	light blue gray 5Y 6/1	Sandy Lean Clay. About 70% nonplastic fines; about 20% medium sand; about 10% coarse sand; moist, bulk sample light blue gray 5Y 6/1
1000	1020	SW Well-graded SAND	multi-colored, brown, white, and gray	Well-Graded Sand. About 60% hard, medium to coarse sand; about 40% fine sand; bulk sample multi-colored, brown, white, and gray
1020	1040	SW Well-graded SAND	multi-colored, gray, black, and white	Well-Graded Sand. About 50% medium sand; about 35% fine sand; about 15% hard, coarse sand; moist, bulk sample multi-colored, gray, black, and white
1040	1050	CL Lean inorganic CLAY with low plasticity	pale olive 10 6/2	Lean Clay with Sand. About 80% fines with low plasticity; about 20% medium sand; moist, bulk sample pale olive 10 6/2
1050	1080	SW Well-graded SAND	multi-colored, gray and white	Well-Graded Sand. About 35% medium sand; about 35% fine sand; about 10% hard gravel; about 20% hard coarse sand; moist, bulk sample multi-colored, gray and white
1080	1140	SW Well-graded SAND	multi-colored, white, gray, and light brown	Well-Graded Sand. About 50% medium sand; about 30% fine sand; about 10% hard, subangular gravel; about 10% subangular coarse sand; moist, bulk sample multi-colored, white, gray, and light brown
1140	1200	SW Well-graded SAND	multi-colored, light gray, and white	Well-Graded Sand w/Gravel. About 35% medium sand; about 35% fine sand; about 15% hard, subangular gravel; about 15% coarse sand; bulk sample multi-colored, light gray, and white

State No. 15N-1W-5G1

WELL DATA

DISTRICT Northern

Owner Colusa Co. Airport
Address Colusa 2915 Hwy. 20 - Colusa
Tenant Caretaker: Connor Davis
Address

State No. 15N/1W-5G1
Other No.

Type of Well: Hydrograph ☐ Key ☐ Index ☐ Semiannual ☐
Location: County Colusa Basin Colusa No.
U.S.G.S. Quad. Meridian Quad. No. 545b
¼ ¼ Section , Twp. , Rge. MD SB Base & Meridian
Description @ the Colusa Co. Airport. SE/ of Colusa on State Hwy 20 about 1 mile. Well is inside an aluminum clad P.H. 100' S/o HWY & 300' W/o gas pumps

Reference Point description Hole T.O.C.

which is T.O 1.4 ft. above below land surface. Ground Elevation 45.0 ft.
Reference Point Elev. 46.0 46.4 ft. Determined from Quad
Well: Use Industrial - Dom. Condition Depth 146 ft.
Casing, size x in., perforations 0-75 CSG, OPEN HOLE T. 140

Measurements By: DWR ☐ USGS ☐ USBR ☐ County ☐ Irr. Dist. ☐ Water Dist. ☐ Cons. Dist. ☐
Chief Aquifer: Name Depth to Top Aq. Depth to Bot. Aq.
Type of Material Perm. Rating Thickness
Gravel Packed? Yes ☐ No ☐ Depth to Top Gr. Depth to Bot. Gr.
Supp. Aquifer Depth to Top Aq. Depth to Bot. Aq.
Driller Beamer & Son Pump Co.
Date drilled 8/20/21 Log, filed #12982 open (1) confidential (2) 12982
Equipment: Pump, type Sub make
Serial No. Size of discharge pipe in.
Power, Kind Make
H. P. Motor Serial No.
Elec. Meter No. Transformer No.
Yield G.P.M. Pumping level ft.

Water Analysis: Min. (1) San. (2) H.M. (3)
Water Levels available: Yes (1) No
Period of Record: Begin 10-21-75 End ACTIVE
Collecting Agency:
Prod. Rec. (1) Pump Test (2) Yield (3)

N

REMARKS

1) ON 11-28-01 I SURVEYED IN A ACCURATE ELEV. TO THE R.P. FROM USGS B.M. . THE R.P. WELL CASING HAD BEEN EXTENDED IN FALL of 2000. No ACCURATE RECORD of THE EXTENSION WAS MADE So I DID THIS. SWH

WELL MEASUREMENT QUALIFICATION
By: P. LORENS 3666 Date 6/11/02
Qualification ~~COMPOSITE~~ Semi-Confined
Confidence: DEFINITE
Water Body: FLOODPLAIN DEPOSITS & older Basin Deposits

Recorded by: J. Bonnimiri
Date June 1989

(Sections 7076, 7077, 7078, Water Code)

STATE OF CALIFORNIA

LOCATION NOT CHECKED

Do Not Fill In

No. 71038

State Well No.

Other Well No. 15N/2W-19

(1)
Na
Ac

(2) LOCATION OF WELL: Lives on Abele Road

County Colusa Owner's number, if any—

R. F. D. or Street No. 30 feet East from Husted road a short way south from Crawford road in the Northwest 1/4 of Section 19, Township 15 North, Range 2 West, M.D.B. & M.

(3) TYPE OF WORK (*check*):

New well [X] Deepening [ ] Reconditioning [ ] Abandon [ ]

If abandonment, describe material and procedure in Item 11.

(4) PROPOSED USE (*check*):

Domestic [ ] Industrial [ ] Municipal [ ]
Irrigation [X] Test Well [ ] Other [ ]

(5) EQUIPMENT:

Rotary [X]
Cable [ ]
Dug Well [ ]

(6) CASING INSTALLED:

SINGLE [X] DOUBLE [ ]

From ft.	to ft.	Diam.	Gage or Wall
0	334	14"	3/16
0	12	24"	"

The 24 inch cemented in from 12 ft to surface

If gravel packed

Diameter of Bore	from ft.	to ft.
24"	0	334
28"	0	12

Type and size of shoe or well ring Point

Describe joint all joints welded

Size of gravel: 5/8"

(7) PERFORATIONS: standard

Type of perforator used Factory punched double /

Size of perforations 1-1/2" in., length, by 3/16 in.

From ft.	to ft.		Perf. per row		Rows per ft.
162	174	4	per ft.	29	
174	182	4	" "	29	
198	206	4	" "	29	
262	274	4	" "	29	
290	294	4	" "	29	

(8) CONSTRUCTION:

Was a surface sanitary seal provided? [X] Yes [ ] No To what depth from surface to 12 ft.

Were any strata sealed against pollution? [ ] Yes [X] No If yes, note depth of strata

From ft. to ft.

Method of Sealing Cement

(9) WATER LEVELS:

Depth at which water was first found 6 ft.

Standing level before perforating 16 ft.

Standing level after perforating 16 ft.

(10) WELL TESTS:

Was a pump test made? [X] Yes [ ] No If yes, by whom? W.P.Wilson&Sons

Yield: See 11 gal./min. with ft. draw down after ? hrs.

Temperature of water ? Was a chemical analysis made? [ ] Yes [X] No

Was electric log made of well? [ ] Yes [X] No

(11) WELL LOG:

Total depth 334 ft. Depth of completed well 334 ft.

Formation: *Describe by color, character, size of material, and structure.*

0 ft. to	3 ft.	Soil
3	9	Sand and gravel
9	31	Clay
31	36	Gravel
36	44	Clay

WATER WELL DRILLERS REPORT

Do not fill in

No. 177869

Notice of Intent No.

Local Permit No. or Date

State Well No.

Other Well No.

(2) LOCATION OF WELL (See instructions):

County Colusa Owner's Well Number

Well address if different from above

Township 18 N Range 2 W Section 36

Distance from cities, roads, railroads, fences, etc.

Extreme Notheast corner of Secion 36

(3) TYPE OF WORK:

New Well [X] Deepening [ ]
Reconstruction [ ]
Reconditioning [ ]
Horizontal Well [ ]
Destruction [ ] (Describe destruction materials and procedures in Item 12)

(4) PROPOSED USE:

Domestic [ ]
Irrigation [X]
Industrial [ ]
Test Well [ ]
Stock [ ]
Municipal [ ]
Other [ ]

WELL LOCATION SKETCH

(5) EQUIPMENT:

Rotary [ ] Reverse [ ]
Cable [X] Air [ ]
Other [ ] Bucket [ ]

(6) GRAVEL PACK:

Yes [ ] No [X] Size

Diameter of bore

Packed from to ft.

(7) CASING INSTALLED:

Steel [X] Plastic [ ] Concrete [ ]

From ft.	To ft.	Dia. in.	Gage or Wall
0	234	18	1/4
230	410	16	8-GA

(8) PERFORATIONS:

Type of perforation or size of screen

From ft.	To ft.	Slot size
88	128	1/4" mills Knife
195	225	1/4" mills Knife
240	340	1/4 mills Knife

(9) WELL SEAL:

Was surface sanitary seal provided? Yes [ ] No [X] If yes, to depth ft.

Were strata sealed against pollution? Yes [X] No [ ] Interval ft.

Method of sealing Clay Seal

(10) WATER LEVELS:

Depth of first water, if known 40 ft.

Standing level after well completion 38 ft.

(11) WELL TESTS:

Was well test made? Yes [X] No [ ] If yes, by whom? Valley Pump

Type of test Pump [X] Bailer [ ] Air lift [ ]

Depth to water at start of test 38 ft. At end of test 36 ft

Discharge 3100 gal/min after 90 hours Water temperature

Chemical analysis made? Yes [ ] No [X] If yes, by whom?

Was electric log made? Yes [ ] No [X] If yes, attach copy to this report

(12) WELL LOG: Total depth 455 ft. Depth of completed well 455 ft.

Irrigation [ ]
Industrial [ ]
Test Well [ ]
Municipal [ ]
Other [X]
(Describe) Monitoring

(5) EQUIPMENT:
Rotary [X] Reverse [ ]
Cable [ ] Air [ ]
Other [ ] Bucket [ ]

(6) GRAVEL PACK: Monterey
Yes [X] No [ ] Size 6 x 12
Diameter of bore 12
Packed from 110 to 155 ft.

(7) CASING INSTALLED:
Steel [X] Plastic [ ] Concrete [ ]

From ft.	To ft.	Dia. in.	Gage or Wall
0	120	6	3/16
140	145	6	3/16

(8) PERFORATIONS:
Type of perforation or size of screen

From ft.	To ft.	Slot size
120	140	.050

(9) WELL SEAL:
Was surface sanitary seal provided? Yes [X] No [ ] If yes, to depth 110 ft.
Were strata sealed against pollution? Yes [ ] No [ ] Interval _____ ft.
Method of sealing _____

(10) WATER LEVELS:
Depth of first water, if known _____ ft.
Standing level after well completion _____ ft.

(11) WELL TESTS:
Was well test made? Yes [ ] No [X] If yes, by whom? _____
Type of test Pump [ ] Bailer [ ] Air lift [ ]
to water at start of test _____ ft. At end of test _____ ft.
Discharge _____ gal/min after _____ hours Water temperature _____
Chemical analysis made? Yes [ ] No [X] If yes, by whom? _____
Was electric log made Yes [ ] No [X] If yes, attach copy to this report

(12) WELL LOG: Total depth 155 ft. Completed depth 145 ft.

from ft.	to ft.	Formation (Describe by color, character, size or material)
0	15	Brn sandy clay
15	25	Brn sandy clay and gravel
25	34	Grey clay and sand

Appendix 5A

Colusa Groundwater Authority and Glenn Groundwater Authority Technical Advisory Committees Records of Decision for Sustainable Management Criteria

(THIS PAGE LEFT BLANK INTENTIONALLY)

INTRODUCTION

This appendix documents the decision-making process and adoption of the Colusa Subbasin Sustainable Management Criteria (SMC) by the Colusa Groundwater Authority and Glenn Groundwater Authority Technical Advisory Committees (referred to as the Joint TAC).

A record of decision is provided for each of the sustainability indicators applicable to the Colusa Subbasin (Subbasin):

1. Chronic Lowering of Groundwater Levels
2. Reduction of Groundwater Storage
3. Seawater Intrusion (not applicable to the Colusa Subbasin)
4. Degraded Water Quality
5. Land Subsidence
6. Depletions of Interconnected Surface Water

Colusa Groundwater Authority and Glenn Groundwater Authority Technical Advisory Committees Record of Decision

SUSTAINABILITY INDICATOR #1: CHRONIC LOWERING OF GROUNDWATER LEVELS

Decision Record

At their joint meeting on May 13, 2021, the Colusa Groundwater Authority (CGA) Technical Advisory Committee (TAC) and Glenn Groundwater Authority (GGA) TAC each voted unanimously to recommend to their respective boards the criteria listed below for setting quantitative Sustainable Management Criteria (SMC) for groundwater Sustainability Indicator #1: Chronic Lowering of Groundwater Levels. These actions were taken in relation to Agenda Item 4.a.i. with the roll call vote documented in the meeting minutes.

The SMC for Chronic Lowering of Groundwater Levels will be calculated and conditioned as follows. The calculation will be made individually for each of the 48 representative monitoring wells comprising the Groundwater Level monitoring network. Water levels are defined as the depth to groundwater below ground surface.

1) Minimum Thresholds will be set equal to the lower of the following two calculated water levels:
    a. 50 percent of the historical range in observed water levels below the observed low water level, AND,
    b. The 20th percentile depth of domestic wells in the Thiessen polygon represented by each monitoring well. This means that 20 percent of the domestic wells are shallower and 80 percent deeper than the 20th percentile depth.
2) Measurable Objectives will be calculated as the average of the most recent five (5) years of available groundwater levels. The calculated water level is fixed and is not a running average that changes over time.
3) An Undesirable Result will be detected when water levels in 25 percent or more (at least 12) of the 48 representative monitoring wells fall below their respective Minimum Thresholds continuously for 24 months. The 12 wells must be the same subset of wells, not any combination of 12 wells.
4) To ensure operational compatibility with adjoining subbasins, the Minimum Thresholds and Measurable Objectives for monitoring wells near subbasin boundaries will be reviewed and adjusted, as needed, in consultation with representatives of adjoining subbasin Groundwater Sustainability Agencies.

Adoption Record

The TAC decisions were presented to and adopted by their respective Boards as follows:

- CGA: Approved May 25, 2021
- GGA: Approved June 16, 2021

Colusa Groundwater Authority and Glenn Groundwater Authority Technical Advisory Committees Record of Decision

SUSTAINABILITY INDICATOR #2: REDUCTION OF GROUNDWATER STORAGE

Decision Record

At their joint meeting on April 23, 2021, the Colusa Groundwater Authority (CGA) Technical Advisory Committee (TAC) and Glenn Groundwater Authority (GGA) TAC the Consultant Team recommended to the TACs that Sustainable Management Criteria (SMC) for groundwater Sustainability Indicator #2: Reduction of Groundwater Storage be addressed using Sustainability Indicator #1: Groundwater Levels as a proxy indicator, as allowed under DWR's Groundwater Sustainability Plan regulations.

The CGA TAC and GGA TAC each voted unanimously to recommend to their respective boards that SMC for groundwater Sustainability Indicator #2: Reduction of Groundwater Storage be addressed by proxy as described above. These actions were taken in relation to Agenda Item 4.b.i. with the roll call vote documented in the meeting minutes.

Supporting Rationale

The Consultant Team explained that the freshwater aquifers in the Colusa Subbasin are deep relative to existing well infrastructure and the Measurable Objectives (MOs) and Minimum Thresholds (MTs) under consideration for Sustainability Indicator #1: Groundwater Levels. Large volumes of fresh groundwater would remain in storage even if MTs were reached. Therefore, the MTs and MOs adopted for Groundwater Levels are protective of Groundwater Storage.

Adoption Record

The TAC decisions were presented to and adopted by their respective Boards as follows:

- CGA: Approved May 25, 2021
- GGA: Approved May 10, 2021

Colusa Groundwater Authority and Glenn Groundwater Authority Technical Advisory Committees Record of Decision

SUSTAINABILITY INDICATOR #3: SEAWATER INTRUSION

Seawater intrusion is not considered to be an applicable sustainability indicator for the Colusa Subbasin. Thus, SMC were not established for seawater intrusion.

Seawater intrusion is not currently occurring in the Subbasin, and is not likely to occur due to the substantial distance between the Subbasin and the Pacific Ocean, bays, deltas, or inlets.

Colusa Groundwater Authority and Glenn Groundwater Authority Technical Advisory Committees Record of Decision

SUSTAINABILITY INDICATOR #4: DEGRADED WATER QUALITY

Decision Record

At their joint meeting on April 9, 2021, the Colusa Groundwater Authority (CGA) Technical Advisory Committee (TAC) and Glenn Groundwater Authority (GGA) TAC each voted to recommend to their respective boards to adopt a policy not to adopt quantitative Sustainable Management Criteria (SMC) for groundwater Sustainability Indicator #4: Degraded Water Quality, and instead to improve the water quality monitoring network and adopt quantitative SMC in the 2027 Groundwater Sustainability Plan (GSP) update.

Subsequent to the April 9 meeting, additional information became available causing the Consultant Team to reconsider its earlier advice to the TACs. The new information included an opinion provided by GGA counsel and results of the Department of Water Resources evaluations of GSPs prepared for other groundwater subbasins. Based on this additional information, the Consultant Team changed its approach and recommended to the TACs at their June 11, 2021, meeting that quantitative SMC for water quality be developed for Sustainability Indicator #4.

At the June 11, 2021, Joint TAC meeting, each TAC voted unanimously, with Ben King of the CGA TAC abstaining, to recommend to their respective boards the criteria listed below for setting quantitative SMCs for Sustainability Indicator #4. These actions were taken in relation to Agenda Item 4.a.i. with the roll call vote documented in the meeting minutes.

The SMCs for Degraded Water Quality pertain to salinity only, applicable to each of 23 representative monitoring wells, are as follows:

1) The Minimum Threshold will be 900 µS/cm[1] (the recommended California Secondary Maximum Contaminant Level) OR the pre-2015 historical maximum measured salinity.
2) The Measurable Objective will be 700 µS/cm (corresponding to an agricultural water quality objective providing for no yield reduction for crops commonly grown in the Colusa Subbasin).
3) An Undesirable Result will be detected when salinity (as indicated by electrical conductivity) in 25 percent of the representative monitoring wells (6 of 23 monitoring wells) exceeds the Minimum Threshold for two (2) consecutive years.

[1] µS/cm stands for micro Siemens per centimeter, a measure of the electrical conductivity (EC) of water. 1,000 µS/cm is equal to approximately 640 parts per million of total dissolved solids in water.

Clarifying Points

The foregoing SMC were established with the TACs' understanding that 23 representative monitoring wells are not sufficient for long-term, sustainable management of the Colusa Subbasin and that additional new or existing wells will need to be added to the monitoring network over time. Additionally, the TACs acknowledge that the SMC will need to be reviewed and evaluated, and potentially refined, as additional monitoring wells are added, and additional data is collected and analyzed.

Adoption Record

The TAC decisions were presented to and adopted by their respective Boards as follows:

- CGA: Approved July 8, 2021
- GGA: Approved June 16, 2021, and approved as amended July 12, 2021

Colusa Groundwater Authority and Glenn Groundwater Authority Technical Advisory Committees Record of Decision

SUSTAINABILITY INDICATOR #5: LAND SUBSIDENCE

Decision Record

At their joint meeting on April 9, 2021, the Colusa Groundwater Authority (CGA) Technical Advisory Committee (TAC) and Glenn Groundwater Authority (GGA) TAC each voted unanimously to recommend to their respective boards the criteria for setting quantitative Sustainable Management Criteria (SMCs) for groundwater Sustainability Indicator #5: Land Subsidence. These actions were taken in relation to Agenda Item 4.b.ii. with the roll call vote documented in the meeting minutes.

In September 2021, the Consultant Team prepared revised recommendations for the land subsidence SMCs to bring those SMCs into closer alignment with neighboring subbasins. Revisions to the quantitative SMCs for groundwater Sustainability Indicator #5: Land Subsidence were presented to and adopted by the CGA and GGA Boards in September and October 2021. During this process, the GGA Board recommended one additional revision regarding the process used to determine whether undesirable results have occurred.

The GGA Board voted unanimously to adopt the amended land subsidence SMCs listed below at their Board meeting on October 11, 2021. These actions were taken in relation to Agenda Item 9.e. with the roll call vote documented in the meeting minutes.

The CGA voted unanimously to adopt the amended land subsidence SMCs at their Board meeting on September 28, 2021, and amended again at the Board meeting on October 26, 2021.[2] These actions were taken in relation to Agenda Item 5 (September 28, 2021) and Agenda Item 7 (October 26, 2021) with the roll call vote documented in the corresponding meeting minutes.

The SMCs for Land Subsidence are as follows. The SMCs are applicable to each of 63 land subsidence monitoring benchmarks belonging to the Sacramento Valley Height Modernization Project.

1) The Minimum Threshold (MT) rate of subsidence at all 63 land subsidence benchmarks is 0.5 feet per five years.
2) The Measurable Objective (MO) rate of subsidence at all 63 land subsidence benchmarks is 0.25 feet per five years.
3) An Undesirable Result is considered to occur when the MT is exceeded at 20 percent (13 of 63) of the land subsidence monitoring benchmarks.

[2] The CGA adopted the revised land subsidence SMCs recommended by the Consultant Team as presented at their September 28, 2021 Board meeting. The CGA later adopted the land subsidence SMCs as revised by the GGA and presented at their October 26, 2021 CGA Board meeting.

Additionally, the GSAs will evaluate adding subsidence monitoring benchmarks, especially in areas of concern and will review InSAR data annually (regulations do not require subsidence reporting in annual reports).

Supporting Rationale and Clarifying Points

1) The SMCs will be reviewed and adjusted to account for potential changes in subsidence rates brought about by implementation of PMAs and future groundwater resource development. The extent of subsidence-prone areas, which may be underlain by sediments that have greater susceptibility to subsidence due to groundwater withdrawal, will continue to be delineated as data gaps are filled through the ongoing subsidence monitoring programs (using data from benchmarks, extensometers and InSAR surveys) and subsidence-prone sediments are characterized during drilling for well construction, extensometer installation or other subsurface investigations needed for the development of specific PMAs.
2) The GSAs expect that projects and management actions would be implemented before the MT rates are reached.
3) DWR reports that the probable error in the subsidence values reported for the monitoring benchmarks is ±0.17 feet, meaning that for any reported value, the actual subsidence value is likely to fall in a range between plus or minus 0.17 feet of the reported value. The selected MO subsidence rate of 0.25 feet per five year is deliberately greater than the reported probable error of ±0.17 feet as a means of avoiding false exceedance of the MO.

Adoption Record

The revised SMC were presented to and adopted by their respective Boards as follows:

- CGA: Approved April 27, 2021, and approved as amended September 28, 2021, and October 26, 2021
- GGA: Approved May 10, 2021, and approved as amended October 11, 2021

Colusa Groundwater Authority and Glenn Groundwater Authority Technical Advisory Committees Record of Decision

SUSTAINABILITY INDICATOR #6: DEPLETIONS OF INTERCONNECTED SURFACE WATER

Decision Record

At their joint meeting on May 19, 2021, the Colusa Groundwater Authority (CGA) Technical Advisory Committee (TAC) and Glenn Groundwater Authority (GGA) TAC each voted to recommend to their respective boards certain criteria for setting quantitative Sustainable Management Criteria (SMCs) for groundwater Sustainability Indicator #6: Depletions of Interconnected Surface Water. The vote of the GGA TAC was unanimous. The vote of the CGA TAC was "yes" for all members except Bill Vanderwaal who voted no. These actions were taken in relation to Agenda Item 4.a.i. with the roll call vote documented in the meeting minutes.

Subsequent to the TACs' May 19 decisions, the CGA Board acted to adopt the CGA TAC's recommendation with a certain modification of the Undesirable Result (UR) criteria. Additionally, the Consultant Team conducted additional analyses to better understand the connectivity of Stony Creek surface water to underlying groundwater, and to address surface water depletion in the Colusa Basin Drain. (Prior surface water depletion discussions had only addressed Stony Creek and the Sacramento River.) The modified UR criteria and results of these additional analyses along with associated recommendations were presented by the Consultant Team to the TACs at their joint meeting on June 11, 2021.

At the June 11, 2021, joint TAC meeting, each TAC voted unanimously to recommend to their respective boards the criteria listed below for setting quantitative Sustainable Management Criteria (SMCs) for groundwater Sustainability Indicator #6: Depletions of Interconnected Surface Water. These actions were taken in relation to Agenda Item 4.a.ii. with the roll call vote documented in the meeting minutes.

The SMCs for Depletions of Interconnected Surface Water will be set or calculated and conditioned as follows. The calculation will be made individually for each of the 12 representative monitoring wells comprising the surface water depletion monitoring network. Water levels are defined as the depth to groundwater below ground surface.

1) Minimum Thresholds will be calculated as the Fall 2015 observed water level minus 10 feet, with the observed Fall 2015 water level being the level recorded closest to October 15, 2015.
2) Measurable Objectives will be calculated as the average of the most recent five (5) years of available, measured groundwater levels. The calculated water level is fixed and is not a running average that changes over time.
3) An Undesirable Result will be detected when water levels in 25 percent of the representative monitoring wells (3 of 12 monitoring wells) fall below their respective Minimum Thresholds continuously for 24 months. The 3 wells must be the same subset of wells, not any combination of 3 wells.

4) To ensure operational compatibility with adjoining subbasins, the Minimum Thresholds and Measurable Objectives for monitoring wells near subbasin boundaries will be reviewed and adjusted, as needed, in consultation with representatives of adjoining subbasin Groundwater Sustainability Agencies.

The foregoing SMCs were established with the TACs' understanding that 12 representative monitoring wells are not sufficient for long-term, sustainable management of the Colusa Subbasin and that additional new or existing wells will need to be added to the monitoring network over time. Additionally, the TACs acknowledge that the SMCs will need to be reviewed and evaluated, and potentially refined, as additional wells are added, and additional data is collected and analyzed.

Adoption Record

The TAC decisions were presented to and adopted by their respective Boards as follows:

- CGA: Approved June 22, 2021
- GGA: Approved June 16, 2021

Appendix 5B

Process and Rationale for Setting Minimum Thresholds and Measurable Objectives for Groundwater Levels and Depletions of Interconnected Surface Waters

(THIS PAGE LEFT BLANK INTENTIONALLY)

Specialists in Agricultural Water Management
Serving Stewards of Western Water since 1993

Technical Memorandum

To: Colusa Groundwater Authority and Glenn Groundwater Authority

From: Davids Engineering and Woodard & Curran

Date: November 30, 2021

Subject: **Process and Rationale for Setting Minimum Thresholds and Measurable Objectives for Groundwater Levels and Depletions of Interconnected Surface Waters**

Introduction

Sustainable Management Criteria (SMC) for the Colusa Subbasin (Subbasin) have been established in consultation with the Technical Advisory Committees of the two groundwater sustainability agencies in the Subbasin, those being the Colusa Groundwater Authority (CGA) and Glenn Groundwater Authority (GGA). SMC consist of the following: the Sustainability Goal adopted for the Subbasin; Undesirable Results describing significant and unreasonable effects to be avoided; quantitative Minimum Thresholds (MTs) that define conditions that, if exceeded, may cause Undesirable Results; and quantitative Measurable Objectives (MOs) to achieve the Sustainability Goal of the Subbasin. Undesirable results, MTs, and MOs are all established in relation to the six sustainability indicators referenced in the GSP Emergency Regulations, five of which are applicable in the Colusa Subbasin.

