ACKNOWLEDGEMENTS

Groundwater Sustainability Agencies

Colusa Groundwater Authority GSA

Member Agencies

County of Colusa, City of Colusa, City of Williams, Glenn-Colusa Irrigation District, Maxwell Irrigation District, Westside Water District, Princeton-Codora-Glenn Irrigation District, Provident Irrigation District, Colusa County Water District, Reclamation District 108, Reclamation District 479, Colusa Drain Mutual Water Company, Two representatives of private groundwater pumpers

Glenn Groundwater Authority GSA

Member Agencies

City of Orland, City of Willows, County of Glenn, Glenn-Colusa Irrigation District, Glide Water District, Kanawha Water District, Monroeville Water District, Orland-Artois Water District, Princeton-Codora-Glenn Irrigation District, Provident Irrigation District

Technical Advisory Committees

Colusa Groundwater Authority TAC
Glenn Groundwater Authority TAC

Table of Contents

PREFACE **P-1**

EXECUTIVE SUMMARY **ES-1**

Introduction (GSP Chapter 1) ES-1

Plan Area (GSP Chapter 2) ES-2

Basin Setting (GSP Chapter 3) ES-4
- Hydrogeological Conceptual Model ES-4
- Groundwater Conditions ES-4
- Water Budget Information ES-7

Monitoring Networks (GSP Chapter 4) ES-10
- Representative Monitoring Networks ES-10
- Groundwater Level Monitoring Network ES-11
- Groundwater Quality Monitoring Network ES-12
- Land Subsidence Monitoring Network ES-13
- Surface Water Monitoring Network ES-13

Sustainable Management Criteria (GSP Chapter 5) ES-14
- Sustainability Goal ES-14
- Sustainability Indicators ES-15
  - Chronic Lowering of Groundwater Levels ES-17
  - Reduction of Groundwater Storage ES-17
  - Seawater Intrusion ES-18
  - Inelastic Land Subsidence ES-18
  - Degraded Water Quality ES-18
  - Depletion of Interconnected Surface Water ES-19

Project and Management Actions (GSP Chapter 6) ES-19

Plan Implementation (GSP Chapter 7) ES-21

CHAPTER 1 Introduction **1-1**

1.1 Purpose of the Groundwater Sustainability Plan 1-1

1.2 Sustainability Goal 1-2

1.3 Agency Information 1-2
- 1.3.1 Agency Organization and Management Structure 1-3
  - 1.3.1.1 Coordination Agreements 1-4
- 1.3.2 Legal Authority 1-4
- 1.3.3 Estimated Implementation Cost and Agencies' Approach to Meet Costs 1-4

1.4 GSP Organization 1-5

CHAPTER 2 Plan Area **2-1**

2.1 Summary of Jurisdictional Areas and other Features 2-1
- 2.1.1 Groundwater Basin Boundaries 2-1
- 2.1.2 Groundwater Sustainability Plan Area 2-4

Table of Contents

2.1.2.1 Water Purveyors 2-4
Municipal Water Purveyors 2-4
City of Colusa, Colusa County 2-8
City of Williams, Colusa County 2-8
City of Orland Water System, Glenn County 2-8
City of Willows/Cal Water Willows District, Glenn County 2-9
Agriculture Water Purveyors 2-9
National Wildlife Refuges 2-9
2.1.2.2 Jurisdictional Boundaries of Other Agencies 2-11
2.1.2.3 Disadvantaged Communities 2-11
2.1.2.4 Well Density per Square Mile 2-14
2.1.3 Existing Land Use Designations 2-14

2.2 Water Resources Monitoring and Management Programs 2-17
2.2.1 Monitoring and Management Programs 2-17
2.2.1.1 Water Planning Documents 2-17
2.2.1.2 Surface Water Monitoring and Management Programs 2-21
Federal, State, and Regional Programs 2-21
Local Programs 2-21
Efficient Water Management Practices 2-22
Irrigated Lands Regulatory Program 2-22
2.2.1.3 Groundwater Monitoring and Management Programs 2-22
Groundwater Level Monitoring 2-23
Groundwater Extraction Monitoring 2-23
Groundwater Quality Monitoring 2-24
Land Subsidence Monitoring 2-25
2.2.2 Impacts to Operational Flexibility 2-25
2.2.3 Groundwater Ordinances 2-26
2.2.4 Conjunctive Use Programs 2-26

2.3 Land Use Elements or Topic Categories of Applicable General Plans 2-27
2.3.1 Summary of General Plans/Other Land Use Plans 2-27
2.3.1.1 Colusa County General Plan 2-27
2.3.1.2 Glenn County General Plan 2-28
2.3.1.3 City of Colusa General Plan 2-28
2.3.1.4 City of Williams General Plan 2-28
2.3.1.5 City of Orland General Plan 2-28
2.3.1.6 City of Willows 2-28
2.3.2 Implementation Effects on Water Demands and Sustainability 2-29
2.3.2.1 Effects on Colusa County Water Demands 2-29
2.3.2.2 Effects on Glenn County Water Demands 2-30
2.3.2.3 Effects on City of Colusa Water Demands 2-30
2.3.2.4 Effects on City of Williams Water Demands 2-30
2.3.2.5 Effects on City of Orland Water Demands 2-31
2.3.2.6 Effects on City of Willows Water Demands 2-31
2.3.3 Effects of Land Use Plans Outside Subbasin 2-31

Table of Contents

2.4 GSP Implementation Effects on Water Supply Assumptions 2-31

2.5 Summary of Permitting Process for Wells in Colusa Subbasin 2-32
2.5.1 Human Right to Water 2-32
2.5.2 Colusa County 2-32
2.5.3 Glenn County 2-33
2.5.4 Wellhead Protection 2-33

2.6 Additional GSP Elements 2-33

2.7 Notice and Communication 2-34
2.7.1 Overview 2-34
2.7.1.1 COVID-19 Global Pandemic 2-35
2.7.1.2 Description of Beneficial Uses and Users in the Basin 2-36
2.7.1.3 Decision-Making Processes 2-38
2.7.2 Engagement Opportunities 2-39
2.7.2.1 Public Engagement Opportunities 2-39
2.7.2.2 Soliciting Written Comments 2-42
2.7.3 Informing the Public about GSP Development Progress 2-43
2.7.3.1 Interested Parties List 2-43
Tribal Engagement 2-43
2.7.3.2 Distribution of Meeting Information 2-43
2.7.3.3 Outreach and Branding 2-43
2.7.3.4 Traditional Media Outreach 2-43
2.7.3.5 Social Media Outreach 2-44
2.7.3.6 GSA Websites 2-44
2.7.3.7 Beneficial User Input and Responses 2-44

CHAPTER 3 Basin Setting 3-1

3.1 Hydrogeologic Conceptual Model 3-1
3.1.1 Regulatory Requirements 3-1
3.1.2 Background Information 3-2
3.1.3 Climate and Precipitation 3-4
3.1.4 Topography 3-7
3.1.5 Hydrology 3-7
3.1.5.1 Natural Surface Waters and Conveyance Infrastructure 3-10
3.1.5.1.1 Black Butte Lake and Stony Creek 3-10
3.1.5.1.2 Sacramento River 3-13
3.1.5.1.3 Tehama-Colusa Canal 3-13
3.1.5.1.4 Glenn-Colusa Canal 3-13
3.1.5.1.5 Colusa Basin Drainage Canal System 3-13
3.1.5.1.6 Other Streams 3-15
3.1.5.2 Imported Water Sources and Points of Delivery 3-15
3.1.6 Soils 3-17
3.1.7 Geologic Framework 3-19
3.1.7.1 Regional Geologic History 3-19

Table of Contents

3.1.7.2 Primary Freshwater-Bearing Formations 3-30
3.1.7.2.1 Tuscan Formation 3-30
3.1.7.2.2 Tehama Formation 3-30
3.1.7.2.3 Riverbank and Modesto Formations 3-31
3.1.7.2.4 Stream Channel and Basin Deposits 3-32
3.1.7.3 Geologic Structures 3-32
3.1.7.3.1 Faults 3-32
3.1.7.3.2 Folds 3-33
3.1.7.3.3 Orland Buttes 3-34
3.1.7.3.4 Sutter Buttes 3-35
3.1.7.3.5 Colusa Dome 3-35
3.1.8 Basin Boundaries 3-35
3.1.8.1 Lateral Boundaries 3-35
3.1.8.2 Vertical Boundaries 3-36
3.1.9 Stratigraphic and Structural Features Potentially Affecting Flow 3-38
3.1.9.1 Topography 3-38
3.1.9.2 Faults 3-38
3.1.9.3 Folds 3-38
3.1.9.4 Stratigraphic Pinchouts 3-38
3.1.9.5 Manmade Features 3-39
3.1.10 Principal Aquifers and Aquitards 3-39
3.1.10.1 Physical and Structural Properties 3-39
3.1.10.2 Primary Uses 3-42
3.1.10.3 Water Quality 3-42
3.1.11 Groundwater Inflows and Outflows 3-43
3.1.11.1 Groundwater Underflow 3-43
3.1.11.2 Groundwater Recharge Areas 3-43
3.1.11.2.1 Agricultural Recharge 3-43
3.1.11.2.2 Soil Suitability for Groundwater Recharge 3-44
3.1.11.2.3 On-Farm Multi-Benefit Managed Aquifer Recharge and Shorebird Habitat Program 3-44
3.1.11.3 Groundwater Discharge Areas 3-46
3.1.12 Data Gaps, Uncertainty, and Recommended Actions 3-51
3.1.12.1 Extent of Geologic Units, Principal Aquifer, and Base of Fresh Water 3-51
3.1.12.2 Hydraulic Parameters 3-53
3.1.12.3 Groundwater Quality 3-54
3.1.12.4 Groundwater Level Measurements 3-54
3.1.12.5 Springs 3-54

3.2 Existing and Historical Groundwater Conditions 3-55
3.2.1 Regulatory Requirements 3-55
3.2.2 Groundwater Elevations 3-55
3.2.2.1 Temporal and Spatial Trends 3-56
3.2.2.2 Lateral and Vertical Flow Gradients 3-58
3.2.3 Estimate of Groundwater Storage 3-65

Table of Contents

3.2.4 Seawater Intrusion 3-66
3.2.5 Groundwater Quality 3-66
3.2.5.1 Major Naturally Occurring Constituents 3-67
3.2.5.1.1 Salinity 3-67
3.2.5.1.2 Major Cations and Anions 3-69
3.2.5.2 Other Naturally Occurring Constituents 3-70
3.2.5.2.1 Arsenic 3-70
3.2.5.2.2 Boron 3-70
3.2.5.2.3 Iron and Manganese 3-71
3.2.5.2.4 Hexavalent Chromium 3-71
3.2.5.3 Non-Point Sources of Groundwater Pollution 3-72
3.2.5.3.1 Nitrate 3-72
3.2.5.4 Point Sources of Groundwater Pollution 3-72
3.2.6 Land Subsidence 3-73
3.2.7 Interconnected Surface Waters 3-76
3.2.7.1 Simulated Stream Gains and Losses 3-77
3.2.7.2 Stony Creek Thalweg Analysis 3-79
3.2.8 Groundwater Dependent Ecosystems 3-81
3.3 Water Budget Information 3-84
3.3.1 Selection of Hydrologic Periods 3-85
3.3.2 Use of the C2VSimFG Integrated Hydrologic Model 3-86
3.3.3 Water Budget Assumptions 3-87
3.3.3.1 Historical 3-88
3.3.3.2 Current Conditions 3-89
3.3.3.3 Future Conditions Scenarios 3-91
3.3.4 Water Budget Estimates 3-93
3.3.4.1 Historical Simulation 3-97
3.3.4.1.1 Availability or Reliability of Historical Surface Water Supplies 3-100
3.3.4.1.2 Suitability of Tools and Methods for Planning 3-101
3.3.4.1.3 Ability to Operate the Subbasin within the Sustainable Yield 3-101
3.3.4.2 Current Conditions Baseline 3-101
3.3.4.3 Future Conditions Scenarios 3-103
3.3.4.3.1 Future Conditions, No Climate Change Baseline 3-103
3.3.4.3.2 Future Conditions, 2030 Climate Change Baseline 3-105
3.3.4.3.3 Future Conditions, 2070 Climate Change Baseline 3-107
3.3.4.3.4 Comparison of Water Budget Scenarios 3-109
3.3.5 Water Budget Uncertainty 3-110
3.3.6 Overdraft Conditions 3-111
3.3.7 Sustainable Yield Estimate 3-111
3.4 Management Areas 3-112
CHAPTER 4 Monitoring Networks 4-1
4.1 Monitoring Network Objectives 4-1
4.2 Monitoring Networks 4-1

Table of Contents

4.2.1 Groundwater Level Monitoring 4-2
4.2.1.1 Requirements 4-2
4.2.1.2 Groundwater Level Monitoring Network 4-3
4.2.1.3 Monitoring Protocols 4-12
4.2.1.3.1 Methodology 4-12
4.2.1.3.2 Frequency 4-13
4.2.1.4 Data Gaps in Groundwater Level Monitoring Network 4-13
4.2.1.5 Proposed Actions to Address Data Gaps 4-14
4.2.2 Groundwater Quality Monitoring 4-15
4.2.2.1 Requirements 4-15
4.2.2.2 Groundwater Quality Monitoring Network 4-15
4.2.2.3 Monitoring Protocols 4-18
4.2.2.4 Data Gaps in Groundwater Quality Monitoring Network 4-19
4.2.2.5 Proposed Actions to Address Data Gaps 4-20
4.2.3 Land Subsidence Monitoring 4-20
4.2.3.1 Requirements 4-20
4.2.3.2 Land Subsidence Monitoring Network 4-21
California DWR Ground Surface Displacement - Land Subsidence Monitoring 4-21
UNAVCO Plate Boundary Observatory GPS/GNSS Network 4-21
Sacramento Valley Height Modernization Project 4-21
InSAR Remote Sensing 4-24
4.2.3.3 Monitoring Protocols 4-24
4.2.3.4 Data Gaps in Land Subsidence Monitoring Network 4-25
4.2.3.5 Proposed Actions to Address Data Gaps 4-25
4.2.4 Surface Water Monitoring 4-25
4.2.4.1 Requirements 4-25
4.2.4.2 Surface Water Monitoring Network 4-26
4.2.4.3 Monitoring Protocols 4-29
4.2.4.4 Data Gaps in Surface Water Monitoring Network 4-29
4.2.4.5 Proposed Actions to Address Data Gaps 4-29
4.2.5 Representative Monitoring Sites 4-30
4.2.5.1 Representative Groundwater Level Monitoring Network 4-30
4.2.5.2 Representative Groundwater Quality Monitoring Network 4-30
4.2.5.3 Representative Land Subsidence Monitoring Network 4-33
4.2.5.4 Representative Surface Water Depletion Monitoring Network 4-33

CHAPTER 5 Sustainable Management Criteria 5-1

5.1 Sustainability Terminology 5-1
5.1.1 Sustainability Indicators 5-1

5.2 Sustainability Goal 5-3
5.2.1 Sustainable Operation of the Subbasin 5-3
5.2.2 Achieving Sustainability within 20 Years 5-4

5.3 Undesirable Results 5-4

Table of Contents

5.3.1 Chronic Lowering of Groundwater Levels 5-5
5.3.1.1 Description of Undesirable Results for Chronic Lowering of Groundwater Levels 5-5
5.3.1.2 Identification of Undesirable Results 5-6
5.3.1.3 Potential Causes of Undesirable Results 5-7
5.3.1.4 Potential Effects of Undesirable Results 5-7
5.3.1.5 Evaluation of the Presence of Undesirable Results 5-8
5.3.2 Reduction of Groundwater Storage 5-8
5.3.2.1 Description of Undesirable Results for the Reduction of Groundwater Storage 5-8
5.3.2.2 Justification of Groundwater Levels as a Proxy 5-8
5.3.2.3 Identification of Undesirable Results 5-9
5.3.2.4 Potential Causes of Undesirable Results 5-10
5.3.2.5 Potential Effects of Undesirable Results 5-10
5.3.2.6 Evaluation of the Presence of Undesirable Results 5-10
5.3.3 Seawater Intrusion 5-11
5.3.4 Degraded Water Quality 5-11
5.3.4.1 Description of Undesirable Results for Degraded Water Quality 5-11
5.3.4.2 Identification of Undesirable Results 5-12
5.3.4.3 Potential Causes of Undesirable Results 5-13
5.3.4.4 Potential Effects of Undesirable Results 5-13
5.3.4.5 Evaluation of the Presence of Undesirable Results 5-13
5.3.5 Inelastic Land Subsidence 5-14
5.3.5.1 Description of Undesirable Results for Inelastic Land Subsidence 5-14
5.3.5.2 Identification of Undesirable Results 5-14
5.3.5.3 Potential Causes of Undesirable Results 5-14
5.3.5.4 Potential Effects of Undesirable Results 5-15
5.3.5.5 Evaluation of the Presence of Undesirable Results 5-15
5.3.6 Depletions of Interconnected Surface Water 5-15
5.3.6.1 Description of Undesirable Results for Depletions of Interconnected Surface Water 5-15
5.3.6.2 Justification of Groundwater Elevations as a Proxy 5-15
5.3.6.3 Identification of Undesirable Results 5-16
5.3.6.4 Potential Causes of Undesirable Results 5-17
5.3.6.5 Potential Effects of Undesirable Results 5-17
5.3.6.6 Evaluation of the Presence of Undesirable Results 5-17
5.4 Sustainability Thresholds 5-17
5.4.1 Chronic Lowering of Groundwater Levels 5-19
5.4.1.1 Minimum Thresholds 5-19
5.4.1.1.1 Potential Effects on Other Sustainability Indicators 5-22
5.4.1.2 Measurable Objectives 5-23
5.4.1.3 Margin of Operational Flexibility 5-23
5.4.1.4 Interim Milestones 5-23
5.4.2 Reduction of Groundwater Storage 5-26
5.4.2.1 Proxy Monitoring 5-26
5.4.3 Seawater Intrusion 5-26

Table of Contents

5.4.4 Degraded Water Quality 5-26
5.4.4.1 Minimum Thresholds 5-27
5.4.4.2 Measurable Objectives 5-27
5.4.4.3 Margin of Operational Flexibility 5-28
5.4.4.4 Interim Milestones 5-28
5.4.5 Inelastic Land Subsidence 5-28
5.4.5.1 Minimum Thresholds 5-28
5.4.5.2 Measurable Objectives 5-29
5.4.5.3 Margin of Operational Flexibility 5-29
5.4.5.4 Interim Milestones 5-30
5.4.6 Depletions of Interconnected Surface Water 5-30
5.4.6.1 Minimum Thresholds 5-30
5.4.6.2 Measurable Objectives 5-35
5.4.6.3 Margin of Operational Flexibility 5-35
5.4.6.4 Interim Milestones 5-35
5.4.7 Effects of Minimum Thresholds on Adjacent Subbasins 5-36

CHAPTER 6 Projects and Management Actions 6-1

6.1 Projects and Management Actions Development Approach 6-1
6.1.1 Overview 6-1
6.1.2 Evaluation of Projected Future Conditions to Develop Projects and Management Actions 6-2
6.1.3 Identification and Categorization of Projects and Management Actions 6-5

6.2 Project and Management Actions Summary 6-6
6.2.1 Overview of All Proposed Projects and Management Actions 6-6
6.2.2 Benefits of Projects and Management Actions to Sustainability Indicators and Communities in the Subbasin 6-12

6.3 Planned Projects and Management Actions 6-15
6.3.1 Colusa County Water District In-Lieu Groundwater Recharge 6-17
6.3.1.1 Project Overview 6-17
6.3.1.2 Implementation 6-19
6.3.1.3 Notice to Public and Other Agencies 6-20
6.3.1.4 Construction Activities and Requirements 6-20
6.3.1.5 Water Source 6-20
6.3.1.6 Circumstances and Criteria for Implementation 6-21
6.3.1.7 Legal Authority, Permitting Processes, and Regulatory Control 6-21
6.3.1.8 Project Operations and Monitoring 6-22
6.3.1.9 Project Benefits 6-22
6.3.1.10 Project Costs 6-22
6.3.2 Colusa Drain Mutual Water Company (CDMWC) In-Lieu Groundwater Recharge 6-23
6.3.2.1 Project Overview 6-23
6.3.2.2 Implementation 6-25
6.3.2.3 Notice to Public and Other Agencies 6-26
6.3.2.4 Construction Activities and Requirements 6-26

Table of Contents

6.3.2.5 Water Source 6-26
6.3.2.6 Circumstances and Criteria for Implementation 6-26
6.3.2.7 Legal Authority, Permitting Processes, and Regulatory Control 6-27
6.3.2.8 Project Operations and Monitoring 6-27
6.3.2.9 Project Benefits 6-27
6.3.2.10 Project Costs 6-28
6.3.3 Colusa Subbasin Multi-Benefit Groundwater Recharge 6-30
6.3.3.1 Project Overview 6-30
6.3.3.2 Implementation 6-31
6.3.3.3 Notice to Public and Other Agencies 6-33
6.3.3.4 Construction Activities and Requirements 6-33
6.3.3.5 Water Source 6-33
6.3.3.6 Circumstances and Criteria for Implementation 6-33
6.3.3.7 Legal Authority, Permitting Processes, and Regulatory Control 6-34
6.3.3.8 Project Operations and Monitoring 6-35
6.3.3.9 Project Benefits 6-35
6.3.3.10 Project Costs 6-35
6.3.4 Orland-Artois Water District Land Annexation and In-Lieu Groundwater Recharge 6-36
6.3.4.1 Project Overview 6-36
6.3.4.2 Implementation 6-38
6.3.4.3 Notice to Public and Other Agencies 6-38
6.3.4.4 Construction Activities and Requirements 6-38
6.3.4.5 Water Source 6-39
6.3.4.6 Circumstances and Criteria for Implementation 6-39
6.3.4.7 Legal Authority, Permitting Processes, and Regulatory Control 6-39
6.3.4.8 Project Operations and Monitoring 6-40
6.3.4.9 Project Benefits 6-40
6.3.4.10 Project Costs 6-41
6.3.5 Sycamore Slough Groundwater Recharge Pilot Project 6-42
6.3.5.1 Project Overview 6-42
6.3.5.2 Implementation 6-42
6.3.5.3 Notice to Public and other Agencies 6-44
6.3.5.4 Construction Activities and Requirements 6-44
6.3.5.5 Water Source 6-44
6.3.5.6 Circumstances and Criteria For Implementation 6-44
6.3.5.7 Legal Authority, Permitting Processes, and Regulatory Control 6-44
6.3.5.8 Project Operations and Monitoring 6-44
6.3.5.9 Project Benefits 6-45
6.3.5.10 Project Costs 6-45
6.4 Ongoing Projects and Management Actions 6-45
6.4.1 Ongoing Projects 6-47
6.4.1.1 Reclamation District 108 and Colusa County Water District Agreement for Five-Year In-Lieu Groundwater Recharge Project 6-48

Table of Contents

6.4.1.2 Glenn-Colusa Irrigation District Strategic Winter Water Use for Groundwater Recharge and Multiple Benefits 6-49
6.4.1.3 Sycamore Marsh Farm Direct Recharge Project 6-52
6.4.1.4 Glenn-Colusa Irrigation District Expansion of In-Basin Program for In-lieu Groundwater Recharge 6-53
6.4.1.5 Orland Unit Water Users Association Irrigation Modernization for Increased Surface Water Delivery and Reduced Groundwater Pumping 6-54
6.4.2 Ongoing Management Actions 6-55
6.4.2.1 Urban Water Conservation in Willows 6-56
6.5 Potential Projects and Management Actions 6-57
6.5.1 Potential Projects 6-59
6.5.1.1 Glenn-Colusa Irrigation District In-lieu Groundwater Recharge 6-60
6.5.1.2 Westside Streams Diversion for Direct or In-lieu Groundwater Recharge 6-61
6.5.1.3 Sites Reservoir 6-65
6.5.1.4 Delevan Pipeline Colusa Drain Intertie 6-66
6.5.1.5 Orland Unit Water Users Association Flood Water Conveyance 6-68
6.5.1.6 Orland-Artois Water District Direct Groundwater Recharge 6-69
6.5.1.7 Sycamore Slough Colusa Basin Drain Multi-Benefit Recharge Project 6-70
6.5.1.8 Tehama-Colusa Canal Trickle Flow to Ephemeral Streams 6-72
6.5.1.9 Enhanced Infiltration of Precipitation on Agricultural Lands 6-73
6.5.1.10 Colusa Subbasin Flood-MAR 6-74
6.5.1.11 Reclamation District 108 "Boards In" Program 6-75
6.5.1.12 Colusa County Public Water System Water Treatment Plant 6-76
6.5.1.13 Glenn-Colusa Irrigation District Water Transfers to TCCA CVP Contractors 6-78

Preface

Development of the Colusa Subbasin Groundwater Sustainability Plan (GSP), like many others throughout California, has coincided with one of the most severe and extensive droughts that has ever gripped the western United States. As of this writing in December 2021, as the final Colusa Subbasin GSP is being assembled, drought conditions throughout most of California, including the Colusa Subbasin (Subbasin), are classified as "exceptional", the most extreme classification defined by the U.S. Drought Monitor (USDM)[1]. Historically, observed impacts during exceptional drought generally include: widespread water shortages, depleted surface water supplies, extremely low federal surface water deliveries, curtailment of water rights, extremely high surface water prices, increased groundwater pumping to satisfy water demands, dry groundwater wells, increased well drilling and deepening, increased pumping costs, wildfire, decreased recreational opportunities, and poor water quality, among other potential impacts reported by the USDM. All of these conditions are currently being experienced to some degree across California and, at least in part, within the Subbasin. In particular, surface water supplies available for irrigation were significantly reduced in both 2020 and 2021, resulting in reduced plantings of some annual crops (primarily rice), and increased groundwater pumping, primarily to sustain permanent tree crops and, to a lesser extent, some annual crops.

As of November 30, 2021, the County of Glenn had received 282 reports of problems associated with groundwater wells, with about 65 percent of those being reports of dry wells. While a few of the reported dry wells are in the foothills outside of the Subbasin, the large majority lie within the Colusa and Corning Subbasins, concentrated in areas around Orland and the northern portion of the County. As of November 30, 2021, the County of Colusa had received 30 landowner reports of problems associated with groundwater wells, with 20 of the reported wells being located within the Subbasin. Of those wells in the Subbasin, 18 are reported as dry. Most reported dry wells are used for domestic water supply. Counts of dry wells in both counties are likely to be low because some landowners choose not to report well problems to the counties. In addition to reported dry wells, there are anecdotal reports of land subsidence around the Arbuckle area in the Colusa County portion of the Subbasin.