This Technical Memorandum (TM) documents the process and rationale for setting MTs and MOs for two specific sustainability indicators: Chronic Lowering of Groundwater Levels (Groundwater Levels), and Depletions of Interconnected Surface Water (Streamflow Depletion). As specified in 23 CCR 354.28(c)(6), Streamflow Depletion MTs and MOs shall be based on "the rate or volume of surface water depletions caused by groundwater use that has adverse impacts on beneficial uses of the surface water and may lead to undesirable results." However, the regulations also allow the use of groundwater levels as a proxy for streamflow rates or volumes. Because the location and accuracy of existing stream gages on the Sacramento River and its tributaries are not sufficient to directly analyze streamflow accretions and depletions with respect to the Colusa Subbasin, water levels were used as a proxy. Analyses of streamflow depletions in the Colusa Subbasin are described in the GSP and in Appendix 3G of the GSP. Thus, both of the sustainability indicators addressed in this TM involve groundwater levels and are therefore related. In particular, for representative monitoring network wells that are included in the monitoring networks for both indicators, there are two MTs and MOs. Both are valid with respect to their associated indicator but operationally the shallower MTs and MOs will govern.

The discussion of MOs and MTs for Groundwater Levels and Streamflow Depletion follow, preceded by a brief description of the outreach process used for SMC development (not just for Groundwater Levels and Streamflow Depletion, but also for other sustainability indicators and other GSP development tasks), and brief statements of the Sustainability Goal and Undesirable Results for the two sustainability indicators addressed here.

Outreach and Public Involvement Process

Outreach and public involvement in support of SMC development in the Colusa Subbasin were achieved primarily through a series of public meetings with the Technical Advisory Committees (TACs) formed by the Colusa Groundwater Authority (CGA) and Glenn Groundwater Authority (GGA), respectively. The meetings were publicly noticed on the CGA and GGA websites, with agendas noting action items posted in advance of each meeting, and minutes prepared following each meeting. The technical topics and content for each meeting were developed by the Colusa Subbasin GSP Technical Team led by Davids Engineering, with Woodard & Curran serving as the lead SMC subconsultant. The TACs met together, with the meetings referred to as Joint TAC meetings.

Joint TAC meetings were held approximately monthly, with a total of 13 meetings held between May 8, 2020, and June 11, 2021. SMC were addressed at nine of the 13 meetings, and at all of the seven meetings held between January 8 and June 11, 2021. TAC members engaged in a very thorough, thoughtful, and constructive manner, giving consideration to all interests in the Subbasin involved with or affected by groundwater use and management, including domestic well users, disadvantaged communities, small disadvantaged communities, California Native American Tribes, and environmental beneficial uses and users. This engagement process and consideration for these stakeholders is documented in Chapter 2 of the GSP, as well as meeting minutes and related materials available online.[1] SMC were ultimately vetted and approved by both the CGA and GGA Boards at open Board meetings. Public notice was given in advance of those meetings. The decision records for the SMC are documented in Appendix 5A of the GSP.

Members of the public were welcome to attend the Joint TAC and open Board meetings and were encouraged to express their opinions, suggestions, and comments on the SMC, as well as other aspects of the GSP. Members of the public attended and participated in most Joint TAC meetings, including those in which SMC were discussed.

Sustainability Goal

The Sustainability Goal for the Colusa Subbasin as accepted by the TACs and adopted by the CGA and GGA is:

> *…to maintain, through a cooperative and partnered approach, locally managed sustainable groundwater resources to preserve and enhance the economic viability, social well-being and culture of all Beneficial Uses and Users, without experiencing undesirable results.*

Undesirable Results

The undesirable results statements proposed for Groundwater Levels and Streamflow Depletion, respectively, are as follows:

- The undesirable result for the chronic lowering of groundwater levels is a result that would cause significant and unreasonable reduction in the long-term viability of beneficial uses and users over the planning and implementation horizon of this GSP.

[1] CGA meeting materials are available at: https://colusagroundwater.org/meetings/.
GGA meeting materials are available at: https://www.countyofglenn.net/dept/planning-community-development-services/water-resources/glenn-groundwater-authority/gga.

- The undesirable result for the depletion of interconnected surface water is a result that causes significant and unreasonable adverse effects on beneficial uses and users of interconnected surface waters within the Colusa Subbasin over the planning and implementation horizon of this GSP.

Additional consideration for undesirable results is discussed in Chapter 5 of the GSP.

Measurable Objectives

MOs represent the desired conditions for sustainable operation of the Subbasin while MTs define conditions that are to be avoided because of the risk that Undesirable Results could occur if the MTs are exceeded. For both sustainability indicators addressed in this TM, the MOs were set as the numerical average of all recorded groundwater levels over the most recent five years of record available for each well. For all but four wells, the most recent five years of record ends in Spring 2020. Setting MOs in this manner reflects the GSAs' intention to operate the Subbasin without persistent declines below recent historical groundwater levels, consistent with the Sustainable Groundwater Management Act (SGMA).

Minimum Thresholds

The rationale and parameters considered in establishing MTs for Groundwater Levels and Streamflow Depletion are discussed below in respective sections.

Groundwater Levels

The primary parameters and general objectives considered in establishing Groundwater Levels MTs were:

1. Avoiding significant and unreasonable impacts to shallow (primarily domestic) wells: setting MT groundwater levels shallow enough to be reasonably protective of a majority of existing domestic wells.
2. Avoiding significant and unreasonable effects on groundwater dependent ecosystems (GDEs): setting MT groundwater levels shallow enough to be reasonably protective of GDEs and potential GDEs.
3. Avoiding significant and unreasonable impacts to (constraints on) conjunctive management of Colusa Subbasin surface water and groundwater supplies: setting MT groundwater levels deep enough to allow a range of operational flexibility that ensures adequate water supply reliability over variable, wet and dry hydrologic conditions.

Available GDE mapping was analyzed and GDE areas ranked with regard to their likelihood of actually being dependent on groundwater as opposed to being sustained by streamflow or applied irrigation water. However, due to lack of reliable shallow groundwater elevation data, the analysis was inconclusive[2] and objectives 1 and 3, above, became the primary focus for setting Groundwater Level MTs. However, GDEs were still considered in the selection of Streamflow Depletion SMC and monitoring sites (see below). To reconcile potential conflicts between objectives 1 and 3, setting MTs involved striking balance and compromise between them to reasonably protect domestic well users while also supporting ongoing conjunctive management of the Subbasin.

[2] The lack of shallow groundwater data is identified as a data gap and will be addressed along with other data gaps during plan implementation.

For each of the 48 wells in the Groundwater Level representative monitoring network, Thiessen polygons were drawn around each well and the depths of all domestic wells expressed as an exceedance function. For example, the 20 percent exceedance for the domestic wells in any given polygon is the depth at which 20 percent of the wells are shallower and 80 percent deeper, meaning 80 percent of the wells would be protected and 20 percent would be subject to potential stranding if groundwater levels fell to the 20 percent exceedance depth. Information about existing domestic well infrastructure in the Colusa Subbasin was obtained from Well Completion Reports (WCR) available in DWR's database[3]. The WCR database generally includes all historical wells that have been reported in the system, which may include old wells that are no longer operational, have been refurbished, or have been dewatered for many years, long preceding conditions in 2015. The data is self-reported, and some data entries are incomplete. As such, the domestic well inventory for the Subbasin is incomplete and will be addressed with other data gaps in the Subbasin to support GSP implementation (see Chapters 4, 6 and 7). The analysis to support setting MT was developed considering these limitations.

The analyses of well completion depths conducted to support the MT development process is conservative and protective of beneficial uses because it included domestic wells that were shallower than the historic low groundwater level in each polygon. As documented in Appendix 5C, for the Subbasin as a whole, approximately 46 percent of the domestic wells in the WCR database are shallower than the pre-2015 historical groundwater levels as defined by the Groundwater Level representative monitoring network. Many of these shallow wells may no longer be used or they may have been deepened because they would have otherwise been dry at times prior to 2015. Including these shallow, and potentially unused or deepened wells in the well depth analysis, resulted in Groundwater Level MTs that are shallower than they would have been if the wells had been excluded.

As described in Chapter 4 of the GSP, data gaps related to domestic wells will be addressed in future GSP updates, and this analysis may be refined with new information. Based on the available information at the time of GSP development, technical team analysis, and TAC discussion, a 20 percent exceedance threshold emerged as being reasonable for protection of existing domestic well infrastructure.

For the same 48 representative monitoring wells, historical water levels, generally for the period from spring 2000 to spring 2020 (subject to availability for any particular well), were reviewed and analyzed as a basis for understanding how groundwater levels have fluctuated and when historical minimum groundwater levels have occurred. In particular, the magnitude of the range of historical fluctuation was regarded as an indicator of how the well has behaved over wet and dry hydrologic periods, and whether there are any persistent upward or downward trends. For many wells, especially those relatively far from streams, groundwater levels have trended downward since approximately the mid-2000s and record low groundwater levels were observed in the fall of 2015 following back-to-back critically dry years. These observations led to the approach of alternatively setting MTs at historical low levels plus some percentage of the observed groundwater level range to allow for conjunctive operation of the Subbasin during droughts. The TACs considered 20 percent and 50 percent of historical range as the increment to add to the observed historical low groundwater level. After careful review of the 48 well records, 50 percent of historical range below the historical low was selected as an MT that would allow the range of fluctuation necessary to manage through future dry periods while avoiding undesirable results. To support evaluation of Groundwater Level MTs, the technical team developed an economic analysis of the costs (additional pumping costs, domestic well replacement costs) and benefits (avoided costs of other projects and management actions) associated with the proposed MTs. The analysis illustrated the direct monetary cost-benefit tradeoffs of setting MTs at different levels. The central

[3] Available at: https://data.cnra.ca.gov/dataset/well-completion-reports

conclusion was that the additional cost of raising the MT for most monitoring wells was substantially greater than the additional benefit to groundwater users in the Subbasin. Results of this analysis were presented to the TAC at a public meeting held on May 13, 2021 and are described in more detail in Appendix 5C of the GSP.

Hydrographs for the 48 wells in the Groundwater Level representative monitoring well network are provided in Attachment A illustrating both possible MTs: one based on the 20th percentile domestic well depth exceedance and the other on 50 percent of historical range below the historical low. The two MTs are shown in relation to available historical data for each well. For 13 of the wells, the lower of the MTs is represented by the 50 percent of range below the historical low with the lower MT for the remaining 35 wells represented by 20th percentile domestic well depth exceedance. Based on the information in these graphs and supporting analysis by the technical team, the technical team recommended, and the TACs accepted, adopting the lower of the two MTs as the governing threshold.

For the 13 wells with MTs based on 50 percent of historical range below the historical low, it was possible that more than 20 percent of domestic wells would be shallower than the MT, and therefore would be at risk of dewatering. An additional analysis was developed to quantify the share of domestic wells that could potentially be affected under the selected MT. The inventory of domestic wells for each polygon was screened to remove wells that were shallower than the historical low groundwater level observed prior to January 1, 2015. These wells would have been dewatered based on historical groundwater levels that occurred in the Subbasin prior to the implementation of SGMA. The proportion of the remaining wells that are shallower than the proposed MT was calculated for each polygon. In aggregate, less than 20 percent of domestic wells are shallower than the proposed MT. This was viewed as an acceptable balance between avoiding significant and unreasonable impacts to domestic (and other shallow) wells and allowing sufficient flexibility for conjunctive management of Subbasin surface and groundwater supplies, given the uncertainty of available information on domestic wells in the WCR database. As described in Chapter 4 of the GSP, data gaps related to domestic wells will be addressed in future GSP updates, and this analysis may be refined with new information.

It is important to emphasize that groundwater levels will be managed for MOs, which are generally set substantially above MTs. MTs define the levels that would not be exceeded to avoid Undesirable Results. However, recognizing the importance of protecting domestic wells in the Subbasin, the GSP includes a potential management action in which the GSAs would develop a domestic well mitigation program[5]. This would provide an additional safety net for domestic well users by providing potential compensation for impacts to domestic wells that are associated with GSP implementation.

A hydrograph series showing the selected MT relative to historical water levels at each representative monitoring well is presented in Attachment B.

Streamflow Depletion

As explained in the Introduction, Streamflow Depletion MTs are based on groundwater levels as a proxy for streamflow depletion volume or rate. The basic rationale postulated, evaluated, and recommended by the Environmental Defense Fund (EDF) in support of using groundwater levels as a proxy for depletion volumes or rates is that adverse impacts to surface water uses and users can be avoided if

[5] See Chapter 6, Section 6.5.2 of the GSP.

groundwater gradients and levels near interconnected streams are maintained at levels that existed when implementation of the SGMA began in 2015[6].

Only 12 wells could be identified that were considered to reasonably represent groundwater levels near the three major, potentially interconnected streams in the Subbasin, based on an assessment of their proximity to the streams and the depth to the bottom of their screened interval. The 12 wells were selected based on the following criteria developed using recommendations in the EDF report:

- Located greater than 2,000 feet and not more than 5 miles from an interconnected stream
- Depth to bottom of screened interval less than or equal to 200 feet

The three streams are: Stony Creek, which borders the Subbasin to the north; the Sacramento River, which mostly borders the Subbasin to the east but also runs through a portion of the Subbasin (approximately between Princeton and Colusa); and, the Colusa (Basin) Drain, which originates in and flows southward out of the Subbasin at the Colusa-Yolo Subbasin boundary (county line). The 12 wells are not considered adequate for long-term sustainable groundwater management but are determined to be the best available monitoring sites at this time for evaluating streamflow depletion. Additional dedicated near-stream shallow monitoring wells are needed and will be designed and installed during GSP implementation.

Nevertheless, quantitative MTs were established for these wells as described below. These MTs are considered to be provisional pending additional data collection and analysis and updating and refining the C2VSim FG-Colusa model.

Three *alternative* MTs were evaluated for the 12 wells currently in the Streamflow Depletion representative monitoring network, as follows:

1. The observed Fall 2015 groundwater level (on the date closest to October 15), OR
2. 20 percent of the historical range in groundwater levels below the observed Fall 2015 groundwater level (depth to water), OR
3. 10 feet below the observed Fall 2015 groundwater level (on the date closest to October 15).

The first MT is consistent with the EDF recommendation that aims to avoid or minimize incremental post-SGMA effects on stream depletions but prevents any opportunity for exercising groundwater storage, such as might be needed during prolonged droughts. The second MT is based on a similar concept as that used for Groundwater Levels, where the MT is set at 20 percent of the historical range below the observed Fall 2015 water level. However, historical water levels in most near-stream wells are generally stable and do not fluctuate much. Thus, the historical range is typically small, and the resulting MT was still very constraining on the ability to exercise groundwater storage when needed. Finally, due to concerns among TAC members regarding overly constrained groundwater operations, a third MT was introduced defined as 10 feet deeper than the Fall 2015 groundwater level at each well.

A series of hydrographs showing all three alternative MTs in relation to historical groundwater levels at each of the 12 wells is presented in Attachment C. For all wells, the highest MT is represented by the Fall 2015 water level. The lowest MT is represented by the 10 feet deeper than Fall 2015 groundwater level at 10 of the 13 wells. For the three wells where the 20 percent of historical range below the

[6] Environmental Defense Fund, (EDF), 2018, Addressing Regional Surface Water Depletions in California: A Proposed Approach for Compliance with the Sustainable Groundwater Management Act. Available online at http://edf.org/california-surface-water-report.

observed Fall 2015 groundwater level is the deepest MT, the margin between the two deepest MTs is typically small.

Based on careful consideration of the alternative Streamflow Depletion MTs and evaluation of historical groundwater levels at the wells, the TAC selected the MT defined as 10 feet deeper than the observed Fall 2015 water level. A series of hydrographs showing the selected MT relative to historical groundwater levels is presented in Attachment D.

Appendix 5C

Economic Analysis of Groundwater Level Minimum Thresholds

(THIS PAGE LEFT BLANK INTENTIONALLY)

Technical Memorandum

To: Glenn and Colusa County Groundwater Authorities

From: ERA Economics

Date: November 24, 2021

Subject: Economic Benefit-Cost Analysis of Potential Groundwater Level Minimum Thresholds

Introduction

Sustainable Management Criteria (SMC) for the Colusa Subbasin (Subbasin) were established in consultation with the Technical Advisory Committees (TACs) of the Colusa Groundwater Authority (CGA) and Glenn Groundwater Authority (GGA). SMCs consist of the following: the Sustainability Goal adopted for the Subbasin; Undesirable Results describing significant and unreasonable effects to be avoided; quantitative Minimum Thresholds (MTs) that define conditions that, if exceeded, may cause Undesirable Results; and quantitative Measurable Objectives (MOs) to achieve the Sustainability Goal of the Subbasin. Undesirable Results, MTs, and MOs are all established in relation to the six sustainability indicators referenced in the GSP Emergency Regulations, five of which are applicable in the Subbasin.

Subbasin MTs were developed with substantial public and technical team input. A total of 13 joint meetings of the TACs were held between May 8, 2020, and June 11, 2021, and SMCs were addressed at 9 of the 13 meetings. This included all 7 meetings held between January 8 and June 11, 2021. Several technical analyses were developed to evaluate potential MTs. This appendix describes an economic analysis of MTs that was developed and presented to the TAC at the June 11, 2021 meeting.

The Subbasin MTs are described in detail in Chapter 5 and Appendices 5A and 5B. The general approach to setting MTs for Groundwater Levels was developed with consideration for both the historical groundwater levels at each well and the distribution of shallow (primarily domestic) well depths in the area surrounding the well. Potential MTs were considered based on a percent margin below historical lows or domestic well depths. These were set to balance avoiding significant and unreasonable impacts to domestic wells while also allowing sufficient flexibility for conjunctive management of Subbasin surface and groundwater supplies.

To support evaluation of MTs, an economic analysis was developed to assess whether it would be cost-effective to set MTs higher (or lower) than the MTs based on the lower of 50 percent below the historical low groundwater level or 20th percentile of domestic well depths.

This appendix describes the economic analysis, assumptions, and results considered for evaluating potential Groundwater Level MTs. The reconnaissance-level economic analysis was based on the data available for GSP development and the simplifying assumptions described in the sections below. Important assumptions include: (i) the analysis was developed for MTs, not MOs that the Subbasin will be managed for and are substantially higher than MTs, (ii) only a subset of costs and benefits (pumping cost, well replacement cost, avoided costs of projects and management actions (PMA)) associated with PMA implementation and potentially dewatered domestic were considered, and (iii) the example PMA considered was demand management (reducing pumping). The analysis can be refined and expanded as GSP data gaps are addressed and additional information

becomes available. It is also noted that the GSP includes additional potential actions for monitoring potential impacts to domestic wells, as described in Section 6.5.2.1, Domestic Well Mitigation Program.

Economic Analysis Overview

A benefit-cost analysis was developed to monetize and compare the benefits and costs to groundwater users in the Subbasin under the Groundwater Level MTs. It was developed as a reconnaissance-level assessment to establish preliminary costs and benefits associated with different level MTs. There are additional benefits and costs associated with MTs that relate to four other sustainability indicators defined in the GSP Emergency Regulations that are applicable to the Subbasin that were not considered in this analysis. The analysis could be refined in the future to support updates to the GSP or additional consideration of threshold levels. The information presented in this appendix is developed to illustrate the general magnitude of costs, benefits, and the associated tradeoff.

The benefit of higher MTs is the avoided cost of replacing dewatered domestic wells and the avoided energy cost of additional pumping lifts from lower groundwater levels. Dewatered domestic well costs would fall on individual domestic well owners. Additional pumping costs would fall on Subbasin groundwater users in the vicinity of the monitoring well (defined by Thiessen polygons). In contrast, the incremental cost of setting higher MTs is due to more rapid (and larger scale) implementation of projects and management actions. For example, preventing additional declines in groundwater levels may require larger recharge projects, and these projects would need to be implemented more rapidly. This imposes additional costs on groundwater users in the Subbasin.

The benefit-cost ratio is calculated from the monetized benefits and costs over the relevant planning horizon (in this case, the 20-year GSP implementation period). When the benefit-cost ratio is greater than 1, the benefits are at least as large as the cost, suggesting it could be cost-effective to make the MTs shallower in selected areas.

The following costs were considered in the economic analysis of groundwater level MTs:

1. Capital cost of replacing or refurbishing potentially dewatered domestic wells. For the purposes of this analysis, a domestic well is defined as dewatered, and completely replaced when the groundwater level MT is below the total well depth. In practice, pumping impacts would occur earlier depending on the screened interval of the well and other aquifer- and well-specific characteristics. The domestic well inventory in the Subbasin is based on DWR's Well Completion Report (WCR) data (see GSP Chapter 3).
    a. The capital cost of well replacement is set at $40,000 per well based on costs for domestic well replacement used in other GSPs[1] and adjusted for inflation. These costs generally include drilling at $40 per foot, a sanitary seal for $2,500, and a pump for $5,000. This does not include permit costs. Actual costs will vary based on the costs of materials and supply and demand for well drilling services.

[1] Madera Joint GSP. Technical Appendix 3C: Economic Analysis and Framework for Potential Domestic Well Mitigation Program.

2. Additional energy costs caused by additional pumping lifts that would affect all groundwater users in the Subbasin. Lower groundwater levels increase the energy cost to pumpers (domestic and agriculture) in the Subbasin.

    a. Agricultural pumping energy cost depends on lift, pump efficiency, and the power rate which varies by time of use and size of load. For purposes here, the analysis used an average over several 2021 PG&E agricultural power rates to get a total variable pumping cost of about $0.52 per acre-foot per foot of lift.

The following benefits (avoided costs) were considered in the economic analysis of groundwater level MTs:

1. Cost of demand management (reducing pumping) to prevent additional declines in groundwater levels. The cost of demand management is used instead of the cost of specific projects because demand management could be implemented more rapidly than most projects (there is no construction required). It is noted that demand management is not a planned PMA in the Subbasin, and these costs are used as a proxy for the costs of other projects. Chapter 6 Appendix 6B describes the cost of demand management in the Subbasin. The costs include the direct cost of land idling only, and do not include any additional indirect costs or administrative costs to set up and implement a demand management program.

Existing domestic well infrastructure in the Subbasin is based on WCR available in DWR's database[2]. The WCR data generally include all historical wells that have been reported in the system, which may include old wells that are no longer operational or have been refurbished. The domestic well inventory for the Subbasin will be addressed with other data gaps in the Subbasin to support GSP implementation (see Chapter 3).

An analysis was developed to evaluate the WCR data regarding well depths for the wells in the inventory. For each well in a Thiessen polygon, the reported well depth was compared to the historical low groundwater level recorded prior to January 1, 2015. The purpose of the analysis was to establish what share of domestic wells in the WCR database may have been previously dewatered and/or are no longer used. Wells that were shallower than the historic low were flagged, counted, and compared to the total domestic wells for each Thiessen polygon. In total, approximately 46 percent of the domestic wells in the WCR database for the Subbasin show a total depth that is shallower than the historic groundwater level low. The results of the analysis for each Thiessen polygon are summarized in Table 1.

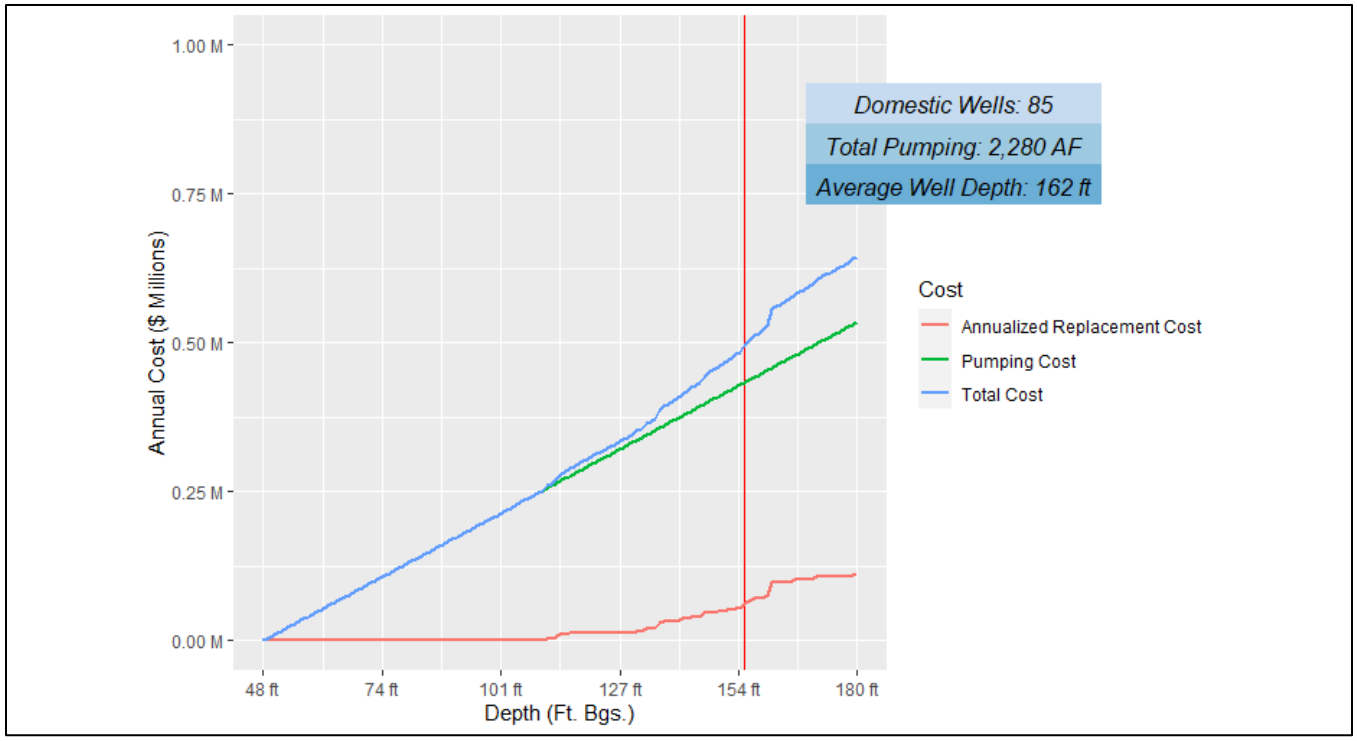
Economic Analysis of Subbasin MTs

The economic analysis considers the Subbasin groundwater level MTs. It is important to note that the Subbasin will be managed to meet MOs, which are set substantially higher than MTs. The costs and benefits described in this TM are generally conservative, corresponding to Groundwater Level MTs that are lower than current groundwater levels, MOs, and observed historical levels in many areas.

Figure 1 illustrates the aggregate annual cost curve for an example Thiessen polygon (21N03W01R002) in the Subbasin. The same calculations are repeated for the other 47 polygons. A range of groundwater depths including the MT (155 feet bgs) specified in the GSP are evaluated. Costs increase as depth to groundwater increases. The capital cost of replacing dewatered domestic wells is annualized using a discount rate of 5 percent over a 30-year economic life. Pumping costs are the additional annual energy cost of pumping from a lower depth in that year. The total cost is the sum of the pumping cost and well replacement cost. All costs are additional (incremental) costs in addition to the current pumping costs at current groundwater depths.



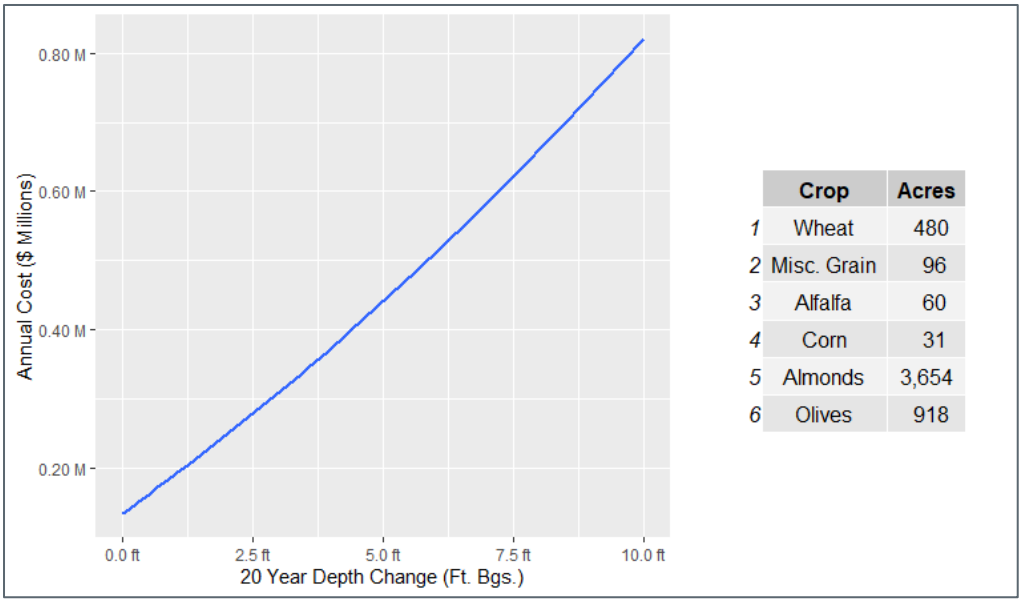


Figure 1. Colusa Subbasin Incremental Annual Cost by Depth to Groundwater

Figure 2 illustrates the benefit (avoided cost) of a change in the MT for the same example Thiessen polygon (21N03W01R002) in the Subbasin (1 of 48 total polygons). In contrast to the static pumping and well replacement costs shown in Figure 1, the benefit is an avoided cost and is therefore expressed as a change in depth to groundwater. The irrigated acreage within the Thiessen polygon is also shown in the figure. The mix of crops grown affects the cost of demand management. The example polygon is predominantly planted to permanent crops (almonds and olives), which are costly to idle due to higher net return relative to other annual crops and the substantial capital investment required to establish orchards. A range of projects and management actions that are specified in the GSP could be implemented to achieve a change in groundwater levels across the Subbasin (see Chapter 6). As described above, the cost of demand management to reduce pumping is used to develop the aggregate cost curve shown in Figure 2 (and the individual cost curves for each polygon). The change is shown over the full GSP implementation timeline (20 years).

	Crop	Acres
1	Wheat	480
2	Misc. Grain	96
3	Alfalfa	60
4	Corn	31
5	Almonds	3,654
6	Olives	918

Figure 2. Colusa Subbasin Incremental Demand Management Cost by Depth to Groundwater

As described in Chapter 5 and Appendices 5A and 5B, the MT for groundwater levels is set based on the lower of 50 percent below the historical low groundwater level or the 20th percentile of the domestic well depth within each of the 48 Thiessen polygons corresponding to the 48 monitoring wells. The benefit-cost analysis evaluates whether an incremental change in the MT would result in a positive benefit-cost ratio in each polygon. The analysis is developed for an incremental increase in the MT of 5 feet.

Table 2 summarizes the benefit-cost analysis of an incremental (defined as 5 feet) increase in the MT. This illustrates the central economic tradeoff: whether a change in the MT (in this case an increase in the MT level by 5 feet) would generate economic benefits for the Subbasin that are greater than the costs that would be incurred. The table summarizes each polygon and the annual benefits, costs, and net benefits. Since the analysis evaluates an incremental increase in the MT, the benefits are defined as the avoided pumping and well replacement cost. Costs are defined as the additional cost of idling land (demand management) to achieve the 5-foot increase in MT. The net benefit shows the absolute difference between benefits and costs, and the final column shows the associated benefit-cost ratio. A benefit-cost ratio greater than 1 shows benefits are greater than costs, implying that a 5-foot shallower MT would generate benefits greater than costs. The aggregate benefit-cost ratio over all polygons is 0.33 (each dollar of cost returns only 33 cents in benefits). There are five polygons where the benefit-cost ratio is slightly greater than 1 (between 1.0 and 2.1). However, the total annual net benefit across these five polygons is $70,000, which is less than 1 percent of the estimated -$3,800 thousand (-$3.8 million) in total annual net benefits across the Subbasin.

Total	$1,854	$5,547	($3,799)	0.33

Notes: "NA" or missing values reflect polygons with zero acreage or insufficient data to support the benefit-cost calculations.

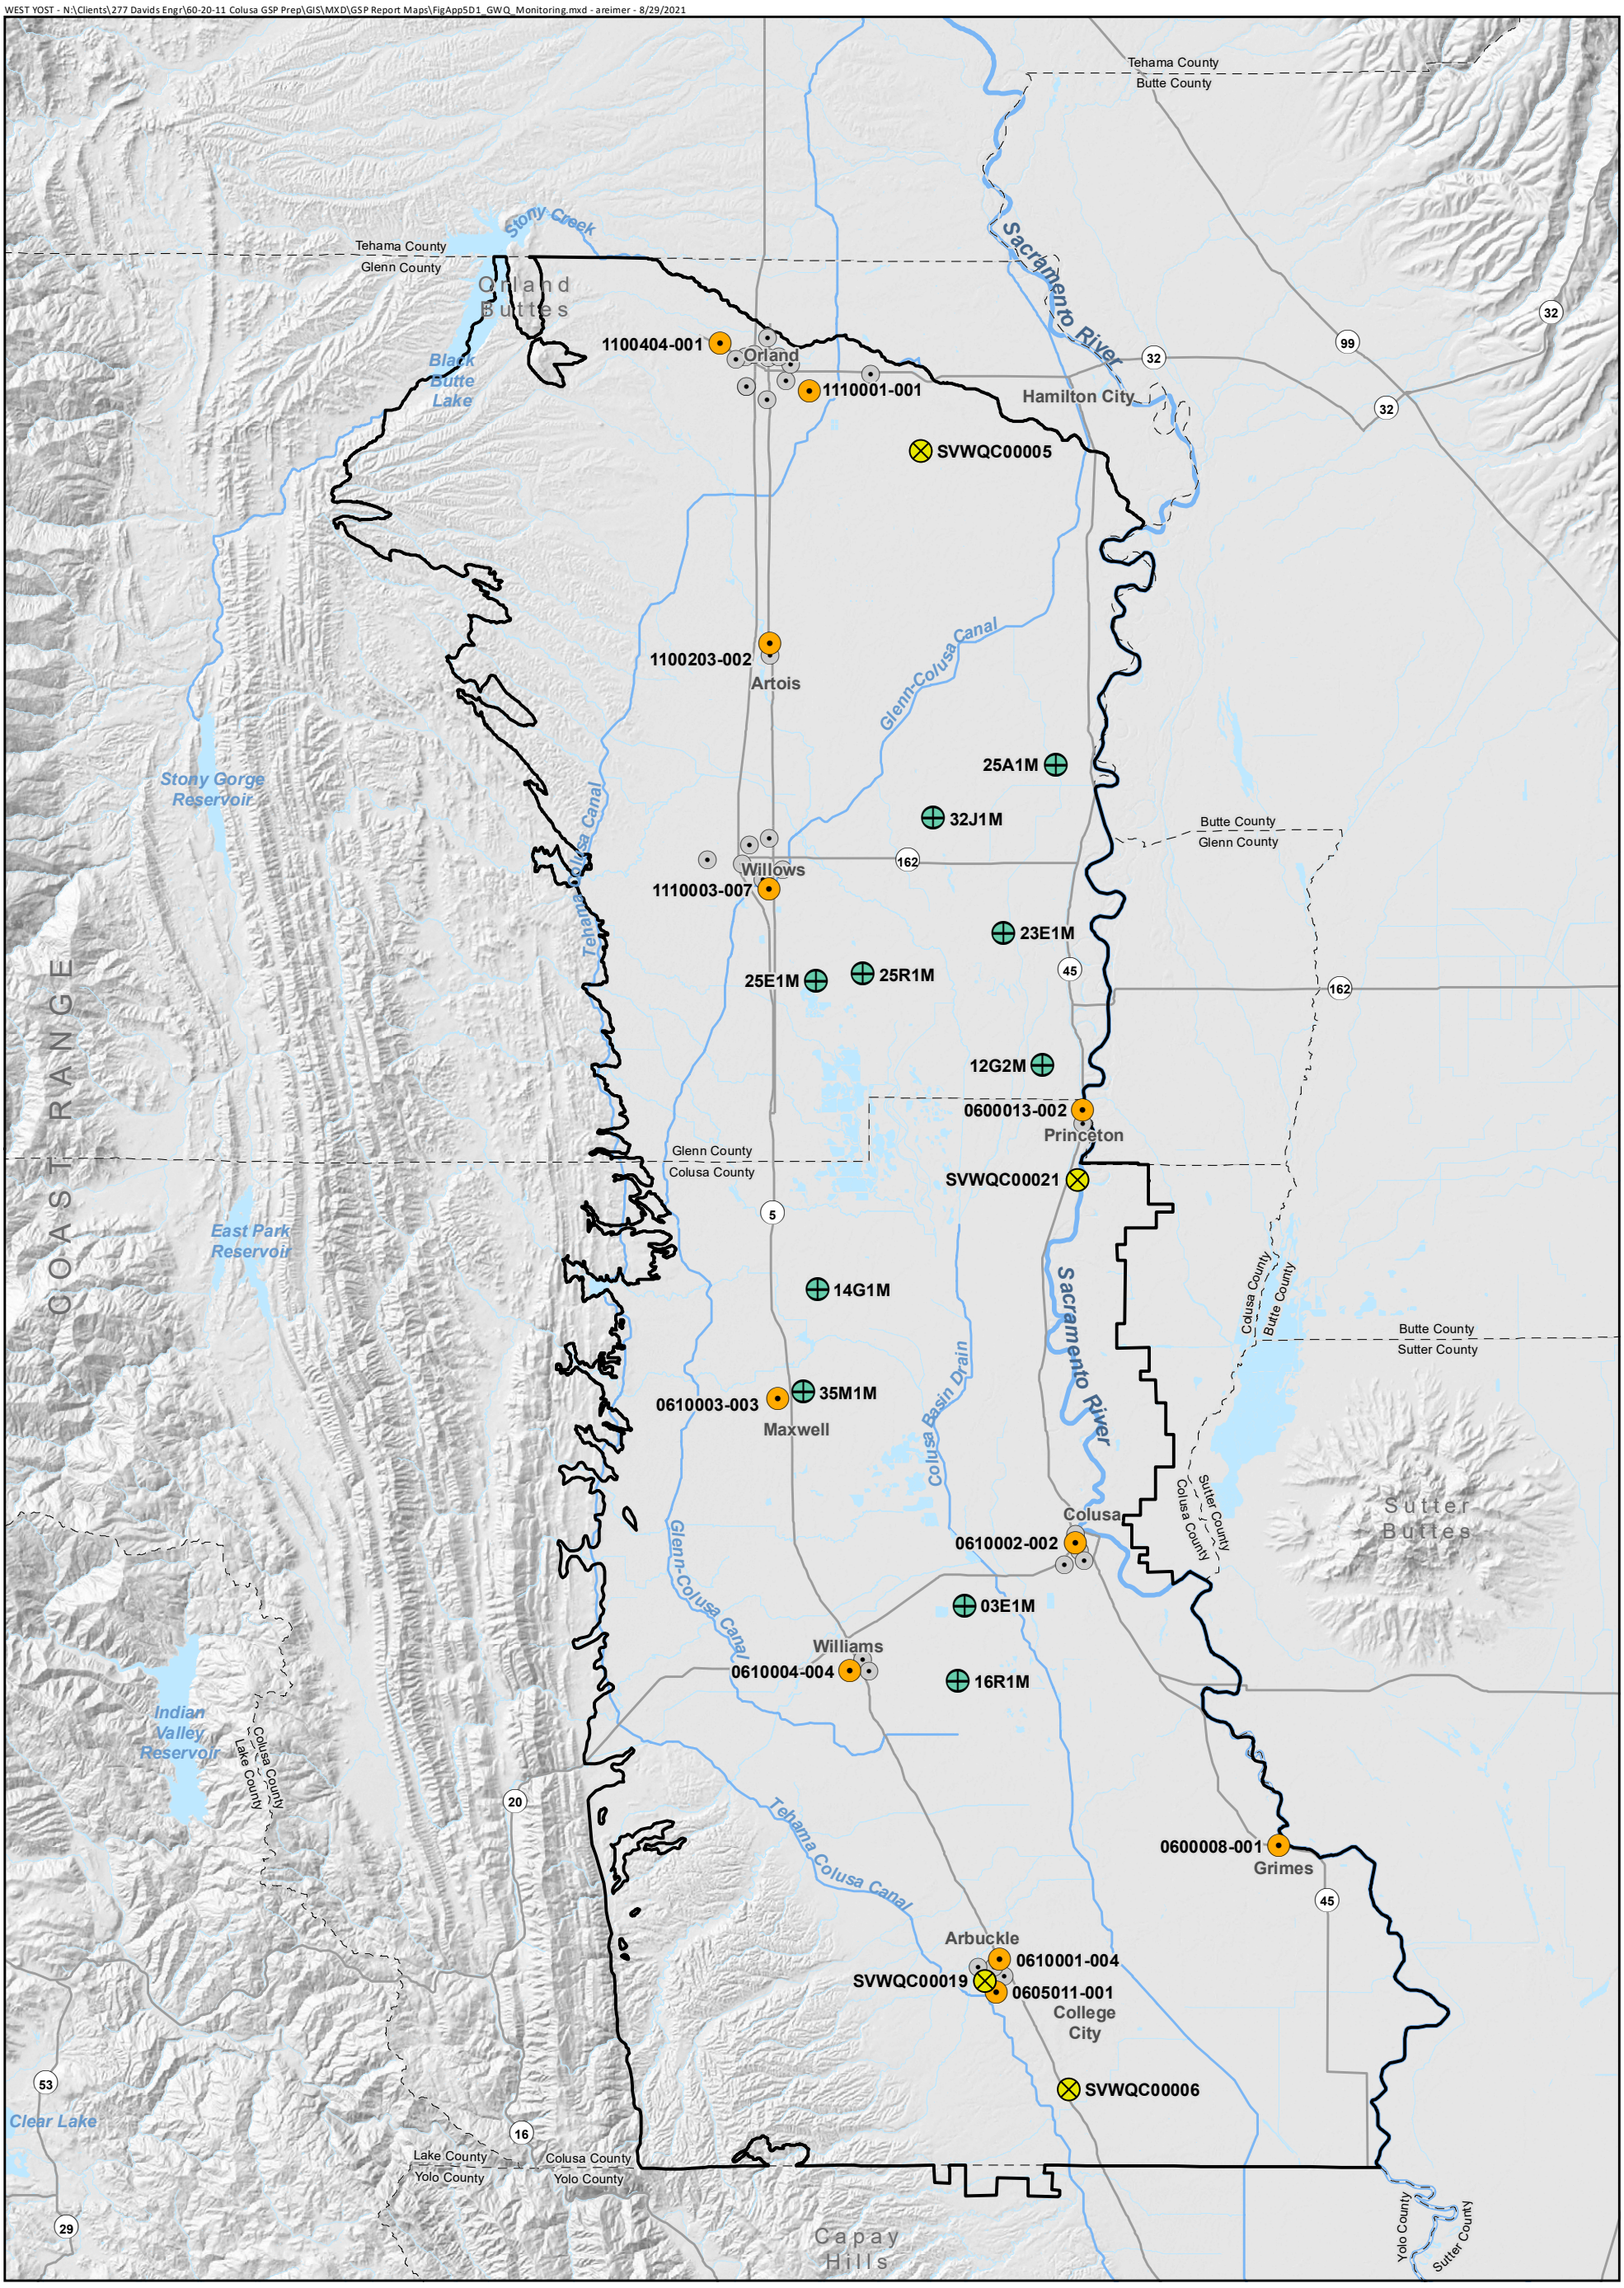
Discussion

The results indicate that the cost of raising the MT would not be cost effective from a Subbasin-wide perspective, or for most individual polygons. The aggregate benefit-cost ratio of 0.33 shows each dollar of cost from setting MTs incrementally higher returns only 33 cents in benefits across the entire Subbasin. The avoided costs (fewer domestic wells requiring replacement and reduced pumping lifts) would be modest ($1.9 million) relative to the cost of lost agricultural net return from demand management ($5.5 million). The general conclusions are robust to the assumptions used – that is, results are not sensitive to reasonable ranges in key assumptions, including the loss in net return per acre-foot of demand management, additional pumping costs, or the cost of replacing a domestic well. The analysis is developed to support long-run planning for setting MTs. PMAs needed to support higher MTs require time to develop and implement and cannot be implemented rapidly in response to severe, unprecedented drought. The short-run costs of wells running dry during severe drought events can include other cost factors that were not explicitly analyzed. For example, in the crisis of a severe drought, local drilling capacity and well repair services can be limited, which can result in higher cost or increased wait times. This can place additional financial stress on households with domestic wells.

There are five polygons that show a benefit-cost ratio slightly greater than 1, indicating that benefits would be slightly greater than the costs. The total net benefit is $70,000 across these five polygons. The benefit-cost ratio for these polygons is between 1.1 and 2.1. These occur in polygons 21N02W36A002, 21N02W04G002,

21N03W01R002, 21N02W01F001, and 20N02W18R005.The total annual net benefit of $70,000 is less than 1 percent of the estimated -$3,800 thousand (-$3.8 million) in total annual net benefits across the Subbasin. In addition, the cost of setting higher MT includes the direct cost of demand management only, and does not include other program administrative costs, or potential third-party impacts that may occur in the Subbasin. Including these costs would push the benefit-cost ratio below one in these areas. Finally, it is noted that the inventory of domestic wells for each polygon includes all wells in the DWR WCR database. Many wells are shallower than the historical low groundwater level observed prior to January 1, 2015. These wells would have been dewatered based on historical groundwater levels that occurred in the Subbasin prior to the implementation of SGMA. Removing these wells from the database would reduce the benefit of increasing MT, further reducing the benefit-cost ratio in all polygons.

The conclusion of the economic analysis is that it would not be cost-effective from a Subbasin or polygon-wide perspective to raise Groundwater Level MTs in the Subbasin. Therefore, the proposed MTs were viewed as an acceptable balance between avoiding significant and unreasonable impacts to domestic (and other shallow) wells and allowing sufficient flexibility for conjunctive management of Subbasin surface and groundwater supplies. In addition, as summarized in Table 1 and described in Appendices 5A and 5B, a substantial share of domestic wells in the WCR database appear to be shallower (total depth) than the observed low groundwater levels in each of the Thiessen polygons.



It is important to emphasize again that groundwater levels will be managed for MOs, which are set substantially above MTs. MTs are set below where the Subbasin is expected to be operated, defining the levels that would not be exceeded to avoid increasing risk of Undesirable Results. However, recognizing the importance of protecting domestic wells in the Subbasin, the GSP includes a potential management action in which the GSAs would develop a domestic well impact mitigation program (see Chapter 6). This would provide an additional safety net for domestic well users by providing potential compensation for impacts to domestic wells that are associated with GSP implementation.

Appendix 6A

Surface Water Available for Recharge and Financial Incentives in the Colusa Subbasin

(THIS PAGE LEFT BLANK INTENTIONALLY)

Technical Memorandum

To: Glenn and Colusa Groundwater Authorities

From: Davids Engineering and ERA Economics

Date: July 1, 2021

Subject: **Surface Water Available for Recharge and Financial Incentives**

Purpose

More than 30 projects and management actions (PMAs) are included in the Colusa Subbasin GSP to achieve and maintain sustainable groundwater management. Five of the PMAs are on track for implementation, six are ongoing, with the remaining PMAs being in various stages of investigation and evaluation. The five projects on track for implementation are all groundwater recharge projects involving the use of surface water for direct or in-lieu recharge. Three of the five projects are substantial in-lieu recharge projects, meaning that they will require regulated surface water sources available on an irrigation demand schedule. All three projects are planning to acquire all or most of the required surface water through transfers of Central Valley Project (CVP) water supplies that are surplus to the needs of other CVP water supply contractors or Sacramento River Settlement Contractors (Settlement Contractors).

All three in-lieu recharge projects on track for implementation include incentivizing landowners to utilize existing CVP supplies. CVP supplies in some years are surplus to CVP contractor needs in some cases because contractors are still building out their systems and acreage over time to use the CVP water, but in other cases, the cost of CVP supply is too high to be competitive with groundwater pumping or other local transfers. Growers currently using groundwater also benefit from the convenience of having a clean, reliable, on-demand supply from their pumps and not having to order water for delivery through local district conveyance.

This appendix serves two purposes. First, it summarizes the three in-lieu recharge projects and the potential sources of surface water available for irrigation use to enable reduction of groundwater pumping. Second, it provides an overview of the current costs of CVP water, how those costs are changing, and provides a discussion of financial incentives to increase use of those supplies for some contractors in some years. The description uses information for two districts, Orland-Artois Water District and Colusa County Water District, but the concept could be applied to other districts as well.

Colusa Subbasin In-Lieu Recharge Projects On-track for Implementation

The three substantial in-lieu groundwater recharge projects that are on track for implementation are described below.

Colusa County Water District In-Lieu Groundwater Recharge

Colusa County Water District (CCWD) has a total service area of approximately 46,000 acres of which 39,875 are currently irrigable with existing district infrastructure. This area is planted to predominantly permanent crops. The district delivers surface water to approximately 35,000 acres, with the remaining acres being idle or irrigated with privately pumped groundwater. CCWD has a CVP water supply contract that provides a maximum

of 62,200 acre-feet (AF) annually. The district also holds a CVP contract water supply for 5,666 AF that was part of a Colusa County subcontract assigned to CCWD in 2006. Both contracts are subject to curtailments determined by the Bureau of Reclamation (Reclamation) each year based on Sacramento River watershed hydrologic conditions and planned CVP operations.

Additionally, CCWD typically transfers in additional CVP water supplies to augment water available under its CVP contract. Historical transfers have been primarily from Westside Water District and, more recently, from Reclamation District 108 (RD108) under a five-year pilot transfer agreement that ends in 2022. Despite the availability of district surface water, some CCWD growers choose to pump groundwater because is it less expensive than surface water (and because groundwater requires less screening and filtering compared to district surface water).

Under the CCWD In-Lieu Groundwater Recharge project, the district will acquire additional surface water and incentives will be put in place to make the cost of surface water the same or less expensive than pumped groundwater, thereby incentivizing growers who would otherwise use groundwater to use surface water. The additional surface water is expected to be acquired under long-term water transfer agreements with other CVP contractors, including Sacramento River Settlement Contractors, and potentially other sources. The plan is to acquire and deliver 30,000 acre-feet per year (AF/yr) except in Shasta Critical years[1] when groundwater banked through in-lieu recharge in prior years would be used. It is estimated that the average additional surface water use over the long term would be approximately 27,000 AF/yr.

Colusa Drain MWC In-Lieu Groundwater Recharge

The Colusa Drain Mutual Water Company (CDMWC) encompasses approximately 46,000 acres of agricultural land and environmental habitat located adjacent to the Colusa Basin Drain (Drain) in the Colusa Subbasin (Subbasin). Shareholders in CDMWC divert water for summer irrigation from the Drain under a combination of appropriative water rights held individually by the shareholders, a long-term water supply agreement with Reclamation, and annual and multi-year transfer agreements with neighboring Sacramento River Settlement Contractors. Historically, many CDMWC diverters use both groundwater and surface water for irrigation because flow in the Drain is often insufficient and unreliable to fully satisfy all irrigation requirements on a timely basis.

For the period 1990 through 2015, average surface water diversions from the Drain were estimated to be 48,000 AF/yr while groundwater pumping during the same period was estimated to be 40,000 AF/yr. It is estimated that approximately 70 percent of the historical groundwater pumping can be eliminated through the provision of additional surface water, provided that the surface water cost is approximately equal to the cost of groundwater. The cost comparison of surface and groundwater would include the full cost of each source (e.g., filtering, system costs, and other on-farm costs in addition to the delivery charge per AF of surface water and variable cost to pump groundwater). The potential in-lieu recharge is estimated to be 28,000 AF/yr on average across all years, and 31,000 AF in Shasta Non-Critical years. The planned source of additional surface water is primarily upstream Sacramento River Settlement Contractors that can discharge water into the Drain for use downstream by CDMWC shareholders.

Orland-Artois Water District Land Annexation and Groundwater Recharge

Orland-Artois WD (OAWD) has an existing service area of about 29,000 acres and delivers water to district landowners through 110 miles of pipelines and 300 metered deliveries. Surface water delivered by the district is available under a CVP water supply contract with Reclamation and through short- and long-term transfer

[1] In general, Shasta Critical conditions are declared when the forecast inflow to Lake Shasta for a particular water year is equal to or less than 3.2 million AF.

agreements with other CVP water contractors and Sacramento River Settlement Contractors. The district's water supply contract provides a maximum of 53,000 AF/yr, subject to curtailments determined by Reclamation each year based on Sacramento River watershed hydrologic conditions and planned CVP operations. Historically, water transfers have been from Maxwell Irrigation District, Princeton-Codora-Glenn Irrigation District, and others.

The district is working with a group of neighboring, non-district landowners to annex approximately 12,000 acres of groundwater-dependent agriculture into the district. Additional surface water for the annexed lands would be secured through multi-year purchase or transfer agreements with willing sellers, conveyed through the existing Tehama-Colusa Canal[2] (TCC), and distributed to the annexed lands through new distribution facilities. Potential transferors include CVP water supply contractors and Sacramento River Settlement Contractors. The plan is to acquire and deliver 25,000 AF/yr of surface water to the annexed lands except in Shasta Critical years when groundwater banked through in-lieu recharge in prior years would be used. It is estimated that the average additional surface water use, and thus in-lieu groundwater recharge, over the long term would be about 23,000 AF/yr.

Sources of Surface Water for In-Lieu Recharge

The aggregate volume of water needed for the three in-lieu recharge projects described above is 86,000 AF/yr, in Shasta Non-Critical years, as summarized in Table 1.

Table 1. Proponents and Water Needs Associated with Colusa Subbasin In-Lieu Groundwater Recharge Projects on Track for Implementation

Project	Average Additional Surface Water Needed in Shasta Non-Critical Years (acre-feet)
Colusa County Water District	30,000
Colusa Basin Drain Mutual Water Company	31,000
Orland Artois Water District	25,000
Total	86,000

Potential surface water sources to meet these requirements are discussed below:

Full use of Available CVP Contract Water

In recent years, both CCWD and OAWD have not used all the water available under their respective CVP water supply contracts, due primarily to the high cost of the upper two price tiers according to Reclamation pricing policy. The cost of CVP water is determined by CVP pricing policy and cost allocation. Up until recently, all CVP water contracts in the Tehama-Colusa Service Area were Water Service Contracts, and the water price was calculated using three[3] components: The O&M (operations and maintenance) charge, the capital component

[2] The Tehama-Colusa Canal has a maximum capacity of approximately 2,530 cubic feet per second at the canal inlet (Stene, 1994), and a capacity of approximately 1,700 cubic feet per second at the southern end of the canal. Considering historical canal operations, it is likely that conveyance capacity is available to facilitate such a program, subject to certain conditions (see Attachment A).