At the State level and as a result of the unprecedented dry conditions, Governor Gavin Newsom declared a drought emergency on April 21, 2021, which was subsequently expanded on May 10 to include new drought-impacted areas, including the Sacramento-San Joaquin Delta Watershed. Most recently, on October 19, Governor Newsom issued a proclamation extending the drought emergency statewide. On August 20, the State Water Resources Control Board (SWRCB) issued surface water curtailment orders to approximately 4,500 water right holders in the Sacramento-San Joaquin Delta Watershed to protect drinking water supplies, prevent salinity intrusion into fresh water supplies, and minimize impacts to fisheries and the environment. Given that these curtailment orders are in place for a period of one year, these curtailments have immediate impacts on existing surface water supplies and could impact surface water suppliers' ability to store water this coming winter, thereby potentially impacting available surface water supplies for 2022 and beyond. Given the recent curtailments and an already bleak surface water

[1] The U.S. Drought Monitor (https://droughtmonitor.unl.edu/) is produced through a partnership between the National Drought Mitigation Center at the University of Nebraska-Lincoln, the United States Department of Agriculture, and the National Oceanic and Atmospheric Center. Information for the State of California is available online at: https://droughtmonitor.unl.edu/CurrentMap/StateDroughtMonitor.aspx?CA.

supply condition, there is an increased reliance on groundwater. Currently, all of California's 58 counties have declared drought emergencies, including both Colusa and Glenn Counties.

The reported numbers of dry wells discussed above, many of which were reported relatively early in the dry season, are unprecedented in both counties, raising concerns among landowners and residents, and prompting mitigation and response actions by both counties. The counties are maintaining well reporting and tracking systems to identify localized areas where wells are going dry and/or where other groundwater issues may exist. The counties are also supporting the public through local and regional programs offered through the counties, the U.S. Department of Agriculture (USDA), the Rural Community Assistance Corporation (RCAC), DWR, and the SWRCB that assist with well assessments, well repair and replacement, installation or updates to household water systems, potable water hauling, and low-interest loans to businesses and organizations affected by drought. Both counties have applied for drought relief funding through DWR. At this time, prior to completion and adoption of the GSP, drought response efforts in the Subbasin are the responsibility of the counties, cities, and other local agencies. At some point following adoption of the GSP, those responsibilities may shift to or be coordinated with the GSAs. A strategy for guiding potential coordination between the GSAs, counties, cities, and other local agencies is described in Chapter 7 of the GSP. Coordination would ensure preservation of public health and safety (the purview of the counties and cities) and groundwater sustainability for all beneficial users and uses (the purview of the GSAs).

Technical work and related public involvement processes supporting development of the Colusa Subbasin GSP began in earnest in May 2020 and are nearing completion as of December 2021. Development of the GSP has utilized the best available science and tools, with the most sufficient and credible information and data available for the decisions being made and the time frame available for making those decisions. Current and historical groundwater conditions and water budgets have been evaluated for the Subbasin in alignment with the GSP regulations. The technical work is based primarily on historical records of surface water and groundwater conditions from 1966 through 2015, which includes the prior drought in 2014 to 2015, but not the current drought in 2020 to 2021.

Unfortunately, drought conditions in 2020 and 2021 have coincided with development of the GSP, a timing that has not permitted complete evaluation and inclusion of data from these years in the GSP at this time. Due to the schedule mandated by the Sustainable Groundwater Management Act (SGMA) for completion of GSPs by January 31, 2022, it has not been possible to include conditions that have manifested due to the current drought in development of the Subbasin GSP. Records of drought-related conditions in 2020 to 2021 will not be systematically compiled, quality-controlled, and made publicly available until after the Colusa Subbasin GSP has been adopted. However, those conditions will be factored into the required GSP annual reports and particularly the periodic (five-year) evaluations as they become available.

It is noted that ongoing management of the Subbasin under the GSP will follow an "adaptive management" strategy that involves active monitoring of Subbasin conditions and addressing any challenges related to maintaining groundwater sustainability by scaling and implementing projects and management actions (PMAs) in a targeted and proportional manner in accordance with the needs of the Subbasin. Notwithstanding the information noted above regarding the challenges with GSP preparation and the current drought, some of the planned projects contained within this GSP are being fast tracked

to address impacts associated with the current drought. GSP annual reports provide an opportunity each year to evaluate current Subbasin conditions and assess the need for further PMAs. During the periodic evaluations, the GSP will also be reviewed and revised, as needed and as more is known about the effects of current and future conditions.

Colusa County, Glenn County, and the stakeholders within the Subbasin recognize that this GSP isn't the finish line; it is the starting line for sustainable management of the Subbasin. As conditions within the Subbasin change, the GSAs within the Subbasin are committed to an open, transparent, and all-inclusive adaptive management strategy aimed at tackling the important local issues that they face. At the heart of SGMA is the power for locals to solve local problems with local resources. All parties in the Subbasin are committed to doing just that.

(THIS PAGE LEFT BLANK INTENTIONALLY)

In September 2014, the California legislature passed, and Governor Jerry Brown signed, the Sustainable Groundwater Management Act (SGMA), which was composed of Assembly Bill (AB) 1739, Senate Bill (SB) 1168, and SB 1319. SGMA is codified in Section 10720 et seq. of the California Water Code. The California Department of Water Resources (DWR) subsequently initiated development of regulations to implement SGMA. In February 2016, DWR released draft emergency regulations for the development of Groundwater Sustainability Plans (GSPs). In July 2016, DWR provided notice of proposed emergency rulemaking and submitted the emergency regulations to the Office of Administrative Law (OAL). These are in California Code of Regulations (CCR), Title 23 Waters, Division 2 Department of Water Resources, Chapter 1.5 Groundwater Management, Subchapter 2 Groundwater Sustainability Plans.

The practical implication of SGMA, and associated regulations to implement SGMA, is to provide for local control of groundwater resources while requiring sustainable management of the state's groundwater subbasins. Under the provisions of SGMA, local agencies must establish governance of their subbasins by forming Groundwater Sustainability Agencies (GSAs) with the authority to develop, adopt, and implement a Groundwater Sustainability Plan (GSP) for the subbasin. The GSP provides a full accounting and description of subbasin groundwater conditions and provides a roadmap for subbasin groundwater management. Under the GSP, GSAs must adequately define and monitor groundwater conditions in the subbasin and establish criteria to maintain or achieve sustainable groundwater management within 20 years of GSP adoption.

The timeline for GSP development and adoption depends on subbasin conditions that are defined by DWR in its Bulletin 118. The Colusa Subbasin (Subbasin) is defined in Bulletin 118 by DWR as a high priority subbasin. This means that the Colusa Subbasin GSAs must develop, adopt, and submit a GSP (or GSPs) covering the entire Subbasin to DWR by January 31, 2022 (CWC Section 10720.7(a)(2)). The Subbasin is managed by two GSAs: the Glenn Groundwater Authority (GGA) and the Colusa Groundwater Authority (CGA). The GSAs have worked collaboratively to develop this single GSP to meet the requirements under SGMA for the entire Subbasin.

The following subsections in this Executive Summary provide an overview of each section of the Colusa Subbasin GSP.

INTRODUCTION (GSP CHAPTER 1)

Groundwater serves as an important source of supply for agricultural, municipal, domestic, industrial, and environmental beneficial uses throughout the Subbasin[1], which underlies approximately 723,823 acres within Colusa and Glenn Counties. Agriculture in the Subbasin relies on approximately 500,000 acre-feet (af) of groundwater (and nearly 1.2 million af of surface water, plus precipitation) annually, on average, to produce an array of commodities that contribute to the agricultural economies of both Colusa County and Glenn County, which have a total combined value of over $1.7 billion dollars.[2] Groundwater also supports essentially all domestic, municipal, and industrial water use in both Counties. The sustainable

[1] Groundwater basin number 5-021.52, part of the Sacramento Valley Groundwater Basin, as defined by DWR Bulletin 118 (DWR, 2006) and updated in February 2019. Additional basin boundary modifications were submitted to DWR in June 2021; however, the modifications have not been approved as of the writing of this GSP.

[2] According to the Colusa County Department of Agriculture, the gross production value of agriculture in the County was $932,963,000 (Crop Report, 2019). According to the Glenn County Department of Agriculture/Weights and Measurements, the gross production value of all agricultural commodities in the County was $806,668,000 (Crop & Livestock Report, 2019).

management of groundwater in the Subbasin is important for long-term prosperity of the communities in the region.

Sustainable management of groundwater is defined under SGMA as the "management and use of groundwater in a manner that can be maintained during the planning and implementation horizon without causing undesirable results" (California Water Code [CWC] Section 10721(v)). Undesirable results are associated with each of six sustainability indicators, including chronic lowering of groundwater levels, reduction of groundwater storage, seawater intrusion, degraded water quality, land subsidence, and depletions of interconnected surface water. Undesirable results occur when significant and unreasonable effects for any of the sustainability indicators are caused by groundwater conditions occurring throughout the subbasin. Sea water intrusion, while a SGMA-defined sustainability indicator, was determined to be inapplicable to the Subbasin due to the distances between the Subbasin and the Pacific Ocean, bays, deltas, or inlets ranging from about 30 to 60 miles.

The purpose of this GSP is to characterize groundwater conditions in the Subbasin, evaluate and report on existing conditions relating to the six sustainability indicators, describe existing monitoring, management programs and policies relating to groundwater resource use, document public outreach and communication, establish sustainability goals, and describe projects and management actions (PMAs) the GSAs will implement to achieve sustainable groundwater management within 20 years of implementing the GSP (CCRs Title 23, Section 350.4 (f)).

PLAN AREA (GSP CHAPTER 2)

Figure ES-1 illustrates the Plan Area. The Plan Area, described in detail in Chapter 2 of the GSP, is defined as the Colusa Subbasin (5-021.52), part of the Sacramento Valley Groundwater Basin, as described in Bulletin 118 (DWR, 2006b) with Subbasin boundary updates approved by DWR in February 2019. The Subbasin is generally bounded by Stony Creek to the north, the Coast Ranges to the west, the Sacramento River to the east, and the Colusa-Yolo County boundary and the Colusa County Water District boundary to the south. The Subbasin currently includes about 2.4 square miles (1,500 acres) within Yolo County, but is otherwise located fully within Glenn and Colusa Counties. Additional basin boundary modifications were submitted to DWR in June 2021; however, the modifications have not been approved as of the writing of this GSP. The modifications would adjust the eastern Subbasin boundary to better conform to the boundary of Reclamation District 1004 in Colusa County and would reduce the area of the Subbasin to 1,129 square miles (722,768 acres). The vertical boundaries of the Subbasin are the land surface (upper boundary) and the definable bottom of the basin (lower boundary). The vertical extent of the Subbasin is subdivided into a surface water system (SWS) and groundwater system (GWS). The SWS represents the land surface down to the bottom of plant root zone[3], within the lateral boundaries of the Subbasin. The GWS extends from the bottom of the root zone to the bottom of the Subbasin as defined by the Hydrogeologic Conceptual Model (HCM), within the lateral boundaries of the Subbasin.

[3] The depth to the bottom of the root zone varies by crop, but typically ranges from 2 to 7 feet (ASCE, 2016).

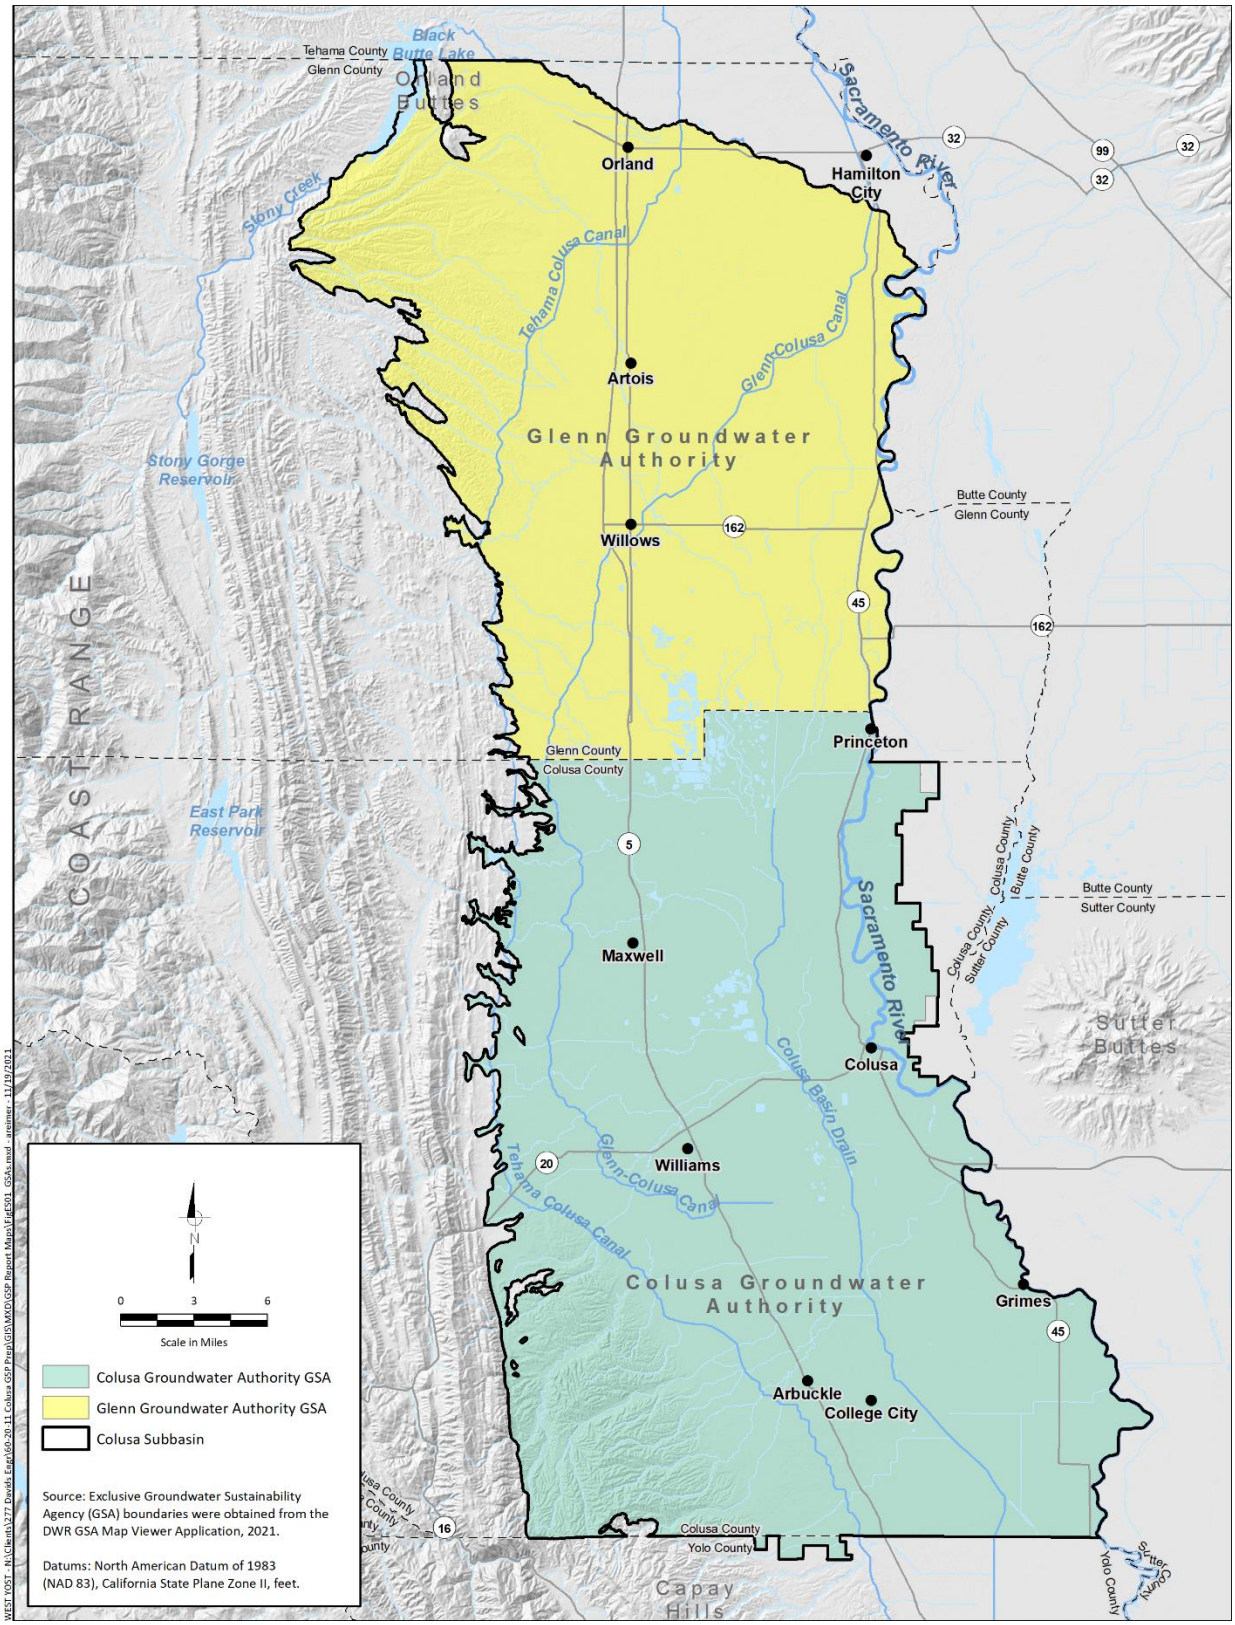

Figure ES-1. Colusa Subbasin GSAs

BASIN SETTING (GSP CHAPTER 3)

Chapter 3 describes the basin setting, including the HCM, current and historical groundwater conditions, and water budget information describing the movement of surface water and groundwater into, through and out of the Subbasin. Each of the three components of the basin setting are summarized below.

Hydrogeological Conceptual Model

The HCM provides the conceptual understanding of the hydrogeologic physical setting, characteristics, and processes that occur within the Subbasin and provides the foundation upon which the components of the water budget are based. The components of the HCM include surficial and subsurface features. Surficial features include topography, hydrology, water supply features, land use, soil types, and geologic outcrops. Subsurface features of the HCM include geologic formations and structures and the presence and characteristics of aquifers and aquitards.

Figure ES-2 shows the geologic component of the HCM. The Subbasin is underlain by one principal aquifer with interconnected unconfined and semiconfined to confined zones. Shallow groundwater in the Subbasin occurs under unconfined conditions in the Holocene stream channel deposits, except where these units are overlain by Holocene basin deposits, creating semiconfined to confined conditions. At greater depths, groundwater occurs under semiconfined to confined conditions in a single heterogeneous aquifer system, composed of predominantly fine-grained sediments enclosing discontinuous lenses of sand and gravel. The aquifer properties, including hydraulic conductivity and degree of confinement are dependent on the properties of the fine-grained units.

Most of the fresh groundwater within the Subbasin is contained within the Tehama Formation (shown as orange in Figure ES-2). The fraction of fresh groundwater contained within the Tehama Formation decreases in the northeastern portion of the Subbasin, where sediments of the Tuscan Formation are more prevalent (shown as pink in Figure ES-2). The interface between sediments of the Tehama and Tuscan Formations, referred to in this GSP as the Tehama-Tuscan Transition Zone, has been documented as mixed Tehama and Tuscan Formation sediments.

There are no defined principal aquitards within the Subbasin, however, the formations deposited under alluvial conditions or volcanic flows with lahars, such as exist in the Tehama and Tuscan Formations, respectively, tend to consist of thick low-permeability sediments interbedded with interconnected channels or lenses of higher-permeability sediment. The low-permeability sediments may impede vertical groundwater flow, but generally do not separate the aquifer system into separate, definable principal aquifers in the Subbasin.

Groundwater Conditions

Chapter 3 describes current and historical groundwater conditions in the Subbasin to support development and implementation of the GSP pursuant to the requirements of SGMA. Current and historical conditions are described for groundwater elevations, estimates of groundwater storage, groundwater quality, land subsidence, and interconnected surface waters. The description of current and historical groundwater conditions directly supports the development of sustainable management criteria presented in Chapter 5.

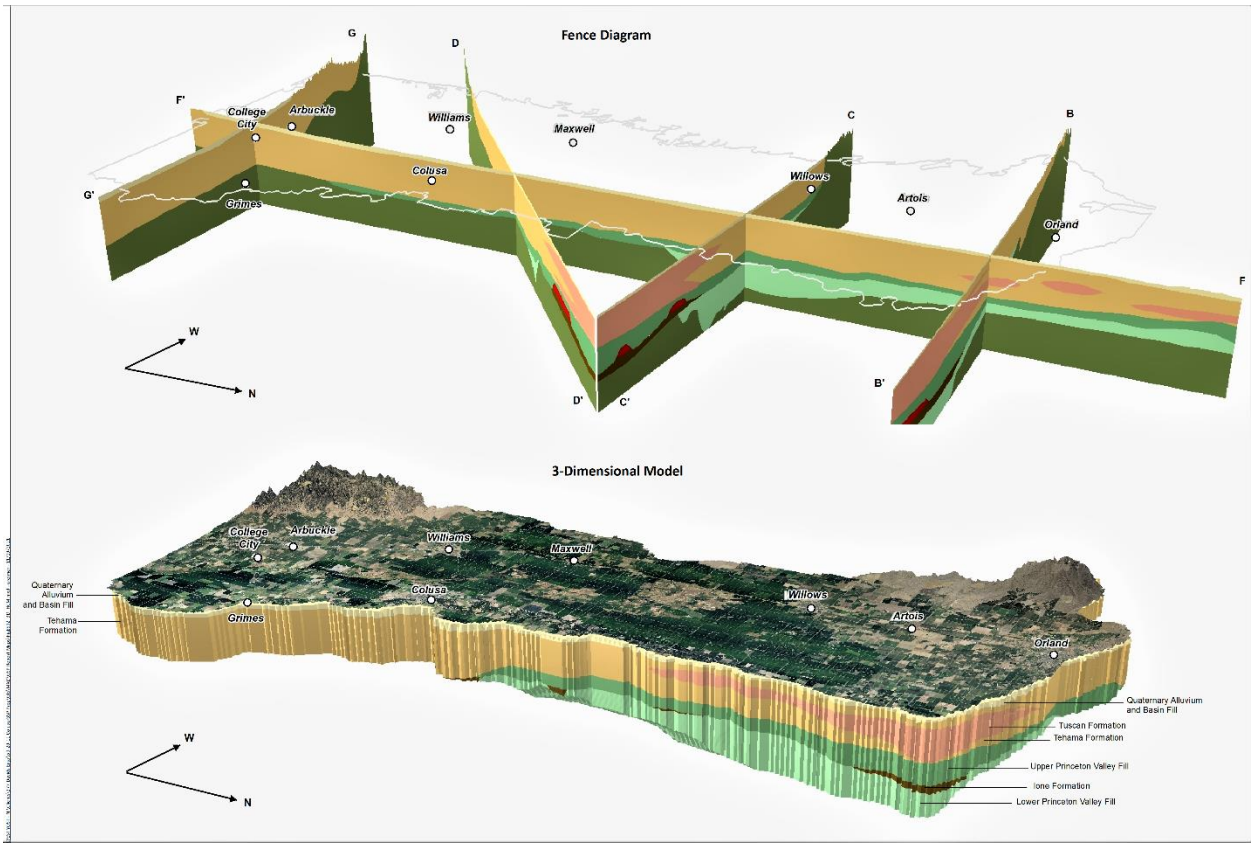

Figure ES-2. 3D Hydrogeologic Conceptual Model

Groundwater elevations measured in spring 2020 are shown on Figure ES-3. Regional groundwater flow within the Subbasin is generally eastward from the margins of the Sacramento Valley toward the Sacramento River and southward towards the Sacramento-San Joaquin Delta. For most of the Subbasin, the groundwater flows in a southeasterly direction, consistent with typical regional trends. South of Arbuckle, however, groundwater flows northeast down from the western uplands before flowing southeast down the valley.

Groundwater pumping has resulted in localized cones of depression that disrupt the regional groundwater flow gradients. Dry conditions and changes in land use have led to increased groundwater pumping in recent years.

Groundwater elevations throughout the Subbasin declined over the prolonged dry period beginning after 2006. The alternating years of average to dry conditions after 2006 have affected shallow wells, some of which have gone dry. The CGA and GGA support the State of California's policy on the Human Right to Water and recognize that drought emergencies have a disproportionate effect on California Native America Tribes (Tribes), Disadvantaged Communities (DAC) and Severely Disadvantaged Communities (SDAC) that rely on groundwater for their drinking water supplies. Many of the communities within the Subbasin are considered disadvantaged or severely disadvantaged. Nearly all of the Subbasin is considered an Economically Distressed Area. This GSP includes information on drought relief efforts coordinated by the Colusa and Glenn Interagency Drought Task Forces to address the effects of drought across the Subbasin and throughout these communities.