[3] Contractors also pay for power use and a restoration charge, which is currently about $11 per AF.

(paid back without interest), and the full cost rate that includes O&M and capital plus interest. The sum of the O&M and capital components is called the cost of service rate. Some or all of the rate's capital component could be removed as "ability-to-pay" relief, and many of the area contractors have received this in the past. The resulting contract rate (cost of service potentially reduced by ability-to-pay relief) applies to the first 80 percent of the contract maximum. The full cost rate includes cost of service plus interest on the capital component and is generally substantially greater than the cost of service rate. In 2020 for example, OAWD's contract rate (cost of service) was about $60 per AF and its full cost rate was about $218 per AF, calculated according to section 205(a)(3) of the Reclamation Reform Act. According to federal law (the CVP Improvement Act of 1992), CVP irrigation (and M&I) water supply contracts required payment of tiered water rates for contractual water entitlements, which are summarized as follows:

- Tier 1: The Cost of Service water rate developed through the federal water rate setting process. The Tier 1 rate applies to the first 80% of the delivered contractual water entitlement.
- Tier 2: The rate is the numerical average of the Tier 1 rate and the Tier 3 rate. The Tier 2 rate applies to the next 10% of the delivered contractual water entitlement.
- Tier 3: This rate is the full cost rate developed through the federal water rates setting process. Tier 3 applies to the last 10% of the delivered contractual water entitlement.

Even when blended with Tier 1 water, using Tier 2 and Tier 3 water resulted in excessive water cost, and so some or all of the Tier 2 and Tier 3 water went unused.

Incentivizing Utilization of CVP Supplies

As of 2021, Tehama-Colusa Canal (TCC) CVP water service contractors have converted their contracts to repayment contracts, thus paying off and removing the capital component from their CVP water rates. The new repayment rates (not including restoration charges and other power charges) are $23.43 per AF for CCWD and $26.67 per AF for OAWD. Under the revised rates, these contractors intend to use all of their CVP contract water. The additional CVP water (the difference between what OAWD and CCWD would have used under their old rate structure versus under their new repayment rate) can fulfill a portion of the in-lieu recharge quantities shown.

Repayment of CVP capital required the contractors to borrow money that they will be paying off over the next 15 years or more. Contractors vary in how they recover that fixed cost. Some, like OAWD, have acreage assessments on lands in the district. Others, like CCWD, include more fixed costs in their water rate, so when CVP delivery goes down, the water rates must go up to cover the fixed costs. Due to critical drought conditions, the CVP has announced no contract deliveries to the Tehama Colusa Service Area in 2021. As a result, CCWD's announced water rate for 2021 is currently estimated to be $288 per AF, though this may change as conditions and availability of water transfers change.

OAWD has estimated that its water rate after conversion to the repayment contract would be about $42 per AF under conditions of full CVP supply and $62 per AF with a 50 percent supply.[4] CCWD has estimated that its water rate after conversion to the repayment contract would be in the range of $70 per AF under conditions of full CVP supply.[5]

Depending on the relative costs of district supply versus groundwater, under the repayment contracts, the districts' rates may be low enough already to encourage full use of CVP supply. However, if groundwater pumping remains a lower cost alternative to CVP water for some growers, incentivizing their use of CVP water in lieu of pumping would require paying at least the difference between district surface supply and the variable

[4] According to a Proposition 218 informational presentation to the OAWD Board in August 2020.

[5] This is a rough estimate based on personal communication with CCWD Manager, Shelly Murphy, June 30, 2021.

cost of pumping groundwater. Other advantages of groundwater over delivered surface water include the growers' convenience of having a clean, reliable, on-demand supply from their pumps. Some groundwater users also may need to incur some on-farm water distribution costs to take surface water.

A program to incentivize CVP use would be specific to individual districts. Therefore, a full evaluation was not developed for the GSP. It is anticipated that an economic analysis to establish incentives and program design would be completed as part of GSP implementation activities. The economic analysis would generally include the following components:

- The initial evaluation would include estimating the incentive payments needed to achieve greater or full use of CVP contract water. The payments should compensate for the difference between CVP water cost (full cost as delivered by the district) and variable cost of groundwater pumping in areas receiving the in-lieu recharge, plus the value of any additional advantages or cost savings of groundwater over surface water.
- Estimate the projected total annual cost of the incentive payments, considering the payments per AF (which may vary by area) and the expected additional amounts of CVP water purchased and used in lieu of pumping. The estimate should account for variability in CVP supply by year and the costs of other supplies or activities related to that variability. In addition, economic benefits should be quantified and assigned to project beneficiaries.
- Estimate the recharge benefits to the GSA or to subareas within the GSA, considering avoided pumping costs and/or cost of other PMAs that could be avoided by this action. This would include an assessment and assignment of economic benefits that accrue to different parties and over time.
- Consider and evaluate other policies that may be used to assure that increased use of CVP water is effective as in-lieu groundwater recharge and does not simply enable expansion of irrigated area with little or no effect on groundwater recharge.
- Using the results of the cost and benefits calculations developed in the economic analysis described above, develop a method for assigning (if necessary) project costs in proportion to benefits received.

It is important to note that the switch to repayment contracts could provide alternative ways to incentivize use of CVP supplies with districts. An economic analysis could develop strategies to shift and restructure district charges to lower the effective cost of CVP water. This would generally include recovering a greater proportion of fixed costs as land-based charges rather than through variable water rates. For example, OAWD's recent approval of an acreage assessment to recover costs of its CVP capital conversion loan effectively reduces the per AF cost of CVP water. As a result, its water rate is substantially lower than before it converted to a repayment contract. This approach could be explored by other districts if they find that their water rate discourages full use of available CVP supply.

Transfers of Other Unused CVP Contract Project Water

Other CVP water contractors (not Sacramento River Settlement Contractors) within and outside the Colusa Subbasin, including members of the Tehama Colusa Canal Association served by the TCC, also have contract water available for transfer in some years. Historically, some but not all of this water has been transferred under the provisions of Section 3405(a) of the Central Valley Project Improvement Act (CVPIA) (Title 34 of Public Law 102-575).

Transfers of Available Settlement Contract Water

There are 127 Sacramento River Settlement Contractors. The total surface water supply quantities associated with each settlement contract have a "base supply" component and a "project water" component[6]. In general, project water can be transferred in-basin under the provisions of CVPIA Section 3405(a) and base supply cannot[7].

There are 17 Sacramento River Settlement Contractors with total contract supplies of 10,000 AF or more (Table 2). The aggregate base supply for these entities is approximately 1.7 million AF, and the project water supply is about 296,000 AF. The 110 remaining, smaller Settlement Contractors, have aggregate base supplies of about 92,000 AF and project water supplies of about 34,000 AF. Thus, the total quantity of project water under the settlement contracts is about 330,000 AF.

It is estimated that in Shasta Non-Critical years about 25 percent of this volume, or approximately 83,000 AF, is available for transfer. Glenn Colusa Irrigation District and RD108, the two largest Settlement Contractors, estimate that they could provide approximately 40,000 AF and 14,000 AF of project water for transfer in Shasta Non-Critical years, respectively. The combined quantity of 54,000 AF constitutes roughly two-thirds of the estimated 83,000 AF of project water available for transfer.

[6] Base supply is intended to replace water that could have been diverted under each entity's underlying, senior water right(s), while project water is an additional amount negotiated as part of the settlement to supply supplemental water during the summer that might not have been available under the underlying rights. All settlement contracts have a base supply component and most, but not all, also have a project water component.

[7] Base supply can be transferred to the extent its use is reduced by land fallowing, groundwater substitution, or conservation.

Table 2. Sacramento River Settlement Contractors with Total Supplies of 10,000 AF or More

Name	Contract Number	Base Supply	Project Supply	Total Supply
Glenn-Colusa Irrigation District	14-06-200-855A-R-1	720,000	105,000	825,000
Sutter Mutual Water Company	14-06-200-815A-R-1	169,500	56,500	226,000

Anderson-Cottonwood Irrigation District	14-06-200-3346A-R-1	121,000	7,000	128,000
Maxwell Irrigation District	14-06-200-6078A-R-1	11,980	6,000	17,980
Provident Irrigation District	14-06-200-856A-R-1	49,730	5,000	54,730
Redding, City of	14-06-200-2871A-R-1	17,850	3,150	21,000
Pleasant Grove-Verona Mutual Water Company	14-06-200-5520A-R-1	23,790	2,500	26,290
Bardis, Christo D., et al. (Broomieside Farms)	14-06-200-1286A-R-1	8,070	2,000	10,070
Pacific Realty Associates, L.P. (M&T Chico Ranch)	14-06-200-940A-R-1	16,980	976	17,956
Conaway Preservation Group, LLC	14-06-200-7422A-R-1	50,190	672	50,862
River Garden Farms Company	14-06-200-878A-R-1	29,300	500	29,800
	Total	1,669,800	296,098	1,965,898

Summary

There are three in-lieu groundwater recharge projects on track for implementation in the Colusa Subbasin with a combined surface water requirement of approximately 86,000 AF in Shasta Non-Critical years. Each project intends to acquire the necessary surface water primarily via water transfers from other entities with available CVP contract supplies and CVP Settlement Contract project water under the provisions of CVPIA Section 3405(a). Transfer of available project water supplies under settlement contracts alone would nearly meet these needs, with full use of existing contract supplies (CCWD and OAWD only) and potential transfers of surplus CVP contract supplies adding to that amount.

It is recognized that the actual feasibility of acquiring the water is subject to the willingness of both buyers and sellers, and the negotiation of mutually acceptable contract terms. These negotiations have been initiated informally and will be continued as the projects move toward implementation.

A key element of all three projects will be creating incentives for growers to use the surface water made available rather than pumping groundwater. The preliminary analysis presented in this appendix suggests that the variable cost to pump groundwater may already be greater than the district rate under the new repayment contracts in some districts. In other districts, the water rate is around $10 to $25 per AF greater than the variable cost to pump groundwater. These are just the variable costs of water supply, and do not include additional on-farm costs associated with each source. As described above, incentivizing use of surface water can be accomplished by developing an incentive program funded by the beneficiaries of such a program, or through adjustments to the district water rate structure. It is anticipated that these specific incentive structures would be evaluated and developed as part of project implementation.

It is also noted that the in-lieu recharge volumes referred to above are maximum quantities. Based on monitoring of project performance and groundwater conditions, it may be possible to operate the Subbasin within its sustainable yield with less than the maximum in-lieu recharge quantities described above.

Subject: RE: TCC Capacity

Grant,

Caveated with the following first blush comments (reserve the right to add to this list), I respond:

1. TCCA will not be responsible for providing the subject water rights or water supply that is diverted for this purpose.
2. TCCA will not be responsible for any permits, mitigation, or other regulatory responsibilities associated with such a program.
3. CCWD and OAWD will be responsible for any and all charges, contracting, Warren Act or other fees and/or costs associated with such a program.
4. TCCA will be paid appropriate conveyance charges pursuant to the rates in the TCCA JPA Agreement that CCWD and OAWD currently pay or other rates as agreed.

I respond to your question as follows: Currently, it is my opinion that under most (in fact all that I currently think of) scenarios experienced, there would be plenty of pumping/diversion capacity (currently maxed out at 2000 cfs) and conveyance capacity in the TC Canal (2500 cfs at the top of the canal, 2100 cfs at Funks Reservoir, 1700 cfs at the south end of the canal) to facilitate such a program. However, historical operations are not always a good predictor of future conditions. In a typical year, we typically divert/convey a maximum amount of water of around 1300-1500 cfs. I would also add that I have not yet discussed particulars details of such a program (because I have not been provided such details until this time) with my Board of Directors. Bill Vanderwaal and Emil Cavagnolo did generally outline the recharge concept being explored at my last meeting, which the Board was generally supportive of - notwithstanding the need to hear the details. However, I anticipate that this water would have to somewhat take a second tier position in the atypical case of a conflict over the available diversion/conveyance capacity.

I hope this is helpful Grant, sorry for the long caveated answer. But I don't want to give the misimpression of complete acquiescence or create a reliance on a simple statement of "sure we have capacity" until all of the details are more fully vetted and the necessary terms have been contemplated. I will leave it to your discretion on how you wish to articulate capacity availability in the Colusa GSP based on the foregoing.

Economic Analysis of Demand Management and Conceptual Allocation Approaches

(THIS PAGE LEFT BLANK INTENTIONALLY)

ERA Economics
Environment • Resources • Agriculture

Technical Memorandum

To: Glenn and Colusa County Groundwater Authorities

From: ERA Economics

Date: November 19, 2021

Subject: **Economic Analysis of Demand Management and Conceptual Allocation Approaches**

Introduction

More than 30 projects and management actions (PMAs) are included in the Colusa Subbasin GSP to achieve and maintain sustainable groundwater management. Five projects are on track for implementation, which are all groundwater recharge projects that use surface water for direct and/or in-lieu recharge. Recognizing that projects can take several years to develop, and in light of the current severe drought conditions across the Colusa Subbasin (Subbasin) and state, the GSP includes two "backstop" demand management actions that could be implemented relatively quickly, primarily because they do not require construction of new infrastructure. These management actions include a targeted demand management program that would incentivize temporary pumping reductions (and/or local water transfers) in periods of extreme drought, and a broader demand management program that would incentivize pumping reductions, if necessary, due to future groundwater conditions in the Subbasin.

Demand management can be implemented fairly quickly and can be included as part of a cost-effective mix of PMAs to achieve and maintain sustainable groundwater conditions. This appendix describes the direct economic costs of demand management in the Subbasin. It also describes considerations for, and the process of setting, a groundwater allocation. It is noted that a groundwater allocation is not required to implement the demand management programs included in the GSP, but it does generate incentives to manage demand and increase supply. To provide some context for the costs of demand management, a general summary of agricultural water use, economic values, and Subbasin conditions is presented first. This is followed by a summary of an economic analysis of the direct costs associated with two example demand management programs: one targeted to specific areas with groundwater sustainability concerns, and another targeted more broadly across the Subbasin. The allocation discussion is presented last.

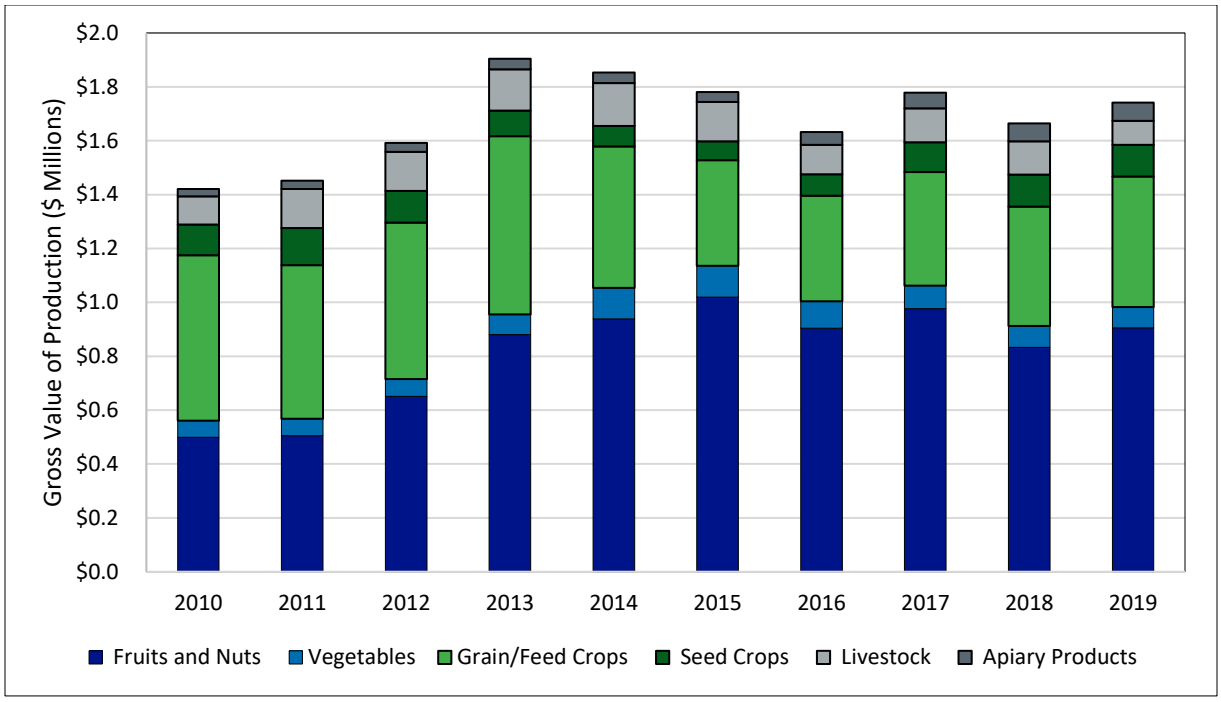
Economic Value of Agriculture in the Colusa Subbasin

Glenn and Colusa County agriculture includes a diverse mix of rice, nut crops, seed, feed, and other field and row crops. Farming activities to raise these crops support jobs, income, and economic activity for a range of transportation, processing, manufacturing, and retail industries in the Subbasin. These activities support the local tax base as well as jobs and income in businesses not directly related to agriculture. Changes in the cost and availability of water under the PMAs included in the GSP, as well as potential demand management programs, can have important implications for the local economies and communities in the Subbasin. This section describes the current contribution of agriculture to the Subbasin economies.

The Subbasin spans most of Glenn and Colusa counties. The annual economic activity, measured as value-added, across all industries (including agriculture) in the counties is around $7.4 billion. These industries support around 26,000 full-time equivalent (FTE) jobs, mostly for individuals that both live

and work in the counties. Table 1 summarizes the top ten industry sectors by value, and the direct jobs associated with each industry. Eight of the top 10 industry sectors are agriculture and related industries. Notable exceptions include local government industries and the wholesale trade sector. However, wholesale trade includes warehousing and storage industries that are closely linked to the agricultural sector.

Table 1. Top 10 Industries, Glenn, and Colusa Counties



Rank	Industry	Annual Value Added ($ in Millions)	Direct FTE Jobs
1	Tree nut farming	$965	2,790
2	Rice milling	$750	450
3	Local government	$625	3,750
4	Grain farming	$500	405
5	Wholesale trade	$475	1,620
6	Canned fruits and vegetables manufacturing	$470	695
7	Vegetable and melon farming	$180	630
8	Dairy cattle and milk production	$160	155
9	Support activities for agriculture and forestry	$145	1,690
10	Other animal food manufacturing	$145	70

Source: IMPLAN 2014 R3 multipliers, current USDA crop prices and returns, current 2021 dollars

A substantial share of local economic activity is directly or indirectly related to farming. A conservative analysis using the IMPLAN model data shows that at least one in three jobs depend on farming activities in the Subbasin. Similarly, a substantial share of local wage income for employees, value added, and gross output are a result of farming-related industries in the Subbasin.

The primary crops produced in the Subbasin include rice, walnuts, and almonds. The total rice acreage footprint has been largely steady for several years, with annual fluctuations in planted acreage based on rice market conditions and water availability in the Sacramento and San Joaquin Valleys. On average, Colusa and Glenn counties produce around 45 percent of California's annual rice crop. The share of acreage planted to almonds and walnuts has been steadily increasing, driven by favorable market conditions and consistent with trends across the state. Relative to annual crops, these permanent plantings require a substantial capital investment to establish and require consistent irrigation in all years. This has led to hardening of irrigation water demand in areas with increasing permanent plantings.

Figure 1 illustrates recent trends in the gross value of production by crop type in Glenn and Colusa Counties. The gross output value of the crops produced in the Subbasin is around $1.75 billion per year, with fruit and nut crops accounting for more than half of the total value in recent years. Fruit and nut crops accounted for around 30 percent of gross value in 2010, increasing to nearly 60 percent by 2015.

Source: Glenn and Colusa County Crop Reports

Figure 1. Trends in Gross Value of Crop Production, 2010 – 2019

The trends in crop acreage and value in Glenn and Colusa counties are consistent with trends in other parts of the state. Robust export demand for California almonds and walnuts through the mid-2010's supported strong prices and profitability. This led to increasing plantings that are continuing across the state. However, new plantings of nut trees have slowly leveled-off in response to softer prices caused by increasing supply (production) in California and other regions (e.g., Australia) and a weaker export market (e.g., tariffs and macroeconomic conditions including a stronger U.S. dollar). Groundwater concerns in Critically Overdrafted subbasins in the San Joaquin Valley may continue to push permanent plantings north into the Sacramento Valley, and as such this general trend appears likely to continue in Glenn and Colusa Counties for the next several years.

The agricultural industries in the Subbasin create a substantial share of local jobs, business, and economic activity. Demand management programs can be structured in ways to minimize the economic costs to growers and the regional economy. The following section quantifies the direct costs of potential demand management programs in the Subbasin.

Demand Management Costs

Demand management generally refers to actions that reduce the net consumptive use of water, which in turn reduces net groundwater pumping[1] in the Subbasin, or selected areas of the Subbasin. Areas selected for demand management would be determined by the GSAs in consideration of local groundwater conditions and sustainability indicators.

This appendix summarizes the results of an analysis that establishes the potential costs of demand management in the Subbasin. The results of the analysis can be used for multiple purposes. Demand management costs can be compared to the cost of potential projects to support developing a cost-effective portfolio of PMAs. In addition, demand management costs are interpreted as the minimum willingness to accept payment to forgo irrigation, which can be used to structure potential incentives to reduce groundwater pumping under applicable PMAs.

To illustrate the cost of demand management, two scenarios are developed. The cost of a specific demand management program will ultimately depend on the location, scale, and market conditions at the time the program is implemented. The outputs summarized in this report are intended to support PMA development for the GSP, and comparison of demand management with other projects and management actions. These cost estimates would be refined in the future and would be specific to each PMA. The final section in this appendix describes the general steps for this future analysis.

The cost of demand management depends on the location, scale, and timing of the program. For the purposes of this analysis, it was assumed that the timing of the program would be the GSP implementation period (2022 – 2042). The scale of the program (i.e., total volume of demand management achieved in each year) was developed over a range consistent with preliminary changes in groundwater storage shown in the initial GSP water budgets (see Chapter 3). Lastly, two alternatives were developed for the location of the program. The first alternative would apply Subbasin-wide and the second would target demand management to specific areas of concern near the Orland and Arbuckle areas in the Subbasin (as generally defined below).

The direct cost of demand management is estimated here as the loss of net return to irrigated lands and is expressed on a per acre-foot (AF) basis for comparison to other PMA costs. Costs were established in the Subbasin using a standard economic analysis that considers the water budget (e.g., quantity of water applied and consumed by Subbasin crops), costs and returns to farming, and current market conditions for major Subbasin crops. The results of the analysis show how the cost of demand management changes over an increasing scale of a potential program, and how those costs vary across different areas.

Reduced net return from crop production may, in turn, lead to secondary losses to other sectors within the local economy. The extent of such losses would depend on how irrigated agriculture on other lands changes. For example, if production shifts to other lands within the same regional economy (e.g., the broader Sacramento Valley), then regional secondary effects on input suppliers, trucking, processing, farm labor, and other businesses may be small. But if this does not occur, then secondary economic impacts may warrant more analysis and quantification. These secondary impacts have not been quantified in this appendix. In addition, this analysis does not quantify any additional administrative costs for the GSAs to develop and administer a demand management program. These indirect costs would be assessed as part of demand management program design in the future.

[1] Net groundwater pumping would be defined as part of the demand management program. In general, it would include crop ETAW plus any unrecoverable return flows.

Methods

The cost of demand management fundamentally depends on supply and demand for irrigation water. Examples of factors that affect supply include annual water year conditions, carry-over storage, CVP allocation, GSA costs, water supply costs, and other GSP implementation (e.g., PMAs). Examples of factors that affect demand include export and domestic market conditions for California crops that affect returns to farming and willingness to pay for water.

An economic model of the Subbasin was applied to evaluate the supply and demand for water and establish the cost of demand management. It reflects the local water supplies and uses, financial data on returns to farming, and current crop market conditions for Sacramento Valley crops. This includes current crop prices and yields. Production costs are representative averages based on University of California Cooperative Extension crop budgets. The model is calibrated to the GSP water budget (applied water and evapotranspiration of applied water) and geospatial land use data described in Chapter 3 of the GSP. A technical description of the economic calibration method is beyond the scope of this technical appendix. The method applied is a standard, peer-reviewed economic analysis approach that is widely applied for valuation of water supply and water supply projects in California[2]. This same technical approach was applied for calibration of an economic optimization model of the Subbasin.

The model quantifies the effect of changes in water supply availability and cost on farm income (e.g., net income and gross farm revenues) and simulates how the agricultural sector would respond to changes in water availability and cost. Responses include switching to higher value and/or lower water use crops, adjusting input use, and idling land. The decision to switch crops and/or idle land depends on agricultural market conditions simulated by the model under increasing levels of a range of (hypothetical) demand management. The economic analysis quantifies the direct economic cost of changing crops and idling land under implementation of demand reduction. For this technical appendix, costs are expressed on a per acre-foot basis for comparability to other PMAs in the GSP.

The analysis reflects average water supply conditions. That is, the results of the analysis are the incremental cost of demand management in an average water supply year, not under critical drought conditions, or conversely, years with above-average supplies. The framework can be extended to evaluate these factors as part of future program design.

The economic model is developed on a geospatial scale that can be refined to evaluate Subbasin-wide demand management and demand management in specific areas. Two “areas of concern” were defined in the model. Figure 2 illustrates areas of concern and crop types[3] in the economic model for the Subbasin. Areas of concern are more precisely defined based on hydrogeologic conditions that are described in Chapter 3 of the GSP. Areas shown below include two broad regions: North (around Orland) and South (between Williams and Arbuckle).

[2] See the following references for example:

Department of Water Resources. Water Plan Update. 2009. Data and Tools Technical Appendix. Economic Modeling of Agriculture and Water in California using the Statewide Agricultural Production Model.

U.S. Bureau of Reclamation. 2019. CVP Long Term Operations EIS. Appendix 12A: Statewide Agricultural Production Model (SWAP) Documentation.

[3] Crop types are aggregated into seven groups for map display purposes. The economic analysis has 20 crop types that better reflect the unique costs, returns, and markets for each crop.