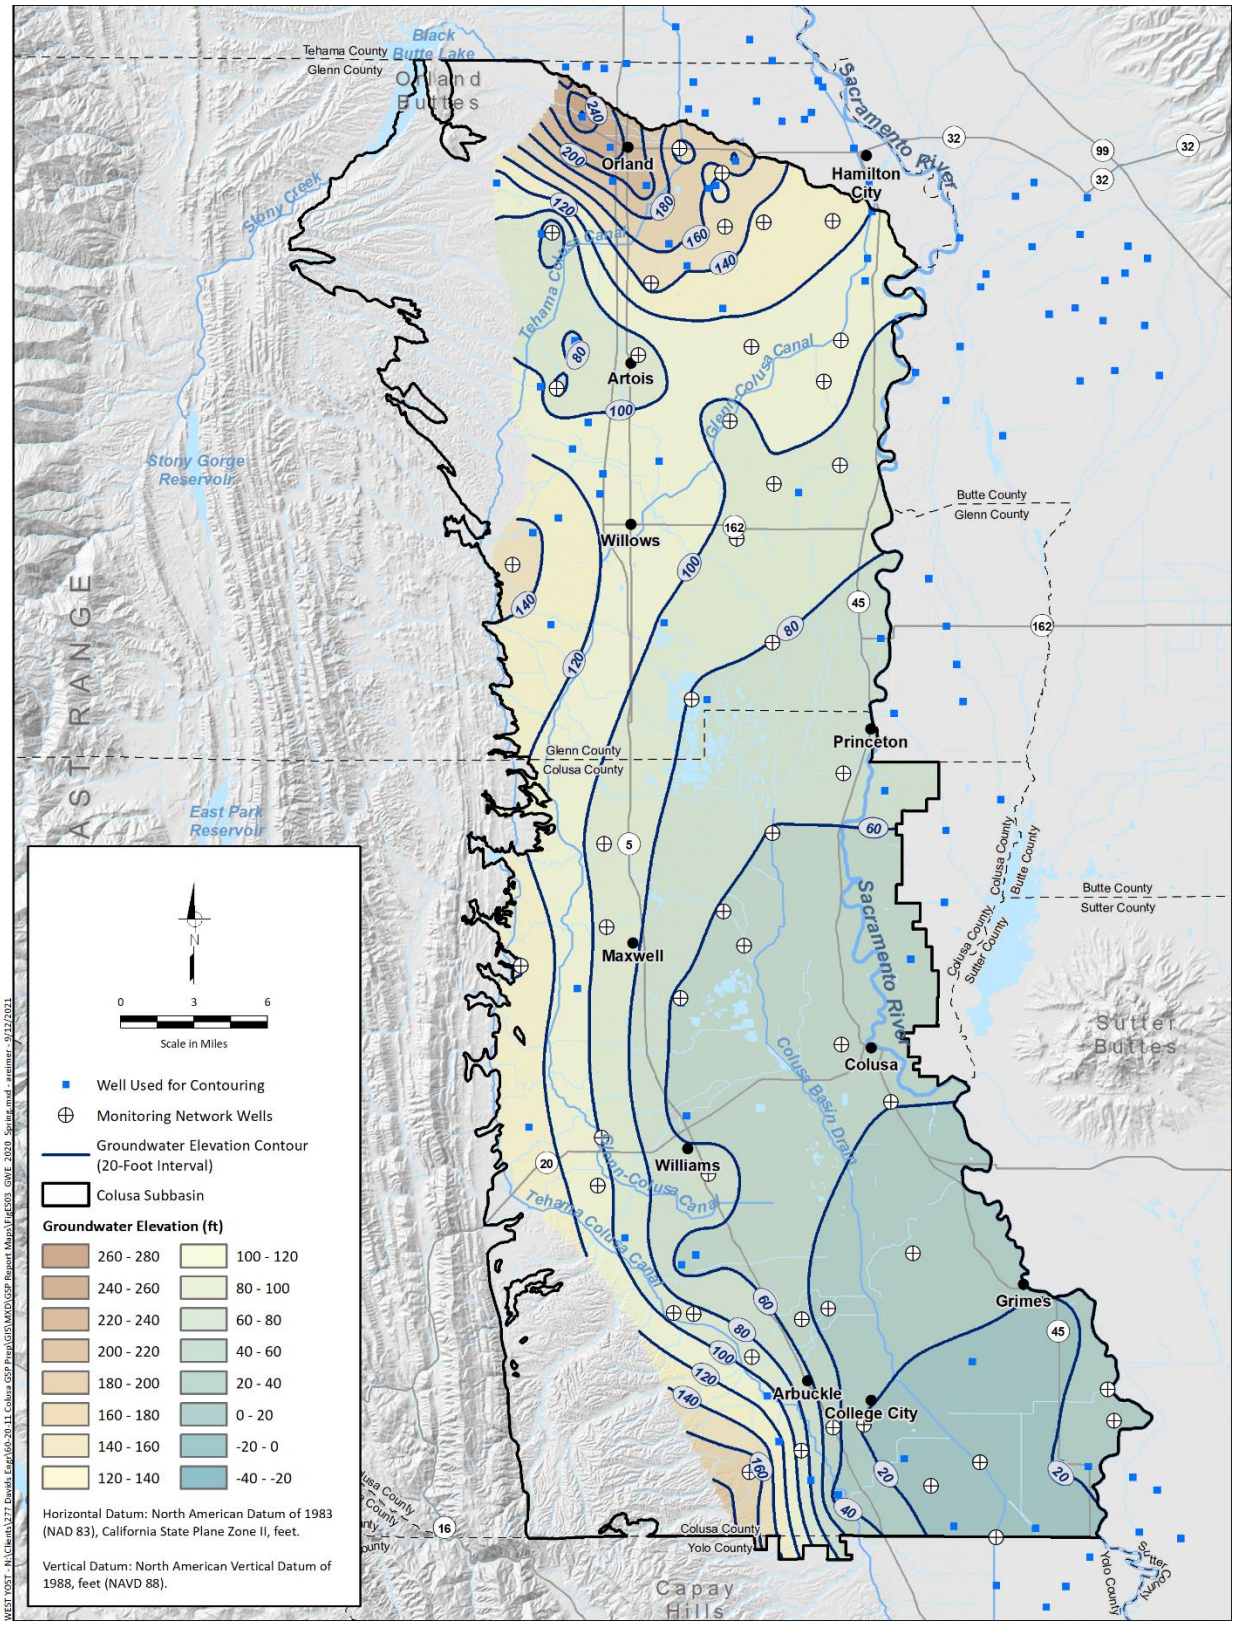

Figure ES-3. Groundwater Elevation Contours Spring 2020

Water Budget Information

A water budget is defined as a complete accounting of all water flowing into and out of a defined volume, which is the entire Subbasin within its defined horizontal and vertical boundaries, over a specified period of time. The water budget facilitates assessment of the total volume of groundwater and surface water entering and leaving the Subbasin over time, along with the change in the volume of water stored within the Subbasin. As required by the GSP emergency regulations, water budgets were developed for historical, current, and projected conditions. A numerical integrated groundwater-surface water flow model was developed based on the fine grid California Central Valley Groundwater-Surface Water Simulation Model (C2VSimFG) and used to support development of water budgets. Three water budgets were developed (including three climate scenarios for projected future conditions):

- A historical water budget evaluates availability or reliability of past surface water supplies and aquifer response to water supply and demand trends relative to water year type. The historical water budget was calculated for the 1990 through 2015 period, which was found to be reasonably representative of the long-term average conditions in the Subbasin. The historical water budget supports understanding of past groundwater conditions, considering surface water and groundwater supplies utilized to meet water demands.
- A current water budget establishes potential future baseline conditions under the assumptions of current land use and water supplies and historical hydrology. Current land use and water supplies are based on observed conditions in 2013 and 2015, representing Shasta Non-Critical and Shasta Critical years, respectively[4]. Historical hydrology from 1966 through 2015 was used to represent an analysis period from 2016 through 2065.
- Future water budgets establish potential future baseline conditions under different scenarios defined by different climate conditions. Three scenarios were developed: baseline without climate change, with 2030 climate change, and with 2070 climate change. The climate change scenarios correspond to the Central Tendency (CT) climate projections. These future water budgets are based on current land use over the same 50-year (1966 through 2015) historical hydrology as was used in the current water budget.

Table ES-1 summarizes the assumptions used in developing the water budgets.

[4] Because surface water supplies are curtailed in Shasta Critical years, the irrigated area and therefore water demands and use are less than in Shasta Non-Critical years.

Table ES-1. Summary of Water Budget Assumptions

Water Budget	Analysis Period	Hydrology	Land Use	Water Supplies
Historical Simulation	1990-2015	Historical	Historical	Historical
Current Conditions Baseline	2016-2065	Historical (1966-2015)	Current (2013 and 2015) used for Shasta Non-Critical and Shasta Critical, respectively	Current (2013 and 2015) used for Shasta Non-Critical and Shasta Critical, respectively, for water diversions; 2006-2015 average for urban demands
Future Conditions, No Climate Change Baseline	2016-2065	Historical (1966-2015)	Current (2013 and 2015) used for Shasta Non-Critical and Shasta Critical, respectively	Current (2013 and 2015) used for Shasta Non-Critical and Shasta Critical, respectively, for water diversions; 2006-2015 average for urban demands
Future Conditions, 2030 Climate Change Baseline	2016-2065	Historical (1966-2015), adjusted based on 2030 climate change with central tendency	Current (2013 and 2015) used for Shasta Non-Critical and Shasta Critical, respectively	Same as Current (see above), adjusted for 2030 climate change
Future Conditions, 2070 Climate Change Baseline	2016-2065	Historical (1966-2015), adjusted based on 2070 climate change with central tendency	Current (2013 and 2015) used for Shasta Non-Critical and Shasta Critical, respectively	Same as Current (see above), adjusted for 2070 climate change

1

2

Average annual water budget estimates for the historical water budgets and for the current and projected future water budget scenarios are summarized in Table ES-2 for the groundwater system. Volumes are reported in units of thousand af per year (taf/yr). It is anticipated that the water budgets will be refined and updated over time as part of GSP implementation.

Table ES-2. Average Annual Groundwater System Inflows, Outflows, and Changes in Storage in taf/yr

Component	Historical Simulation	Current Conditions Baseline	Future Conditions, No Climate Change Baseline	Future Conditions, 2030 Climate Change Baseline[a]	Future Conditions, 2070 Climate Change Baseline[a]
Inflows[b]					
Subsurface Water Inflows	200	203	203	205	209
Deep Percolation	441	416	415	415	411
Precipitation	174	162	162	160	156
Applied Surface Water	196	162	162	161	158
Applied Groundwater	72	92	91	94	97
Seepage	345	379	379	387	401
Streams	206	231	231	239	253
Canals and Drains	139	148	148	148	148
Total Inflow	**986**	**997**	**997**	**1,008**	**1,021**
Outflows					
Subsurface Water Outflows	146	149	149	148	147
Groundwater Pumping	502	499	499	525	559
Agricultural	463	458	458	484	516
Urban and Industrial	11	11	10	10	10
Managed Wetlands	28	30	30	31	32
Stream Gains from Groundwater (Stream Accretions)	366	349	349	337	323
Total Outflow	**1,014**	**997**	**996**	**1,011**	**1,028**
Change in Storage (Inflow - Outflow)	**-28**	**1**	**1**	**-3**	**-7**

(a) Central Tendency Climate Change Projections.
(b) Sacramento River Diversions and Stony Creek Diversions are diversions from boundary streams outside the Subbasin. About 20 percent of the total diversions come from streams within the Subbasin and are included in the Sacramento River Inflow.

GSP regulations require the water budget to quantify the sustainable yield for the Subbasin. Sustainable yield is dependent upon conditions in existence at the time, and therefore changes during the implementation period as projects are completed and climate conditions change. Provisional estimates of sustainable yield have been calculated from water budget parameters for each scenario as the long-term annual average groundwater pumping, minus the average annual decrease in groundwater storage. Using this approach, the Subbasin is estimated to have a sustainable yield between 500,000 af and 550,000 af per year.

MONITORING NETWORKS (GSP CHAPTER 4)

Chapter 4 of the GSP documents the Subbasin monitoring networks. Monitoring networks are required to better understand and evaluate changing conditions within the groundwater, surface water, and land surface systems.

To optimize data collection and analysis, the networks need to be easily accessible, spatially and temporally relatable to other monitoring networks, sufficient for demonstrating spatial and temporal trends, and representative of actual conditions. Four monitoring networks meeting these standards are defined for the Subbasin:

1. Groundwater Level Monitoring Network
2. Groundwater Quality Monitoring Network
3. Land Subsidence Monitoring Network
4. Surface Water Monitoring Network

The data collection objectives for the monitoring networks are to characterize:

- Groundwater levels, availability, and flow characteristics, including changes in groundwater storage;
- Groundwater quality;
- Extent and rate of land subsidence; and
- Surface water availability and interactions with groundwater, including impacts to native riparian land and groundwater dependent ecosystems (GDEs).

Data gaps were identified within all of the monitoring networks, and recommended actions are provided in Chapters 4 and 7. Annual reports and future revisions to the GSP will provide updates on actions taken to address data gaps in the monitoring networks over the reporting period.

Representative Monitoring Networks

Representative monitoring networks (RMN) were designated as subsets of the Subbasin monitoring networks. Per 23 CCR §354.36, "Each Agency may designate a subset of monitoring sites as representative of conditions in the basin or an area of the basin…" to evaluate or monitor for sustainability indicators. Representative monitoring locations were designated to evaluate undesirable results due to chronic lowering of groundwater levels, reduction of groundwater storage, degraded water quality, inelastic land subsidence, and depletions of interconnected surface water.

Per DWR's Sustainability Management Criteria Best Management Practice document (BMP), the sustainable management criteria for groundwater levels may be used as a proxy for sustainability indicators that have a significant, demonstrated correlation to groundwater levels. As documented in Chapters 3 and 5 and their supporting technical appendices, reduction of groundwater storage and depletions of interconnected surface water are significantly correlated to groundwater levels in the Subbasin, and therefore those sustainability indicators utilize groundwater levels as a proxy.

In addition to data collected using the RMNs, the GSAs will use data collected using the monitoring networks described in the following sections to evaluate groundwater conditions in the Subbasin. The monitoring networks will be periodically reviewed and modified as needed.

The following subsections provide a summary of each of the Subbasin monitoring networks and the RMNs used to assess groundwater conditions relative to the five sustainability indicators applicable to the Subbasin.

Groundwater Level Monitoring Network

The Subbasin groundwater level monitoring network is based on the existing groundwater monitoring networks of Colusa and Glenn Counties. There are 104 completions in 48 wells in the Subbasin groundwater level monitoring network. All of these wells are currently included in the California's Statewide Groundwater Elevation Monitoring Program (CASGEM) database.

Groundwater level monitoring network requirements documented in the DWR's Monitoring Network BMP and 23 CCR §354.34 were used to evaluate the groundwater monitoring wells in the Subbasin groundwater monitoring network. These requirements are addressed under the following categories:

- Known Construction Characteristics
- Nested Multiple Completion Wells
- Non-Dedicated Monitoring Wells
- Proximity to Streams and Interconnected Surface Waters
- Lateral and Vertical Density
- Accessibility and Usability

Data gaps within the groundwater monitoring network were evaluated for all criteria and categorized as follows:

- Usability of the monitoring site due to:
  - Wells screened across multiple water-bearing units and principal aquifer
- Spatial distribution of monitoring sites with regard to:
  - Presence near a surface water body
  - Lateral and vertical extent of coverage
  - Areas and depths with known groundwater level decline.

Recommended actions to address the data gaps include the addition of existing wells or the construction of new wells to add to the monitoring network. Field studies or surveys are recommended to verify well conditions and construction, and to identify wells to include in the network.

The RMN for chronic lowering of groundwater levels and reduction of groundwater storage sustainability indicators consists of one completion from each of the 48 wells in the groundwater monitoring network.

Groundwater Quality Monitoring Network

Existing regulatory programs address most water quality concerns in the Subbasin, and the CGA and GGA will coordinate with these programs, the lead regulatory agencies, and the regulated community during implementation of this GSP, including during development and implementation of PMAs.

The State Water Resources Control Board (SWRCB) and the Central Valley Regional Water Quality Control Board (CVRWQCB) regulate point and nonpoint source discharges to land that have potential to impact groundwater quality under a range of policy and regulatory programs, including the Basin Plan Amendment for the Salt and Nitrate Control Program, and the Irrigated Lands Regulatory Program (ILRP). The California Department of Toxic Substance Control regulates releases of toxic substances, including those that impact groundwater quality.

The California Safe Drinking Water Act addresses the regulation and control of public water systems in the State of California, including enforcing provisions of the federal Safe Drinking Water Act. The SWRCB Division of Drinking Water (DDW) is the lead agency responsible for enforcement in Colusa and Glenn Counties, including the entire Subbasin.

The CGA and GGA will rely on existing monitoring and reporting carried out by the regulated community within the Subbasin when and where possible to address water quality concerns. The CGA and GGA will conduct supplemental water quality monitoring using existing wells or new monitoring wells constructed for that purpose when and where necessary to fill data gaps and to develop and implement PMAs.

Groundwater quality in the Subbasin is generally good, with local exceedances of water quality objectives for some constituents. The sole groundwater quality concern not addressed by the existing groundwater quality regulatory programs is mobilization of saline water from deeper parts of the aquifer along faults, other geologic structures, or other naturally-occurring zones with high salinity as a result of GSP PMAs and other groundwater development.

Groundwater quality monitoring network locations for the Subbasin consist of wells identified and currently being monitored for salinity (i.e., total dissolved solids or electrical conductivity) under the ILRP and public drinking water supply systems regulated by DDW. The Subbasin groundwater quality monitoring network includes 54 monitoring sites.

The GSAs will coordinate and collaborate with other agencies regarding their monitoring programs, including changes to monitoring sites, monitoring protocols or frequencies, and management actions. Data gaps within the groundwater quality monitoring network were identified with regard to sampling frequency and spatial or vertical coverage in areas of concern.

The RMN for the degraded water quality sustainability indicator consists of 25 monitoring sites to monitor for groundwater quality degradation due to mobilization of brackish or saline groundwater.

Land Subsidence Monitoring Network

The Subbasin land subsidence monitoring network is comprised of benchmarks, continuous global positioning system (GPS) stations, extensometers, and remote sensing data. The land subsidence monitoring network sites and remote sensing programs are managed and monitored through the following agencies and programs.

- California DWR Ground Surface Displacement - Land Subsidence Monitoring Program
  - Includes five extensometers located in or within five miles of the Subbasin.
- University NAVSTAR Consortium (UNAVCO) Plate Boundary Observatory GPS/GNSS Network
  - Includes five continuous GPS stations.
- Sacramento Valley Height Modernization Project
  - Includes 76 benchmarks locations in or within five miles of the Subbasin.
- InSAR Remote Sensing
  - Includes studies and evaluations conducted by assorted federal and international agencies.

Inelastic land subsidence within the Subbasin is monitored at 63 sites in DWR's Sacramento Valley Subsidence Monitoring Benchmark Network.

Data gaps include insufficient benchmark density and insufficient frequency of measurements in the Sacramento Valley Subsidence Monitoring Benchmark Network. Additional benchmarks, continuous GPS stations and extensometers should be installed in areas with known or suspected subsidence, and the Sacramento Valley Subsidence Monitoring Benchmark Network should be resurveyed at least once every five years.

The RMN for land subsidence consists of the 63 Sacramento Valley Height Modernization Project benchmarks within the Subbasin. The benchmarks are evenly distributed throughout the Subbasin, including in areas with known land subsidence.

Surface Water Monitoring Network

Surface water monitoring is necessary for evaluating stream-aquifer relations. Comparing stream flows and stages with groundwater levels from specific monitoring wells can provide insight into how surface waters are interconnected with the groundwater system. The surface water monitoring network includes stream gages on rivers, streams, and canals. All of the stream gages included in the surface water monitoring network are managed and monitored via existing federal and state programs.

Data collected from the surface water monitoring network will be used to:

- Characterize flow conditions including surface water discharge, stage, and baseflows.
- Identify locations and flow periods of ephemeral and intermittent stream channels, if any. The DWR Monitoring Network BMP states that monitoring of ephemeral or intermittent streams should be conducted annually or as appropriate to characterize flow changes.
- Identify temporal trends due to localized, regional, and seasonal surface water discharge and groundwater extraction effects.

- Identify and collect information necessary to evaluate adverse effects to the beneficial use of surface water.
- Support evaluation of stream-aquifer interactions, including effects on surface water supplies due to changes in groundwater levels and effects on native riparian or groundwater dependent ecosystems.

There are 15 active stream gages in the Subbasin surface water monitoring network. The Subbasin surface water monitoring network was established using the best available data and science to identify, assess, and select existing monitor wells and stream gages meeting these requirements. However, significant data gaps exist, which need to be addressed during implementation of this GSP. Until these data gaps are filled, groundwater levels measured in selected wells are being used as a proxy for measurement of the volume and rates of depletions in interconnected surface waters.

The RMN for the depletions of interconnected surface waters sustainability indicator consists of 12 shallow wells from the groundwater level monitoring network meeting the following criteria:

- Constructed to a maximum depth of 200 feet.
- Located more than 2,000 feet and less than five miles from the interconnected surface water feature.

SUSTAINABLE MANAGEMENT CRITERIA (GSP CHAPTER 5)

Sustainable management criteria encompass several important components of GSP development, including a Subbasin sustainability goal that qualitatively describes the overall objectives of the GSP and desired conditions for the Subbasin, and undesirable results statements for each of the five sustainability indicators applicable to the Subbasin. For each of the applicable sustainability indicators, undesirable results occur when groundwater conditions cause significant and unreasonable effects on the beneficial uses and users of groundwater in the Subbasin. The Subbasin will be managed to achieve the sustainability goal and to avoid undesirable results, as consistent with the sustainable management criteria established for each sustainability indicator. Sustainable management criteria include measurable objectives (targets for management), interim milestones (evaluation points over time), and minimum thresholds (the point beyond which undesirable results could occur for a sustainability indicator).

Sustainability Goal

The sustainability goal for the Subbasin is:

> *…to maintain, through a cooperative and partnered approach, locally managed sustainable groundwater resources to preserve and enhance the economic viability, social well-being and culture of all Beneficial Uses and Users, without experiencing undesirable results.*

This goal was created through collaborative, public discussions and evaluation of historical, current, and projected future Subbasin conditions identified in the basin setting (Chapter 3), in alignment with the requirements of §354.24. Through implementation of planned monitoring, projects, management actions, and studies identified in this GSP, the Subbasin will be managed to its sustainability goal to avoid undesirable results for each applicable sustainability indicator.

Sustainability Indicators

The GSP regulations define undesirable results as occurring when significant and unreasonable effects are caused by groundwater conditions occurring for a given sustainability indicator. Significant and unreasonable effects occur when minimum thresholds are exceeded for one or more sustainability indicators. A summary of the sustainable management minimum thresholds, measurable objectives and undesirable results is provided in Table ES-3.

Undesirable results occur when significant and unreasonable effects to any of the six sustainability indicators defined by SGMA, five of which are applicable to the Subbasin, are caused by groundwater conditions occurring throughout the Subbasin. The overarching sustainability goal and the absence of undesirable results are expected to be achieved by 2042 through implementation of PMAs. The sustainability goal will be maintained through proactive monitoring and management by the GSAs. Table ES-4 summarizes whether, for each of the six sustainability indicators, undesirable results have occurred, are occurring, or are expected to occur in the future in the Subbasin without and with GSP implementation.

Table ES-3. Summary of Minimum Thresholds, Measurable Objectives, and Undesirable Results

Sustainability Indicator	Monitoring Network	Undesirable Result	Minimum Threshold (MT)	Measurable Objective (MO)
Chronic Lowering of Groundwater Levels	48 Representative Monitoring Network (RMN) wells monitored at least 2 to 3 times annually by DWR	25% (12 of 48) RMN wells fall continuously below their MT for 24 consecutive months	The lower of 50% of measured historical groundwater elevation range below the historical measured low elevation and the elevation corresponding to the 20th percentile of domestic well depths in the RMN well's Thiessen polygon, subject to interbasin coordination and consistency to ensure operational compatibility	Mean of the most recent 5 years of available groundwater elevation measurements up to 2020 subject to interbasin coordination and consistency to ensure operational compatibility; A fixed value, not a rolling average
Reduction in Groundwater Storage	48 RMN wells monitored at least 2 to 3 times annually by DWR (same as Groundwater Level monitoring network)	Use groundwater levels as proxy	Use groundwater levels as proxy	Use groundwater levels as proxy
Seawater Intrusion	Not applicable	Not applicable	Not applicable	Not applicable
Degraded Groundwater Quality	25 RMN wells monitored by others at variable intervals under existing State of California regulatory programs	Electrical conductivity (EC) in 25% (6 of 23) of the RMN wells exceeds the MT for two (2) consecutive years	The higher of EC of 900 microSiemens per centimeter (µS/cm) (the recommended California Secondary Maximum Contaminant Level) OR the pre-2015 historical maximum measured EC	EC of 700 µS/cm (corresponding to an agricultural water quality objective providing for no yield reduction for crops commonly grown in the Subbasin)
Land Subsidence	Existing Sacramento Valley Height Modernization Project (SVHMP) benchmarks (63 sites)	20% or more (13 of 63) monitoring sites (benchmarks) experience subsidence rates above the MT	0.5 feet per five years	0.25 feet per five years
Depletions of Interconnected Surface Waters	12 RMN wells less than 200 feet deep and between 2,000 feet and five miles of interconnected stream (Sacramento River, Colusa Drain, Stony Creek)	25% (3 of 12) RMN wells fall below their MT for 24 consecutive months	Ten (10) feet below the observed fall 2015 groundwater level (Fall 2015 level is the measured elevation recorded on the date closest to Oct 15)	Mean of last 5 years available groundwater elevation measurements subject to interbasin coordination and consistency to ensure operational compatibility; A fixed value, not a rolling average

1

Table ES-4. Summary of Undesirable Results Applicable to the Plan Area

Sustainability Indicator	Historical Period	Existing Conditions	Future Conditions without GSP Implementation	Future Conditions with GSP Implementation (after 2040)
Chronic Lowering of Groundwater Levels[(a)]	No	No	No	No
Reduction of Groundwater Storage	No	No	No	No
Land Subsidence[(b)]	No	No	Possible	No
Seawater Intrusion	Not Applicable	Not Applicable	Not Applicable	Not Applicable
Degraded Water Quality	No	No	No	No
Depletion of Interconnected Surface Water	No	No	No	No

(a) Groundwater levels have declined in response to generally dry conditions after 2006, leading to localized cones of depression in the Orland-Artois area of Glenn County and the Arbuckle area of Colusa County. Dry wells have been reported in both counties during the 2014 and 2021 droughts. As described in Chapter 7, interagency drought task forces are responding to the drought emergency in both counties. These local efforts, which are coordinated with state and federal agencies, are expected to address short-term needs, and undesirable results requiring state intervention are not expected to be triggered.

(b) Historical rates of inelastic land subsidence have exceeded measurable objectives and minimum thresholds at some locations in the Subbasin but have not triggered undesirable results. Undesirable results are expected to be avoided through implementation of the GSP and associated PMAs.

Chronic Lowering of Groundwater Levels

An undesirable result for chronic lowering of groundwater levels in the Subbasin is experienced if sustained groundwater levels are too low to reasonably satisfy beneficial uses within the Subbasin over the planning and implementation horizon of this GSP. Undesirable results for the chronic lowering of groundwater levels have not occurred historically and are not currently occurring. The projected Subbasin water budget finds that these effects are not likely to occur under future scenarios, including under projected climate change.

Minimum thresholds for the chronic lowering of groundwater levels were developed primarily by considering historical and current groundwater conditions, with lesser emphasis on projected future groundwater conditions. The minimum threshold for each groundwater level representative monitoring well (48 in total) is calculated by the deeper of the 20th percentile of the shallowest domestic well depths in each monitoring well's Thiessen polygon or the 50 percent of range below the historical low groundwater elevation. The minimum threshold is calculated as the 20th percentile of the shallowest domestic well depths at a majority of sites (35 sites). The minimum thresholds align with the State's Human Right to Water policy by supporting the ability of drinking water beneficial users, including DACs, SDACs and Tribes, to access safe, clean, and affordable water for human consumption, cooking, and sanitary purposes.

Reduction of Groundwater Storage

An undesirable result for the reduction of groundwater storage is experienced if storage volumes are insufficient to reasonably satisfy beneficial uses within the Subbasin over the planning and implementation horizon of this GSP. This GSP uses groundwater level minimum thresholds as a proxy for

the reduction of groundwater storage sustainability indicator. Undesirable results related to groundwater storage have not occurred historically and are not currently occurring. The projected Subbasin water budget finds that these effects are not likely to occur under future scenarios, including under projected climate change.

Monitoring for a reduction of groundwater storage in the Subbasin uses groundwater levels as a proxy for determining sustainability, as permitted by 23 CCR §354.28(d). Minimum thresholds are defined using the groundwater levels criteria. Benefits to groundwater storage are expected to coincide with groundwater level management.

Seawater Intrusion

Seawater intrusion is not an applicable sustainability indicator because seawater intrusion is not present and is not likely to occur in the Subbasin due to the distances between the Subbasin and the Pacific Ocean, bays, deltas, or inlets ranging from about 30 to 60 miles.

Inelastic Land Subsidence

An undesirable result is experienced if groundwater withdrawal causes inelastic land subsidence that substantially interferes with the condition or functionality of critical infrastructure (e.g., roads, canals, pipelines) within the Subbasin over the planning and implementation horizon of this GSP. The thresholds set for inelastic land subsidence have been established so that when 20 percent of representative monitoring locations (i.e., 13 of 63 locations) exceed their minimum thresholds, an undesirable result is detected.

The minimum threshold for this sustainability indicator has been set at 0.5 feet per five years (6 inches), which was determined through review of historical subsidence conditions between 2008 and 2017 using data from DWR's Sacramento Valley Height Modernization Project.

Degraded Water Quality

An undesirable result for degraded water quality in the Subbasin is experienced if, as the result of PMAs implemented under the GSP or other groundwater development (such as groundwater extraction or groundwater recharge), groundwater quality for regulated constituents is degraded to levels exceeding historical levels existing prior to January 1, 2015, or applicable water quality objectives, including drinking water standards, whichever are greater over the planning and implementation horizon of this GSP. Existing regulatory programs address most water quality concerns, and the CGA and GGA will coordinate with these programs, the lead regulatory agencies, and the regulated community within the Subbasin during implementation of this GSP, including during development and implementation of PMAs.

The minimum threshold for degraded water quality has been established as the higher of either 900 microSiemens per centimeter (µS/cm) EC, which is consistent with the recommended California Secondary Maximum Contaminant Level (SMCL), or the pre-2015 historical maximum recorded EC value. In developing the minimum thresholds for groundwater quality, beneficial uses of groundwater as a drinking water supply and as an agricultural supply were considered. Setting minimum thresholds using this methodology is protective of beneficial users and uses of groundwater, including agricultural, municipal, and domestic uses in the Subbasin. The minimum threshold for degraded water quality is calculated to be at an EC level that allows for adequate flexibility within the pre-2015 historical maximum EC level, to compensate for changing groundwater conditions during drought periods, while protecting SMCLs established for aesthetic reasons, such as taste, odor, and color.

The minimum threshold aligns with the State's Human Right to Water policy by supporting the ability of drinking water beneficial users, including DACs, SDACs and Tribes, to access safe, clean, and affordable water for human consumption, cooking, and sanitary purposes.

Depletion of Interconnected Surface Water

An undesirable result for depletions of interconnected surface water is experienced if significant and unreasonable effects to stream flows, significant and unreasonable effects to riparian and riverine habitat, and significant and unreasonable effects to groundwater dependent ecosystems (GDEs) occur. This GSP uses minimum thresholds based on groundwater levels as a proxy for the depletion of interconnected surface water indicator. It is necessary to use groundwater levels as a proxy due to the surface water monitoring network being inadequate to monitor effects of groundwater on surface water flows. This is discussed in more detail in Chapter 5. The undesirable result for depletions of interconnected surface water is considered to occur during GSP implementation when 25 percent of representative monitoring wells (i.e., 3 of 12 wells) fall below their minimum groundwater elevation thresholds for 24 consecutive months. The three wells must be the same subset of wells, not any combination of three wells. These criteria were determined based on the evaluation of best available data pertaining to the Subbasin's specific conditions and characteristics, as described in the Plan Area and Groundwater Conditions sections of this GSP, in conjunction with input and feedback from the public, local stakeholders and GSA members.

The minimum thresholds set for managing depletions of interconnected surface water differ from the minimum thresholds set for managing chronic lowering of groundwater levels. Minimum thresholds for depletions of interconnected surface waters were determined based on evaluation of historical data from the monitoring network for interconnected surface water, which is composed of 12 monitoring wells no deeper than 200 feet located between 2,000 feet and five miles of interconnected streams in the Subbasin. The minimum thresholds set at these sites for assessing impacts to interconnected surface waters were calculated by finding the groundwater elevations in Fall of 2015 and adding 10 feet to that depth. Measurements selected for Fall 2015 were found by selecting measurements closest to October 15, 2015, considered to the be period of lowest groundwater elevations during the last drought based on review of historical groundwater levels and hydrologic data. The minimum threshold was selected such that groundwater levels near interconnected surface water courses would be protective of the beneficial use of shallower groundwater near streams and rivers, including those of shallower domestic users and potential groundwater dependent ecosystems. Levels from Fall 2015 represent conditions during a drought period but are generally believed to have still protected beneficial users at that time and therefore avoid undesirable results. The addition of 10 feet to the Fall 2015 groundwater depth to water is intended to provide an appropriate margin of operational flexibility in the future during GSP implementation based on recommendations made through discussion with the GSAs and stakeholders.

PROJECT AND MANAGEMENT ACTIONS (GSP CHAPTER 6)

The overarching sustainability goal and the absence of undesirable results are expected to be achieved by 2042 through implementation of PMAs. PMAs were formulated primarily to address possible future changes in Subbasin conditions that could cause undesirable results over the long term, and in the near term, to address effects of recent historical (2014-2015) and current (2020-2021) drought conditions that pose challenges to groundwater management in the northwest and southwest portions of the Subbasin respectively.

PMA development and implementation in the Subbasin applies an adaptive management approach informed by continued monitoring of groundwater conditions using the monitoring networks. Recognizing the GSP data gaps and uncertainties in the basin setting (per 23 CCR §354.44(d)), and recognizing known areas with declining groundwater levels, the adaptive management approach in the Subbasin includes:

- Planned PMAs that are expected to be implemented primarily to address current, localized declining groundwater levels in the Orland and Arbuckle areas. At full implementation, planned PMAs are expected to provide more than 80 taf/yr in combined gross average annual benefits that will offset groundwater pumping and support groundwater sustainability in the Subbasin.
- A portfolio of other ongoing and potential PMAs to achieve and maintain long-term sustainable groundwater management across the Subbasin, which will be implemented if established measurable objectives cannot be maintained and minimum thresholds are being approached.

Development of PMAs was informed by an evaluation of possible future changes in Subbasin conditions through comparison of the projected future water budget conditions without climate change and projected future water budget conditions adjusted by 2070 CT climate change factors. The aggregate changes in groundwater storage, 0.8 percent, and net stream accretion, 0.5 percent, across the Subbasin without PMAs are considered to be within standard modeling error for this type of analysis. However, there are localized declining groundwater levels that have occurred over the past 15 to 20 years in the northwest and southwest portions of the Subbasin near the cities of Orland and Arbuckle, respectively. Water budget analyses suggest that groundwater level decline in these areas is due primarily to drought. A series of mostly dry years beginning in about 2007 has resulted in increased irrigation demands, curtailments of Central Valley Project surface water supplies, and consequent increases in groundwater pumping in these areas. Similar dynamics exist in the Orland area, compounded by recent expansion of irrigated agriculture into previously undeveloped lands that rely on groundwater supplies only. Localized effects of declining groundwater levels include stranding of shallow domestic and irrigation wells and increased rates of land subsidence, raising concerns both locally and more broadly within the Subbasin that mitigation actions should be taken as soon as possible.

PMAs described in this GSP are expected to manage the balance of groundwater extractions and recharge to ensure that lowering of groundwater levels or depletion of supply during periods of drought is offset by increases in groundwater levels or storage in other years. In particular, PMAs that provide in-lieu and direct recharge benefits in the Orland and Arbuckle areas are planned to increase the use and recharge of available surface water supplies during wetter years, offsetting any potential increases in groundwater pumping during drought when curtailments of surface water supplies may occur.

PMAs are classified according to implementation status. Planned PMAs are those that will support sustainable groundwater management in the Subbasin over the GSP implementation period, and in the nearer-term will help to mitigate historical and current drought effects. Ongoing PMAs are those that have already been implemented and support groundwater management. Potential PMAs are a suite of options available to the GSAs if future monitoring indicates the need for such actions. Table ES-5 summarizes the planned PMAs for the Subbasin. The average annual gross benefit of these PMAs at full implementation is 84,000 af per year.

Table ES-5. Summary of Planned PMAs

Project	Project Type	Proponent	Year Implemented	Estimated Capital / Establishment Cost, $ (thousands)[a]	Gross Average Annual Benefit, taf/yr
Colusa County Water District (CCWD) In-Lieu Groundwater Recharge	In-Lieu GW[b] Recharge	CCWD	2021	$100	27
Colusa Drain MWC (CDMWC) In-Lieu Groundwater Recharge	In-Lieu GW Recharge	CDMWC	2021	$100	28
Colusa Subbasin Multi-Benefit Recharge	Direct GW Recharge	CGA, GGA, and TNC[c]	2021	$4 per site	5.2
Orland-Artois Water District (OAWD) Land Annexation and In-Lieu Groundwater Recharge	Direct and In-Lieu GW Recharge	OAWD	2020	$20,000	23
Sycamore Slough Groundwater Recharge Pilot Project	Direct GW Recharge	Landowner	2021	$28	0.5[d]

(a) Annual costs are summarized in the "Project Costs" sections of the project descriptions, below.
(b) GW = Groundwater
(c) TNC = The Nature Conservancy
(d) Project goal is to recharge 5 taf over 10 years.

PLAN IMPLEMENTATION (GSP CHAPTER 7)

The estimated average annual cost of implementing the GSP increases from approximately $1.5 million to about $9.5 million per year by 2027 (including annualized capital costs). Implementation costs are summarized across four categories:

- **One-Time Capital Costs and Studies**. These include capital costs that are not debt financed and studies to support GSP and PMA implementation. Studies include updates to the HCM to support required annual and five-year reports for DWR as well as other planning studies to support GSP implementation. To expand monitoring network data and evaluate Subbasin conditions more comprehensively, 15 GSP studies will be conducted. These include various planning, technical, and economic/fiscal studies that will aid in implementing PMAs and the monitoring of sustainability indicators outlined in Chapter 5. The studies are described in Chapter 7.
- **Debt-Financed Capital**. This includes capital costs that would likely be debt-financed. There is only one planned PMA that may be debt-financed, the OAWD land annexation project. GSP implementation costs shown below correspond to the annual debt service payment, not the total capital cost. Project proponents are concurrently working to refine estimated project costs

- **PMA Operations and Maintenance**. This includes annual expenses for the operation of planned PMAs, for example, annual water supply purchases for within-subbasin transfers to support in-lieu recharge.
- **GSA Administration**. These costs include operating expenses such as administration of the GSP, plan development, legal services, and communications for GSA staff and its technical advisers. This also includes costs for annual reporting and preparation of five-year assessments that must be submitted to DWR.

Table ES-6 summarizes the estimated annual expenses for each of these cost categories. The GSAs will continually evaluate GSP implementation progress and reassess the implementation plan and associated costs.

Table ES-6. Summary of Estimated Total GSP Implementation Costs

Cost Category	2022	2023	2024	2025	2026	2027+
Other Capital/Studies	$556,000	$1,120,000	$685,000	$460,000	$460,000	$630,000
Debt-Financed PMA Capital Repayment	-	$1,020,000	$1,020,000	$1,020,000	$1,020,000	$1,020,000
PMA O&M	-	$4,033,000	$6,675,000	$6,675,000	$6,675,000	$6,675,000
GSA Admin/Studies	$914,700	$987,900	$968,200	$968,200	$968,200	$1,148,200
Total	**$1,470,700**	**$7,160,900**	**$9,348,200**	**$9,123,200**	**$9,123,200**	**$9,473,200**

Development of this GSP was funded through a Proposition 1 Grant, and contributions from individual GSAs (e.g., through in-kind staff time, or separately contracted consulting services). Each GSA is also funding additional, ancillary studies and implementation efforts. To fund GSA operations and GSP implementation, the GSAs are developing a financing plan that will include one or more of the following financing approaches:

- **Grants and low-interest loans**. GSAs will continue to pursue grants and low interest loans to help fund planning studies and other GSA activities. However, grants and low-interest loans are not expected to cover most GSA operating costs for GSP implementation.
- **Other fees and charges**. Other fees may include permitting fees for new wells or development, transaction fees associated with contemplated groundwater markets, or commodity-based fees, all directed at aiding with sustainability objectives. Depending on the justification and basis for a fee, it may be considered a property-related fee subject to voting requirements of Article XIII D of the California Constitution (passed by voters in 1996 as Proposition 218).
- **Assessments**. Special benefit assessments under Proposition 218 could include a per-acre (or per parcel) charge to cover GSA costs. This could also include per acre-foot assessments, or a hybrid approach.
- **Taxes**. This could include general property related taxes that are not directly related to the benefits or costs of a service (ad valorem and parcel taxes), or special taxes imposed for specific purposes related to GSA activities.

The GSAs are pursuing a combined approach, targeting available grants and low interest loans, and considering a combination of fees and assessments to cover operating and program-specific costs. As required by statute and the Constitution, GSAs would complete a rate study and other analysis to document and justify any rate, fee, or assessment. GGA and CGA activities are currently supported under assessments associated with a rate study that runs through 2024.

The GSP implementation schedule allows time for GSAs to develop and implement PMAs and meets all sustainability objectives by 2042. While some sustainability projects began immediately after SGMA became law and are already contributing to Subbasin goals, the GSAs will begin implementing other GSP activities in 2022, with full implementation of PMAs to achieve sustainability by 2042. Figure ES-4 illustrates the GSP implementation schedule for PMAs implemented by each GSA. The GSP implementation schedule also shows mandatory reporting and updating for all GSAs, including annual reports and five-year periodic updates (evaluations) prepared and submitted to DWR.

CHAPTER 1
Introduction

1.1 PURPOSE OF THE GROUNDWATER SUSTAINABILITY PLAN

On September 16, 2014, Governor Jerry Brown signed into law a three-bill legislative package composed of Assembly Bill (AB) 1739, Senate Bill (SB) 1168, and SB 1319, collectively known as the Sustainable Groundwater Management Act (SGMA), which is codified in Section 10720 et seq. (§10720) of the California Water Code.

This legislation created a statutory framework for sustainable groundwater management in California and required local agencies of high- and medium-priority groundwater basins to halt overdraft and bring basins into balanced levels of pumping and recharge within 20 years. SGMA empowered local agencies to form Groundwater Sustainability Agencies (GSAs) to manage basins sustainably and required GSAs to adopt Groundwater Sustainability Plans (GSPs) for non-critically overdrafted medium- and high-priority groundwater basins in California by calendar year 2022.

SGMA defines sustainable groundwater management as *"management and use of groundwater in a manner that can be maintained during the planning and implementation horizon without causing undesirable results"* (SGMA Regulations §10721(v)). Undesirable results are defined by SGMA as the following effects:

1. Chronic lowering of groundwater levels indicating a significant and unreasonable depletion of supply
2. Significant and unreasonable reduction of groundwater storage
3. Significant and unreasonable seawater intrusion
4. Significant and unreasonable degraded water quality, including the migration of contaminant plumes that impair water supplies
5. Significant and unreasonable land subsidence that substantially interferes with surface land uses
6. Depletions of interconnected surface water that have significant and unreasonable adverse impacts on beneficial uses of the surface water

The Colusa Groundwater Authority (CGA) and Glenn Groundwater Authority (GGA), or Authorities, are exclusive GSAs covering the entire geographic extent of the Colusa Subbasin (Subbasin). The CGA GSA and GGA GSA are referred to as the Subbasin GSAs. The Authorities and their member agencies are discussed more in Chapter 2. The Authorities have worked collaboratively with all interested stakeholders to prepare this GSP. The purpose of this GSP is to characterize groundwater conditions in the Subbasin; evaluate and report on existing conditions relating to the six sustainability indicators; describe existing monitoring programs, management programs, and policies relating to groundwater resource use; identify data gaps within the aforementioned GSP topics and provide recommended actions to address those data gaps[1]; document public outreach and communication;; establish sustainability goals; and describe programs and management actions the GSAs will implement to achieve sustainable groundwater management within

[1] Chapter 3 defines data gaps within the hydrogeologic conceptual model and provides recommendations to close them. Chapter 4 of the GSP describes analyses of existing data gaps in the Subbasin, and proposed actions to address data gaps in each monitoring network. Chapter 7 further describes proposed studies and actions to address and fill data gaps identified throughout the Colusa Subbasin GSP.

20 years of implementing the GSP (California Code of Regulations [CCR] Title 23 Section 350.4(f) [23 CCR §350.4(f)]).

While the GSP focuses on groundwater projects and management actions by the Subbasin GSAs, these actions are considered in the context of the entire basin setting. The Authorities have and will continue to coordinate the actions of other GSAs in the region in an effort to achieve sustainability at a regional level.

1.2 SUSTAINABILITY GOAL

As mandated under 23 CCR §354.24, the Subbasin GSAs have established a *"sustainability goal for the basin that culminates in the absence of undesirable results within 20 years of the applicable statutory deadline."*

The sustainability goal for the Subbasin GSP is:

> *… to maintain, through a cooperative and partnered approach, locally managed sustainable groundwater resources to preserve and enhance the economic viability, social well-being and culture of all Beneficial Uses and Users, without experiencing undesirable results.*

Chapter 5, Sustainable Management Criteria, of the GSP describes the sustainability goal for the GSAs and is based on information from the basin setting, discussions of the measures that will be implemented to ensure that the Subbasin will be operated within its sustainable goal, and an explanation of how the sustainability goal is likely to be achieved and maintained within the 20-year planning and implementation horizon. The Subbasin GSAs can and should continue to assess the reasonableness of the sustainability goal in the years to come.

1.3 AGENCY INFORMATION

The CGA and the GGA have led the effort to develop a single GSP for the Subbasin, in collaboration with interested Subbasin stakeholders and interbasin agencies (described extensively in Section 2.7). Collectively, these two GSAs have been deemed exclusive GSAs and cover the entire Subbasin.

The Subbasin is located within the larger Sacramento Valley Groundwater Basin and spans the eastern portions of Colusa and Glenn Counties. It is generally bounded by Stony Creek to the north, the Coast Ranges to the west, the Sacramento River and the Reclamation District 1004 western boundary to the east, and the Colusa-Yolo County boundary and the Colusa County Water District Boundary to the south.

The Subbasin has been designated as a high-priority basin by the California Department of Water Resources (DWR) with implications under the SGMA. In compliance with SGMA deadlines, the Subbasin GSP will be completed, adopted, and submitted to DWR by January 31, 2022. Both the CGA and GGA will adopt the GSP and continue to work collaboratively on GSP implementation.

1.3.1 Agency Organization and Management Structure

The CGA and the GGA have been deemed the exclusive GSAs that cover the entire Subbasin. The CGA was formed on June 29, 2017 as a 12-member Joint Powers Authority (JPA) with 12 Director seats. It is the exclusive GSA for the Colusa County portion of the Subbasin, and a small portion of the Butte Subbasin in Colusa County. Members of the CGA Board include:

- County of Colusa
- City of Colusa
- City of Williams
- Glenn-Colusa Irrigation District
- Maxwell Irrigation District and Westside Water District
- Princeton-Codora-Glenn Irrigation District and Provident Irrigation District
- Colusa County Water District
- Reclamation District 108
- Reclamation District 479
- Colusa Drain Mutual Water Company
- Two (2) Private Pumper Representatives recommended by the Colusa County Groundwater Commission and appointed by the Colusa County Groundwater Board of Supervisors

The GGA was formed on June 20, 2017, as a nine-member JPA with eight Director seats. The JPA was later amended on October 14, 2019, to add a tenth member and one additional Director seat, for a total of nine Director seats. The GGA is the exclusive GSA for the Glenn County portion of the Subbasin. Members of the GGA include:

- City of Orland
- City of Willows
- County of Glenn
- Glenn-Colusa Irrigation District
- Glide Water District
- Kanawha Water District
- Monroeville Water District
- Orland-Artois Water District
- Princeton-Codora-Glenn Irrigation District
- Provident Irrigation District

Each GSA Board has final authority for GSP implementation. Except for the Private Pumper Representatives, Board members are chosen in public meetings by the respective governing boards of the Member Agencies. Alternates for each Board member are chosen in the same manner by the same Member Agencies. Private Pumper Representatives on the CGA Board are recommended by the Colusa County Groundwater Commission and appointed by the Colusa County Board of Supervisors in a public meeting.

Contact information for each GSA Manager is provided below:

Colusa Groundwater Authority:

Denise Carter, County Supervisor

lhunter@countyofglenn.net

1.3.1.1 Coordination Agreements

23 CCR §357.4(a) states that "*Agencies intending to develop and implement multiple Plans pursuant to Water Code Section 10727(b)(3) shall enter into a coordination agreement to ensure that the Plans are developed and implemented utilizing the same data and methodologies, and that elements of the Plans necessary to achieve the sustainability goal for the basin are based upon consistent interpretations of the basin setting.*"

The two Subbasin GSAs have jointly prepared one GSP for the entire Colusa Subbasin. As such, coordination agreements are neither required nor applicable to the Subbasin.

1.3.2 Legal Authority

On May 14, 2018, the CGA and GGA notified DWR of their intent to prepare a GSP for the Subbasin (5-021.52). The preparation of the GSP is being coordinated and overseen by the GSAs. The Authorities hold regular meetings that are open to the public and have formed a Joint Technical Advisory Committee (TAC) to coordinate Subbasin-wide activities. Periodic TAC meetings, which are also open to the public, allow coordination with the technical consulting team tasked with preparing the GSP and coordination activities in adjacent subbasins. All meeting materials and information relevant to SGMA planning and implementation are readily available to the public via websites, newsletters, emails, presentations, and public meetings. Public engagement, notices, and communication records are discussed in Chapter 2.

1.3.3 Estimated Implementation Cost and Agencies' Approach to Meet Costs

Total GSP implementation costs are estimated to increase from approximately $1.5 million per year in 2022 to approximately $9.5 million per year by 2027. These estimated costs are inclusive of all currently envisioned GSP-related activities required for successful implementation. This includes GSA administrative costs and technical studies that are required for annual updates and five-year reporting requirements totaling around $1 million per year. Projects and management action (PMAs) capital repayment costs are estimated at approximately $1 million (the total capital outlay is approximately $20 million). Project and management action development technical studies and non-debt financed capital is estimated to equal $0.5 to $1.1 million per year. Annual operations and maintenance (O&M) for projects is approximately $4 to $6.7 million per year. A substantial share of project O&M costs are attributed to water purchases for in-lieu recharge projects providing approximately 84,000 acre-feet of benefits at full implementation. Table 1-1 summarizes estimated annual GSP implementation costs for the Subbasin as a whole.

Table 1-1. Total Estimated Annual GSP Implementation Cost Summary

Cost Category	2022	2023	2024	2025	2026	2027+
Other Capital/Studies	$556,000	$1,120,000	$685,000	$460,000	$460,000	$630,000
Debt-Financed PMA Capital Repayment	-	$1,020,000	$1,020,000	$1,020,000	$1,020,000	$1,020,000
PMA O&M	-	$4,033,000	$6,675,000	$6,675,000	$6,675,000	$6,675,000
GSA Admin/Studies	$914,700	$987,900	$968,200	$968,200	$968,200	$1,148,200
Total	**$1,470,700**	**$7,160,900**	**$9,348,200**	**$9,123,200**	**$9,123,200**	**$9,473,200**

Development of this GSP was primarily funded through a Proposition 1 Sustainable Groundwater Planning Grant. In addition, the GSAs' activities were funded by fees collected under separate rate studies covering the five-year period spanning fiscal years 2019/20 through 2023/24. These were prepared as property-related fees for water service under Proposition 218. The implementation of the GSP and future SGMA compliance will be a substantial undertaking. It will likely require GSAs and other local entities to collect some combination of fees, assessments, and taxes, as well as seek additional outside funding, grants, and low-interest borrowing. The Subbasin GSAs will develop a financing plan for the overall implementation of the GSP that will specify funding sources and cost-allocation approaches across entities for the different GSP implementation activities (see Chapter 7 and Appendix 7A for a description of existing options).

1.4 GSP ORGANIZATION

The GSP is organized in accordance with 23 CCR §354 as follows:

- **Preface** sets the context for development and adoption of the GSP during a drought emergency
- **Executive Summary** provides a summary of the major topics discussed in the GSP
- **Chapter 1** introduces the Subbasin GSAs and the development of this GSP
- **Chapter 2** provides a summary of the Plan Area, monitoring and management programs, land uses, additional GSP elements and notice and communication
- **Chapter 3** discusses the Basin Setting, including the hydrogeologic conceptual model for the Subbasin, water features and conveyance infrastructure, groundwater conditions, and water budget analyses
- **Chapter 4** reviews the Monitoring Networks within the Subbasin pertaining to groundwater levels, water quality, inelastic land subsidence, and depletions of interconnected surface water
- **Chapter 5** identifies Sustainable Management Criteria, including goals, measurable objectives, minimum thresholds, and undesirable results
- **Chapter 6** identifies Projects and Management Actions that work to achieve the GSAs' sustainability goal
- **Chapter 7** discusses Plan Implementation, including anticipated costs, schedule of implementation, and annual reporting and evaluations
- **Chapter 8** provides References cited in the GSP

To facilitate DWR review and provide references to the applicable GSP regulations, Table 1-2, Checklist for GSP Submittal, cross-references the chapters of this GSP to applicable GSP regulations. Terminology used in this GSP is consistent with the SGMA definitions provided in California Water Code (CWC) §10721 and in 23 CCR §351. Appendix 1A provides a glossary of terms.

(THIS PAGE LEFT BLANK INTENTIONALLY)

CHAPTER 2
Plan Area

2.1 SUMMARY OF JURISDICTIONAL AREAS AND OTHER FEATURES

2.1.1 Groundwater Basin Boundaries

The Plan Area is defined as the Colusa Subbasin (Groundwater Basin No. 5-021.52), which is part of the Sacramento Valley Groundwater Basin, as described in California Department of Water Resources (DWR) Bulletin 118 (DWR, 2006a) with boundary updates approved in February 2019. The current configuration of the Subbasin covers approximately 1,131 square miles (723,823 acres).

The Subbasin is generally bounded by Stony Creek to the north, the Coast Ranges to the west, the Sacramento River to the east, and the Colusa-Yolo County boundary and the Colusa County Water District to the south. The Subbasin currently includes about 2.4 square miles (1,500 acres) within Yolo County. Additional basin boundary modifications were submitted to DWR in June 2021; however, the proposed basin boundary modifications have not been approved as of the submittal of this GSP. The modifications would adjust the eastern Colusa Subbasin (Subbasin) boundary to better conform to the boundary of Reclamation District 1004 in Colusa County and would reduce the area of the Subbasin to 1,129 square miles (722,768 acres).

The vertical boundaries of the subbasin are the land surface (upper boundary) and the definable bottom of the subbasin (lower boundary). The definable bottom was established as part of development of the hydrogeologic conceptual model (HCM) discussed in Chapter 3. The vertical extent of the subbasin is subdivided into a surface water system (SWS) and groundwater system (GWS). The SWS extends from the land surface down to the bottom of root zone, within the lateral boundaries of the subbasin. The GWS extends from the bottom of the root zone to the base of the aquifer system, as defined in the HCM based on the base of freshwater and bedrock structural contours, within the lateral boundaries of the subbasin.