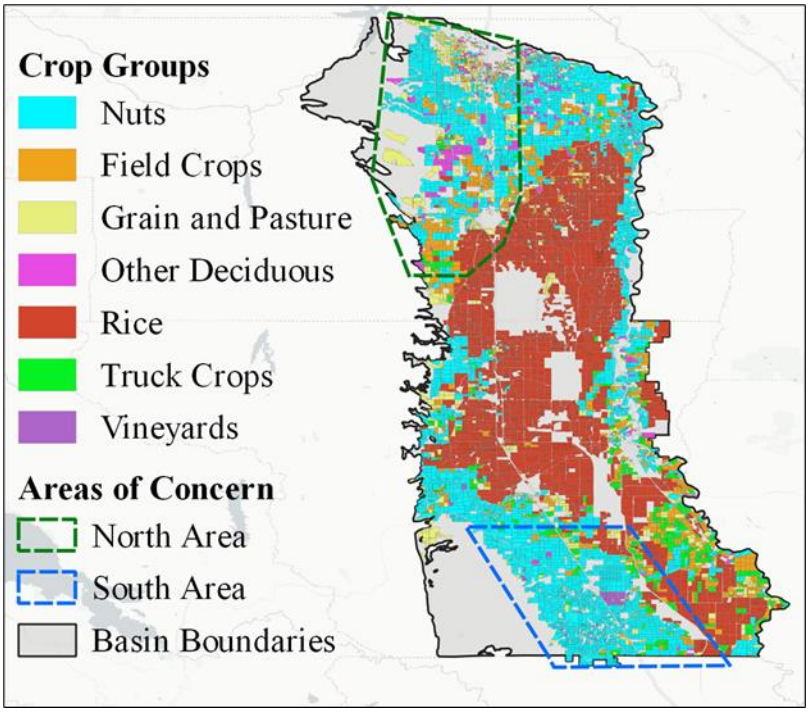


Figure 2. Colusa Subbasin Crops

Colusa Subbasin Demand Management Costs

This section summarizes the direct cost of demand management for the following alternatives:

- **Colusa Subbasin-wide demand management**. This assumes demand management would occur across the entire Subbasin. That is, demand management is not targeted to specific areas. The implicit assumption is that water can be moved (exchanged, conveyed, in-lieu) across the Subbasin.
- **Targeted demand management**. This assumes demand management would occur in specific areas defined as the North and South areas of concern.

For each alternative, the cost of demand management was estimated as the mix of crops that could be idled at the lowest loss in net return. This is based on the aggregate supply of the crops produced in the Subbasin evaluated as part of the economic analysis (i.e., the lowest net return is not a static accounting measure of the least profitable crop). This is the minimum cost of the demand management program, defined by the opportunity cost of water for the crops that would be idled (the net return that the water would have provided on those crops).

Costs of Demand Management Applied to Entire Colusa Subbasin

This section summarizes the results of the demand management costs for the scenario where demand management is applied broadly to the entire Subbasin.

Figure 3 illustrates the range of demand management costs over a program scale of 2,500 and 25,000 AFY reduction in irrigation water demand. The cost ranges from around $120 per AF at 2,500 AFY of demand management to $210 per AF at 25,000 AFY. These are the direct cost of idling land, inclusive of groundwater pumping cost. The analysis estimates that the lowest net return lands and crops would idle first (hence the low cost for the smallest scale program), with higher net return lands included as the program scale increases.

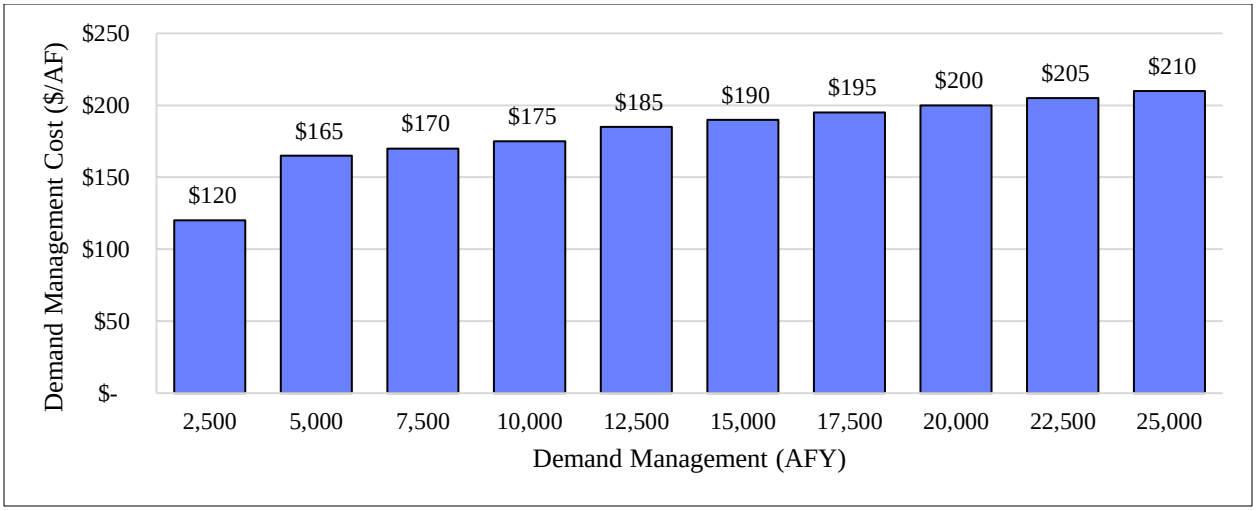

Figure 3. Costs of Demand Management Applied to Entire Subbasin

Costs of Demand Management Targeted to Areas of Concern

This section summarizes the results of the demand management costs for the scenario where demand management is targeted to two areas of concern. The specific lands are not identified. Rather, the demand management program is broadly defined for the general region.

Figure 4 illustrates the range of demand management costs for a demand management program between 1,250 and 12,500 AFY. The demand management volumes are specific to each region (e.g., 1,250 AFY in the north area and south area, separately). A smaller scale program for each region (up to 12,500 rather than 25,000 AFY) is shown because the total level of demand management is independent in each region. The cost ranges from $115 to $185 per AF in the north area of concern and $115 to $250 per AF in the south area of concern. These higher values reflect the crop mix in these areas – more permanent crops with less flexible water demand and higher-value annual crops. These are the direct cost of idling land, inclusive of groundwater pumping cost.

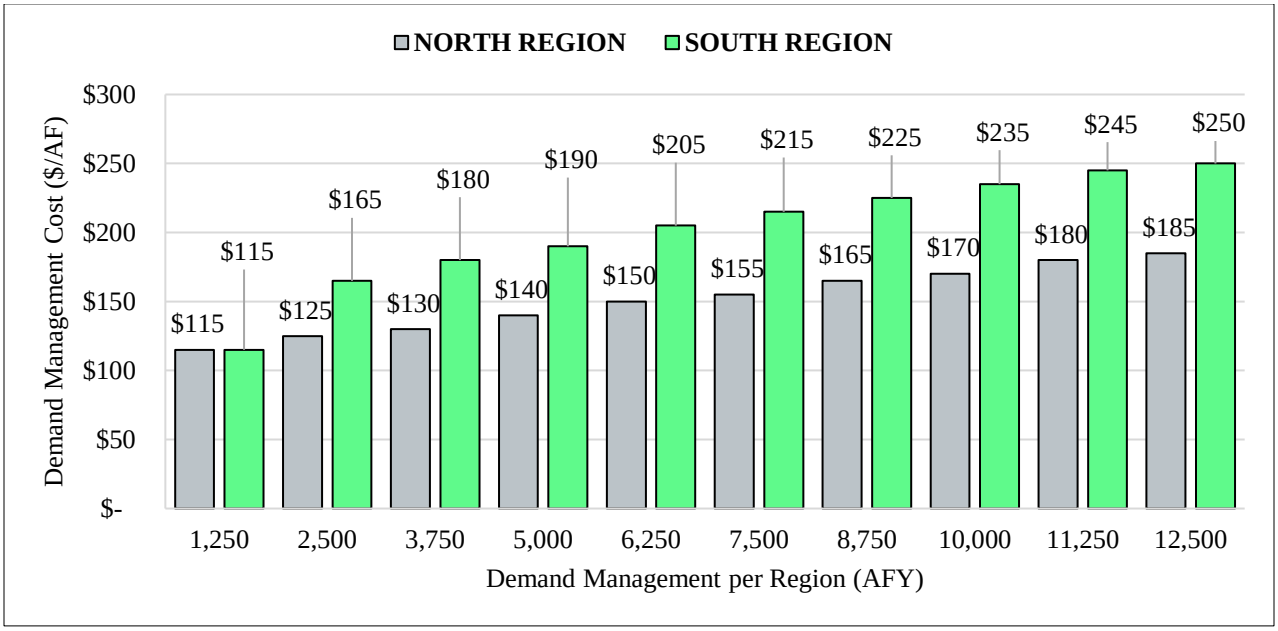

Figure 4. Costs of Demand Management Targeted to Areas of Concern

Groundwater Allocation Concepts

Demand management can be achieved without a groundwater allocation, so long as the program is able to quantify and verify the program demand management targets are achieved. However, an allocation can support implementation of a demand management program. It can also provide incentives for other PMAs (e.g., recharge) by defining the amount of groundwater available, and the additional quantities that would be associated with the development of new projects.

This section provides an overview of concepts and approaches related to allocation of groundwater in a Subbasin with diverse water users, water rights, and sources of recharge. It is not an allocation plan for the Subbasin, it is a discussion of the analysis that would be completed to set an allocation at a future date, if the GSAs decide to do so, either separately or together.

Introduction and Definitions

A groundwater allocation specifies quantities of groundwater available to groundwater pumpers, which for the purposes of GSP development would include irrigators in the Subbasin. According to the Sustainable Groundwater Management Act (SGMA) and its regulations, *de minimis* pumpers (defined as less than two AF per year) would not be limited by an allocation. This section provides a general overview of allocation approaches, technical considerations, and summary of economic implications of alternative approaches. It is not an allocation plan for the Subbasin and it does not address all necessary considerations for defining and implementing an allocation. Developing a specific allocation would require careful analysis of the legal, hydrogeologic, economic, and engineering implications, and would require vigorous and informed discussions with stakeholders.

Allocation involves setting an overall amount of permissible net groundwater extraction for the subbasin and the apportionment of that overall amount among pumpers. It is important to note that implementing an allocation does not necessarily result in reducing groundwater use. For example, if the allocation is greater than historical use and it is apportioned in a way that all pumpers receive more than their historical use, then the allocation would not constrain groundwater users and would not result in less consumptive groundwater use. In the context of GSP implementation, the first step – the overall allocation – is typically tied to the sustainable yield (defined below) of the Subbasin. The second step – apportioning the allocation among users – can be based on different factors related to, for example, land use, recent water use, location, and other policy goals. Apportionment of the overall allocation can be made to individual wells, parcels, farming operations, or other defined entities. When the sustainable yield (including yield of other PMAs like recharge projects) is less than current pumping, the effect of an allocation is an overall reduction in net groundwater use.

Allocation based on sustainable yield often considers the various components of the subbasin water balance that contribute to sustainable yield. This is useful because the components vary geographically across the basin, under future conditions, and PMAs may affect those components over time. Defining the different types of groundwater and components of sustainable yield typically involves substantial data, modeling, and stakeholder input. Sources of groundwater that can be included in the allocation can include native/natural recharge, percolation of water developed and imported into the basin, other intentional recharge, and net subsurface groundwater flow into the basin from/to adjacent areas. Some concepts used in discussing allocation are defined below:

- **Native/natural recharge**. Native or natural recharge is recharge that is from deep percolation of precipitation or losses through natural water ways and channels in the Subbasin. These are sources of groundwater recharge that do not rely on the action of any individual entity within the basin, although certain actions (e.g., conversion of native land to urban uses) can affect their quantity.

- **Imported/developed water recharge**. Imported or developed sources of groundwater recharge are a result of investments by specific entities in the subbasin. For example, groundwater recharge from unlined canals developed, and paid for, by a district to import and deliver surface water rights. This is considered separately from native/natural recharge because it would not have contributed to groundwater recharge in the Subbasin without the investments of the district. A substantial amount of the developed water recharge is percolation from applied irrigation of developed water supply, some occurs during conveyance of the developed water, and some is the result of projects designed specifically to recharge groundwater, either in dedicated recharge areas, spread over lands during uncropped or dormant periods of the season (Flood MAR)[4]. Another kind of recharge, in-lieu recharge, does not increase percolation but rather reduces or avoids the net extraction of groundwater by providing a replacement supply.
- **Net subsurface flow.** Groundwater flows laterally across the Subbasin boundaries to and from adjacent areas outside the subbasin, driven by the gradients resulting from groundwater elevation differences. Many subbasins have groundwater flowing both in from some adjacent areas and out to other adjacent areas. The net flows change over time according to changes in precipitation, land use, and groundwater management both in the subbasin and in adjacent areas.
- **Transitional pumping**. Transitional pumping is also referred to as planned depletion of groundwater storage. SGMA provides for GSAs to transition to sustainable yield over a period of twenty years. In areas where current groundwater extraction is greater than the sustainable yield, an allocation will need to be less than current groundwater use. PMAs typically require time to implement, during which time growers subject to an allocation must reduce pumping, for example, by switching crops or idling land. A gradual time path for adjustment helps lessen the economic costs of this type of adjustment. Transitional water is effectively an overdraft that, consistent with SGMA and the GSP, decreases to zero over time as extraction is brought into balance with recharge.

Time Dimension of Allocations

Allocation quantities are typically defined on an annual basis using long-run average components of the current and projected water balances. However, an allocation need not be the same every year; it can include transitional water that declines over time or it can be reduced or increased annually according to conditions, so long as on average it follows the path to sustainability laid out in the GSP. For example, the allocation can be increased in drought years to allow better conjunctive use of surface and groundwater, and then reduced in non-drought years to offset the increases in pumping in drought years. The yearly pattern of allocation could vary by subregion within the GSA (or subbasin) according to the situation. For example, lands fully dependent on groundwater may do better on a more consistent allocation, whereas lands with access to both ground and surface water might benefit from a variable allocation.

Another option to implement and manage a groundwater allocation is to allow growers to carryover some or all of their assigned allocation. The ability to carryover unused allocation may vary by different components. For example, unused natural recharge allocation may be carried over and used in subsequent years, but transitional pumping may not. In addition, carryover could be limited to a not-to-exceed amount each year, limited in the number of years an allocation carryover can be used, or even subject to annual "losses". The ability to "borrow" current pumping against next year's allocation could

[4] These sources of developed recharge are typically part of GSP PMAs, which can be included as separate categories of recharge under an allocation, but are discussed jointly here.

be considered. Essentially a carryover could be implemented like a bank account, where growers take responsibility to manage their account over time within the rules defined by the GSA.

The allocation can be and probably will be adjusted over time. Transitional allocation has already been described above. In addition, periodic reassessment of quantities will be made as more current data is acquired (e.g., as data gaps are filled), changes in hydrologic conditions (e.g., climate change) are observed, and PMAs are implemented.

Spatial Dimension of Allocations

An overall allocation is typically developed initially at a subbasin, or GSA-level based on the water balance. It is also possible to subdivide the GSA into smaller subareas or zones based on important variations in the components of an allocation, and with respect to groundwater conditions. For example, some zones may receive percolation from imported surface water that is included in their allocation, whereas other zones do not. Or some smaller areas may support and pay for a recharge project to boost their allocation while another zone does not need to do this. These kinds of differences can be easier to understand and manage if the allocation is built up from components rather than a single, annual amount.

Another possible rationale for subregional differences can involve sustainability criteria other than groundwater elevation. Groundwater dependent ecosystems, streamflow effects, and subsidence are examples of other conditions that may be considered in subregional allocations.

Apportionment of the Allocation

After the components of groundwater are defined and the overall allocation is determined (either for the entire GSA or for subareas), the next step in groundwater allocation is defining how to apportion the allocation among the irrigators in the subbasin.

Some important considerations include:

- **Allocation eligibility**. Once the volume for different components of a groundwater allocation is defined, it is necessary to determine which lands and users are eligible for an allocation and how specific volumes are assigned. This could vary by groundwater component. For example, native recharge could be allocated on a per acre basis to all eligible parcels in the subbasin. Transitional water could be allocated in the same manner, or it could be allocated based on historical use. The yield from a recharge project could be assigned according to proportionate contributions to the cost of the project. Allocations may also consider other non-consumptive uses, such as habitat benefits.
- **Non-irrigated parcels**. A topic of much discussion during development of many GSPs (and GSP implementation in Critically Overdrafted subbasins) is whether and how non-irrigated lands are included in the allocation. Non-irrigated parcels can include parcels that were never irrigated and parcels that were previously irrigated but are not currently irrigated. Never irrigated parcels may not be economically feasible to develop into irrigated agriculture, whereas currently unirrigated parcels may have been temporarily retired for various reasons. An allocation typically includes defining a point in time where a parcel is defined as non-irrigated (e.g., if it has not been irrigated since a specific date). Non-irrigated parcels may be eligible for some components of the groundwater allocation. This may include portions of the sustainable yield, but typically does not include any transitional water. Additional considerations may include lands near sensitive habitat areas.

Additional Considerations and Analysis

Developing a groundwater allocation should include consideration of legal, economic, engineering, hydrogeologic, and political considerations. In areas with both ground and surface water supplies, the ability to use them conjunctively can provide sufficient water (from delivered surface water and groundwater allocation) during droughts.

In areas where the groundwater allocation is less (and in some cases substantially less) than current groundwater use, there can be important economic implications for different allocation design approaches. An analysis to inform allocation development typically includes quantifying the economic implications of alternative groundwater allocation design approaches. This includes evaluating financial impacts to individual groundwater users (e.g., growers) as well as the regional economic implications.

Assigning quantities of groundwater available to individual pumpers can incentivize them to think about the costs and benefits of reducing their water use or developing new recharge opportunities. An allocation effectively creates a scarcity of groundwater, whereby the value of groundwater is driven by the economic value (net return) it can produce. Economic effects of an allocation depend on many factors, including: the size of the allocation relative to crop water demand (how limiting is the allocation); the sources, costs, and distribution of current and prospective surface supplies; and the flexibility allowed to growers in how they manage their allocation.

A strict allocation and apportionment are a rigid method for implementing demand management. They effectively limit water use on a well, parcel, or operation basis. Economic analysis can illustrate the advantages, both to individual growers and to the regional economy, of increasing the flexibility of allocations. Allowing growers to move their allocated groundwater freely (subject to some review) is one step to increase flexibility. Rather than allocating pumping to each well or parcel, a grower can make choices about distributing allocation among fields and crops, in maximize return, and reduce the costs of demand management. A more ambitious step is to allow growers to buy and sell allocation among themselves, using either short-term or long-term agreements. A number of other GSAs in California are currently evaluating and pilot-testing groundwater trading markets for this purpose.

Administering an Allocation

If a GSA, or subbasin, decides to adopt an allocation and defines the mechanism to calculate how to assign allocation to different individuals, entities, or wells, it must then monitor pumping and enforce the allocation. If carryover across years is allowed, the GSA must also track that and incorporate it in the annual water budget accounting. Most groundwater management entities outside the state use some form of measurement, including wellhead metering, to track allocations. In California, many GSAs are proposing or considering direct measurement or using crop type and/or ET calculations to estimate water use and groundwater pumping. Estimation versus measurement is a GSA policy decision that can have important effects on the cost and its ability to manage the allocation effectively.

Summary of Steps in Considering and Implementing an Allocation

1. Develop the key components of the GSP – baseline conditions, water budgets, criteria and thresholds, and PMAs.
2. Determine if an allocation is necessary and useful to achieve targets and implement PMAs, particularly demand management actions, effectively.

3. If an allocation is warranted, use data and analysis to evaluate, compare, and select allocation amounts and other characteristics that best meet the needs of the GSA.
4. Monitor conditions and pumping over time to verify the effectiveness of the allocation and to modify as needed.

Discussion

This appendix summarized an analysis of the cost of demand management for two hypothetical programs: one covering the entire Subbasin, and another targeted to two areas of concern. The cost of demand management is estimated as the loss in net return to farming. It does not include program administrative costs or any secondary impacts, and it does not consider what the market price for water would be under a local groundwater market. Secondary economic impacts should be considered in future iterations of this analysis to support implementation of PMAs.

Implementing an annual allocation can provide a strong impetus for growers to adopt demand management and may be a prerequisite for effective demand management in some cases. It is not clear that an allocation is warranted at this time for the Subbasin, though it may become more useful in the future. Developing a specific allocation would require careful analysis of the legal, hydrogeologic, economic, and engineering implications, and would require vigorous and informed discussion with stakeholders.

Future analysis of demand management program costs and allocation design would be specific to the program being considered in the Subbasin. For example, under the "targeted demand management" PMA summarized under Chapter 6 Section 6.5.2, the economic analysis would be developed for the regions that would participate in the program (both buyer and seller regions). This would define incentives to participate in the program. The general steps to define a demand management program costs include:

1. Define the location, scale, and timing of the program. Prepare economic data specific to the program areas and define any program-specific conditions that would affect participation.
2. If a groundwater allocation will be included, define the groundwater allocation approach and specify the allocation to lands/entities in the Subbasin. Prepare an economic analysis and hydrogeologic analysis of the impacts of alternative groundwater allocation designs.
3. Use the general method described above to quantify the direct cost of demand management in each area. The analysis would additionally consider the opportunity cost of water in other, non-farming, uses, such as a local or regional water transfer market. Market prices can exceed the values in irrigated agriculture in some years and would drive demand management program costs in these years.
4. Evaluate potential secondary economic impacts, and to whom those impacts may occur. Also consider any benefits associated with the program, and to whom those benefits accrue. For example, this may include broader groundwater level benefits in the area, and regions down-gradient. Monetize any anticipated secondary economic impacts and benefits.
5. Use the results of the steps above to develop an appropriate incentive structure (accounting of costs and benefits) that would support demand management program design. See Section 6.5.2 of GSP Chapter 6 for a summary of different types of potential demand management programs.

Appendix 6C

Overview of Projects and Management Actions

(THIS PAGE LEFT BLANK INTENTIONALLY)

Specialists in Agricultural Water Management

Technical Memorandum

To: Glenn and Colusa County Groundwater Authorities

From: Davids Engineering

Date: November 19, 2021

Subject: **Overview of Projects and Management Actions**

Introduction

More than 30 projects and management actions (PMAs) are included in the Colusa Subbasin GSP to achieve and maintain sustainable groundwater conditions in the Colusa Subbasin (Subbasin). PMAs are categorized and presented in this appendix according to the current status of implementation and development:

- **Planned Projects and Management Actions** are PMAs that the GSAs or other project proponents are working to implement that will support sustainable groundwater management in the Subbasin, and mitigate historical and current drought effects. Five projects are currently planned for implementation, all of which are groundwater recharge projects that use surface water for direct and/or in-lieu recharge.
- **Ongoing Projects and Management Actions** are PMAs that are ongoing and will support sustainable groundwater management in the Subbasin. In accordance with 23 CCR §354.44(a), these are PMAs that would allow GSAs to achieve the sustainability goal for the Subbasin and avoid reaching the minimum thresholds defined in this GSP under future, changing conditions. Six PMAs are currently ongoing in the Subbasin.
- **Potential Projects and Management Actions** are PMAs that may be implemented if necessitated by groundwater conditions in the Subbasin. These may have been studied by the project proponent or in earlier regional water planning documents, but most project design, cost estimates, and planning work have yet to be completed, and would only be initiated if the project is eventually triggered for implementation as a result of continued monitoring of groundwater conditions. There are more than 20 potential PMAs proposed for the Subbasin.

Each of the PMAS are designed to support the long-term sustainability of groundwater resources of the Subbasin. The information currently available for each of these PMAs is provided in Tables 1 through 6 below. These tables summarize the following information:

- Table 1. Brief Description of all Projects and Management Actions
- Table 2. Project Type, Category, Proponent, and Location for all Projects and Management Actions.
- Table 3. Implementation Criteria, Notice Process, Permitting and Regulatory Process, and Timeline for all Projects and Management Actions.
- Table 4. Anticipated Benefits of all Projects and Management Actions.
- Table 5. Benefit Evaluation and Water Source for all Projects and Management Actions.

- Table 6. Legal Authority Requirements, Estimated Cost, and Potential Funding Sources for all Projects and Management Actions.

The fields in these tables have been designed to meet the requirements for PMAs as described in the California Code of Regulations (CCR); when applicable, a reference to a specific CCR location is provided as the first row of each table.

Table 1. Brief Description of all Projects and Management Actions.

CCR § 354.44	CCR §354.44(a)
Project/Management Action Name	**Brief Project Description**
Planned	
Colusa County Water District (CCWD) In-Lieu Groundwater Recharge	CCWD will utilize up to an additional 30 thousand acre-feet (taf) of surface water for irrigation in all years but Shasta Critical years for in-lieu recharge (an average of 27 taf per year). The additional surface water will be made available through full use of the CCWD's existing CVP contract and annual and multi-year water purchase and transfer agreements. The additional water will be conveyed through the existing Tehama-Colusa Canal (TCC) and CCWD facilities. It is expected to be used on existing district lands, though as an optional component of this project CCWD is considering relatively small annexations of lands adjoining the district and supplying surface water to these lands (currently dependent on groundwater, requiring additional infrastructure for surface water delivery), resulting in in-lieu groundwater recharge through reduction of groundwater pumping.
Colusa Drain MWC (CDMWC) In-Lieu Groundwater Recharge	CDMWC encompasses approximately 46,000 acres of agricultural land and environmental habitat adjacent to the Colusa Basin Drain (Drain). Shareholders in CDMWC divert water for summer irrigation from the drain under a combination of appropriative water rights held individually by the shareholders, a long-term service supply agreement with USBR and annual and multi-year transfer agreements with neighboring USBR settlement contractors. Historically, many CDMWC diverters use both groundwater and surface water for summer irrigation because physical supplies of water in the Colusa Drain are often unreliable and insufficient to satisfy those irrigation requirements. This project would provide additional surface supplies averaging approximately 28 taf per year, allowing CDMWC diverters to increase their diversions of surface water from the Drain to provide in-lieu groundwater recharge and decrease groundwater pumping by an equal amount.
Colusa Subbasin Multi-Benefit Groundwater Recharge	The Nature Conservancy (TNC) is partnering with growers and the Colusa and Glenn Groundwater Authorities for an on-farm, multi-benefit groundwater recharge incentive program. Program objectives are to benefit disadvantaged communities and other communities in the Subbasin by replenishing critical domestic and agricultural water supplies, growers economically through incentive payments, migratory shorebirds through the creation of critical winter habitat on farms, and groundwater conditions (via groundwater recharge). Surface water from the Sacramento River, subject to availability, is conveyed to and applied to flood and maintain ponds on selected fields using existing diversion, conveyance, and on-farm infrastructure. The pilot program was initiated in Colusa County in 2018 and concluded in the spring of 2021, with plans to expand and continue into the future. DWR will be participating in the Colusa Subbasin Multi-Benefit Groundwater Recharge project as it is expanded into a larger program.

Table 1. Brief Description of all Projects and Management Actions.