The Subbasin is hydraulically connected with surrounding subbasins along shared boundaries, the western boundary of Reclamation District 1004, and the Glenn and Colusa County boundaries. The Subbasin adjoins the following subbasins (Table 2-1 and Figure 2-1):

- Corning Subbasin (5-021.51) to the north
- Butte Subbasin (5-021.70) to the east/northeast
- Sutter Subbasin (5-021.62) to the east/southeast
- Yolo Subbasin (5-021.67) to the south

No groundwater subbasins border the western portion of the Subbasin.

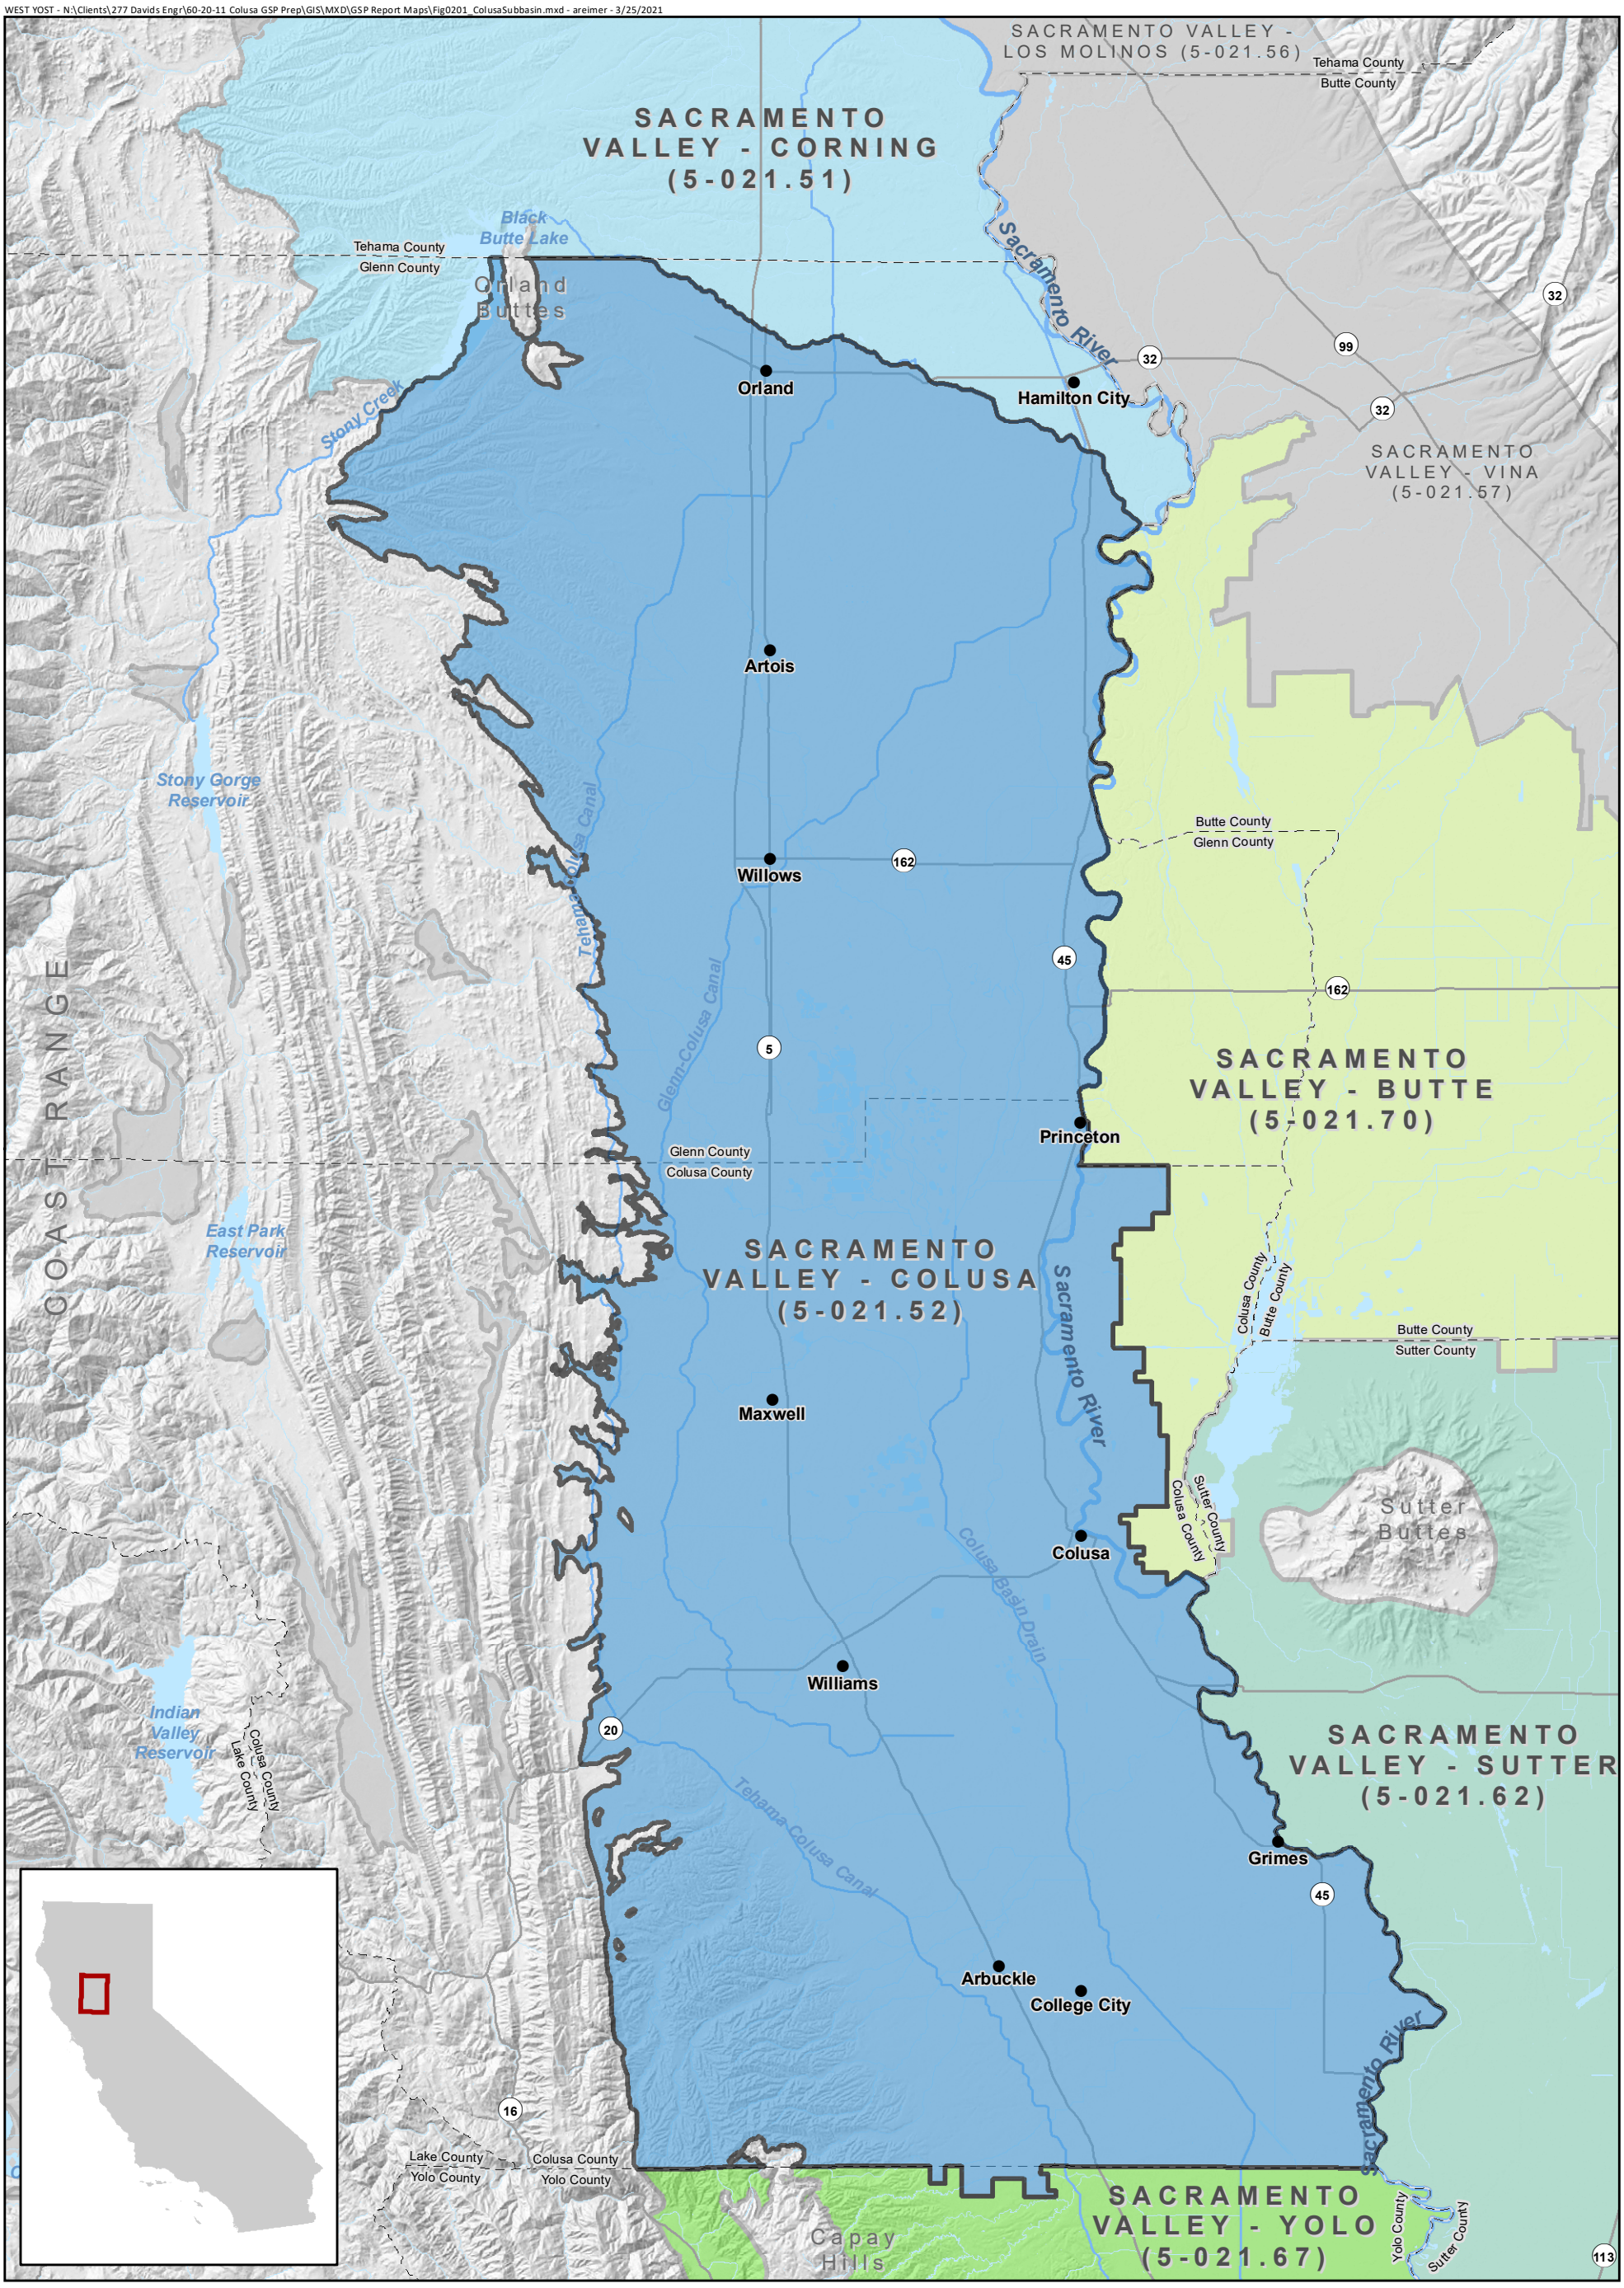

Table 2-1. Adjacent Subbasins and Associated GSAs

Colusa Groundwater Authority and Glenn Groundwater Authority

Colusa Subbasin

Groundwater Sustainability Plan

2.1.2 Groundwater Sustainability Plan Area

The Subbasin is divided among two GSAs for GSP development (Figure 2-2). Figure 2-3 shows the agencies comprising each GSA. The Colusa Groundwater Authority (CGA) for the Colusa County portion of the Subbasin is a Joint Powers Authority (JPA) with 12 member agency representatives/Director seats. The CGA is comprised of Colusa County, two cities, six[1] water districts, two reclamation districts, a water company, and two appointed private groundwater pumper representatives. The Glenn Groundwater Authority (GGA) is similarly a JPA for the Glenn County portion of the Subbasin. The GGA is comprised of ten member agency representatives including Glenn County, two cities, and seven water/irrigation districts.

Primary urban areas within the Subbasin include the incorporated cities of Orland and Willows in Glenn County and the cities of Colusa and Williams in Colusa County as well as the unincorporated communities of Artois, Princeton, Maxwell, Arbuckle, Grimes and College City. Interstate 5 and State Route 45 traverse the Subbasin north to south while State Routes 20, 32, and 162 are the primary east-west thoroughfares.

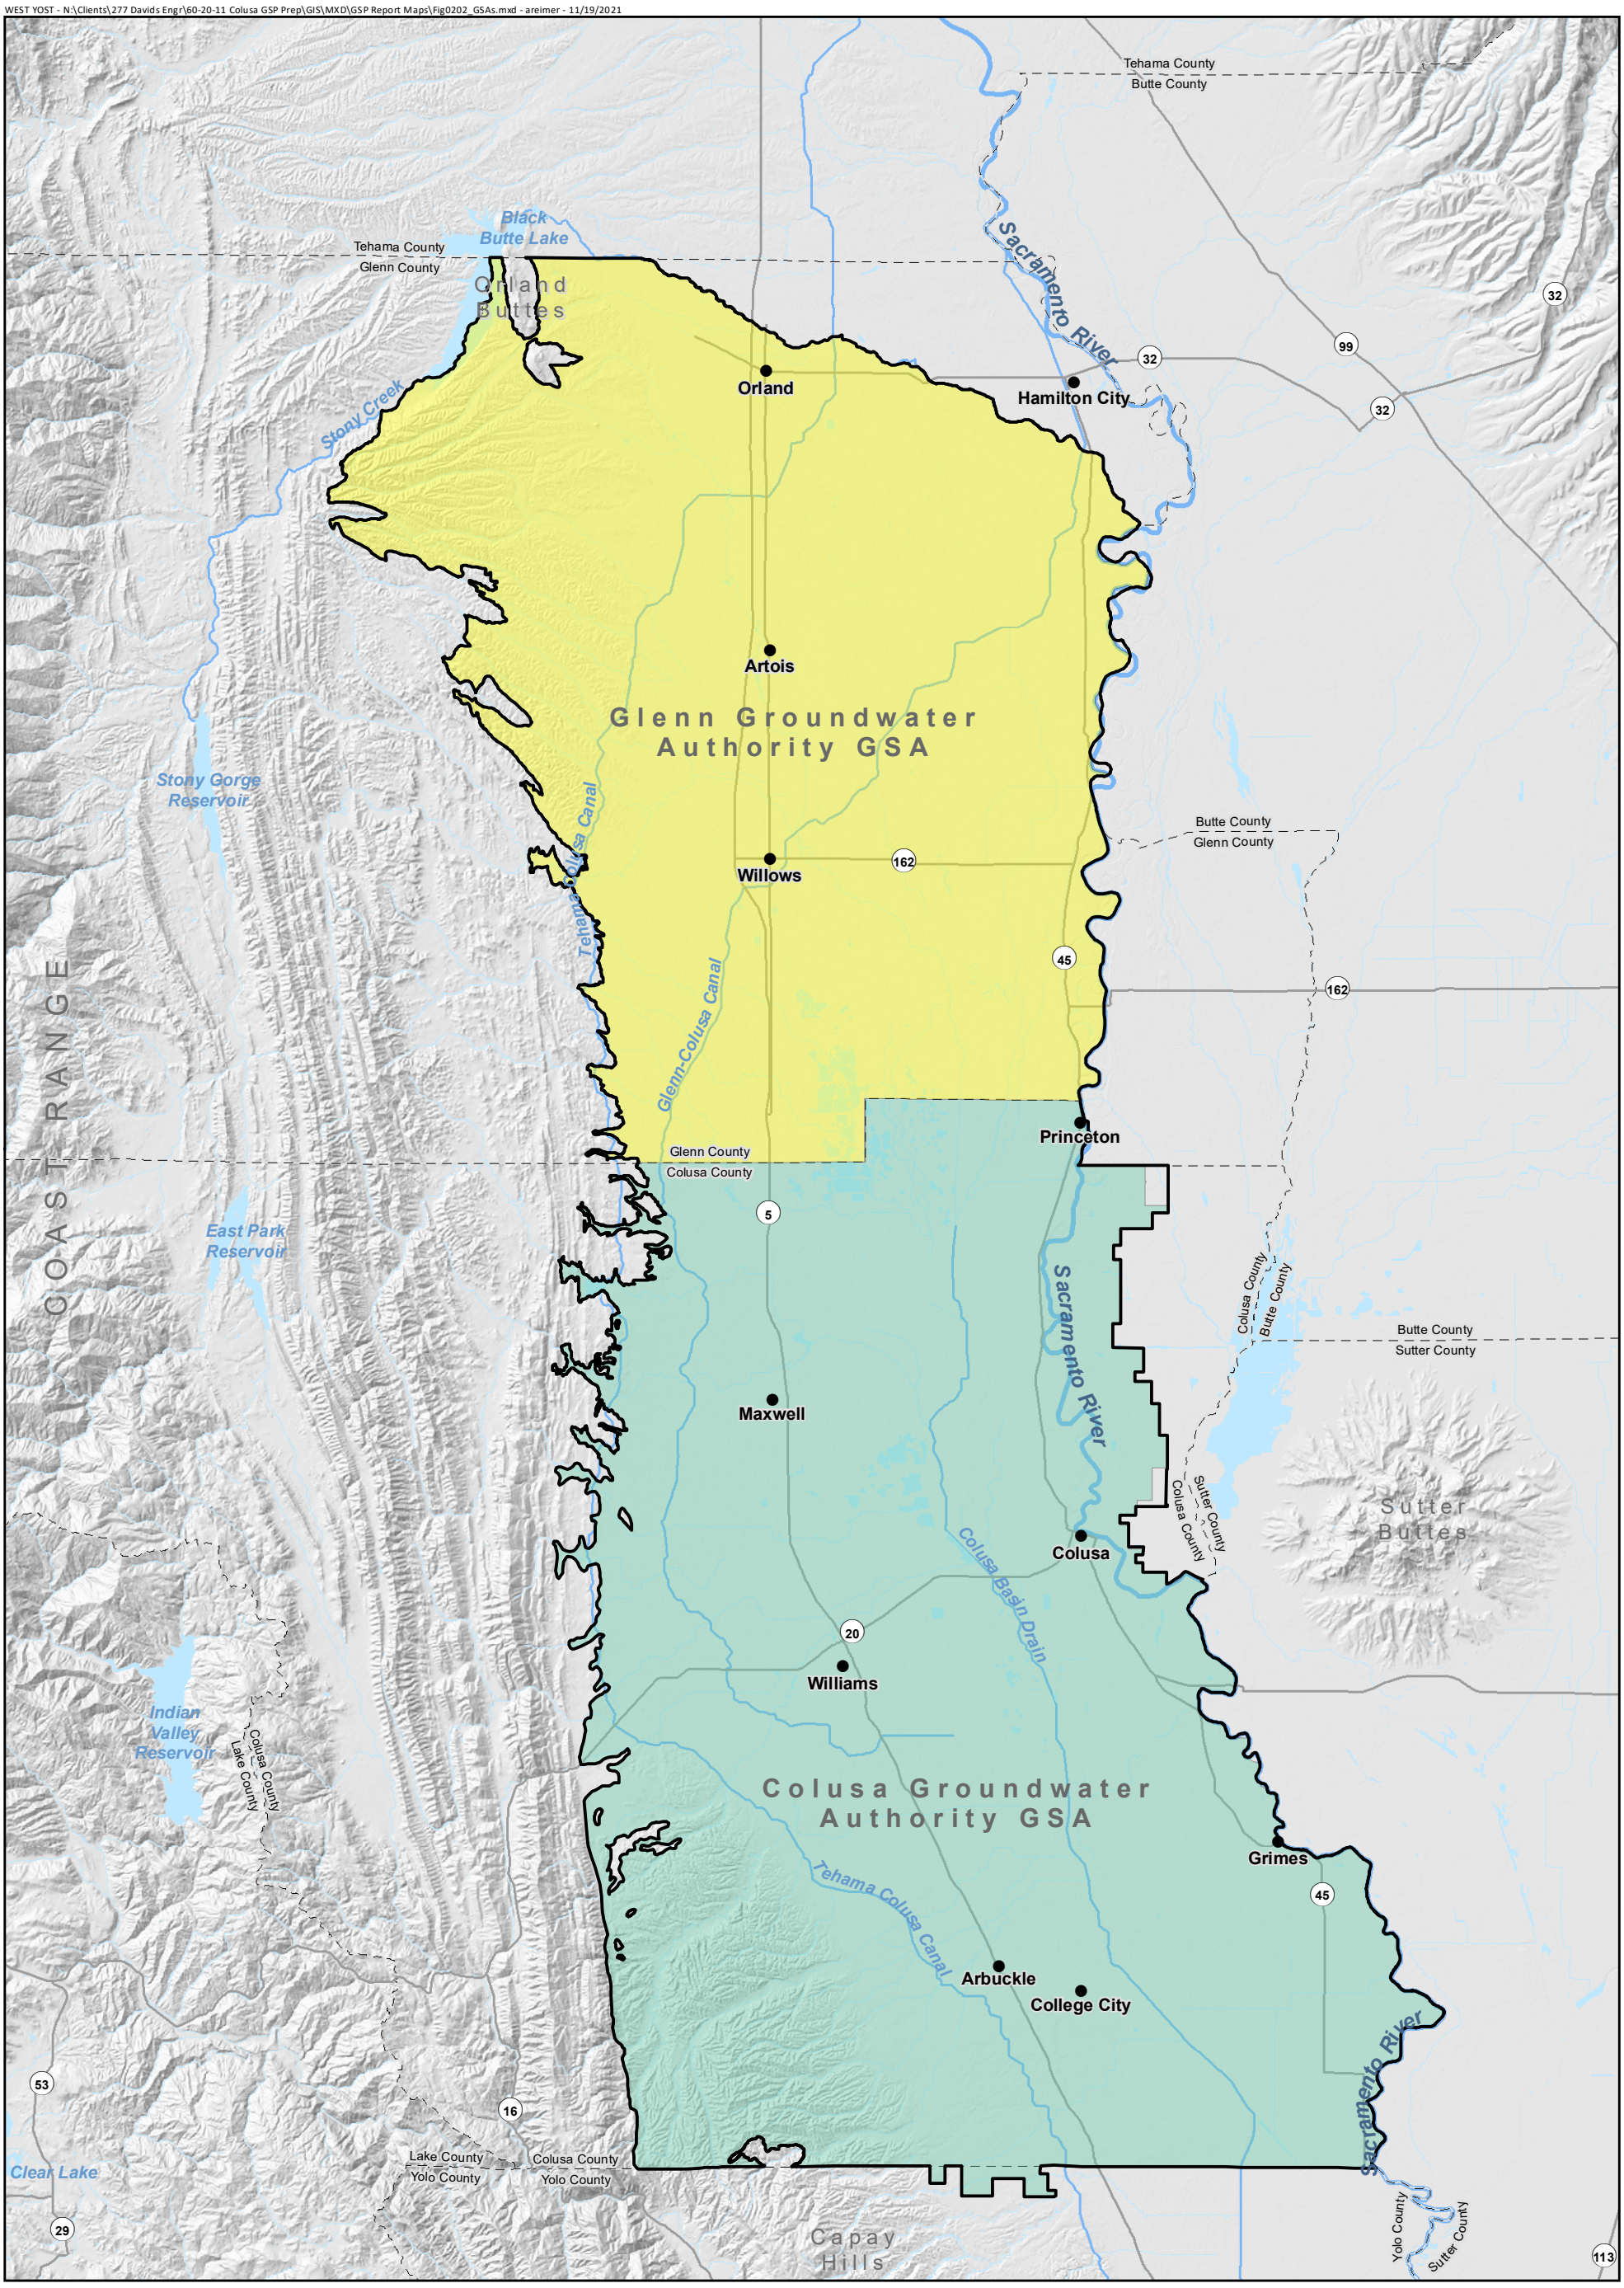
There are no adjudicated areas or areas addressed in an alternative to a GSP within the Subbasin.

2.1.2.1 Water Purveyors

The Subbasin is served by several water purveyors, providing water for urban, agricultural, and environmental resource uses (Figure 2-4). These water purveyors include cities, special districts, mutual water companies, reclamation districts, and investor-owned water utilities

Municipal Water Purveyors

Municipal water purveyors and municipal water users in the Subbasin rely on groundwater to meet domestic water needs. Refer to Table 2-2, Municipal Water Purveyors, for the municipal water purveyors in the Subbasin. A description of each of the incorporated cities' water services facilities is provided further below.



Several small water systems are located in the Subbasin. State small water systems provide piped water to the public for human consumption; serve at least five, but not more than 14, service connections; and do not regularly serve drinking water to more than an average of 25 individuals daily for more than 60 days out of the year (California Health and Safety Code §116275). State small water systems may rely on either groundwater or surface water supply.

In addition to the municipal water purveyors and State small water systems, rural domestic water needs are typically met with groundwater from individual private wells. These private groundwater pumpers are represented on the CGA Board by two appointed private groundwater pumper representatives that serve on the Colusa County Groundwater Commission. Glenn County private groundwater pumpers are represented in GGA by Glenn County and Monroeville Water District.

Municipal and rural domestic water supplies in the Subbasin largely serve Disadvantaged Communities (DACs), Severely Disadvantaged Communities (SDACs), and Economically Distressed Areas (EDAs). As described in Section 2.1.2.3, nearly all of the Subbasin is considered an EDA and many communities within the Subbasin are considered DACs, including the City of Orland, the City of Willows, the City of Colusa, and the communities of Artois, Princeton, and Grimes. Additionally, many of the rural residential and agricultural properties located within the unincorporated areas of Glenn County and Colusa County are identified as DACs or SDACs. These users typically rely on groundwater to meet their water needs.

[1] Four water agencies are represented by two member agency representatives/Director seats. Maxwell Irrigation District and Westside Water District share one Director seat. Princeton-Codora-Glenn Irrigation District and Provident Irrigation District also share one Director seat.

(a) Average annual acre-feet (af) from 2016-2020
(b) Public Water System Annually Reported Water Production and Deliver Information - 2016 average annual

City of Colusa, Colusa County

The City of Colusa provides domestic water for residential, commercial, and industrial uses within the City limits. The City obtains water from five groundwater wells that are 200 feet or more in depth. Based on the 2007 General Plan Update Master Environmental Impact Report, there were 2,126 service connections and a population of approximately 5,698. Of the service connections, 1,914 are residential land uses, 195 commercial uses, and the remainder are industrial and other uses. In 2006, the annual production for all five wells was approximately 545.8 million gallons (mg) or 1,675 acre-feet (af).