CCR § 354.44	CCR §354.44(a)
Project/Management Action Name	**Brief Project Description**
Orland-Artois Water District (OAWD) Land Annexation and Groundwater Recharge	OAWD is working with a group of neighboring non-district landowners to annex approximately 12,000 acres of groundwater-dependent agriculture into the district. Surface water for the annexed lands would be secured through multi-year purchase or transfer agreements with willing sellers, conveyed through the existing TCC, and distributed to the annexed lands through new distribution facilities. It is estimated that a long-term average of approximately 23 taf per year of surface water would be available, reducing groundwater pumping by 23 taf per year. Additionally, certain annexed lands with high infiltration characteristics would be configured for direct recharge by surface spreading, primarily using Section 215 water. Preliminary project design shows seven proposed recharge areas totaling 371 acres in the project. OAWD is evaluating recharge potential and will refine these estimates. The direct recharge capacity has not yet been estimated. This project will address an area within the Subbasin where groundwater levels have been in decline in recent years due to drought and increasing water demands being met through increasing groundwater pumping.
Sycamore Slough Groundwater Recharge Pilot Project	Proctor and Gamble (P&G) and Davis Ranches have entered into a cooperative agreement to implement a 10-year groundwater recharge pilot project. The project will apply surface water diverted from the Sacramento River to a 66-acre field on Davis Ranches for groundwater recharge and to provide habitat for migrating shorebirds for 30 to 45 days during the fall or winter each year. The timing of the project may be targeted to provide fall and winter habitat for migratory shorebirds, in addition to groundwater recharge benefits. However, the precise timing of the project is flexible to accommodate changes in water availability and other factors between years. Sacramento River water is available to Davis Ranches under riparian rights and a Sacramento River settlement contract with Reclamation. If the project starts before November 1, settlement contract water would be used. Otherwise, riparian water rights would be exercised for beneficial use (habitat). The goal is to recharge 5,000 af over the 10-year study period and to revegetate a portion of Sycamore Slough. Monitoring of groundwater conditions will be done in eight existing groundwater wells, including dedicated monitoring wells and production wells. If the project is successful and cost effective, it could be continued in perpetuity to sustain long-term groundwater recharge and environmental benefits. Subject to acquisition of funding, an expansion of the project is planned for recharge and revegetation in the neighboring Sycamore and Dry Sloughs.

Table 1. Brief Description of all Projects and Management Actions.

CCR § 354.44	CCR §354.44(a)
Project/Management Action Name	**Brief Project Description**
Ongoing	
Reclamation District 108 (RD 108) and Colusa County Water District (CCWD) Agreement for Five-Year In-Lieu Groundwater Recharge Project	CCWD (and Dunnigan Water District [DWD] located in the Yolo Groundwater Subbasin) purchase surface water from RD108 for distribution within their service areas under a five-year agreement, expiring after 2022. Under the five-year agreement, 10,000 af is purchased by and transferred to CCWD and DWD, with 80 percent to CCWD and 20 percent to DWD. This project supplies additional surface water to CCWD and DWD that provides in-lieu recharge to meet water demands that otherwise would be met through groundwater pumping.
Glenn-Colusa Irrigation District (GCID) Strategic Winter Water Use for Groundwater Recharge and Multiple Benefits	GCID holds a 1999 water right permit to divert Sacramento River water for irrigation and rice straw decomposition between November 1 and March 31; water used under the permit is referred to as "winter water." The potential exists to increase the groundwater recharge and habitat enhancement benefits of winter water use by increasing winter use for rice straw decomposition, winter irrigation, and frost control provided that certain constraints can be alleviated. Under this project, working in collaboration with partners within the subbasin and with environmental advocacy groups, GCID will investigate opportunities to increase winter water use by alleviating these constraints.
Sycamore Marsh Farm Direct Recharge Project	Sycamore Marsh Farm has been in process of developing a groundwater recharge plan to store water in our aquifer by several different methods. The plan provides for 205 acres of year-round recharge basins and 163 additional acres of winter recharge areas.
Glenn-Colusa Irrigation District (GCID) Expansion of In-Basin Program for In-lieu Groundwater Recharge	In cooperation with Reclamation, GCID has developed temporary arrangements to supply district surface water to neighboring non-district agricultural lands that primarily use groundwater. These temporary arrangements were implemented under agreements that recently expired in 2020. There is interest in continuing and expanding this in-basin surface water use. GCID is currently working in cooperation with Reclamation to renew these agreements and expand this program for the purpose of reducing groundwater pumping and in-lieu groundwater recharge.
Orland Unit Water Users Association (OUWUA) Irrigation Modernization for Increased Surface Water Delivery and Reduced Groundwater Pumping	Continue the modernization of the association's southside irrigation conveyance and distribution system; these improvements are expected to result in more reliable and flexible farm deliveries that will provide incentive for growers to use more surface water and less groundwater.
Urban Water Conservation in Willows	California Water Service - Willows District is implementing urban water conservation measures through water waste prevention ordinances, metering, conservation pricing, public education and outreach, programs to assess and manage distribution system real loss, water conservation program coordination and staffing support, and other demand management measures. These are described in greater detail in Chapter 9 of the 2020 UWMP for California Water Service - Willows District.

Table 1. Brief Description of all Projects and Management Actions.

CCR § 354.44	CCR §354.44(a)
Project/Management Action Name	**Brief Project Description**
Potential	
Colusa County Public Water System Water Treatment Plant	Construct a water treatment plant on the Sacramento River between Colusa and Grimes to provide fresh drinking water to public water supply systems in Colusa and possibly Sutter and Yolo Counties.
Delevan Pipeline Colusa Basin Drain Intertie	Construct an intertie between the proposed Delevan Pipeline component of the Sites Reservoir Project and the Colusa Basin Drain. Currently, the only proposed intertie is the Dunnigan intertie. This intertie will provide a connection to downstream water users to utilize surface water storage from Sites Reservoir, improve conjunctive use, and potentially decrease groundwater pumping. This intertie will also provide protection for the ecosystems upstream of the proposed Dunnigan intertie and redundancy in case the TCC becomes inoperable due to subsidence or earthquake damage.
Sycamore Slough Colusa Basin Drain Multi-Benefit Recharge Project	Restoration of portions of Sycamore Slough through voluntary landowner participation in a multi-benefit recharge project. The recharge site will be hosted by Davis Ranches, a participating landowner within the Sycamore Mutual Water Company service. Water would be sourced from the Sacramento River during high flows in the system. The Sycamore Mutual Water Company is a Sacramento River Settlement Contractor, and could use a portion of its settlement contract water supplies for recharge if the project is initiated prior to November 1. If the project is initiated after November 1, water could be accessed using existing riparian water rights exercised for beneficial use (habitat). Field flooding would provide recharge, restoration, and multi-benefits such as winter floodplain habitat for migrating shorebirds/waterfowl, or habitat restoration for monarch butterflies and other pollinator species. Excess flows in winter could be diverted from the Colusa Basin Drain for recharge, and restoration could include a multi-benefit focus with environmental benefits such as habitat restoration for monarch butterfly or other pollinator species.
Tehama-Colusa Canal (TCC) Trickle Flow to Ephemeral Streams	The TCC has existing gates that are used to dewater sections of the canal. The gates discharge into ephemeral streams that intersect the canal. Water could be discharged from the TCC into these streams at a rate where they do not flow out of the subbasin, but recharge the groundwater system. Flow measurement devices would need to be added to the gates. Surface water for recharge would be Sacramento River available water under existing Bureau of Reclamation water supply contracts held by TCC contractors, existing water rights settlement contracts, and annual Section 215 contracts.
Westside Streams Diversion for Direct or In-lieu Groundwater Recharge	There are a number of ephemeral streams that originate in the Coastal Range to the west of the Subbasin and flow eastward into the Subbasin. During periods of flow in the winter and spring, a portion of these flows could be diverted for either (1) off-stream storage and subsequent use for irrigation or (2) direct groundwater recharge through Flood-MAR, dedicated recharge basins, or modified stream beds.
Reduce Non-beneficial Evapotranspiration/Invasive Species Eradication (Arundo, Eucalyptus, Tamarisk, etc.)	Removal of invasive, non-native plant species (i.e., arundo donax, eucalyptus, tamarisk, etc.) from riparian corridors, and other areas they may be present, will provide both a reduction in evapotranspiration from shallow groundwater and native ecosystem restoration.

Table 1. Brief Description of all Projects and Management Actions.

CCR § 354.44	CCR §354.44(a)
Project/Management Action Name	**Brief Project Description**
Enhanced Infiltration of Precipitation on Agricultural Lands	Current cultural practices, particularly in almond orchards, tend to reduce infiltration and increase runoff of precipitation. Development and adoption of on-farm cultural practices to reduce precipitation runoff and increase infiltration would result in increased storage of precipitation in the crop root zone, thereby reducing irrigation water requirements. Additionally, to the extent that infiltrated precipitation percolates through the root zone, this would result in direct groundwater recharge. This project is proposed as a potential research management action, for example, a collaborative initiative between the GSAs and other interested organizations.
Colusa Subbasin Flood-MAR	The CGA and GGA, in coordination with landowners and other agencies, would investigate, develop, and implement a program to divert flood waters within the Subbasin, when available, for spreading across agricultural lands or other working landscapes for direct groundwater recharge.
Reclamation District 108 "Boards In" Program	RD108 would institute a voluntary or financially incentivized program in which landowners leave their spill board in place during the winter to capture rainfall and hold it on the fields for recharge.
Glenn-Colusa Irrigation District (GCID) In-lieu Groundwater Recharge	Despite GCID having highly reliable surface water supplies, a small percentage of district lands rely primarily on groundwater for irrigation supply. GCID will investigate, develop, and implement measures to incentivize associated growers to utilize surface water supplied by GCID, which will provide in-lieu recharge through reduced groundwater pumping.
Glenn-Colusa Irrigation District (GCID) Water Transfers to TCCA CVP Contractors	GCID is exploring the possibility of transferring surface water to Central Valley Project (CVP) contractors served by the Tehama Colusa Canal to provide in-lieu groundwater recharge and reduce groundwater pumping. Transferred water would be diverted into the TCC at the Red Bluff Pumping Plant and Fish Screen facility rather than at the GCID pumping plant and fish screen facility north of Hamilton City.
Orland-Artois Water District (OAWD) Direct Groundwater Recharge	OAWD would directly recharge groundwater through Managed Aquifer Recharge (MAR) on agricultural land to improve aquifer conditions, especially in the groundwater cone of depression to the west of Artois. A pilot project for MAR was conducted in 2017 on the VanTol site using water from a Section 215 Temporary Water Contract from USBR. Section 215 water is low-cost, but is only available during high flow conditions in rivers and streams.
Orland Unit Water Users Association (OUWUA) Flood Water Conveyance	During periods of high flow and reservoir release on Stony Creek, divert water at OUWUA's south diversion and convey it to various locations for direct recharge within the OUWUA service area.
Sites Reservoir	The Sites Project would utilize existing infrastructure to divert unregulated and unappropriated flow from the Sacramento River at Red Bluff and Hamilton City and convey water to a new off stream reservoir west of the town of Maxwell. New and existing facilities would move water into and out of the reservoir. Depending on project operation and yield, there is potential for groundwater benefits to accrue to the Subbasin using water from Sites Reservoir.

Table 1. Brief Description of all Projects and Management Actions.

CCR § 354.44	CCR §354.44(a)
Project/Management Action Name	**Brief Project Description**
Colusa Subbasin In-lieu Recharge & Banking Program	Incentivize landowners to take surplus contract surface water in-lieu of pumping groundwater. A predetermined portion of the additional water brought into the districts would be dedicated to contributing to local groundwater sustainability and some portion of the remaining quantities would be available for delivery, directly or by exchange, to South Valley members in the San Joaquin Valley.
Sycamore Marsh Farm In-lieu Recharge Project	Sycamore Marsh Farm is in the process of developing an in-lieu groundwater recharge plan. Sycamore Marsh Farm encompasses approximately 420 acres in the Colusa Drain Mutual Water Company (CDMWC) and has an additional 449 acres that could potentially be annexed into the CDMWC, allowing for diversion of surface water from CDMWC.
Westside Off-stream Reservoir and In-Lieu Groundwater Recharge	TCCA Contractors would construct off-stream surface reservoirs along the western edge of the Subbasin and up-slope from the TCC diverting surplus Sacramento River flows (e.g., Section 215 water) into these storage reservoirs. Stored water would be released into the TCC for irrigation supply to enable reduction of groundwater pumping (i.e. in-lieu groundwater recharge). New facilities on the TCC and new storage impoundments would need to be planned, designed and constructed subject to a determination of economic and environmental feasibility.
Domestic Well Mitigation Program	Groundwater level measurable objectives (MOs) adopted for sustainable management of the Subbasin operation should be highly protective of domestic water supply wells. However, it is possible that in certain portions of the Subbasin, groundwater levels will fall. Projects and management actions will be implemented for recovery of groundwater levels, but some domestic wells may go dry. To mitigate the effects of domestic well stranding due to groundwater level decline, the CGA and GGA will investigate implementing domestic well mitigation programs in their respective portions of the subbasin.
Strategic Short-Term Demand Management	The program would be focused in specific local areas with sustainability challenges and would provide GSAs with a voluntary, flexible, short-run response to alleviate impacts of drought. It would be voluntary and provide financial incentives (payments) to encourage participation. Payment terms and other conditions would be specified as part of program design. Two potential structures for the program are idling lands in drought-affected areas of the subbasin with groundwater sustainability challenges or idling lands in participating surface water-using portions of the Subbasin and conveying the saved surface water to the drought-affected areas with groundwater sustainability challenges.
Long-Term Demand Management Action	Demand management broadly refers to any water management activity that reduces the consumptive use of irrigation water. A demand management action is one that incentivizes, enables, or possibly requires water users to reduce their consumptive use.
Well Abandonment Outreach and Funding Program	The CGA and GGA will coordinate with Colusa and Glenn counties, respectively, to create a program providing outreach and education to landowners regarding the proper procedures for well decommissioning and abandonment, as well as a funding source to assist landowners with these procedures. This program is anticipated to improve the subbasin well inventory and potentially have water quality benefits, as improperly abandoned wells are a potential point source for water quality contaminant transport from the ground surface to the underlying groundwater system.

Table 1. Brief Description of all Projects and Management Actions.

CCR § 354.44	CCR §354.44(a)
Project/Management Action Name	**Brief Project Description**
Preservation of Lands Favorable for Recharge	The CGA and GGA will coordinate with those agencies having authority over land use planning in and Glenn counties, respectively, to investigate, design, and implement a program providing incentives to landowners with lands favorable to groundwater recharge to preserve them as agricultural or undeveloped lands on which groundwater recharge will be possible in perpetuity.
Review of County Well Permitting Ordinances	Review and revise the county well permitting processes in the Subbasin to ensure that future well permitting aligns with the Subbasin sustainability goal and that future changes to well permitting are reviewed by the GSAs. The GSAs would work with the counties to review and suggest revisions to ordinances (these are outside of the jurisdiction of the GSAs).
Drought Contingency Planning for Urban Areas	The CGA and GGA will coordinate with cities, towns and other municipal and industrial water suppliers, which are all fully dependent on groundwater in the Subbasin, to encourage drought contingency planning and drought preparedness in a manner consistent with sustainable groundwater management according the GSP.
Development of a Dedicated Network of Shallow Monitoring Wells for GDE Monitoring	Evaluate and develop a dedicated network of shallow monitoring wells specifically planned and sited for monitoring conditions in areas of the Subbasin where GDEs are most likely to be found. This action is also expected to incorporate biological monitoring to inform the location of new shallow monitoring wells and monitor whether GDEs are being impacted by changing groundwater conditions

Notes:

1. This project is currently in the early conceptual stage. Thus the implementation and termination dates have yet to be determined. Criteria for implementation may, among other factors, be linked to the measurable objectives and provided in annual reports.
2. Public and/or Inter-Agency Noticing is being facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
3. Public and/or Inter-Agency Noticing will be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
4. Required permitting and regulatory review is being initiated through consultation with applicable governing agencies. Governing agencies for which consultation is being initiated may include, but is not limited to: the California Department of Water Resources (DWR), the California State Water Resources Control Board (SWRCB), the California Department of Fish and Wildlife (CDFW), the Central Valley Flood Protection Board (Flood Board), Regional Water Boards, the United States Bureau of Reclamation (Reclamation or USBR), the United States Army Corps of Engineers (USACE), the United States Fish and Wildlife Service (USFWS), the National Marine Fisheries Service (NMFS), Local Agency Formation Commissions (LAFCO), the Counties of Colusa and/or Glenn, and the California Air Resources Board (CARB).
5. Required permitting and regulatory review will be project specific and initiated through consultation with applicable governing agencies. Governing agencies for which consultation is being initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USBR, USACE, USFWS, NMFS, LAFCO, Counties of Colusa and/or Glenn, and CARB.
6. This project is currently in the early conceptual stage. Thus, the start and completion dates for this project have yet to be determined and will be provided in annual reports when known.

Table 4. Anticipated Benefits of all Projects and Management Actions.

CCR § 354.44	CCR §354.44(b)(5)			
Project/Management Action Name	**Measurable Objectives Expected to Benefit**	**Multi-Benefits Expected**	**Serves Disadvantaged Community (If so, which one?)**	**Expected Yield**
Planned				
Colusa County Water District In-Lieu Groundwater Recharge	Groundwater levels, groundwater storage, and depletions of interconnected surface water		See Note 1 below	27,000 af/year
Colusa Drain MWC In-Lieu Groundwater Recharge	Groundwater levels, groundwater storage, and depletions of interconnected surface water		See Note 1 below	28,000 af/year
Colusa Subbasin Multi-Benefit Groundwater Recharge	Groundwater levels, groundwater storage, and depletions of interconnected surface water	Ponded habitat for migratory birds	See Note 1 below	5,200 af/year
Orland-Artois Water District Land Annexation and Groundwater Recharge	Groundwater levels, groundwater storage, and depletions of interconnected surface water		See Note 1 below	23,000 af/year
Sycamore Slough Groundwater Recharge Pilot Project	Groundwater levels, groundwater storage, and depletions of interconnected surface water	Ponded habitat for migratory birds	See Note 1 below	5,000 af over 10 years
Ongoing				
Reclamation District 108 and Colusa County Water District Agreement for Five-Year In-Lieu Groundwater Recharge Project	Groundwater levels, groundwater storage, and depletions of interconnected surface water		See Note 1 below	8,000 af/year
Glenn-Colusa Irrigation District Strategic Winter Water Use for Groundwater Recharge and Multiple Benefits	Groundwater levels, groundwater storage, and depletions of interconnected surface water	Increased ponded habitat for migratory birds and improved air quality through reduced rice straw burning	See Note 1 below	See Note 2 below

Table 4. Anticipated Benefits of all Projects and Management Actions.

CCR § 354.44	CCR §354.44(b)(5)			
Project/Management Action Name	**Measurable Objectives Expected to Benefit**	**Multi-Benefits Expected**	**Serves Disadvantaged Community (If so, which one?)**	**Expected Yield**
Sycamore Marsh Farm Direct Recharge Project	Groundwater levels, groundwater storage, depletions of interconnected surface water, land subsidence, and potentially groundwater quality	Ponded habitat for migratory birds	See Note 1 below	See Note 2 below
Glenn-Colusa Irrigation District Expansion of In-Basin Program for In-lieu Groundwater Recharge	Groundwater levels, groundwater storage, and depletions of interconnected surface water		See Note 1 below	See Note 2 below
Orland Unit Water Users Association Irrigation Modernization for Increased Surface Water Delivery and Reduced Groundwater Pumping	Groundwater levels, groundwater storage, and depletions of interconnected surface water		See Note 1 below	See Note 2 below
Urban Water Conservation in Willows	Groundwater levels, groundwater storage, and depletions of interconnected surface water		See Note 1 below	2 af/year
Potential				
Colusa County Public Water System Water Treatment Plant	Groundwater levels, groundwater storage, and depletions of interconnected surface water	Improved drinking water quality; Arbuckle and Dunnigan face loss of well supply; Grimes and Princeton have drinking well arsenic contamination; Williams has elevated salinity (TDS) levels	See Note 1 below	See Note 2 below
Delevan Pipeline Colusa Basin Drain Intertie	Groundwater levels, groundwater storage, depletions of interconnected surface water, and land subsidence (to the extent that project yield is dedicated to recharge projects)		See Note 1 below	See Note 2 below

Table 4. Anticipated Benefits of all Projects and Management Actions.

CCR § 354.44	CCR §354.44(b)(5)			
Project/Management Action Name	**Measurable Objectives Expected to Benefit**	**Multi-Benefits Expected**	**Serves Disadvantaged Community (If so, which one?)**	**Expected Yield**
Sycamore Slough Colusa Basin Drain Multi-Benefit Recharge Project	Groundwater levels, groundwater storage, and depletions of interconnected surface water	Ponded habitat for migratory birds, along with other environmental benefits	See Note 1 below	See Note 2 below
Tehama-Colusa Canal Trickle Flow to Ephemeral Streams	Groundwater levels, groundwater storage, and depletions of interconnected surface water		See Note 1 below	See Note 2 below
Westside Streams Diversion for Direct or In-lieu Groundwater Recharge	Groundwater levels, groundwater storage, depletions of interconnected surface water, land subsidence	Reduced flood impacts to the extent that diversions reduce the severity of downstream flooding	See Note 1 below	Dependent on scale of implementation; between roughly 1,000 to 16,000 af/year
Reduce Non-beneficial Evapotranspiration/Invasive Species Eradication (Arundo, Eucalyptus, Tamarisk, etc.)	Groundwater levels, groundwater storage, and depletions of interconnected surface water	Decreased ET; increased native vegetation / habitat; decreased sediment trapping	See Note 1 below	See Note 2 below
Enhanced Infiltration of Precipitation on Agricultural Lands	Groundwater levels, groundwater storage, and depletions of interconnected surface water	Increased groundwater recharge	See Note 1 below	See Note 2 below
Colusa Subbasin Flood-MAR	Groundwater levels, groundwater storage, and depletions of interconnected surface water		See Note 1 below	See Note 2 below
Reclamation District 108 “Boards In” Program	Groundwater levels, groundwater storage, and depletions of interconnected surface water	Possible ponded habitat for migratory birds	See Note 1 below	Dependent on scale of implementation; estimated 1,800 af/year (if 20% of rice fields in RD108 participate)
Glenn-Colusa Irrigation District In-lieu Groundwater Recharge	Groundwater levels, groundwater storage, and depletions of interconnected surface water		See Note 1 below	See Note 2 below

Table 4. Anticipated Benefits of all Projects and Management Actions.

CCR § 354.44	CCR §354.44(b)(5)			
Project/Management Action Name	**Measurable Objectives Expected to Benefit**	**Multi-Benefits Expected**	**Serves Disadvantaged Community (If so, which one?)**	**Expected Yield**
Glenn-Colusa Irrigation District Water Transfers to TCCA CVP Contractors	Groundwater levels, groundwater storage, and depletions of interconnected surface water		See Note 1 below	See Note 2 below
Orland-Artois Water District Direct Groundwater Recharge	Groundwater levels, groundwater storage, and depletions of interconnected surface water	Possible ponded habitat for migratory birds depending on timing of flooding	See Note 1 below	See Note 2 below
Orland Unit Water Users Association Flood Water Conveyance	Groundwater levels, groundwater storage, and depletions of interconnected surface water		See Note 1 below	See Note 2 below
Sites Reservoir	Groundwater levels, groundwater storage, depletions of interconnected surface water, and land subsidence (to the extent that project yield is dedicated to recharge projects).	Increased local, regional, and statewide water supply reliability, climate change resiliency, recreation, increased cold water pool for endangered salmon	See Note 1 below	See Note 2 below
Colusa Subbasin In-lieu Recharge & Banking Program	Groundwater levels, groundwater storage, depletions of interconnected surface water, land subsidence, and potentially groundwater quality		See Note 1 below	See Note 2 below
Sycamore Marsh Farm In-lieu Recharge Project	Groundwater levels, groundwater storage, depletions of interconnected surface water, land subsidence, and potentially groundwater quality		See Note 1 below	See Note 2 below
Westside Off-stream Reservoir and In-Lieu Groundwater Recharge	Groundwater levels, groundwater storage, and depletions of interconnected surface water		See Note 1 below	See Note 2 below
Domestic Well Mitigation Program	None		See Note 1 below	None

Table 4. Anticipated Benefits of all Projects and Management Actions.

CCR § 354.44	CCR §354.44(b)(5)			
Project/Management Action Name	**Measurable Objectives Expected to Benefit**	**Multi-Benefits Expected**	**Serves Disadvantaged Community (If so, which one?)**	**Expected Yield**
Strategic Short-Term Demand Management	Groundwater levels, groundwater storage, and depletions of interconnected surface water in areas with potential sustainability challenges	Yes, potential for multi-benefits on temporarily idled lands, depending on program design	See Note 1 below	See Note 2 below
Long-Term Demand Management Action	Groundwater levels, groundwater storage, and depletions of interconnected surface water		See Note 1 below	See Note 2 below
Well Abandonment Outreach and Funding Program	Water quality		See Note 1 below	None
Preservation of Lands Favorable for Recharge	Groundwater levels, groundwater storage, and depletions of interconnected surface water		See Note 1 below	See Note 2 below
Review of County Well Permitting Ordinances	Potentially: groundwater levels, groundwater storage, depletions of interconnected surface water, land subsidence, and groundwater quality		See Note 1 below	See Note 2 below
Drought Contingency Planning for Urban Areas	Groundwater levels, groundwater storage, and depletions of interconnected surface water		See Note 1 below	See Note 2 below
Development of a Dedicated Network of Shallow Monitoring Wells for GDE Monitoring	Groundwater levels, groundwater storage, and depletions of interconnected surface water	GDEs, riparian habitat	See Note 1 below	See Note 2 below

Notes:

1. The majority of the areas within the Colusa Subbasin are classified as either Severely Disadvantaged Communities, Disadvantaged Communities, or Economically Distressed Areas.
2. This project is currently in the early conceptual stage. Thus, the expected yield of this project has yet to be determined and will be reported in annual reports when known.

Development of Modeling Parameters for Simulating Projects and Management Actions in the Colusa Subbasin

(THIS PAGE LEFT BLANK INTENTIONALLY)

Specialists in Agricultural Water Management
Serving Stewards of Western Water since 1993

Technical Memorandum

To: Colusa Groundwater Authority and Glenn Groundwater Authority

From: Davids Engineering

Date: July 14, 2021

Subject: **Development of Modeling Parameters for Simulating Projects and Management Actions in the Colusa Subbasin**

Introduction

The Groundwater Sustainability Plan (GSP) emergency regulations, described in 23 CCR §354.44[1], require Groundwater Sustainability Agencies (GSAs) to describe projects and management actions (PMAs) that will achieve the sustainability goal for the basin and respond to changing conditions in the basin. Among other required information, GSAs must describe the benefits that are expected to be realized from the PMAs and how those benefits will be evaluated (23 CCR §354.44(b)(5)). The development and description of PMAs must be supported by the best available information and best available science (23 CCR §354.44(c)).

This technical memorandum (TM) describes the modeling approach and model inputs that were used to simulate the expected benefits of planned PMAs in the Colusa Subbasin (Subbasin) using the C2VSimFG-Colusa model (model). The model inputs reflect the anticipated volume and timing of surface water supply available through specific PMAs for direct and in-lieu groundwater recharge. The model inputs also characterize where that water would be beneficially used within the Subbasin.

In addition to the model inputs, this memorandum summarizes model results from the PMA simulations that represent the quantitative benefits of these PMAs on projected future groundwater conditions in the Subbasin. At the time of GSP development, the model is considered to provide the best available information on groundwater conditions in the Subbasin, and the accuracy of this information is generally sufficient to support GSP preparation, including description of PMA benefits.

[1] California Code of Regulations, Title 23, Division 2, Chapter 1.5, Subchapter 2 Groundwater Sustainability Plans, Article 5, Section 354.28 Minimum Thresholds.

Overview of Modeled PMAs

There are five planned projects described in the Colusa Subbasin GSP that are on track for implementation. Three of those projects were selected for simulation in the model in order to gain initial insights into the magnitude of impacts from these projects. These three projects are substantial recharge projects that could have large effects on groundwater conditions relative to other PMAs. Model inputs and model results for the three modeled projects are the focus of this TM. However, the modeling approach and inputs described for these projects can be adapted to simulate other similar projects.