City of Williams, Colusa County

The City of Williams provides domestic water for residential, commercial, and industrial uses within the City limits. According to the 2012 General Plan, there were approximately 2,100 service connections serving an estimated population of 5,287. Water is supplied by three active and two standby groundwater wells, pumping a total of approximately 2,800 gpm. The wells are approximately 120 to 500 feet deep. The average annual water flow is about 400,000 gallons per day up to 1.2 to 1.5 mg on a peak day; the month of July is historically the peak month with approximately 36.5 mg or 1,039 af pumped in 2016.

City of Orland Water System, Glenn County

The City of Orland's primary water system consists of six wells distributed throughout the City. The wells have an average depth of approximately 200 feet, and the average depth to groundwater is generally between 20 and 50 feet. The wells produce between approximately 500 and 1,200 gpm each. The water transmission and distribution systems consist of approximately 30 miles of pipeline for a population of 7,501 residents and 2,315 service connections.

City of Willows/Cal Water Willows District, Glenn County

Domestic water service in the City of Willows, and the adjacent unincorporated area, is provided by the California Water Service Company (Cal Water), Willows District (District). The District operates seven groundwater wells, two storage tanks, and 36 miles of pipeline. From 2010 to 2015, the District delivered an average of 1.2 mg of water per day to more than 2,342 service connections. The 2015 Urban Water Management Plan prepared by Cal Water, contains many of the elements required by SGMA and thus already serves as a road map toward the implementation of SGMA for the District. Some of these components include actions to develop additional water supplies to maintain supply reliability, water quality, and recycled water.

The City of Willows Water Department owns and operates a small water system just south of the District boundaries, south of Road 53, which consists of one well and three service connections.

Agriculture Water Purveyors

Table 2-3 summarizes the main agricultural water purveyors in the Subbasin, excluding smaller Central Valley Project (CVP) contractors and diverters with service areas less than 1,000 acres.

National Wildlife Refuges

There are three National Wildlife Refuges within the Subbasin, the Sacramento National Wildlife Refuge, Delevan National Wildlife Refuge, and Colusa National Wildlife Refuge. These three refuges along with the Sutter Refuge, Sacramento River Refuge, and three wildlife management areas comprise the Sacramento National Wildlife Refuge Complex. Figure 2-4 shows the locations of the refuges.

The Sacramento National Wildlife Refuge is 10,819 acres and is comprised of 7,086 acres of managed wetlands and 3,360 acres of unmanaged wetlands, grasslands, alkali meadow, vernal pools and riparian habitats.

The Delevan Refuge consists of 5,877 acres and is comprised of approximately 4,600 acres of managed wetlands and approximately 984 acres of unmanaged wetlands, grasslands, alkali meadows, vernal pools, and riparian habitats.

The Colusa Refuge consists of over 4,686 acres. It is comprised of approximately 3,347 acres of managed wetlands and 1,191 acres of unmanaged wetlands, grasslands, alkali meadows, vernal pools, and riparian habitats. The Refuge is bisected by the Colusa Basin Drain, which drains the Subbasin southeast to the Sacramento River.

A Comprehensive Conservation Plan (CCP) guides the management of the Refuges and includes a variety management tools, including Water Management Plans. The recurring five-year Water Management Plan updates document water use, identify water supply system needs, and outline steps required to improve both efficiency and quantity of water used. The preparation of these plans is a requirement of the Central Valley Project Improvement Act, which requires the U.S. Bureau of Reclamation (USBR) to purchase and deliver water to these Refuges.

Table 2-3. Agricultural and Other Water Purveyors within the Colusa Subbasin

County	Water Purveyor	GSA Member Agency		Service Area Size, acres[a]	Primary Water Source	Annual Surface Water Supply Volume, af[b]	Supply Volume Description
		CGA	GGA				
Agricultural Water Purveyor[c]

Glenn	Orland Unit Water Users Association			27,000	SW	88,000	Average annual diversions, 2002-2016 (2017 AWMP)
Glenn	Kanawha Water District		X	17,000	SW	26,000	Average annual USBR CVP deliveries from Tehama-Colusa Canal, 1990 to 2015
Glenn	Glide Water District		X	10,000	SW	11,400	Average annual USBR CVP deliveries from Tehama-Colusa Canal, 1990 to 2015
National Wildlife Refuges							
Colusa/Glenn	USFWS Sacramento National Wildlife Refuge			11,000	SW	33,000 (50,000)[d]	Average annual supplies under all rights and contracts, 1995 to 2004 (2006 WMP) CVPIA Full Level 4 volumes shown in parentheses
Colusa	USFWS Delevan National Wildlife Refuge			6,000	SW	21,000 (30,000)[d]	Average annual supplies under all rights and contracts, 1995 to 2004 (2006 WMP) CVPIA Full Level 4 volumes shown in parentheses
Colusa	USFWS Colusa National Wildlife Refuge			4,000	SW	19,000 (25,000)[d]	Average annual supplies under all rights and contracts, 1995 to 2004 (2006 WMP) CVPIA Full Level 4 volumes shown in parentheses

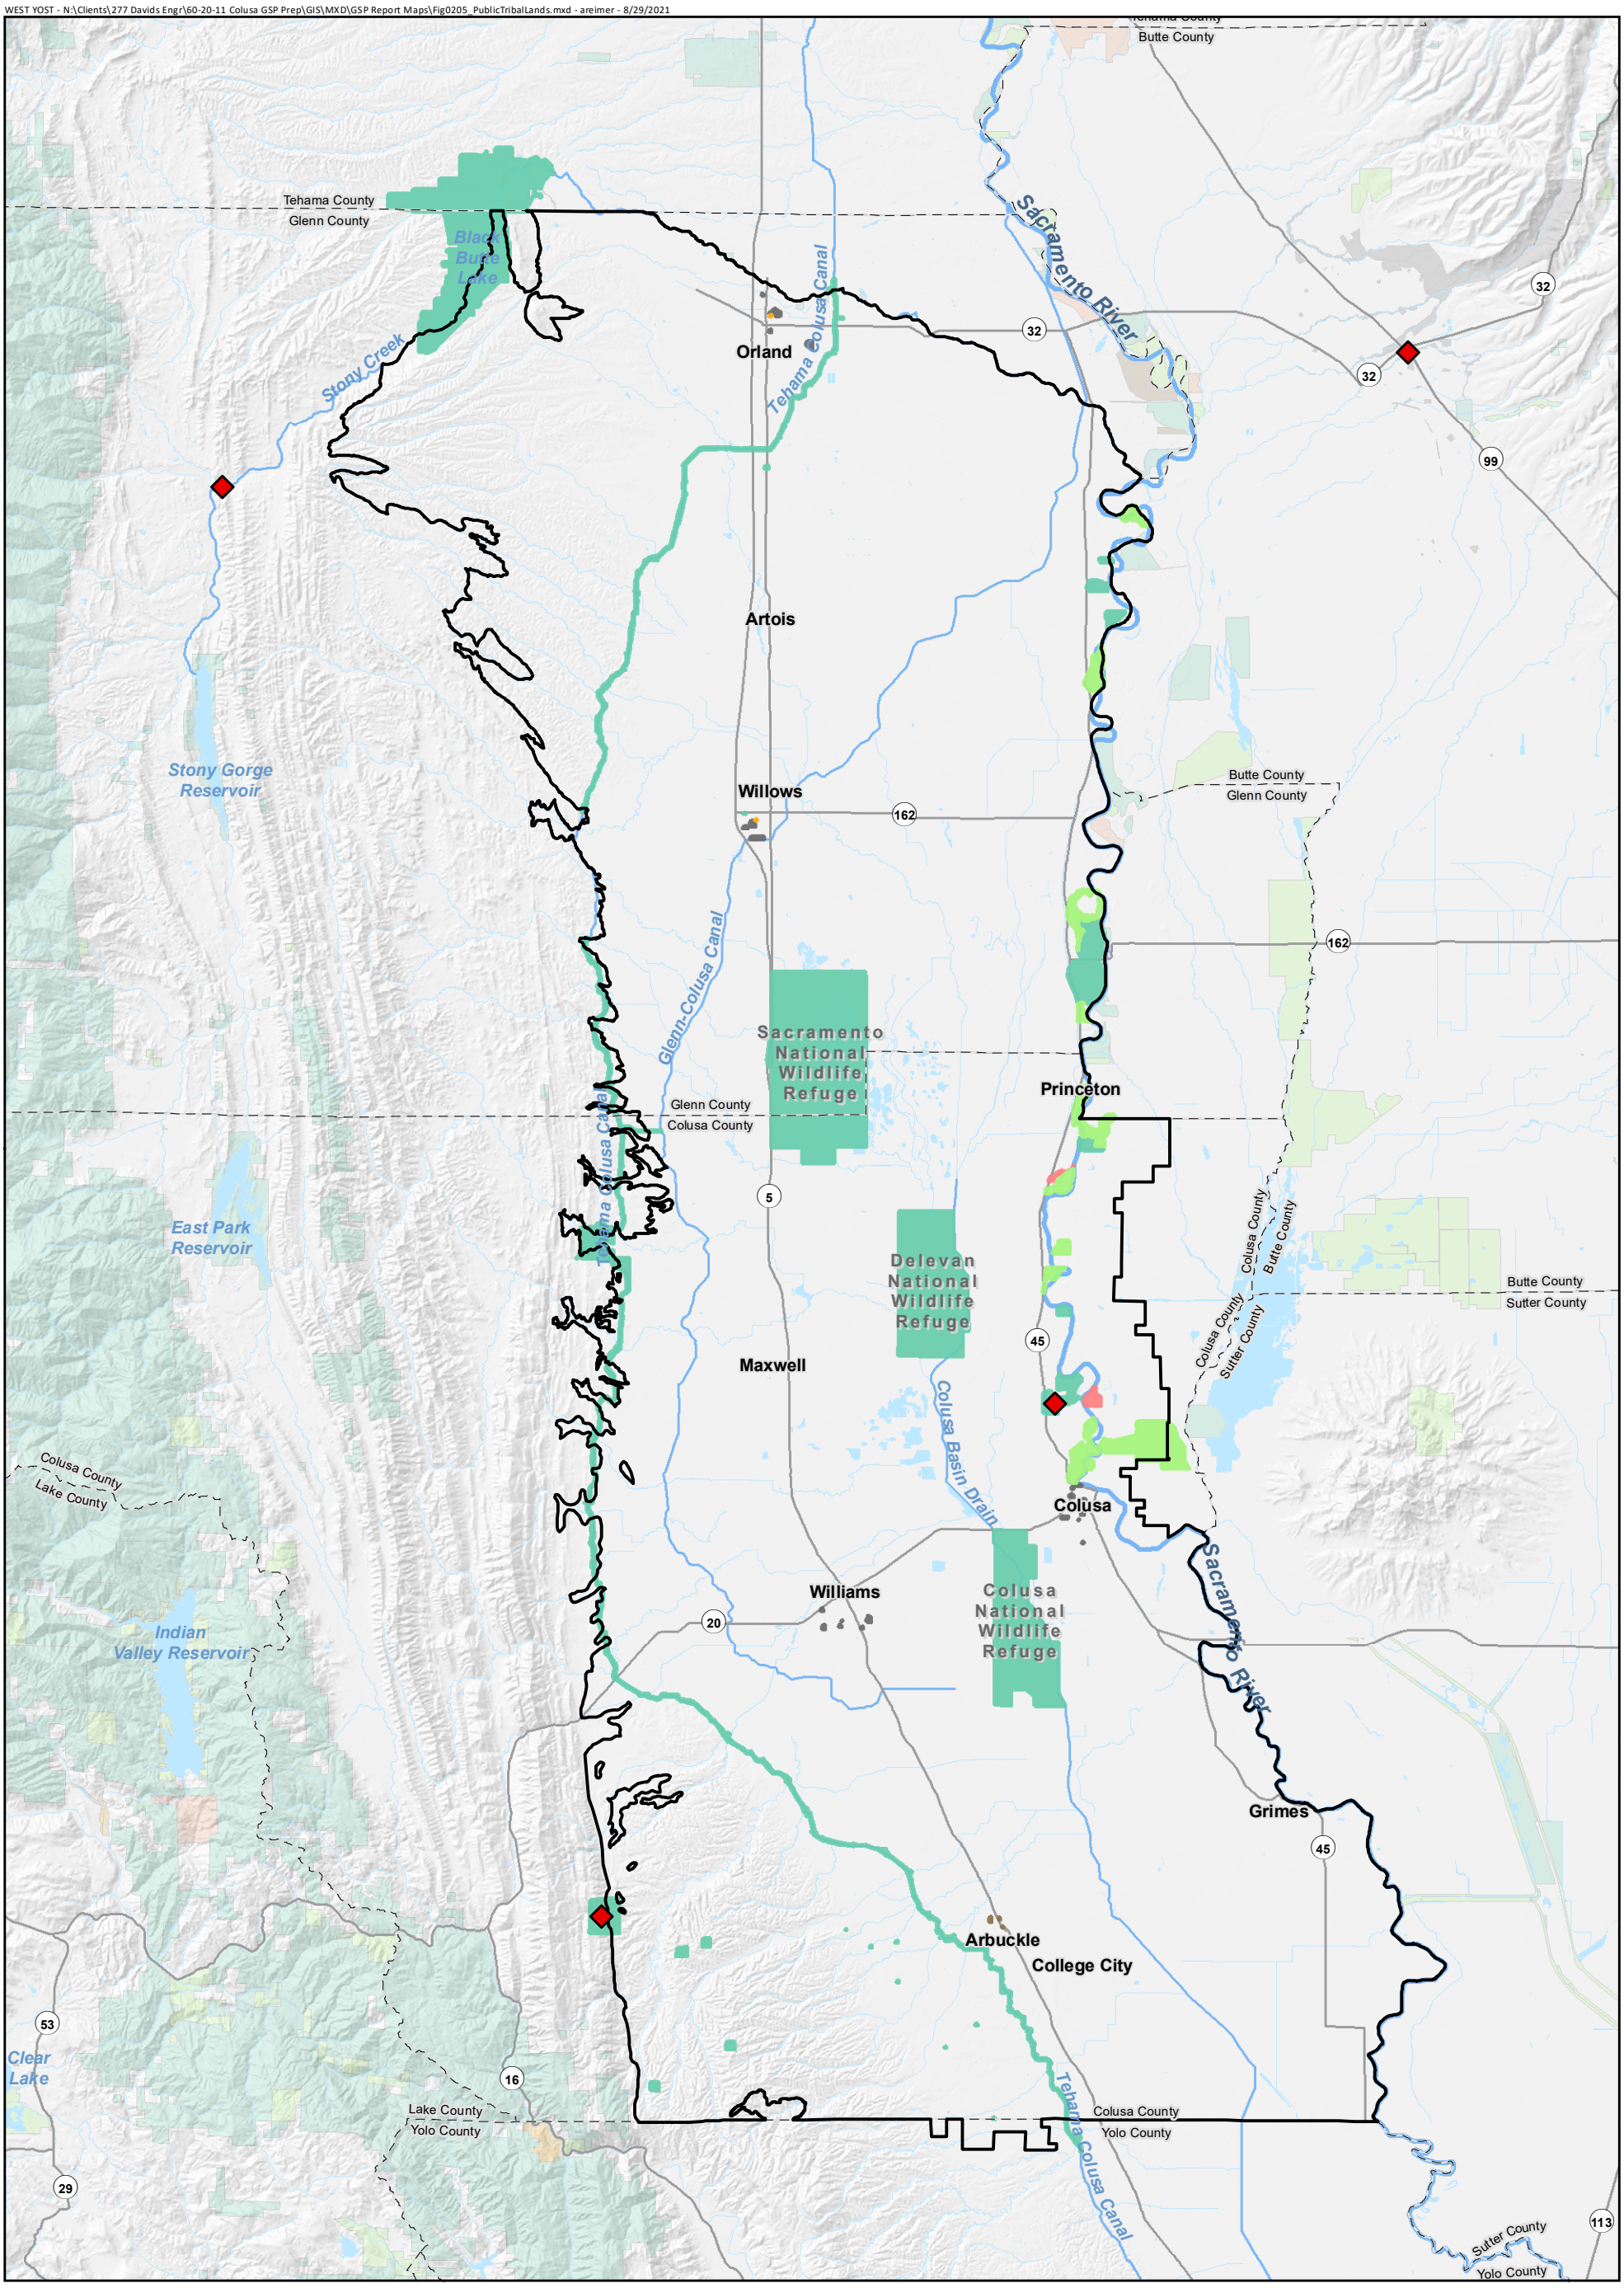
(a) Area from water district shapefiles, rounded to 1,000 acres.
(b) Volume rounded to 100 acre-feet (af). Average annual, typical annual, or maximum contract annual volume (see description).
(c) Main agricultural water purveyors in the Colusa Subbasin, excluding most smaller purveyors and diverters with service areas of less than 1,000 acres and smaller purveyors and diverters without publicly available information.
(d) Annual Full Level 4 water supplies during unconstrained conditions are shown in parentheses. During constrained conditions, these same refuges generally are provided 75% of this quantity, as stipulated in their water delivery agreements with the U.S. Bureau of Reclamation. CVPIA Full Level 4 supply quantities were not used in the projected water budgets due to the uncertainty in those quantities actually being provided.

GW = Groundwater
SW = Surface water
N/A = Not Available

2.1.2.2 Jurisdictional Boundaries of Other Agencies

There are federal, tribal, and state public lands within the Subbasin, as shown on Figure 2-5.

Federal lands located within the Subbasin include portions of land managed by the Bureau of Land Management and USBR. There are three Wildlife Refuges within the Subbasin managed by the United States Fish and Wildlife Service including the Sacramento National Wildlife Refuge, Delevan National Wildlife Refuge, and Colusa National Wildlife Refuge. These Wildlife Refuges are discussed in preceding sections of this GSP.



Tribal lands within the Subbasin are owned by the Cachil Dehe Band of Wintun Indians/Colusa Rancheria and the Cortina Indian Rancheria of Wintun Indians Public and Tribal Lands (Figure 2-5).

State lands managed by the California Department of Fish and Wildlife are primarily located along the Sacramento River.

2.1.2.3 Disadvantaged Communities

Many of the communities within the Subbasin are considered either a DAC, a community whose median household income (MHI) is less than 80 percent of the statewide MHI, or an SDAC, a community whose MHI is less than 60 percent of the statewide MHI. Disadvantaged communities are shown on Figure 2-6. The Cities of Orland, Willows, and Colusa, as well as the communities of Artois, Princeton, and Grimes are classified as census place DACs. Most of Subbasin includes rural residential and agricultural properties located within the unincorporated portions of Glenn County and Colusa County. The majority of these areas are identified as DACs or SDACs based on census blocks and census tracts.

Additionally, nearly all of the Subbasin is considered an EDA because it is rural, has a low population density, and has an MHI of less than 85 percent of the statewide MHI. The only area within the Subbasin that is not considered an EDA is the portion of the Subbasin that exists within Yolo County. The entirety of the Subbasin that is within Glenn and Colusa Counties is considered an EDA.

Source: Public and tribal lands were obtained from the State of California Governor's Office of Emergency Services (CalOES) GIS Data Hub, 2020.

Horizontal Datum: North American Datum of 1983, California State Plane Zone II, feet.

Note: Land designations outside of the Colusa Subbasin are faded back.

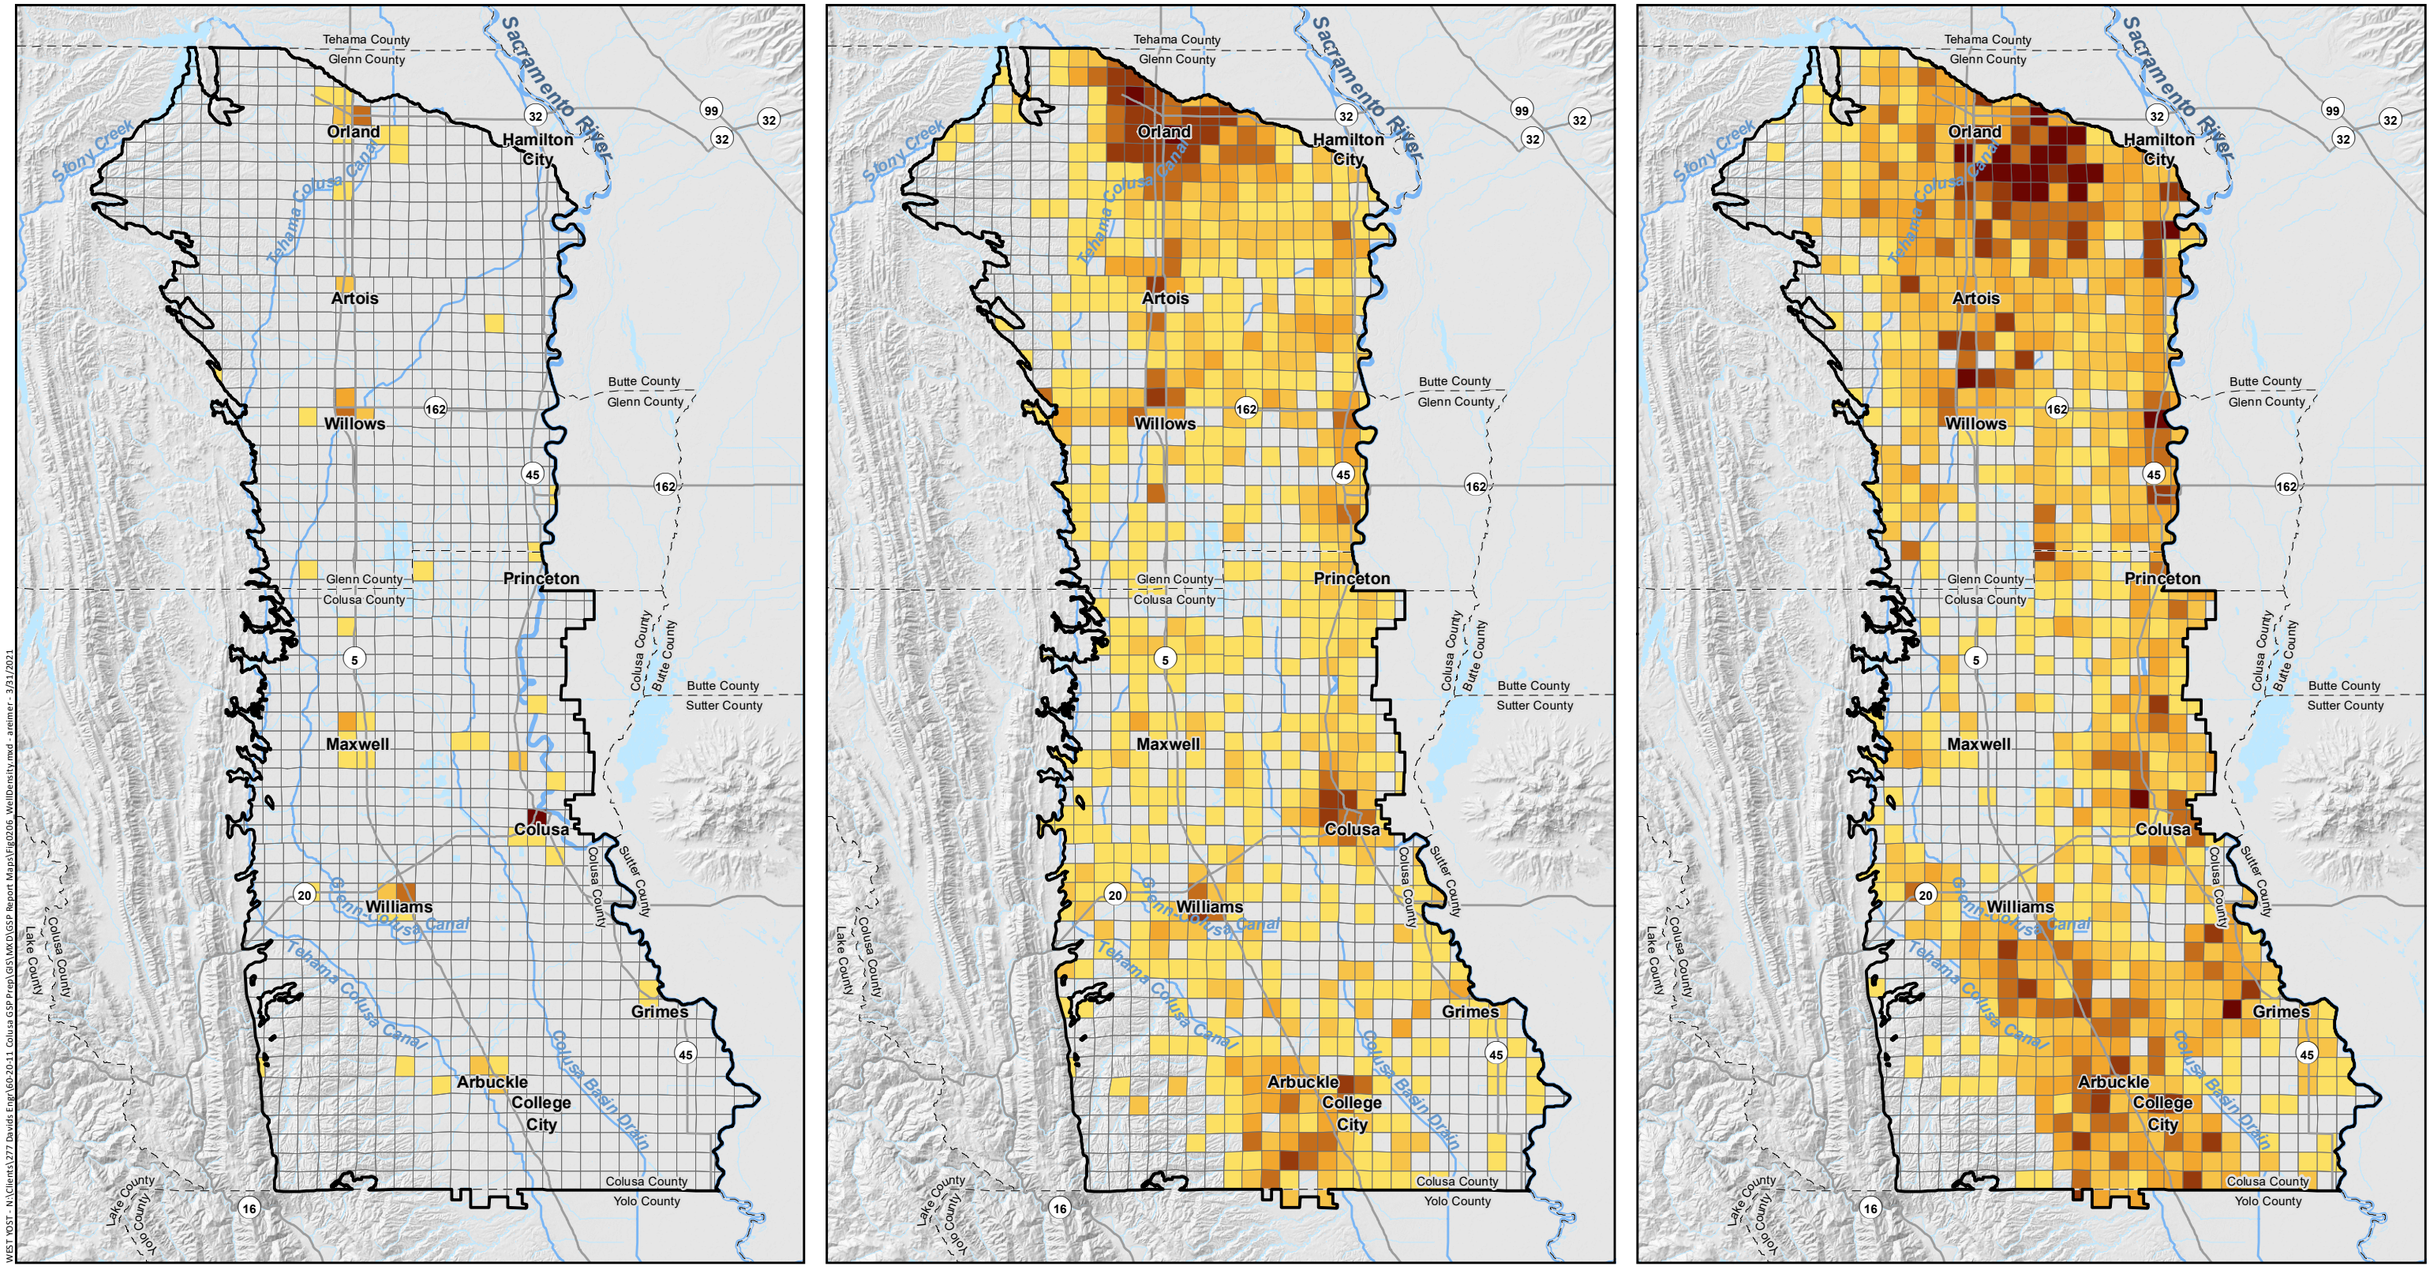
2.1.2.4 Well Density per Square Mile

The densities of public water supply, domestic, and agricultural wells per public land survey section within the Subbasin are shown in panels from left to right on Figure 2-7. Each section is approximately one square mile. The number of wells reported by section was determined using data from the California DWR Online System of Well Completion Reports (OSWCR) well completion report (WCR) database provided via the California Open Data Portal (DWR, 2021a). The downloaded dataset only includes wells with WCRs that have been submitted to DWR and is only as accurate as the information provided on the WCRs. Well locations are based on either information provided in the WCRs or are located at the center of their designated public land survey township, range, and section. As such, the well densities shown on Figure 2-6 and reported here are representative of well distribution but may not reflect the actual number of existing or active wells per well use type within the subbasin (i.e., public water supply, domestic, or agricultural well).

Public water supply wells are mostly concentrated in urban areas near cities and towns. Domestic water supply wells are more spread out throughout the Subbasin but occur in higher numbers surrounding urban areas and along the Sacramento River. The densest square mile concentration of domestic wells exceeds 100 wells and occurs near Orland. Agricultural wells are more widespread than public wells and tend to be concentrated outside the urban areas. The densest square mile concentration of agricultural wells exceeds 10 wells, an order of magnitude less than that of domestic wells.

According to the WCR database, there are approximately 73 public supply wells, 3,500 domestic wells, and 2,600 agricultural wells within the Subbasin. Averaged over the entire Subbasin, this is equivalent to approximately 0.06 public supply wells, 3.1 domestic wells, and 2.3 agricultural wells per square mile. Wells not planned for groundwater extraction, based on information provided on the WCRs, or with an unknown or unspecified use designation were not included in this analysis.



2.1.3 Existing Land Use Designations

Land use areas in the Subbasin are broadly classified across three sectors: agricultural, urban, and native vegetation (Figure 2-8). Agricultural land use (and water use) encompasses all agricultural crops reported in the Subbasin. Urban land uses are associated with the cities and communities within the Subbasin and typically include residential, commercial, industrial, public and quasi-public, and semi-agricultural land. Native lands are designated as native lands that are either privately managed or managed by the U.S. Fish and Wildlife Service as wildlife refuges.

2.2 WATER RESOURCES MONITORING AND MANAGEMENT PROGRAMS

2.2.1 Monitoring and Management Programs

Existing surface and groundwater monitoring and management programs within the Subbasin are identified below with a summary of water planning documents applicable to the Subbasin GSAs. Existing groundwater, surface water, and land subsidence monitoring locations included in the monitoring and management programs below were considered for incorporation into the Subbasin monitoring networks, as discussed in Chapter 4.

Continued monitoring is required to track the progress of the GSP implementation by providing data on groundwater and surface water availability in the Subbasin. See Chapter 6 for more details of applicable projects that require additional monitoring to fill data gaps. See Chapter 7 for details about proposed GSP studies that will fill those data gaps.

2.2.1.1 Water Planning Documents

The local agencies that formed the Subbasin GSAs have prepared and adopted water planning documents that discuss surface and groundwater supplies, distribution infrastructure, and implementation and monitoring programs.

Development and implementation of this GSP has and will continue to consider the interests of all beneficial uses and users of groundwater, including agricultural water users, municipal water users, DACs, SDACs, groundwater dependent ecosystems (GDEs) and environmental users, tribes, and other stakeholders. Implementation of this GSP will support GSP goals for the protection of DACs, SDACs, natural resources, and GDEs, in coordination with implementation of the plans listed below, consistent with SGMA regulations.

Regional Water Plans

- **Northern Sacramento Valley (NSV) Integrated Regional Water Management Plan (IRWMP) (approved 2014, updated 2020, adopted 2021):** The six counties of Butte, Colusa, Glenn, Shasta, Sutter, and Tehama have been working together to take an integrated approach to water-related issues such as economic health and vitality; water supply reliability; stormwater and flood management; water quality improvements; and ecosystem protection and enhancement. The NSV IRWMP is a collaborative effort to enhance coordination of the water resources in a region. The NSV IRWMP involves multiple agencies, stakeholders, tribes, individuals and groups to address water-related issues and offer solutions which can provide multiple benefits to the region. The NSV IRMWP was adopted by the NSV Board on April 14, 2014 and received final approval from the California DWR on July 24, 2014. The NSV IRWMP was updated in 2019/2020 to comply with new DWR requirements. In March 2020, the NSV Board adopted the Revised Draft NSV IRWMP.

- **Sacramento Valley Regional Water Management Plan (RWMP) (adopted 2006, updated 2012):** The RWMP focuses on four subbasins, including the Colusa Subbasin, and addresses water supply and water use of participating water districts. The RWMP discusses regional water measurement programs; provides analysis of water management quantifiable objectives; and actions to implement and achieve quantifiable objectives. The geographic boundary of the area covered by the Sacramento Valley RWMP and served by the participating Sacramento River Settlement Contractors (SRSC) is the portion of the Sacramento River Basin from Shasta Dam to the Sacramento metropolitan area.
- **Agricultural Water Management Plan (2012) – Participating Sacramento River Settlement Contractors:** The 2012 Sacramento Valley Regional Water Management Plan Annual Update (2012 RWMP Annual Update) was prepared by the SRSC in cooperation with the USBR, in accordance with the Regional Criteria for Evaluating Water Management Plans for the Sacramento River Contractors (Regional Criteria). The Regional Criteria specifies that the participating SRSCs will jointly file an annual update every subsequent year to report on implementation actions taken, along with any additions and revisions to the RWMP.
- **Colusa Basin Watershed Management Plan (2012):** This Watershed Management Plan focuses on the following eight goals as identified by stakeholders and the Technical Advisory Committee (TAC):
    1. Protect, maintain, and improve water quality.
    2. Promote activities to ensure a dependable water supply for current and future needs.
    3. Preserve agricultural land and open space.
    4. Manage and reduce invasive plant populations.
    5. Reduce destructive flooding.
    6. Enhance soil quality and reduce erosion.
    7. Preserve and enhance native habitat.
    8. Address unknown future effects of climate change.

Water Management Plans

- U.S. Fish and Wildlife Service (USFWS) Comprehensive Conservation Plan for the Sacramento, Delevan, Colusa, and Sutter National Wildlife Refuges – Water Management Plans
- Colusa County Water District Water Management Plan (2015)
- Orland-Artois Water District Water Management Plan (2020)

Urban Water Management Plans

- Willows District Urban Water Management Plan (2015)

Groundwater Management Plans

- **Colusa County Groundwater Management Plan (adopted 2008):** The Colusa County Groundwater Management Plan was adopted in 2008. In preparing the Groundwater Management Plan, Colusa County intended that it be applicable countywide and serve the following purposes:
    1. To be responsible stewards of the water resources in Colusa County.
    2. To be eligible for grant funding to increase the understanding of the groundwater basins underlying Colusa County.
    3. To retain local control of water management decisions.

  Colusa County's goals for groundwater management (as developed with input from the public through meetings, workshops, and surveys) are to:
    1. Ensure a Reliable Water Supply
    2. Ensure Long-Term Groundwater Sustainability
    3. Optimize Conjunctive Use of Surface Water and Groundwater
    4. Protect Water Rights
    5. Maintain Local Control
    6. Prevent Unnecessary Restrictions on Groundwater Use
- **Glenn County Groundwater Management Plan (adopted 2000, revised 2012):** The Glenn County Groundwater Management Plan was adopted in 2000 (Ordinance No. 1115), and later revised in 2012 (Ordinance No. 1237) with an aim to protect the County's groundwater resource. Incorporation of the Preliminary Plan and the Export Water Transfer Guidelines in Ordinance No. 1237 was especially important for this goal. The Glenn County Groundwater Management Plan uses the Basin Management Objective (BMO) of Groundwater Basin Management, which encompasses six key elements:
    1. Management Areas and Sub-Areas, which groups groundwater users together who have the same vested interest in maintaining the groundwater resource at mutually agreeable levels.
    2. BMO Parameters requires management objectives for minimum groundwater levels.
    3. Public input is provided through the Glenn County Water Advisory Committee.
    4. Establishing a groundwater quality monitoring network.
    5. Adaptive management to resolve non-compliance with management objectives.
    6. Enforcement and conflict resolution when a BMO threshold is exceeded.

Drought Management Plans

- **Sacramento River Settlement Contractors Drought Management Plan (2016):** Water contracts with various entities specify contractual water deliveries be made except during dry periods. During periods of reduced water supplies, deliveries are decreased in accordance with the curtailment terms in the contracts. CVP contractors along the Sacramento River can generally be grouped into two major categories: SRSCs and CVP Water Service Contractors. SRSCs within the Subbasin include Glenn-Colusa Irrigation District, Provident Irrigation District, Princeton-Codora-Glenn Irrigation District, and Reclamation

District 108. CVP Water Service Contractors within the Subbasin include 4-M Water District, Colusa County Water District, Cortina Water District, Davis Water District, Glenn Valley Water District, Glide Water District, Holthouse Water District, Kanawha Water District, La Grande Water District, Myers-Marsh Mutual Water District, Orland-Artois Water District, and Westside Water District.

- City of Willows General Plan

Municipal Service Reviews

- The Local Agency Formation Commission (LAFCO) in each County conducts reviews of municipal services provided in a county by region, subregion or other designated geographic area, as appropriate, for the service or services provided by a governing entity. Municipal Service Reviews (MSRs) provide written summaries of the six topics pertaining to service infrastructure:
    1. Growth and population projections for the affected area.
    2. The location and characteristics of any disadvantaged unincorporated communities within or contiguous to the sphere of influence.
    3. Present and planned capacity of public facilities and adequacy of public services, including infrastructure needs or deficiencies.
    4. Financial ability of agencies to provide services.
    5. Status of, and opportunities for shared facilities.
    6. Accountability for community service needs, including governmental structure and operational efficiencies.
- The following GSA member agencies have readily available MSRs:
    1. City of Colusa MSR (Draft 2021)
    2. City of Orland MSR (2014)
    3. City of Willows MSR (2014)
    4. Kanawha / Glide Water District MSR (2020)
    5. Orland-Artois Water District MSR (2019)

2.2.1.2 Surface Water Monitoring and Management Programs

Surface water flows into and within the Subbasin are monitored through existing federal, state, regional, and local programs. Data and spatial information from these monitoring programs were used to support GSP development, including water budget development, per 23 CCR Section 354.18.

Federal, State, and Regional Programs

Table 2-4 lists the existing surface water monitoring networks with publicly available data and their respective websites.

Table 2-4. Existing Surface Water Monitoring Programs

Surface Water Monitoring Network	Responsible Agency	Surface Water Monitoring Type	Website
National Water Information System (NWIS)	U.S. Geological Survey (USGS)	Discharge	https://waterdata.usgs.gov/nwis
Water Data Library (WDL)	California Department of Water Resources (DWR)	Discharge	http://wdl.water.ca.gov/waterdatalibrary/
California Data Exchange Center (CDEC)	California DWR and U.S. Bureau of Reclamation	Discharge; Reservoir Conditions	http://cdec.water.ca.gov/cdecstation2/ https://www.usbr.gov/

Local Programs

Local monitoring programs in the Subbasin include:

- Colusa County Water District's Supervisory Control and Data Acquisition (SCADA) system, which is used to automate and measure incoming flows to the distribution system from canal side pumping facilities (2010 Water Management Plan [WMP]).
- Colusa County Water District's use of SonTek, McCrometer, and Venturi flow meter devices to measure and record inflows.
- GCID's diversion metering and publicly-available online reporting system, in compliance with SB 88 (https://www.gcid.net/sb88compliance).
- GCID's main canal SCADA and automation project (https://www.gcid.net/operations-main-canal).
- GCID's drain outflow monitoring project, with water measurement and telemetry equipment at key outflow sites (https://www.gcid.net/operations-drain-outflow).
- Orland-Artois Water District's (OAWD) distribution system metering and SCADA system (2020 WMP), including:
  - Metered inflows using Venturi meters and Doppler meters across five locations.
  - SCADA system used for monitoring and operating pumps.

- Orland Unit Water Users Association's (OUWUA) SCADA system, which has been expanded and enhanced in recent years to include more than 10 additional sites and additional outflow monitoring capabilities (2017 Agricultural Water Management Plan [AWMP]).
- OUWUA's use of Rubicon FlumeGates, SonTek acoustic Doppler meters, propeller meters, and McCrometer magnetic flow meters (among other) to measure and record deliveries (2017 WMP).
- OUWUA's records of grower deliveries in its water orders database (2017 WMP).
- Westside Water District's Tehama-Colusa Canal delivery monitoring system, including McCrometer propellers and SonTek meters installed at canal mileposts 71.46 through 90.00 (2010 WMP).
- RD108's SCADA system used to measure incoming flows.
- RD108's delivery measurement system and water accounting database.

Efficient Water Management Practices

Water conservation and water use efficiency are important considerations in achieving groundwater sustainability. Efficient water management practices (EWMPs), as defined in CWC §10902, include all reasonable and economically justifiable programs to improve the delivery and use of water used for agricultural purposes. Broad efforts to improve water use efficiency in areas across the Subbasin are identified in the General Plans of counties and cities that overlie the Subbasin.

For agricultural water suppliers that must develop, adopt, and implement AWMPs, CWC §10608.48 identifies key EWMPs that suppliers must implement, some without exception and some if locally cost-effective and technically feasible. Non-exempted agricultural water suppliers throughout the Subbasin have adopted and are currently implementing AWMPs. Information on specific activities, programs, and efforts to implement key EWMPs can be found in those AWMPs.

For CVP contractors that must develop, adopt, and implement WMPs, implementation of key Best Management Practices (BMPs) is also described throughout their WMPs. These BMPs generally align with EWMPs described in the AWMPs and are aimed at improving water use efficiency. CVP contractors throughout the Subbasin are actively implementing WMPs. Information on specific activities, programs, and efforts to implement key BMPs can be found in those WMPs.

Irrigated Lands Regulatory Program

The Central Valley Regional Water Quality Control Board (CVRWQB) has adopted waste discharge requirements (WDRs) for discharges from irrigated commercial croplands to protect both surface water and groundwater supplies. When land is in agricultural production it is generally irrigated and fertilized. It is assumed that portions of the soil amendments, particularly fertilizer, are converted to nitrate, which has the potential to percolate into the groundwater. The Irrigated Lands Regulatory Program (ILRP) regulates such discharges. Growers can manage the loading of nitrate to groundwater through the implementation of effective management practices. Commercial irrigated lands, including managed wetlands, are required to obtain regulatory coverage.

2.2.1.3 Groundwater Monitoring and Management Programs

Both Counties currently have wells included in California's Statewide Groundwater Elevation Monitoring Program (CASGEM) program. Glenn County also has a Basin Management Objective groundwater level monitoring well network. Colusa County's current groundwater monitoring network consists of wells

originally identified in its Groundwater Management Plan (GMP) but has since been revised. These and other existing groundwater monitoring programs are described in more detail in the following sections. Proposed new groundwater monitoring sites were evaluated based on existing sites from DWR and USGS groundwater monitoring networks, and recommendations from County staff.

Groundwater Level Monitoring

Table 2-5 lists existing groundwater level monitoring programs with publicly available data and their respective websites.

Table 2-5. Existing Groundwater Level Monitoring Programs

County-Specific Groundwater Level Monitoring Programs	County of Colusa and County of Glenn	Colusa County: http://countyofcolusa.org/index.aspx?NID=660 Glenn County: http://www.countyofglenn.net/committee/water-advisory-committee/management-plan

Groundwater Extraction Monitoring

The replenishment of groundwater extractions occurs through various forms of recharge. The types and amounts of historical and current recharge are described in detail in Section 3.3 (Water Budget Information), and future estimates of recharge are discussed in Chapter 3 and detailed in Appendix 3D (Groundwater Model Documentation). Future replenishment of groundwater extractions that will occur with implementation of projects and management actions (PMAs) for this GSP are described in detail in Chapter 6.

Groundwater Quality Monitoring

Table 2-6 lists the groundwater quality monitoring networks with publicly available data and their respective websites.

Violations of drinking water quality regulations, which could impact access to clean drinking water and violate California Water Code Section 106.3, are included in the U.S. Environmental Protection Agency (USEPA) Safe Drinking Water Information System (SDWIS) website, which is listed in Table 2-6.

Table 2-6. Existing Groundwater Quality Monitoring Programs

Groundwater Monitoring Network	Responsible Agency	Website
National Water Information System (NWIS)	U.S. Geological Survey (USGS)	https://waterdata.usgs.gov/nwis
Water Data Library (WDL)	California Department of Water Resources (DWR)	http://wdl.water.ca.gov/waterdatalibrary/
Public Water Agencies and Municipalities	State Water Resources Control Board (SWRCB) Division of Drinking Water (DDW) and U.S. Environmental Protection Agency (USEPA)	https://data.ca.gov/dataset/drinking-water-public-water-system-information , https://sdwis.waterboards.ca.gov/PDWW/ , https://www.epa.gov/enviro/sdwis-search

(a) The InSAR sources currently house unprocessed raw survey data but not interpretative reports for specific regions. Some of the reports using InSAR to study subsidence specific to California can be found on DWR's website

(b) Sacramento Valley Height-Modernization project data are not available online.

2.2.2 Impacts to Operational Flexibility

There are existing groundwater management and/or monitoring programs that may limit the operational flexibility during implementation of the GSP, including design criteria, flood control programs, measures that limit groundwater pumping, or limitations on surface water deliveries reducing surface water supplies available for conjunctive use programs. Ongoing coordination with the entities responsible for these programs will support operational flexibility. Ongoing coordination with the entities responsible for the surface water and groundwater monitoring programs described above will support GSP implementation.

2.2.3 Groundwater Ordinances

Colusa County Code, Chapter 43, Groundwater Management, provides guidance for groundwater transfers and groundwater substitution practices to assure the overall economy and environment of the County is protected by fostering prudent water management practices.

Glenn County Code Section 20.030, Groundwater Coordinated Resource Management Plan, provides guidance for the continued availability of groundwater by limiting the extraction of groundwater through groundwater monitoring, protecting groundwater quality, and minimizing land subsidence. In addition, Section 20.080 provides well drilling requirements prior to the drilling or abandonment of a well, and Exhibit C contains export water transfer guidelines.

2.2.4 Conjunctive Use Programs

Surface water and groundwater are used conjunctively throughout the Subbasin to meet water management objectives. Generally, within each agricultural water purveyor's service area, available surface water is used on a preferential basis to satisfy crop water requirements, with groundwater pumped by private landowners as needed to supplement available surface water supplies. The amount of groundwater pumped in any given year depends primarily on the crop water requirements (which vary by the crop types planted each year and weather conditions), and on the quantity of surface water available during that year.

For the agricultural water purveyors with highly reliable and adequate surface water supplies, including the SRSCs, private groundwater pumping is generally small compared to surface water use, except in years when their surface water supplies are reduced according to settlement contract terms, and in years when surface water is transferred (both within and outside the Subbasin), and groundwater is pumped to substitute for transferred surface water.

The CVP Water Service Contractors along the Tehama Colusa Canal have federal contracts that provide less reliable surface water supplies, which can vary from zero to 100 percent of their maximum contract quantities and is dependent on annual CVP water allocation decisions made by USBR. Consequently, groundwater pumping is highly variable depending on each year's water allocation and, to a lesser extent, variability in crop water demands.

Conjunctive use also occurs across purveyor boundaries involving transfers of temporarily available excess surface water from some agricultural water purveyors to others who desire to use more surface water to conserve groundwater supplies. In some years, surface water transfers occur from entities outside the Subbasin to Subbasin purveyors, also reducing the amount of groundwater pumping.

Colusa County Code, Chapter 43, Groundwater Management, encourages the conjunctive use of surface water and groundwater supplies.

2.3 LAND USE ELEMENTS OR TOPIC CATEGORIES OF APPLICABLE GENERAL PLANS

This section provides information on the general plans within the Subbasin.

2.3.1 Summary of General Plans/Other Land Use Plans

California Government Code (§65350-65362) requires that each county and city in the state develop and adopt a General Plan. The General Plan is a comprehensive long-term plan for the physical development of the county or city and must contain eight state-mandated elements including: land use, housing, circulation, conservation, noise, safety, open space, and environmental justice. The General Plan may also contain other voluntary elements.

General Plans and information from other land use planning activities were compiled for review and consideration during GSP preparation and for coordination during GSP implementation. This section includes a summary of those plans being implemented in the Subbasin.

Two counties and four cities share land use planning responsibilities and authorities for the Subbasin. These include:

- Colusa County
- Glenn County
- City of Colusa
- City of Williams
- City of Orland
- City of Willows

Most of the General Plans prepared by these entities contain goals, objectives, and policies relating to water supplies, water use, water quality, and water resources. Land use designations, assumptions on growth, preservation of agricultural lands, or protection of environmental resources are examples of land use planning that could result in changes in water use over the planning horizon.

As part of the GSP preparation, General Plans for Colusa and Glenn Counties and the cities of Colusa, Williams, Orland, and Willows were reviewed. City and County boundaries are shown in Figure 2-1.

There are no other land use plans applicable within the Subbasin.

2.3.1.1 Colusa County General Plan

In July 2012, Colusa County adopted its 2012 Comprehensive General Plan Update (Colusa County, 2012). The General Plan area covers the entire County, which overlies the Colusa County portion of the Subbasin, as shown in Figure 2-1. Although the protection of natural resources in the County is addressed throughout the General Plan, key goals with respect to water resources are contained in the Agriculture Element and Conservation Element. Table 1 of Appendix 2A identifies the selected Colusa County General Plan Goals and Policies applicable to water resources management.

2.3.1.2 Glenn County General Plan

Glenn County's current General Plan was last updated in 1993, and thus is undergoing a comprehensive update. It is anticipated that the General Plan Update will take place from 2019 through the fall of 2021. The General Plan area covers the entire County, which overlies the Glenn County portion of the Subbasin, as shown in Figure 2-2. The General Plan goals, policies, and implementation presented in Table 2 of Appendix 2A are from the 1993 General Plan and are divided into three subject areas: Natural Resources, Public Safety, and Community Development. Table 2 of Appendix 2A identifies the selected Glenn County General Plan Goals, Policies, and Implementation measures applicable to water resources management.

2.3.1.3 City of Colusa General Plan

In October 2007, the City of Colusa adopted its 2005-2025 General Plan Update (City of Colusa, 2007). The General Plan area covers the City of Colusa, which is located adjacent to the Sacramento River in the eastern portion of Colusa County within the Subbasin, as shown in Figure 2-1. Although the protection of natural resources in the City is addressed throughout the General Plan, key goals with respect to water resources are contained in Land Use Element; Community Character and Design Element; Safety Element; the Parks, Recreation and Resource Conservation Element, of which includes water resources; and Municipal Facilities Element. Table 3 of Appendix 2A identifies the selected City of Colusa General Plan Goals, Policies, and Implementation Actions applicable to water resources management.

2.3.1.4 City of Williams General Plan

In May 2012, the City of Williams adopted its 2010 General Plan Update (City of Williams, 2010). The General Plan area covers the City of Williams, which is located in the central portion of Colusa County within the Subbasin, as shown in Figure 2-1. Key goals with respect to water resources are contained throughout the General Plan Elements. Table 4 of Appendix 2A identifies the selected City of Williams General Plan Goals and Policies applicable to water resources management.

2.3.1.5 City of Orland General Plan

The City of Orland is located in the northeast portion of Glenn County within the Subbasin, as shown in Figure 2-1. In 2003, the City of Orland updated its General Plan through a comprehensive review of all elements. Previous to that, minor revisions to the General Plan had been made in 2000, with the original adoption of the Plan in 1974. The 2008-2028 General Plan Update revises the 2003 General Plan, in order to reflect upon changing conditions and issues, and to provide a direction for the future growth of the City. The Orland General Plan is a comprehensive document that provides policies and guidelines for the future expansion and development of the community. The City addresses key goals and policies with respect to water resources within in Safety Element and Open Space, Conservation and Public Facilities Element. Table 5 of Appendix 2A identifies the selected City of Orland General Plan Goals, Policies, and Programs applicable to water resources management.

2.3.1.6 City of Willows

The City of Willows is located in the southern portion of Glenn County within the Subbasin, as shown in Figure 2-1. The City of Willows General Plan was adopted in 1999, with land use amendments made in 2000 and 2010. The Willows General Plan provides policies and guidelines for the future expansion and development of the community. The City addresses key goals and policies with respect to water resources. Table 6 of Appendix 2A identifies the selected City of Willows General Plan Goals, Policies, and Programs applicable to water resources management.

2.3.2 Implementation Effects on Water Demands and Sustainability

All six of the county and city General Plans in the Subbasin were adopted prior to the development of the GSAs and this GSP. Consequently, these General Plans have not directly considered the potential implications or impacts of this GSP's implementation on urban water demands or supplies within these jurisdictions. It should be noted that Glenn County is currently preparing a comprehensive General Plan Update and may take into consideration sustainable water actions identified in this GSP.