General background on the three modeled projects is provided below. Additional information about these PMAs and others is included in Chapter 6 of the Colusa Subbasin GSP, Projects and Management Actions.

Colusa County Water District In-Lieu Groundwater Recharge

Colusa County Water District (CCWD) has a total service area of approximately 46,000 acres, of which 39,875 acres are currently irrigable with existing District infrastructure. The majority of irrigated land is used to cultivate permanent crops. CCWD delivers surface water to approximately 35,000 acres, with the remaining acres being idle or irrigated with privately pumped groundwater. Currently, CCWD has access to Central Valley Project (CVP) water supplies through its own contracts and through transfers primarily from Westside Water District and, more recently, from Reclamation District 108 (RD108). Despite the availability of surface water, some CCWD growers choose to pump groundwater because it is less expensive than surface water and because groundwater requires less screening and filtering compared to district surface water.

Under the CCWD In-Lieu Groundwater Recharge project, CCWD will acquire additional surface water and will establish incentives to make the cost of surface water the same or less than the cost of pumping groundwater, thereby incentivizing growers who would otherwise use groundwater to use surface water. The additional surface water is expected to be acquired under long-term water transfer agreements with other CVP contractors, including Sacramento River Settlement Contractors (settlement contractors), and potentially other sources. The plan is to acquire and deliver 30,000 acre-feet per year (AF/yr) except in Shasta Critical years (approximately one in 10 years[2]) when groundwater stored through in-lieu recharge in prior years would be used.

Orland-Artois Water District Land Annexation and In-Lieu Groundwater Recharge

Orland-Artois Water District (OAWD) has an existing service area of about 29,000 acres and delivers water to district landowners through 110 miles of pipelines and 300 metered delivery points. Surface water delivered by OAWD is available under a CVP water supply contract with the United States Bureau of Reclamation (Reclamation) and through short- and long-term transfer agreements with other CVP water contractors and settlement contractors. Historically, water transfers have been from Maxwell Irrigation District, Princeton-Codora-Glenn Irrigation District, and others.

As part of the OAWD Land Annexation and In-Lieu Groundwater Recharge project, OAWD is working with a group of neighboring non-district landowners to annex approximately 12,000 acres of groundwater-dependent agricultural land into the district. Additional surface water for the annexed lands would be secured through multi-year purchase or transfer agreements with willing sellers, conveyed through the existing Tehama-Colusa (TC) Canal, and distributed to the annexed lands through

[2] Over the 50-year period from 1966-2015, five years were declared “Shasta Critical.”

new distribution facilities. Potential transferors include CVP water supply contractors and settlement contractors. The plan is to acquire and deliver 25,000 AF/yr of surface water to the annexed lands except in Shasta Critical years (approximately one in 10 years) when groundwater banked through in-lieu recharge in prior years would be used.

Colusa Subbasin Multi-Benefit Groundwater Recharge

The Colusa Groundwater Authority (CGA) and The Nature Conservancy (TNC) collaborated in a multi-benefit pilot project from 2018 through 2021 to demonstrate the project benefits to direct groundwater recharge and creation of habitat for migrating shorebirds. In the pilot project, multi-benefit recharge was conducted by recharging groundwater through normal farming operations at strategic times of year in order to provide critical wetland habitat for shorebirds migrating along the Pacific Flyway, and potential ancillary benefits for water levels near disadvantaged communities in the Subbasin. The pilot project concluded that multi-benefit recharge is feasible and does generate the intended recharge and habitat benefits, serving as an example of how the Subbasin-wide program could work.

The planned Colusa Subbasin Multi-Benefit Groundwater Recharge project would expand on the pilot project to identify and contract with willing landowners who will participate in the program, and to develop program incentives and funding opportunities that will encourage enrollment, especially in areas that are most suitable for multi-benefit recharge. Each year, multi-benefit recharge would be implemented by applying surface water to participating fields and maintaining a shallow depth (4 inches maximum) for typically four to six weeks in the late summer and early fall (July 15 to October 15) and/or spring (March 15 to April 15),) when migratory bird habitat is needed.

While the actual location and scale of the project will depend on voluntary landowner participation, areas in the Subbasin that are potentially favorable for multi-benefit recharge have already been identified through preliminary mapping based on:

- Land use and crop characteristics that are suitable for recharge and could accept flooding in late summer and early fall (the period prioritized for modeling), with minimal impacts to crops and farming operations
- Soil characteristics that are suitable for recharge, using the Soil Agricultural Groundwater Banking Index (SAGBI[3]) rating
- Availability of surface water supplies for field-flooding during prime periods when migratory bird habitat is needed
- Proximity to the Sacramento River, as those lands are expected to have the greatest positive impact on streamflows

[3] SAGBI is a suitability index indicating the potential for groundwater recharge on agricultural land, determined according to five main factors: deep percolation, root zone residence time, topography, chemical limitations, and soil surface condition. SAGBI ratings for lands in California are developed by the California Soil Resource Lab at UC Davis and UC-ANR, and are available online at: https://casoilresource.lawr.ucdavis.edu/sagbi/.

Analytic Approach

Modeling Approach

The quantitative benefits of the three modeled projects to groundwater conditions in the Subbasin were evaluated using the C2VSimFG-Colusa model (model), an integrated hydrologic flow model for the Subbasin. Development and refinement of this model to support GSP development is described in Appendix 3D. The C2VSimFG-Colusa model was adapted from the Fine Grid California Central Valley Groundwater-Surface Water Simulation Model (C2VSimFG).

The model simulates inflows and outflows between the Subbasin surface water system and groundwater system in a grid of land elements, stream nodes, and groundwater nodes that span and surround the Subbasin. The model calculates a water budget for each element and node on a monthly timestep for different historical, current, and projected (future) scenarios described in the GSP. Results of these element and node-level water budgets are aggregated to quantify the historical, current, and projected water budgets for the entire Subbasin, as required in the GSP regulations.

Among their many functions, user-defined model inputs are used to determine when, where, and how much water is applied to lands and ultimately recharges the groundwater system. Key water budget parameters that were evaluated to quantify the groundwater recharge benefits of the three modeled projects include:

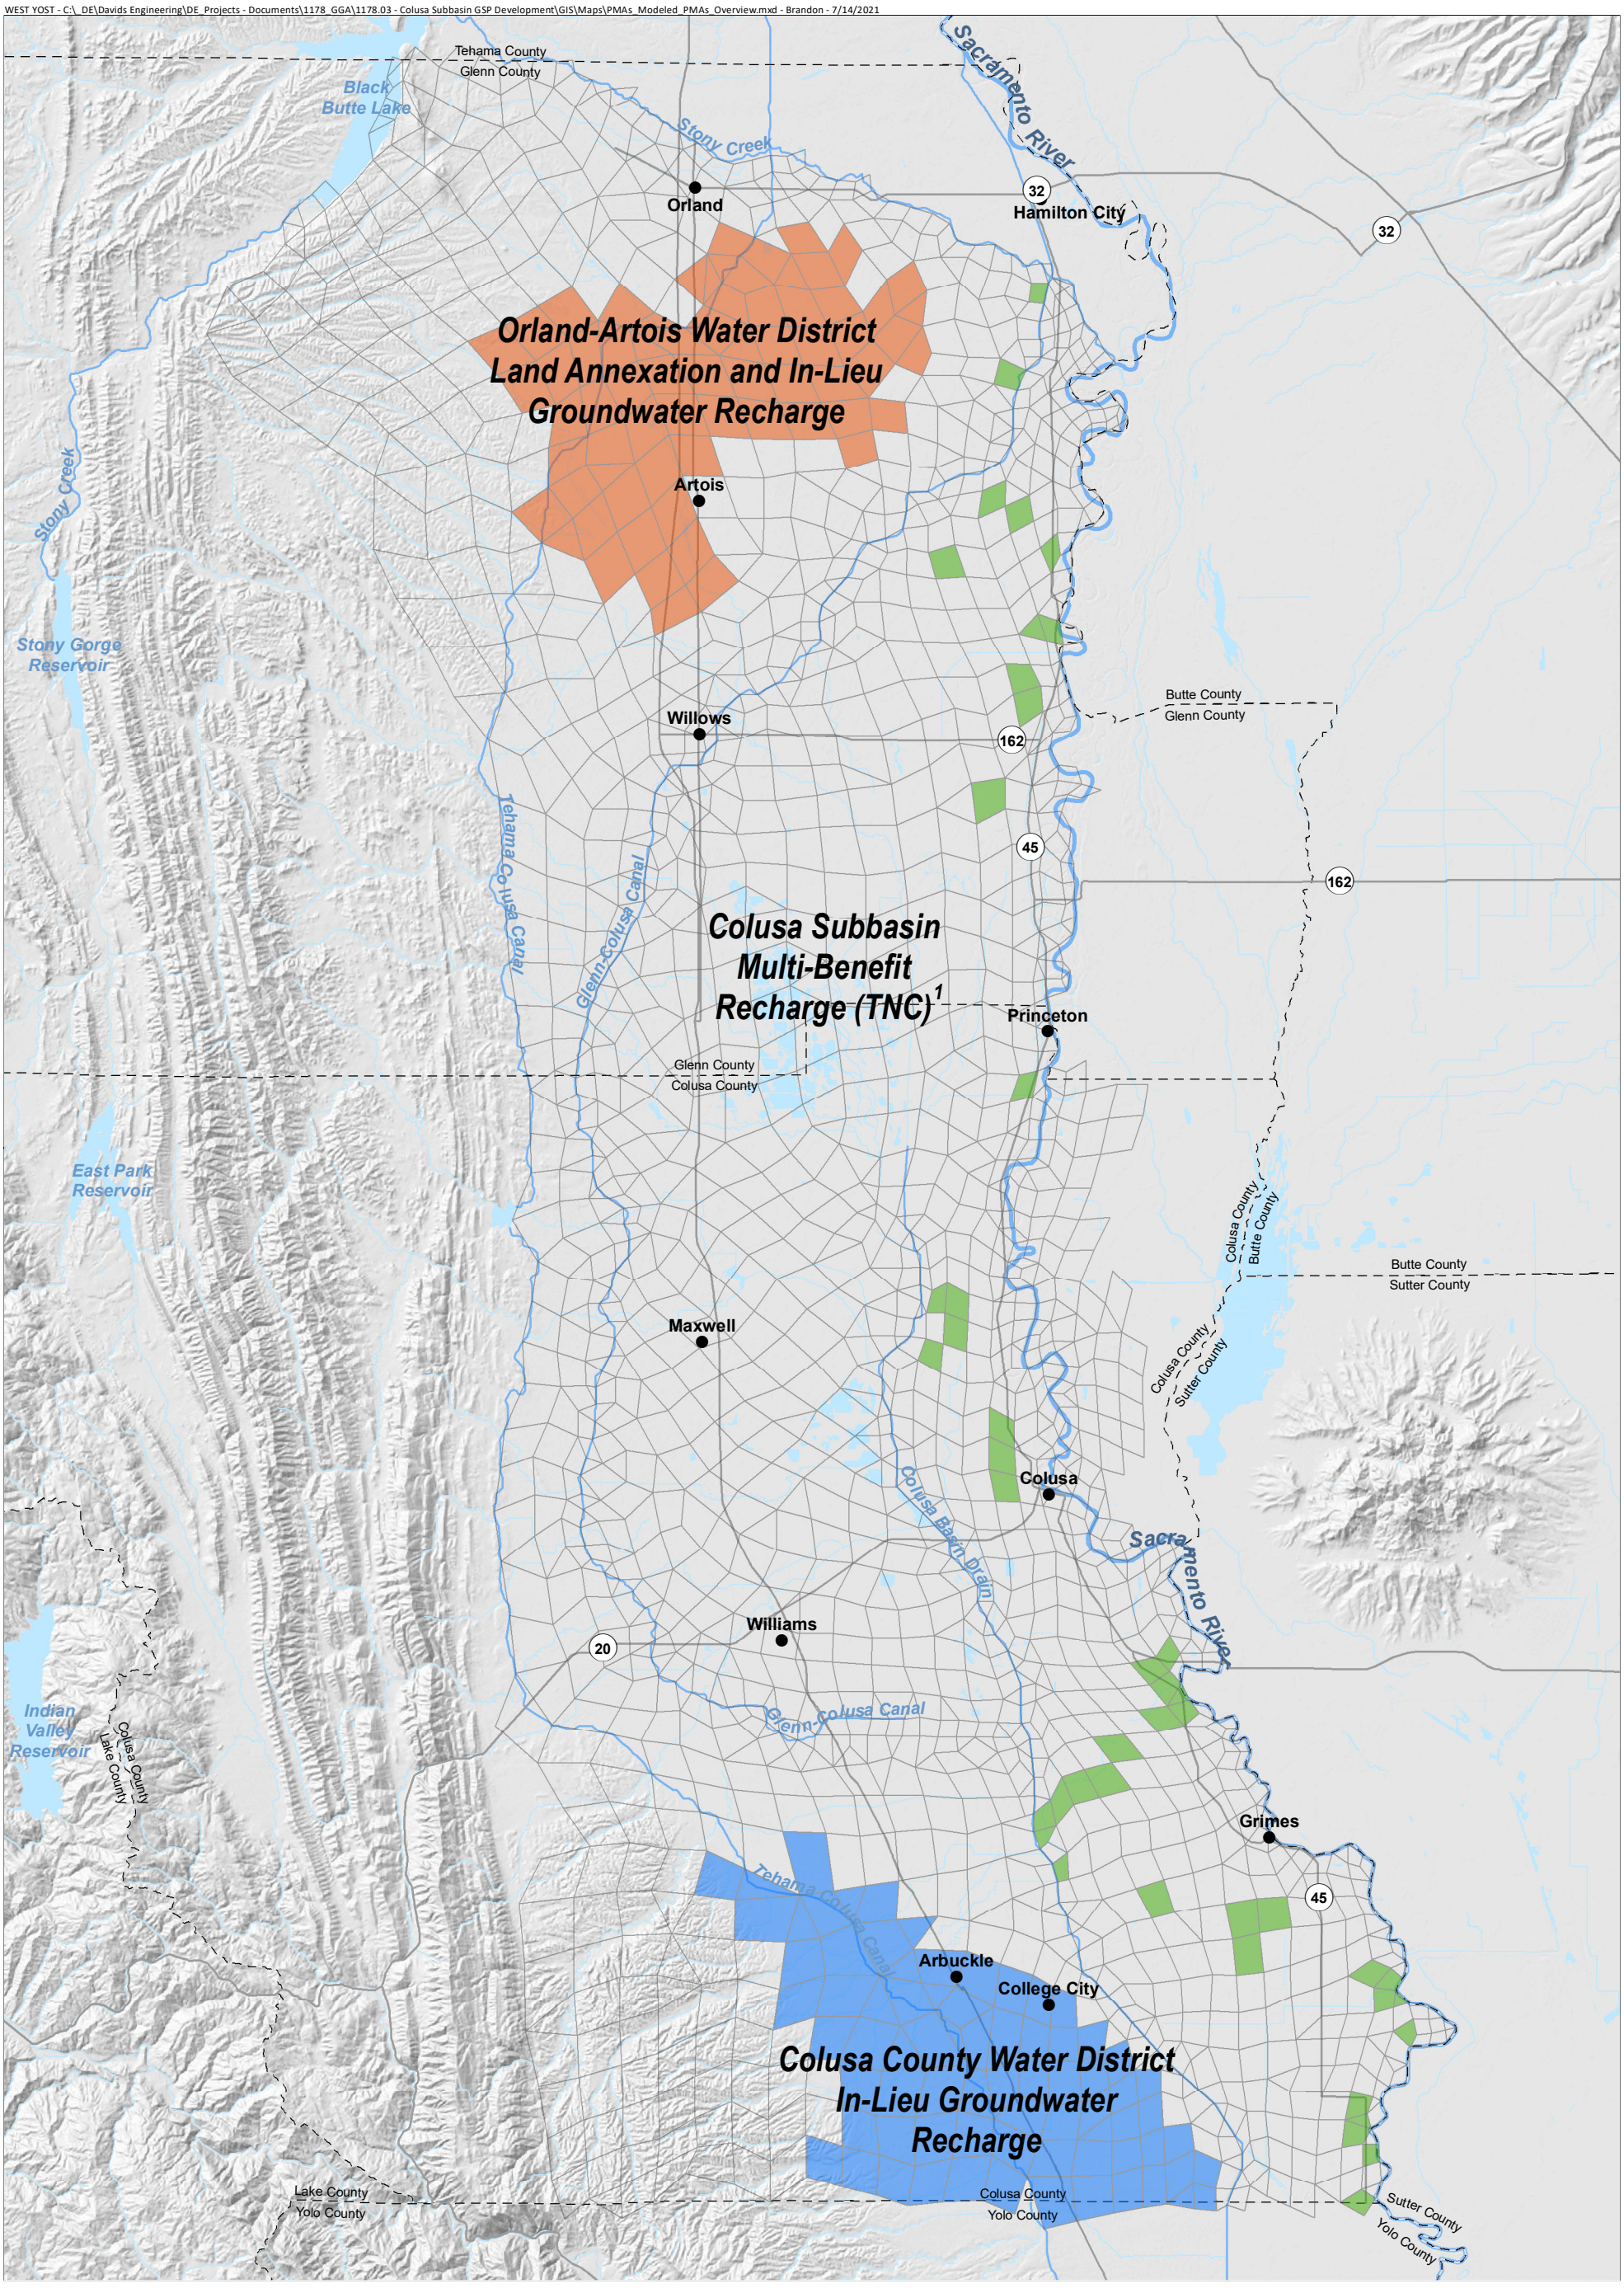
- Surface Water Diversions: Surface water diverted from a stream node and delivered to elements. Surface water diversions are a user-defined model input, and are summarized to describe the average annual surface water volume diverted for the PMA.
- Groundwater Pumping: Groundwater pumped to meet water demand in elements. For these projects, groundwater pumping is calculated by the model to meet the remaining irrigation demand after surface water is applied.
- Seepage: For these projects, seepage represents water that is lost from streams, canals, or conveyance systems, flowing through the soil and to the groundwater system. Seepage is a component of groundwater recharge, and is calculated by the model.
- Deep Percolation: For these projects, deep percolation represents the fraction of water applied to fields that flows through the soil and to the groundwater system. Deep percolation is a component of groundwater recharge, and is calculated by the model.

Additional information about how the model operates, its inputs, and assumptions are provided in the model documentation and Appendix 3D.

Modeled Project Areas

Three project areas were explicitly defined in the C2VSimFG-Colusa model to quantify the effects and benefits of PMAs on the Subbasin water budget, specifically those related to groundwater conditions. These project areas, shown in Figure *1*, include:

1) **Planned CCWD Project Area**: a group of elements that approximately represents the CCWD service area
2) **Planned OAWD Project Area**: a group of elements that approximately represents the existing OAWD service area and the 12,000 acres that OAWD plans to annex



3) **Multi-Benefit Recharge Project Area:** a group of elements that represents a hypothetical selection of potential recharge areas, containing fields identified through the process described later in this TM

Each project area is represented by a group of elements that approximately represents the areas in which specific projects are expected to occur. Model inputs developed for the three modeled PMAs were applied and simulated in the elements represented in each project area.

The C2VSimFG-Colusa model calculates the water budget for each model element for each monthly timestep, including the elements in each project area. For all elements in each project area, the element-level water budget results were summed to aggregate project area water budget results.

Planned CCWD PMA Project Area
Multi-Benefit Recharge PMA Project Area
Planned OAWD PMA Project Area
Model Elements Without Modeled PMAs
Colusa Subbasin Boundary

Horizontal Datum: North American Datum of 1983 (NAD 83), California State Plane Zone II, feet.

Note:
1. Multi-benefit recharge locations will depend on grower enrollment and could be anywhere within the Colusa Subbasin where surface water supplies are available and recharge conditions are favorable. For purposes of modeling project impacts, elements were selected based on lands with cropping schedules that allow for flooding during bird migration periods and total roughly 4,000 acres.

Model Scenarios

Two model scenarios were considered for quantifying the effects and benefits of PMAs on the Subbasin:

- **Without-Projects Scenario**—Projected Future Conditions with 2070 Climate Change and without Projects. This is the projection of future conditions over the 50-year period from 2016 through 2065, assuming climate change effects are occurring, but that no groundwater recharge or other types of projects are implemented. Climate change adjustments were made to the precipitation, evapotranspiration, and surface water supply model inputs to reflect the estimated effects of climate change based on the 2070 Central Tendency climate change datasets provided by DWR to support GSP development.[4] The main effect of these adjustments is an estimated increase in future crop water requirements, which result in the need for increased groundwater pumping.
- **With-Projects Scenario**—Projected Future Conditions with 2070 Climate Change and with Projects. This is the same as the "without-projects" scenario, except that it is assumed that the three modeled projects are in operation during the full duration of the 50-year simulation.

Hereinafter, for convenience, these model scenarios are referred to as the "without-project" and "with-project" scenarios, respectively. The model inputs differ only due to projects; thus, differences in model results between these scenarios are due entirely to the effects of the projects.

The analysis period and assumptions about hydrology, land use, and water supplies associated with each model scenario are summarized in **Table 1**. Projected future water supplies and land use are expected to vary depending on Shasta watershed hydrologic conditions and related CVP operations plans prepared by Reclamation. Water supplies and flows through the Subbasin may be reduced in hydrologic years designated by Reclamation as Shasta Critical[5], such as 2015, resulting in reduced cropped acreage in those years. In Shasta Non-Critical years, water supplies and land use are expected to be similar to current conditions in recent non-drought years, such as 2013. In the future analysis period (2016-2065), future years are mapped to a series of historical years that were selected to represent historical hydrology as the baseline for estimating future hydrology (23 CCR §354.18(c)(3)). The Shasta Critical or Non-Critical designation of those historical years was also mapped to the corresponding future years.

Additional information on these scenarios is provided in Chapter 3, Section 3.3, of the Subbasin GSP.

[4] Climatological, hydrological, and water operations datasets, change factors, and the DWR Climate Change Resource Guide are available at: https://data.cnra.ca.gov/dataset/sgma-climate-change-resources.

[5] In general, Shasta Critical conditions are declared when the forecast inflow to Lake Shasta for a particular water year is equal to or less than 3.2 million AF. Conversely, Shasta Non-Critical conditions are declared when the forecast inflow to Lake Shasta for a particular water year exceeds 3.2 million AF. Between 1966-2015, five years were "Shasta Critical," or approximately 1 in 10 years.

Table 1. Summary of Water Budget Assumptions Used for the Without-Projects Scenario and With-Projects Scenario

Model Scenario	Analysis Period[1]	Hydrology	Land Use	Water Supplies
Without-Projects Scenario: Projected Future Conditions with 2070 Climate Change and without Projects	2016 to 2065	Historical (1966 to 2015), adjusted based on 2070 Central Tendency climate change datasets	Current (2013 and 2015) used for Shasta Non-Critical and Shasta Critical, respectively	Same as Current (see above), adjusted for 2070 Central Tendency climate change
With-Projects Scenario—Projected Future Conditions with 2070 Climate Change and with Projects.	2016 to 2065	Historical (1966 to 2015), adjusted based on 2070 Central Tendency climate change datasets	Current (2013 and 2015) used for Shasta Non-Critical and Shasta Critical, respectively	Same as Current (see above), adjusted for 2070 Central Tendency climate change

[1] Results over the analysis period are summarized by water year (October 1 through September 30)

Model Inputs for PMAs

As described above, model inputs for the three modeled PMAs reflect the anticipated volume and timing of surface water supply available through the PMAs for direct and in-lieu groundwater recharge. The model inputs also characterize where that water is beneficially used within the Subbasin. Model inputs developed for each of the three modeled PMAs are described below.

Colusa County Water District In-Lieu Groundwater Recharge

Under the CCWD In-Lieu Groundwater recharge project, CCWD plans to acquire and deliver 30,000 AF/yr of additional surface water except in Shasta Critical years (approximately one in 10 years[6]).

For modeling, it was assumed in the with-project scenario that an additional 30,000 AF/yr will be delivered to all irrigated agricultural land in model elements that approximately represent the CCWD service area (Figure *1*) during Shasta Non-Critical years in the 2016-2065 analysis period. The 30,000 AF is in addition to surface water supplies delivered in the without-project scenario. In Shasta Critical years, no additional surface water is delivered to those elements.

Orland-Artois Water District Land Annexation and Groundwater Recharge

As part of the OAWD Land Annexation and In-Lieu Groundwater Recharge project, OAWD plans to annex approximately 12,000 acres of groundwater-dependent agricultural land into the district. OAWD also plans to acquire and deliver 25,000 AF/yr of surface water to the annexed lands except in Shasta Critical years (approximately one in 10 years).

For modeling, it was assumed in the with-project scenario that an additional 25,000 AF/yr will be delivered to all irrigated agricultural land in the OAWD project area (Figure *1*) during Shasta Non-Critical years in the 2016 to 2065 analysis period. The OAWD project area contains model elements that approximately represent the OAWD service area as well as the 12,000 acres that OAWD plans to annex. The 25,000 AF/yr is in addition to surface water supplies delivered in the without-project scenario. In

[6] Over the 50-year period from 1966-2015, five years were declared "Shasta Critical."

Shasta Critical years, no additional surface water is delivered to the OAWD service area and groundwater is the sole irrigation supply source for the annexed area.

Colusa Subbasin Multi-Benefit Groundwater Recharge

In the Colusa Subbasin Multi-Benefit Recharge project, voluntarily participating growers will apply surface water to fields and maintain a shallow depth (4 inches maximum) for typically four to six weeks in the late summer and early fall (July 15 to October 15) and/or spring (March 15 to April 15),) when migratory shorebird habitat is needed.

For modeling the multi-benefit groundwater recharge project, key assumptions and analyses were developed to identify one hypothetical project configuration as a "bookend" scenario, in which maximal grower participation occurs in areas with the greatest multi-benefit groundwater recharge potential. In practice, the actual location and scale of the project will depend on voluntary landowner participation from year to year. The assumptions and analyses underpinning the with-project scenario model inputs were formulated to estimate:

- Where the greatest potential combination of multi-benefits could occur (considering groundwater recharge potential, habitat creation suitability, and other factors of interest)
- When the project would be implemented (on a monthly and annual basis)
- How much voluntary participation could occur (assuming, at a maximum, that all lands with the greatest potential combination of multi-benefits will participate each year water is available)

The specific approach and assumptions are as follows:

- A geospatial analysis was completed to identify all "potential recharge areas" in the Subbasin. All lands with the following characteristics were identified as potentially suitable for multi-benefit groundwater recharge, and were assumed to enroll in the program in the with-project scenario:
    - Location:
        - Within the service area of a surface water supplier (Lands were assumed to have access to surface water supplies)
        - Within six miles of the Sacramento River (Lands were considered to allow maximum mitigating effects on streamflow depletion, a factor of interest to modeling; this may not necessarily be a factor in actual program implementation)
    - Soil characteristics: Soils that are suitable for groundwater recharge (indicated by a SAGBI rating of "moderately good," "good," or "excellent")
    - Land use: Crops that are suitable for recharge and could accept flooding in late summer and early fall (the period prioritized for modeling), with minimal impacts to crops and farming operations (excluded lands include: non-agricultural land uses (urban, native vegetation, riparian), permanent crops, ponded crops, and other crops with growing seasons incompatible with flooding between August-October)

- Minimum size of 25 acres

  A total of 4,122 acres were found to satisfy these criteria, and are located within the model elements identified in Figure *1*. These "potential recharge areas" were assumed to all participate in multi-benefit groundwater recharge.

- For all potential recharge areas, it was assumed that:
  - Shasta Non-Critical years: Multi-benefit groundwater recharge would occur and lands would be flooded with surface water for 30 days (during the month of September)
  - Shasta Critical years: Normal farming and irrigation practices would continue, without multi-benefit groundwater recharge due to likely surface water shortages in those years.
- For all potential recharge areas, model inputs for the with-project scenario were changed from the without-project scenario as follows:
  - Crop assignment: In Shasta Non-Critical years, lands were classified as non-ponded crops planted in March or April and harvested by August. In Shasta Critical years, lands remained in their original crop assignment.
  - Soil characteristics: In September, target soil moisture (TSM) was set equal to the total porosity of the soil to simulate ponding. In other months, TSM was estimated as the weighted average TSM of all lands identified from the geospatial analysis.
  - Irrigation period: Set to March or April through September in all years.
  - Crop evapotranspiration: In Shasta Non-Critical years, crop evapotranspiration was estimated as the weighted average evapotranspiration of all lands identified from the geospatial analysis, with adjustment for idle lands that are typically unirrigated. In Shasta Critical years, crop evapotranspiration returned to the original crop assignment.
  - Diversions:
    - In Shasta Non-Critical years: Additional diversions to potential recharge areas were estimated based on a simulation of average additional water demand in project area elements in September of Shasta Non-Critical years. The additional diversions were then specified as new supply from the Sacramento River, and applied to project area elements.
    - In Shasta Critical years: No additional diversions were specified.

Model Results for PMAs

This section compares the model results in the with-projects and without-projects scenarios. The difference between the without-project and with-project model results represents the net effect of the project on those water budget parameters.

Results for Each Modeled Project Area

The tables below summarize key results of the without-project and with-project model scenarios for each of the three modeled PMAs. Results are averaged over the entire 2016 to 2065 projected future period, including Shasta Critical years (approximately 10 percent of all years) when it is expected that

additional surface water supplies will be unavailable for projects. The results are aggregated from the water budgets of elements in the project areas identified in Figure *1*.

The average net benefit to the groundwater system of each modeled project is reported as "net recharge from the surface water system," calculated as the sum of all groundwater recharge (seepage and deep percolation) minus the sum of all groundwater extraction (groundwater pumping) in the project area and model scenario. Positive values indicate that more recharge is occurring, on average, while negative values indicate that more extraction is occurring.

On average across all years, the CCWD In-Lieu Groundwater Recharge project is expected to provide approximately 27,000 AF/yr of additional surface water to the CCWD project area, offsetting a similar volume of groundwater pumping (**Table 2**). The average net benefit to the groundwater system of the CCWD project is estimated to be approximately 27,000 AF/yr.

The OAWD Land Annexation and In-Lieu Groundwater Recharge project is expected to provide approximately 22,500 AF/yr of additional surface water to the OAWD project area, offsetting a similar volume of groundwater pumping on average across all years (**Table 3**). The average net benefit to the groundwater system of the OAWD project is estimated to be approximately 22,500 AF/yr.

The Colusa Subbasin Multi-Benefit Groundwater Recharge project is expected to provide approximately 11,500 AF/yr (2.8 AF per acre [AF/ac]) of surface water to potential recharge areas for field flooding (**Table 4**). A portion of this water results in deep percolation (approximately 4,000 AF/yr, or 1.0 AF/ac) or additional seepage (approximately 900 AF/yr, or 0.2 AF/ac). The average net benefit to the groundwater system of the OAWD project is estimated to be approximately 5,200 AF/yr (1.25 AF/ac).

Table 2. Key Model Results from the Colusa County Water District In-Lieu Groundwater Recharge Project (Average AF/yr, 2016 to 2065)

Scenario	Surface Water Diversions	Groundwater Pumping	Seepage	Deep Percolation	Net Recharge from the Surface Water System[1]
Without-Project	65,859	63,314	0	48,460	-14,854
With-Project	92,901	36,140	0	48,403	12,263

[1] Net Recharge from the Surface Water System = Seepage + Deep Percolation – Groundwater Pumping

[2] Calculated assuming 4,122 acres of "potential recharge area" will participate in multi-benefit groundwater recharge.

Results for the Colusa Subbasin

The tables below summarize key results of the without-projects and with-projects model scenarios for the entire Subbasin. Results are averaged over the entire 2016 to 2065 projected future period, including Shasta Critical years (approximately 10 percent of all years) when it is expected that additional surface water supplies will be unavailable for projects. The results are aggregated across all model elements in the Subbasin.

Table 5 summarizes the water budget results for the Subbasin surface water system. On average across all years, all three modeled projects are expected to reduce groundwater pumping by approximately 49,000 AF/yr and increase the total surface water inflows to the Subbasin by approximately 27,000 AF/yr. Stream gains from groundwater are also expected to increase by nearly 15,000 AF/yr

compared to the without-projects scenario.[7] Deep percolation in the with-projects scenario is expected to slightly increase (approximately 4,000 AF/yr), while seepage is expected to slightly decrease (approximately 10,000 AF/yr) compared to the without-projects scenario.

Table 6 summarizes the water budget results for the Subbasin groundwater system. In the without-projects scenario, the average annual change in groundwater storage across all years is expected to be approximately -7,000 AF/yr, indicating an average net decline in groundwater storage. When all three modeled projects are in effect, the average annual change in groundwater storage across all years is expected to be approximately 0 AF/yr, indicating no net decrease in groundwater storage.

These model results suggest that planned projects in the Subbasin are sufficient to support sustainable management of groundwater extractions and recharge to ensure that chronic lowering of groundwater levels or depletion of supply during periods of drought is offset by increases in groundwater storage during other periods (23 CCR §354.44(b)(9)).

[7] A more detailed assessment of projected streamflow accretion-depletion is presented in Appendix 3-G. The analysis considers the Sacramento River, Stony Creek, and the Colusa Drain individually and collectively, and evaluates temporal accretion-depletion patterns over the 50-year simulation period.

Funding, Financing, and Cost Allocation

(THIS PAGE LEFT BLANK INTENTIONALLY)

Technical Memorandum

To: Glenn and Colusa County Groundwater Authorities

From: ERA Economics

Date: November 19, 2021

Subject: **Funding and Financing Mechanisms and Cost Allocation Overview for the Colusa Subbasin**

Introduction

Development of the Colusa Subbasin GSP was primarily funded through a Proposition 1 Sustainable Groundwater Planning Grant. Additional funding for Glenn and Colusa Groundwater Authorities (GGA and CGA) activities to support GSP development was from fees collected under rate studies covering the five-year period spanning fiscal years 2019/20 through 2023/24. These were prepared as property-related fees for water service under Proposition 218[1]. The rate study fees supported GSP development, which was estimated to cost approximately $465,000 per year in the CGA and $450,000 to $550,000 per year in the GGA. The fee is up to approximately $1.09 and $1.60 per assessable acre in the CGA and GGA in the current fiscal year (actual fees are less than the max).

After submission of the GSP to Department of Water Resources (DWR), CGA and GGA activities will shift from GSP development to GSP implementation[2]. Implementation of the GSP will be a substantial undertaking, encompassing continuing activities for GSP development (e.g., outreach and coordination) as well as new activities to support implementation (e.g., projects and management actions and addressing data gaps in the Subbasin). Implementation will likely require GSAs and other local entities to fund these required activities. As described in Chapter 7 of the GSP, total GSP implementation costs are estimated to increase from approximately $1.5 million to around $9.5 million per year at full implementation of planned projects and management actions (including annualized capital costs).

GSAs and other local entities implementing projects and management actions will develop a GSP financing plan that will likely include a combination of fees, assessments, and taxes, as well as additional outside funding, grants, and low interest borrowing. The financing plan will, among other items, identify funding and financing sources for components of GSP implementation. This will include consideration of allocation of those costs to different entities—and ultimately water users—in the subbasin. This technical memorandum/appendix to the GSP describes options for GSP funding and financing and introduces cost allocation concepts and approaches that may be considered.

[1] Fee Study for the Glenn Groundwater Authority. May 2019.

Fee Study for the Colusa Groundwater Authority. May 2019.

[2] There is substantial overlap between development activities covered under the existing rate study and implementation activities. For example, GSA administration and technical development work, to support refinements to the GSP, are largely the same.

Colusa Subbasin GSP Implementation Costs

The total cost of GSP implementation is approximately $9.5 million per year once planned projects and management actions are fully implemented. GSP implementation costs are broken into the following four categories, which are appropriate for different funding and financing mechanisms:

- **GSA Administration and Studies**. These include general GSA administrative and operating costs for management of the GSP, GSA coordination, other coordination with local entities, annual and five-year reports, and management of technical tasks. Studies include technical work that the GSAs will do to support GSP implementation. Total costs are around $1 million per year. GSA administration and studies are annual costs that are typically covered under local assessments.
- **Project and Management Action Capital Repayment**. Projects and management action (PMAs) capital repayment costs are estimated at approximately $1 million. The total capital outlay is around $20 million, which is primarily attributed to the Orland-Artois Water District (OAWD) land annexation and in-lieu recharge project. Project capital costs may be funded under future bond funding opportunities and other grant solicitations. Low interest borrowing options may be used to finance project capital.
- **Other PMA Capital and Studies**. These include project and management action development technical studies and non-debt financed capital. The estimated cost is $0.4 to $1 million per year. Project capital and studies may be eligible for some sources of grants but are typically paid on a pay-go basis.
- **Project Operations and Maintenance**. Annual O&M for projects is approximately $4 to $6.7 million per year. These are annual costs for the project. A substantial share of project O&M costs are attributed to water purchases for in-lieu recharge projects providing approximately 84,000 acre-feet (af) of benefits at full implementation.

Figure 1 illustrates the estimated costs over the first five years of GSP implementation. The largest single component is the cost to purchase water included in the PMA O&M estimate. The timing of costs may vary from what is shown on Figure 1. For example, some projects and management actions may be implemented more (less) rapidly resulting in accelerated (delayed) costs associated with capital and project operations and maintenance. The financing plan for GSP implementation would be updated to reflect these changes over time.

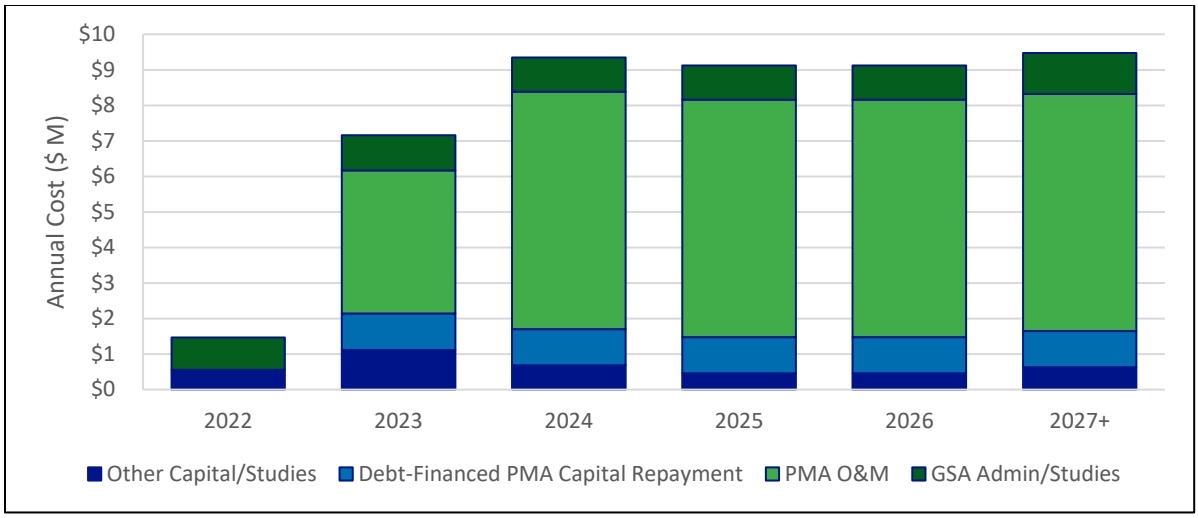

Figure 1. Colusa Subbasin GSP Implementation Cost Summary

Funding and Financing Mechanisms

Administering the GSP, groundwater monitoring, reporting, and project and management action implementation is projected to cost approximately $9.5 million per year across the Colusa Subbasin (Subbasin). GSA annual budgets and GSP implementation costs will be reviewed, revised if needed, and updated by the GSAs based on subbasin conditions, actual expenditures, and the immediate future needs. Expected costs will be adjusted over time as the GSP implementation costs are better understood through sustainable management activities and guidance from DWR on the submitted GSP and subsequent reporting.

Covering the costs of PMAs and general GSP implementation requires evaluating both financing and funding mechanisms. Financing relates to identifying sources of capital (typically state/federal grants, bonds, and bank loans) to pay for project capital expenses. Funding relates to sources of money required to cover capital repayment (pay back the debt-financed projects) as well as project O&M, GSA administration, and other annual expenses.

The agencies in the Subbasin have the powers and authority to impose fees and assessments and pursue other financing sources for capital projects and funding sources for repayment of debt, operations, and other ongoing expenses. The GSAs also have explicit fee authorities under Sustainable Groundwater Management Act (SGMA) legislation (Water Code §10730 and §10730.2). Table 1 summarizes potential financing and funding sources that may be used by GSAs for GSP implementation.

Table 1. Potential Funding and Financing Sources for GSP Implementation

Capital Financing	Considerations
State (DWR) Grants (Prop. 68 and future bonds)	Solicitations are typically targeted to general types of projects and specific benefits that are in the State's interest
US Bureau of Reclamation WaterSmart Grants	Project-specific funding that can support planning studies (e.g., water market strategy grants)
Other targeted potential grant programs (e.g., AB 252)	Potential for multi-benefit projects
Local bond issuance	Local borrowing based on agency authority
Private borrowing	Current low interest rate environment may make these options attractive
State or Federal low interest loans	This could include future bond-funded loan programs
Funding Sources	**Considerations**
Fee – General	General options for legal authority pre- and post-GSP development: Prop. 26, Prop. 218, Water Code §10730, Water Code §10730.2
Regulatory Fee	Typically, pre-GSP fee that is related to regulatory cost. Prop. 26 and Water Code §10730
Service Fee	Related to cost of service. Prop 218 and Water Code §10730.2. Subject to majority protest vote
Special Tax	Subject to 2/3 majority approval vote
Special Benefit	Special benefit assessment subject to majority protest vote

Capital Financing

Capital financing options include a mix of grants and low interest loans. There are typically limits on what costs can be covered by the funding source, or what specific benefits can be paid for. These can be specified in statute or defined by agencies administering the programs.

State opportunities for project capital funding under voter-authorized bonds are a common source of cost share for project capital. For example, Proposition 68, the Parks and Water Bond Act of 2018, bonds support the California DWR Sustainable Groundwater Management (SGM) Grant Program Implementation Grants. Project funding applications are submitted in a competitive process under grant proposal solicitation packages (PSP) administered by DWR. PSP guidelines define the requirements for project applications, eligibility for funding, and the desirable public benefits provided by the proposed project. The 2020 PSP for GSP implementation focused heavily on recharge opportunities and benefits to local disadvantaged communities. Planned GSP projects should be reviewed in advance and positioned for eligibility for future PSPs.

Multi-benefit projects have received increasing attention as part of GSP development and for state grant opportunities. The Governor's Executive Order N-10-19 directed state agencies to work together to prepare a "water resilience portfolio that meets the needs of California's communities, economy, and the environment through the 21st century" and prioritizes multi-benefit projects/policies. The 2020 DWR SGM PSP provided explicit definition of multi-benefit types, minimum requirements for grant eligibility, and weights assigned to project scoring.

Other opportunities for multi-benefit project funding are related to SGMA implementation. For example, AB 252 Department of Conservation: Multi-benefit Land Repurposing Program outlines a potential program for providing state grants to support agricultural land repurposing under GSP implementation[3]. The Governor's May Revise budget included a proposal for a similar $500 million program for drought support administered by the Department of Conservation for "Multi-Benefit Land repurposing[4]" in collaboration with the Department of Food and Agriculture. The program concept is to "prioritize ecosystem-based strategies that are implemented with landowners" to support land repurposing from irrigated agriculture to other uses. While the program would primarily be targeted to the Critically Overdrafted Subbasins, potential multi-benefit recharge projects included in the Colusa Subbasin GSP (see Chapter 6) may be eligible under this or similar programs.

Grant funding opportunities can define specific public benefits that are eligible. Various state and federal laws have established some benefit types as public eligible for public funding. For example, Proposition 1, the Water Quality, Supply, and Infrastructure Improvement Act of 2014, defined five public benefit categories eligible for funding under the Water Storage Investment Program. Flood control benefits have often been considered to include a mix of public (state or federal) and private (local) benefits, so a cost share approach is common. Ecosystem benefits that accrue to the entire state are considered public benefits.

Grants and low interest loans are expected to be an important option for reducing the cost of SGMA to local communities. The Colusa Subbasin GSAs will continue to pursue these opportunities to help fund planning studies, projects, and other GSA activities. However, grants and low-interest loans are not expected to cover most GSA operating costs for GSP implementation or annual operating and maintenance costs of projects. In addition, these rely on relatively unpredictable funding (e.g., state general obligation bonds that require voter approval) and are subject to changing rules and requirements.

Funding Sources

Example funding methods that are available to GSAs to fund projects, studies, and operations were reviewed. Groundwater extraction fees and groundwater permit fees are specifically included in the SGMA legislation (California Wat Code 10730 et seq), but other methods may be available to a GSA, depending on the agency's authorities under law. All methods adopted must comply with the requirements of statute and the California Constitution. The following summary includes many common funding methods but is not necessarily comprehensive.

Assessments based on costs of service or special benefits under Proposition 218 could include a per-acre (or per-parcel) charge to cover GSA costs, or other fees under Proposition 26. For example, benefits of a recharge project might accrue differentially across the Subbasin. The assessment could be calculated in proportion to the special benefit received (by subarea and/or user class), as calculated in the reports supporting the rate study. For cost-based fees and charges (including extraction and permit fees), the report would calculate the cost of providing the service to each parcel or to categories of parcels. Categories would be based on costs imposed on the program and could be based on location, level of use, or other characteristics related to costs.

Another option for funding GSP implementation is taxes. Taxes do not have to be directly tied to the cost or benefit of the service provided. Potential taxes could include general property related taxes that are not directly related to the benefits or costs of a service (ad valorem and parcel taxes), or special taxes imposed for specific purposes related to GSA activities. Based on an initial review of GSA funding

approaches in Critically Overdrafted Subbasins, this is not a common funding mechanism for GSP implementation.

Other fees and charges may include permitting fees for new wells or development, transaction fees associated with contemplated groundwater markets, or commodity-use fees, all directed at aiding with sustainability objectives. Depending on the justification and basis for a fee, it may be considered a property-related fee subject to voting requirements of Article XIII D of the California Constitution (passed by voters in 1996 as Proposition 218) or a regulatory fee exempt from such requirements.

Some of the potential funding approaches can affect the cost of water for specific uses in the Subbasin. For example, districts supplying surface water recognize that recovering GSP related costs as part of their surface water charge can be counter-productive by disincentivizing surface water use. All agencies are concerned that any fees, charges, or assessments will affect business (farm) income and, if large, may affect cropping decisions and farming practices in the Subbasin. Based on groundwater monitoring, land use changes, and other future conditions, the GSAs will reconsider or adjust fees/assessments as needed to achieve sustainability.

Funding and Financing Mechanisms in Example GSAs

A brief review of some GSA funding approaches was developed to illustrate examples of the different bases for their fee or assessment structure. Most of the rate studies were for GSP development. This includes studies stating that the GSA is exempt from voting requirements (see the Kings River East GSA below).

- McMullin Area GSA

  McMullin Area GSA is in central Fresno County within the Kings Subbasin. It adopted a property-based fee to fund GSA costs, calculated as the annual cost of service divided by the number of acres served. The adopted fee excludes parcels that are less than two acres, which it determines are “de minimis” groundwater users under SGMA. The resulting annual fee of $19 per acre was adopted as a water service fee under Proposition 218 after a public hearing at which a majority of land subject to the fee did not protest. The rate study suggested that the agency may consider converting some or all of its fee to a volumetric basis in the future but did not at the time have the information to do so.

- South Fork Kings GSA

  The South Fork Kings GSA is in the Tulare Lake Subbasin. It adopted an annual charge to fund its costs, following requirements for a public hearing and protest vote. Its charge was authorized for five years, beginning at up to $9.80 per acre for 2019 (the first year after the rate study). The amount per acre is calculated as the costs of specified implementation and administrative costs divided by assessable acres within the boundaries of the GSA, except for the City of Lemoore. A separate amount is calculated annually for the City of Lemoore by negotiated agreement. The GSA generally refers to the proposed charge as an assessment and describes the process for justifying a benefit assessment apportioned among parcels according to special benefit received. However, it also describes the fee as apportioned among parcels according to cost of providing the service.

- Kings River East GSA

  The Kings River East GSA is in the Kings Subbasin. It prepared a groundwater fee study to calculate and justify a volumetric fee per af pumped. It used a cost-of-service approach to determine appropriate fees for different areas and jurisdictions within its boundaries. The agency argued that, under Proposition 26, the fee is a regulatory fee that covers the cost of compliance with SGMA, and therefore it is exempt from the public voting requirement. Fees were calculated according to area, land use, and water use. Some areas were not charged a volumetric fee because of their "lack of deep groundwater pumping from the alluvium"; they were only charged a nominal, fixed annual fee to cover a share a share of fixed administrative costs. Other areas were charged $1.45 per af of estimated pumping. Pumping is not currently metered in the area, so the fee was based on land use and a water balance calculation to estimate pumping.

Cost Allocation and Cost Recovery for GSP Implementation

The fee and assessment methods summarized in the previous section allow (and in most cases require) agencies to consider the relative benefits and costs, and to whom they accrue, in setting rates or amounts.

Cost allocation is a multi-step process that determines how costs of implementation components will be spread among and recovered from entities and areas covered by the GSP. The implementation plan includes several categories of activities that must be paid for: administration, projects and management actions, monitoring, and studies. The categories may have their costs spread in different ways (among different entities and areas) depending on discussions and policy decisions about issues like: who is responsible for a cost, who benefits from an activity, what is fair, what is legally allowed or possible, what are the requirements for determining and justifying a cost allocation?

An initial step in cost allocation is to determine which agency (or agencies) are responsible for financing and funding. This may vary based on fairness and equity concerns, and across different GSP PMAs. For example, the lead agency for a specific GSP project may work to secure financing and explore funding mechanisms. Alternatively, the GSA could lead some of these activities and in turn recover costs from the lead agency (or agencies). Under both approaches, the cost allocation would consider the share of benefits received from the project. Using the four GSP cost categories defined above, example considerations for each category include:

- **GSA Administration and Studies**. General GSA administrative costs and required studies to support GSP implementation (e.g., address data gaps) generally provide a benefit to the entire Subbasin. This could be viewed as a basis for allocating costs broadly across all groundwater users. However, some areas may receive a disproportionate share of benefits from the actual implementation of the GSP and this could be reflected in how general costs are allocated. Potentially, some areas could be judged as not responsible for groundwater issues or benefitting from groundwater management.
- **Project and Management Action Capital Repayment**. Projects typically have a single project proponent that has specific financing and funding options available. Project benefits may primarily accrue to the proponent. However, under SGMA requirements for subbasin-wide sustainability, other entities and areas may derive some potential indirect benefits of sustainability. In addition, there may be direct project-related benefits (e.g., higher groundwater elevations that reduce pumping costs or reduce stream depletions) that accrue to other parties.

- **Other PMA Capital and Studies**. Project capital costs that will not be debt-financed and project study costs could be treated similar to PMA capital costs. However, the GSA may initiate studies to support GSP implementation and cover a portion of costs. Some of these studies have been initiated under GSP development (e.g., subbasin conditions, data management system, and data gaps).
- **Project Operations and Maintenance**. Specific PMA O&M costs could be paid by the project proponent. A portion of costs could be allocated to other parties that receive direct or indirect benefits from the project, or to the entire Subbasin for general SGMA benefits.

Cost allocation for a GSP that incorporates many agencies may occur at multiple levels, perhaps including basin-wide, within a GSA, or within an individual entity such as a water district or other local agency. The general steps in cost allocation are:

- Determine costs of implementation activities and when they are to be incurred. Generally, the different cost components of an activity need to be aggregated in a consistent way to allow for a fair and objective allocation. This is especially important if cost components (e.g., capital costs versus annual O&M) may be paid by different parties. A life-cycle cost approach is commonly used, in which all costs over the life of the activity are adjusted for when they occur (using standard financial discounting) and expressed as an annual or lump-sum amount.
- Based on stakeholder discussions and technical support, make decisions about which costs apply across the entire GSA versus apply to subareas or specific agencies. For GSP activities that serve the entire GSA (perhaps GSA administration or certain monitoring costs), the GSA would lead the discussions and policy decisions; for projects proposed by or to be developed by a specific member agency, that agency could take the lead. Discussions and decisions may also address which groups or users will be included in the cost allocation for a particular activity – for example, the discussion could consider a group's past or current use of groundwater.
- Develop information to support the actual calculations needed to allocate and recover costs, which may include cost of service and benefit information. This step is based on the policy decisions and will help determine who pays for the GSP activity. Defensible information is required to meet legal requirements. An open and fair process is essential for the political support needed to implement activities and recover costs.

Allocating and recovering costs involve policy decisions and technical analysis and must follow a process that meets legal requirements. Costs of projects and activities that serve large areas and multiple groups are typically allocated using cost-of-service principles, whereby the total project cost is split based on each area or group's demonstrated proportional split of total cost. Costs can also be allocated based on benefits received (for example the California Constitution allows for assessments to be based on special benefits received). Ultimately, decisions about cost allocation must involve meaningful input from affected parties so that the outcome is viewed both as fair and technically justified.

Summary

Cost allocation and repayment are important and difficult decisions that require ongoing and open discussions. The GSAs are already implementing financing mechanisms to pay for their administrative costs. Development of a financing plan will require making further decisions with stakeholders and member agencies using a timely process that supports the subbasin sustainability goal and GSP implementation schedule.

This memorandum/appendix provides a general overview of funding and financing methods available to Subbasin agencies. Methods generally allow agencies to consider the distribution of costs and benefits when setting a fee or assessment. An analysis to establish a financing plan for the Subbasin would:

- Review specific issues that affect the distribution of costs and benefits within the subbasin. This would include establishing potential project costs and beneficiaries. It would also consider the agency (or agencies) that would be responsible for recovering the costs of different activities.
- Listen to different groups' perspectives on fairness, contribution to groundwater issues, and benefits from groundwater management.
- Coordinate with GSA legal counsel and agency legal counsel to evaluate fee and assessment options.
- Prepare technical analyses to support cost allocation and repayment. This potentially can include some options or examples that illustrate different allocations of fees/assessments, for a specific project or management action with multiple payers and beneficiaries to demonstrate how fees can be calculated when benefits or costs are assigned to different areas and/or customer groups.