Each of the General Plan's land use elements and land use plans forecast future land development and make assumptions for future urban and agricultural water demands.

Typically, unincorporated communities depend on community water systems that may rely on either surface or groundwater, or both. Rural residential land uses not part of a community system typically rely on individual groundwater wells. Developed urban land uses, such as that within cities, typically rely on groundwater supplies accessed by municipal wells. Therefore, when cities grow or rural densities increase, generally surface water use decreases and groundwater demand increases. The GSP incorporates actions that encourage land use agencies to participate in efforts to increase groundwater recharge to offset increased water demands. Depending on changing future conditions in the Subbasin, the GSP also incorporates potential demand management actions that could be implemented, if needed, to offset water demands and support groundwater sustainability (see Section 6.5.2).

2.3.2.1 Effects on Colusa County Water Demands

Several goals and policies of the Colusa County General Plan work to balance agricultural land uses with preserving and protecting waters, soils, and natural resources necessary to ensure agricultural operations. Policies support water development projects that provide additional sources of water for agricultural use, yet also encourage the preservation of water resources. In addition, the General Plan requires that new residential development connect to municipal water systems and requires development to demonstrate sufficient water supplies are available. The General Plan encourages conservation of water resources including the conservation of biological communities that protect wetlands, riparian habitat, and aquatic resources and thus contribute to the protection of groundwater resources and water quality. The General Plan includes goals and policies that work to ensure a sustainable and long-term supply of reliable water to meet the needs of residents, businesses, and agricultural land uses. Land use policies provide for the harmonious use of land and the preservation of the County's resources, including water. Lastly, the General Plan encourages local, regional, and state multi-agency planning efforts as well as coordination with water providers to manage water supplies and avoids groundwater overdraft, water quality degradation and other adverse environmental impacts. Refer to Appendix 2A for selected Colusa County General Plan Goals and Policies.

GSP implementation is anticipated to be consistent with the Colusa County General Plan's goals to balance agricultural land uses with the preservation and protection of water resources necessary to ensure agricultural operations. The GSP supports these policies by identifying and considering PMAs that work to reduce groundwater extraction, promote groundwater recharge, and utilize additional surface water for irrigation. Although implementation of the GSP would alter the source of water for irrigation to promote groundwater sustainability, it does not alter water demands.

2.3.2.2 Effects on Glenn County Water Demands

The Glenn County General Plan is undergoing a comprehensive update. However, the existing General Plan does address the protection of water resources in connection with the preservation of agricultural lands and the recognition of the value of agricultural land uses, particularly ricelands for habitat, watershed management, and groundwater recharge. General Plan policies oppose the exportation of groundwater, protect groundwater recharge areas and groundwater quality, encourages water conservation and education, promotes interagency coordination. The General Plan also addresses wetlands, aquatic resources, and riparian habitat protection in conjunction with supporting efforts to improve water availability for agricultural users. Water quality policies include the protection of groundwater to ensure that the holding capacity of the area is not exceeded. The General Plan address coordination between the County and water purveyors including creating uniform policies and standards for providing cost-effective water services, particularly in unincorporated areas located within city urban limits.

Refer to Appendix 2A for selected Glenn County General Plan Goals and Policies applicable to water demand.

GSP implementation is anticipated to be consistent with the Glenn County General Plan's goals to protect water resources and aquatic resource habitat in connection with the preservation of agricultural land uses. The GSP supports these policies by identifying and considering PMAs that reduce groundwater extraction and focuses on using surface water for agricultural irrigation and groundwater recharge. Although implementation of the GSP would alter the source of water for irrigation to promote groundwater sustainability, it does not alter water demands.

2.3.2.3 Effects on City of Colusa Water Demands

The City of Colusa's General Plan Goals and Policies provide for a logical land use planning process that includes adequate management of public services, including water supply. As part of the implementation of the General Plan the City has prepared water and storm drainage master plans to address water quality, supply, recycling, distribution, and water conservation. The General Plan also works to ensure that new development respects the natural environment, protects the City's water resources, and minimizes the development of new water sources and facilities while providing water services. Refer to Appendix 2A for selected City of Colusa General Plan Goals and Policies applicable to water demand and management.

GSP implementation focuses on the protection of groundwater resources and identifies and considers PMAs that focus on surface water use for agricultural irrigation and groundwater recharge. Implementation of the GSP would not conflict with the City's water supply, service, and conservation goals nor would it alter water demands.

2.3.2.4 Effects on City of Williams Water Demands

The City of Williams General Plan identifies policies that pertain to water supply and associated demand in the land use and character, public safety and facilities as well as open space and conservation elements. New development in the City requires that adequate public services, including water supply, is available. In addition, although not specifically related to water demand, the preservation of water related resources, including wetlands, riparian areas, and other aquatic habitats provides for improved water quality of water supply sources, including groundwater. Implementing actions identify the need for groundwater protection measures in subdivisions as well as developing water efficient landscaping standards for new development. Refer to Appendix 2A for selected City of Williams General Plan Goals, Policies, and Implementing Actions that address water demand and management.

GSP implementation focuses on the protection of groundwater resources and identifies and considers PMAs that focus on surface water use for agricultural irrigation and groundwater recharge. Implementation of the GSP would not conflict with the City's water quality, aquatic resources, and water conservation goals nor would it alter water demands.

2.3.2.5 Effects on City of Orland Water Demands

The City of Orland General Plan Safety Element policies address the potential for subsidence associated with groundwater extraction. Goals include the conservation, enhancement, and management of water resources to protect water quality and ensure adequate long-term supply for domestic, agricultural, and industrial land uses. Policies support maintaining groundwater infiltration, improving groundwater quality, and encourages water conservation. Refer to Appendix 2A for selected City of Orland General Plan Goals and Policies applicable to water demand and supply.

GSP implementation focuses on the protection of groundwater resources and identifies and considers PMAs that focus on surface water use for agricultural irrigation and groundwater recharge. Implementation of the GSP would not conflict with the City's water quality, subsidence, and water conservation goals nor would it alter water demands.

2.3.2.6 Effects on City of Willows Water Demands

The City of Willows General Plan Land Use Element addresses new growth and the desire to maintain flexibility to changing conditions. Goals include the provision of adequate services, including water. Refer to Appendix 2A for selected City of Willows General Plan goals, objectives, and policies. It is anticipated that implementation of the GSP and the PMA addressing urban water conservation for the City of Willows would reduce water demands and thereby reduce groundwater extraction thereby promoting groundwater sustainability.

2.3.3 Effects of Land Use Plans Outside Subbasin

Outside the Subbasin, other land use plans have been developed as part of the general plans for Tehama County to the north, Butte and Sutter Counties to the east, and Yolo County to the south. These general plans are similar in scope to the Colusa and Glenn County General Plans described above in that they each contain goals, policies, and implementing actions that address water supply, water quality, conservation, enhancement, and management of water resources for a variety of land uses. In addition, the subbasins surrounding the Subbasin, which include Corning Subbasin to the north; Vina, Butte, and Sutter Subbasins to the east; and Yolo Subbasin to the south, have been identified as either high or medium priority and are also required to prepare and be managed under a GSP by January 31, 2022. As such, future land use changes in the jurisdictions within these subbasins will also need to be managed to achieve sustainability. As long as these subbasins are managed to achieve sustainability, each jurisdictions' General Plan and corresponding land use plan are not expected to affect the ability of the Subbasin GSAs to achieve sustainable groundwater management.

2.4 GSP IMPLEMENTATION EFFECTS ON WATER SUPPLY ASSUMPTIONS

Implementation of the GSP will require the Subbasin to operate sustainably by 2042. The GSP includes PMAs that focus on balancing groundwater pumping with expanded surface water use and groundwater recharge. Implementation of GSP PMAs generally alter the source of water supplies (i.e., using surface water to supplement groundwater supplies); however, planned PMAs do not reduce the supplies necessary to meet the water demands of the various land uses within the Subbasin.

2.5 SUMMARY OF PERMITTING PROCESS FOR WELLS IN COLUSA SUBBASIN

The GSAs in the Subbasin will seek to work with Colusa and Glenn Counties to align future well permitting with the Subbasin's sustainability goal established under this GSP. Also, in alignment with the findings of California's Third Appellate District, the GSAs will work with their respective counties to address the need to prevent impact on public trust values in surface water from new wells, depending on how this issue evolves in the State.

2.5.1 Human Right to Water

The State recognizes the Human Right to Water pursuant to California Water Code Section 106.3, which states, "*every human being has the right to safe, clean, affordable, and accessible water adequate for human consumption, cooking, and sanitary purposes*." The human right to water extends to all Californians, including disadvantaged individuals and groups and communities in rural and urban areas (SWRCB, 2021). The GSAs will seek to work with their respective counties, SWRCB staff and stakeholders in support of SWRCB's efforts, "*to develop new systems or enhance existing systems to collect data and identify and track communities that do not have, or are at risk of not having, safe, clean, affordable, and accessible water for drinking, cooking, and sanitary purposes*" (SWRCB, 2021). These efforts may have a nexus with well permitting by Colusa and Glenn Counties.

The CGA and GGA are committed to working cooperatively to achieve the core values in California Water Code Section 106.3. Private groundwater pumper representation within the GSAs and community engagement via public workshops and outreach are venues through which those potentially most vulnerable to loss of clean drinking water are able to share information and concerns throughout the GSP development and implementation process. During preparation of this GSP, public meetings were held at times, places and in a manner that supported and allowed for effective engagement of all stakeholders.

2.5.2 Colusa County

Within Colusa County, including the Subbasin, the Colusa County Environmental Health Division is entrusted with all permitting and enforcement for the construction, reconstruction, and destruction of wells. Wells under their oversight include agricultural/irrigation wells, observation/monitoring wells, exploratory/boring wells, and domestic water supply wells.

In order to provide minimum standards for the proper regulation of well drilling and abandonment, Colusa County has adopted the State of California, DWR Bulletin 74-81 and 74-90 water and well standards. In addition, the County provides guidance for the construction or destruction of wells, including well location to protect from pollution or contamination, well casing requirements, and minimum depths of annular seal for various well types.

The application process for Water Well Permits is handled online through the Colusa County Permits Online website: https://www.countyofcolusa.org/725/Water-Wells. This site provides the information necessary to apply and provides a link to submit an application online.

2.5.3 Glenn County

Within Glenn County, including the Subbasin, the Glenn County Environmental Health Department is responsible for all permitting and enforcement for the construction, reconstruction, destruction, and renewals of wells.

Glenn County Code (GCC), Title 20, Chapter 80 - Water Well Drilling Permits and Standards, details the well drilling requirements necessary for the protection of groundwater within the County. A permit is required for any type of well for the extraction of groundwater. An application is required to be submitted for review and approval. Permits to construct expire one year after issuance. In order to provide minimum standards for the proper regulation of well drilling and abandonment, Glenn County has adopted the State of California, DWR Bulletin 74-81 and 74-90 water and well standards. In addition to DWR standards, the County has established standards for annular well seals and well casings (GCC Section 20.080.060). In addition, an inspection is required before grouting occurs and a drilling log is to be submitted to the building inspector. Permits can be revoked if a violation to the County Code has been determined.

Information and fees associated with the well permit process can be found online at:

https://www.countyofglenn.net/dept/planning-community-development-services/environmental-health/eh-resources .

2.5.4 Wellhead Protection

Wellhead protection refers to both the immediate location of the well in terms of well and pump station design features (e.g., well pad, annual seal) and the broader area surrounding the well. Both Colusa and Glenn Counties establish annular seals and other design requirements as part of well design standards.

2.6 ADDITIONAL GSP ELEMENTS

SGMA requires that the following topics are addressed in the GSP. See below for references to where each topic is addressed.

- **Control of seawater water intrusion:** See Chapter 3, Section 3.2.4 for an explanation of why the seawater intrusion sustainability indicator does not apply to the Subbasin.
- **Migration of contaminated groundwater:** Migration of contaminated groundwater is discussed in Chapter 4, Section 4.2.
- **Replenishment of groundwater extractions:** Recharge projects are discussed in Chapter 6.
- **Activities implementing, opportunities for, and removing impediments to, conjunctive use or underground storage:** Projects and management actions are discussed in Chapter 6.
- **Well construction policies:** Well construction policies are contained in Section 2.5.
- **Measures addressing groundwater contamination cleanup, groundwater recharge, in-lieu use, diversions to storage, conservation, water recycling, conveyance, and extraction projects:** Projects and management actions are discussed in Chapter 6.
- **Efficient water management practices, as defined in CWC §10902, for the delivery of water and water conservation methods to improve the efficiency of water use:** Details on efficient water management practices are discussed in Section 2.2.1.

- **Efforts to develop relationships with state and federal regulatory agencies:** Details on this topic can be found in Section 2.7.
- **Processes to review land use plans and efforts to coordinate with land use planning agencies to assess activities that potentially create risks to groundwater quality or quantity:** Details on this topic can be found in Section 2.3.
- **Impacts on GDEs:** GDEs are discussed in Chapter 3, Chapter 4, and Chapter 5.

2.7 NOTICE AND COMMUNICATION

This section documents public notice and communication of GSP activities.

2.7.1 Overview

SGMA requires broad and diverse stakeholder involvement in GSA activities and the development and implementation of the Colusa Subbasin GSP. The intent of SGMA is to ensure successful, sustainable management of groundwater resources at the local level. Success requires engagement by beneficial users (defined below). Engagement is far more likely when beneficial users receive consistent messaging of information and are provided opportunities to shape the path forward as it relates to SGMA.

Section 354.10. (Notice and Communication) of the GSP Regulations states the following requirements:

> *Each Plan shall include a summary of information relating to notification and communication by the Agency with other agencies and interested parties including the following:*
>
> *(a) A description of the beneficial uses and users of groundwater in the basin, including the land uses and property interests potentially affected by the use of groundwater in the basin, the types of parties representing those interests, and the nature of consultation with those parties.*
>
> *(b) A list of public meetings at which the Plan was discussed or considered by the Agency.*
>
> *(c) Comments regarding the Plan received by the Agency and a summary of any responses by the Agency.*
>
> *(d) A communication section of the Plan that includes the following:*
>
> *(1) An explanation of the Agency's decision-making process.*
>
> *(2) Identification of opportunities for public engagement and a discussion of how public input and response will be used.*
>
> *(3) A description of how the Agency encourages the active involvement of diverse social, cultural, and economic elements of the population within the basin.*
>
> *(4) The method the Agency shall follow to inform the public about progress implementing the Plan, including the status of projects and actions. The following addresses these requirements.*

To guide and facilitate beneficial user engagement in the GSP process, a Communication and Engagement Plan (C&E Plan) was created by the GSAs in the Subbasin to:

- Provide the GSAs and beneficial users guidance to ensure consistent messaging of SGMA requirements and related Subbasin data and information,
- Provide a roadmap to the GSAs and beneficial users to ensure everyone has an opportunity for meaningful input into GSA decision-making, including GSP development,
- Describe processes that are experienced by beneficial users as fair and respectful to the diverse range of interests in the Subbasin,
- Make transparent to beneficial users, their opportunities to contribute to the development of a GSP, and
- Ensure that information reaches all beneficial users who have an interest in the Subbasin.

Like many components of this GSP, the C&E Plan has and will periodically be updated throughout GSP development and SGMA implementation. Said updates will reflect changing conditions in the subbasin and responses by the GSAs to address these changes and to ensure effective outreach and communication take place with beneficial users. These updates reflect the role of the C&E Plan as a "living document" that provides a compilation and repository of various engagement activities implemented or planned to be implemented by the GSAs.

The above C&E Plan topics are discussed in the subsections below. Supporting information and record-keeping files are included in the appendices and/or on the respective websites of the Subbasin GSAs (described below):

- Appendix 2B: Comment tracking, copies of received comments, and responses to comments regarding project management actions, draft GSP chapters, and general inquiries
- Appendix 2C: Coordination meeting and outreach contact distribution lists
- Appendix 2D: Engagement and media materials for interbasin coordination meetings, information workshops, public meetings and hearings, SGMA workshops, public events, and Subbasin branding
- Appendix 2E: Communication and Engagement Plan

2.7.1.1 COVID-19 Global Pandemic

In March 2020, the COVID-19 global pandemic necessitated changes in all aspects of California society including public gatherings and the rules defining how public agencies conduct events. Several Executive Orders were issued by Governor Newsom to address necessary changes in the Ralph M. Brown Act (Government Code § 54950-54963) (Brown Act) which dictates the rules and manner in which local public agencies notice and conduct their sponsored meetings and ensures public transparency of, and accessibility to, almost all aspects of said gatherings. Under statewide "shelter-in-place" (SIP) mandates, all public gatherings were prohibited by the State government. These changes required that between March 13, 2020, and continuing to May 25, 2021, all meetings individually and jointly convened by the GSAs were conducted through web-based, virtual meeting and telephone-based methods, consistent with protocols allowable through the COVID-related Executive Orders. The CGA and GGA resumed in-person Board meetings on May 25 and July 12 (respectively) with an accommodation for conference call participants.

The following sections describe actions and events employed to ensure that GSA meetings and GSP development were conducted with the required level of transparency and accessibility. Activities and events that took place prior to March 2020 SIP mandates were conducted in person and virtually thereafter. Despite the June 15, 2021 "Reopening" of California, the GSAs chose to retain virtual meeting methods for TAC meetings and some public engagement events. Other events were and are expected to be conducted in person (described below). Lastly, the following sections also note additional steps taken by the GSAs during the COVID-19 pandemic to modify public engagement and information and ensure that beneficial users remained fully informed of GSA efforts and GSP content. Input received by the GSAs during outreach events or via email correspondence, as well as comments received on the draft GSP are tabulated in Appendix 2B.

2.7.1.2 Description of Beneficial Uses and Users in the Basin

Under the requirements of SGMA, all beneficial uses and users of groundwater must be considered in the development of GSPs, and GSAs must encourage "*the active involvement of diverse social, cultural, and economic elements of the population."* As defined in SGMA (CWC §10723.2), "*the GSA shall consider the interests of all beneficial uses and users of groundwater, as well as those responsible for implementing groundwater sustainability plans. These interests include, but are not limited to, all of the following:*

(a) Holders of overlying ground water rights, including:
(1) Agricultural users.
(2) Domestic well owners.
(b) Municipal well operators.
(c) Public water systems.
(d) Local land use planning agencies.
(e) Environmental users of groundwater.
(f) Surface water users, if there is a hydrologic connection between surface and groundwater bodies.
(g) The federal government, including, but not limited to, the military and managers of federal lands.
(h) California Native American Tribes.
(i) Disadvantaged communities (DAC), including, but not limited to, those served by private domestic wells or small community water systems.
(j) Entities listed in Section 10927 that are monitoring and reporting ground water elevations in all or a part of a groundwater basin managed by the groundwater sustainability agency."

In this context, the GSAs have approached SGMA engagement as needing to include any stakeholders who have an interest in groundwater use and management in the Subbasin. Their interest may be related to GSA activities, GSP development and implementation, and/or water access and management in general. To assist identifying categories of beneficial uses and users in the Subbasin, the C&E Plan included a Stakeholder Engagement Chart for GSP Development (Table 2-8 and Appendix 2E) (consistent with guidance promulgated by DWR). To facilitate regular communication with said stakeholders, the GSAs have maintained and continually updated, distribution lists of GSA-specific Beneficial Users (also known as Interested Parties Lists). These lists are presented in Appendix 2C and described below in Section 2.7.3.1.

Table 2-8. Stakeholder Engagement Chart for GSP Development

Category of Interest	Examples of Stakeholder Groups	Engagement Purpose
General Public	• Citizens groups • Community leaders • Interested individuals • Universities/Academia	Inform to improve public awareness of sustainable groundwater management
Land Use	• Municipalities • Local land use agencies • Regional land use agencies • Community Service Districts	Consult and involve to ensure land use policies are supporting GSPs and there are no conflicting policies between the GSAs / GSP and said local government agencies
Private Users	• Private pumpers (domestic and agricultural) • Schools and colleges • Hospitals	Inform and involve in assessing impacts to groundwater users
Urban/ Agricultural Users	• Water agencies • Irrigation districts • Municipal water companies • Mutual water companies • Resource conservation districts • Farmers/Farm Bureaus • Water Districts • Water user associations • Irrigated Lands Regulatory Program Coalition	Collaborate to ensure sustainable management of groundwater
Industrial Users	• Commercial and industrial self-suppliers • Local trade associations or groups	Inform and involve in assessing impacts to users
Environmental and Ecosystem Uses	• Federal and State agencies • Wetland managers • Environmental groups	Inform and involve to consider / incorporate potential ecosystem impacts to GSP process
Surface Water Users	• Irrigation Districts • Water Districts • Water user associations • Agricultural users	Inform and involve to collaborate to ensure sustainable water supplies
Economic Development	• Chambers of commerce • Business groups/associations • Elected officials • State Assembly members • State Senators • Economic Development Team	Inform and involve to support a stable economy
Human Right to Water	• Disadvantaged communities • Small water systems • Environmental justice groups/community-based organizations • De minimis well owners	Inform and involve to provide safe and secure groundwater supplies to all communities reliant on groundwater
Tribes	• Federally Recognized Tribes: — Cachil Dehe Band of Wintun Indians — Kletsel Dehe Wintun Nation (Cortina Rancheria) • Non-Federally Recognized Tribes	Inform, involve and consult with tribal government
Federal Lands	• U.S. Fish and Wildlife Service • U.S. Bureau of Reclamation • U.S. Army Corps of Engineers	Inform, involve and collaborate to ensure basin sustainability
Integrated Water Management	• Regional water management groups (IRWM regions) • Flood agencies	Inform, involve and collaborate to improve regional sustainability

2.7.1.3 Decision-Making Processes

As noted above, SGMA is implemented in the Subbasin by the CGA and GGA. The GSAs have jointly developed this GSP and as such, the respective Boards are the final decision-makers for GSP content. To ensure effective governance of the GSP process including robust technical analysis and discussions, and associated public engagement, the GSAs convened a TAC and an Executive Committee for each GSA. The GSAs are legal public agencies, formed as Joint Powers Authorities through the execution of Joint Powers Agreements consistent with the Joint Exercise of Powers Act, as codified in California Government Code Section 6500. The Boards, in concert with the TACs and Executive Committees, create the primary structure for governance, information exchange, and decision making for each GSA. From the inception of each GSA, all meetings of all entities within their jurisdictional purview have been conducted with an effort to be inclusive to all stakeholders. All meetings requiring Brown Act compliance were conducted in such a manner, with appropriate public noticing of meeting agendas, associated meeting materials and subsequent availability of meeting summaries. All such materials are and have been available at the respective CGA and GGA websites:

- Colusa Groundwater Authority website: https://colusagroundwater.org/
- Glenn Groundwater Authority website: https://www.countyofglenn.net/dept/planning-community-development-services/water-resources/glenn-groundwater-authority

Prior to and after necessary adjustment in public engagement due to COVID, the TACs have played a particularly key role to ensure public disclosure of all technical information, public discussion of technical factors, and transparent development of technical recommendations that have then been delivered to the respective Boards for their consideration and decision making. The TACs have met in approximately monthly joint sessions. They include members of each GSA Board and other advisory representatives appointed by each Board and who deliberate on technical topics.

Regarding decision-making procedures by the Boards, to ensure compliance with GSP regulations regarding "…*opportunities for public engagement and…how public input and response will be used*" (and additive to Brown Act requirements) the GSAs have adopted a comprehensive tabular GSP comment tracking system as part of the GSP Administrative Record to continually record beneficial user input and to regularly update the respective Boards on said input. Appendix 2B presents the comment tracking system (including GSP development comments and responses). The comment tracking system is updated on a regular basis by facilitation staff and is then included in the agenda packet for each GSA Board meeting. General input comments have been tracked since 2019, and comments on the draft GSP have been tracked since draft chapters were released beginning in spring 2021. The agenda for each Board meeting includes a specific item calling attention to the updated comment tables and allowing time for each Board to make inquiry about and discuss any comments received. Prior to key GSP decision milestones, each Board agenda defines said decision as a formal action which could include discussion by each Board about associated public input recorded in the comments tables that might inform their decision-making. Further, consistent with and expanding on Brown Act requirements, each Board and TAC meeting includes the following periods of public comment on their respective agendas:

- Introductory public comment period at the beginning of the meeting for topics not included in the current agenda
- Public comment periods for each agenda item
- Public comment periods to be held prior to any formal action taken by the Board and/or TAC

2.7.2 Engagement Opportunities

2.7.2.1 Public Engagement Opportunities

Prior to formation of the legal GSAs (2015 through June 2017), and thereafter through October 2021, the parties that make up the CGA and GGA have collectively sponsored, publicized and conducted 242 separate meetings including:

- 40 Pre-Agency Formation SGMA governance meetings,
- 181 GSA meetings (Boards, Committees, Subcommittees and Joint Meetings), and
- 21 public meetings and workshops.[2]

Prior to the respective GSA's being formed as legal public agencies, interested parties and organizations already noticed to the State as intending to form individual GSAs began meeting in the respective counties of Colusa and Glenn. These meetings were funded by DWR's Facilitation Support Services (FSS) program in an effort to support GSA formation. Respectively titled the Colusa GSA Work Group and the Glenn Governance Work Group, all meetings of these groups were publicly noticed and associated information was posted on the websites of the respective counties' websites. In total, the Colusa GSA Work Group met 25 times (including full Work Groups and topic specific subcommittees) between January 2016 and June 2017 (at which point the legal GSA was formed as per statute). Similarly, the Glenn Governance Work Group met 15 times between April 2016 and June 2017 when their work similarly culminated in the formation of the legal GSA as per statute.

Following the formation of the CGA and GGA as legal public agencies, there have been collectively 196 more meetings at which the public has had the opportunity to engage prior to and during the GSP development process.

As referenced above, for all GSA meetings (full and joint Board meetings, Committee and Subcommittee meetings) requiring compliance with the Brown Act, agendas are posted no less than 72 hours before a meeting and all materials presented in said meetings are made accessible for the public to access through either of the respective GSA's websites or through hard copies available at the respective GSA's administrative offices.

For meetings not required to be compliant with the Brown Act, presentation materials and event agendas were posted on the respective GSA websites either before or at the latest, immediately after each event. Once the GSAs had jointly established a social media presence (fall 2020), all public outreach meetings were similarly publicized through Facebook and Twitter. This included TAC, Board, and Executive Committee meetings as well as SGMA Series and other public events.

All meetings described below as "Public Meetings and Workshops" were noticed to the standing lists of media organizations and outreach partners (Appendix 2C), with press releases and associated requests for said organizations to publicize said events through public notices, feature articles, newsletters, email listservs, and similar. The following provides a general description of the engagement venues provided by

[2] "Public meetings" are open to the public and allow comments and feedback from the public, but are not exclusively held for that purpose (e.g., Board meetings, TAC meetings). "Public workshops" and "public outreach meetings" are open to the public and are primarily designed to engage with the public and stakeholders to solicit their opinions and feedback.

the GSAs. Appendix 2D presents background outreach materials for most of the events described below (if said materials are not already accessible through the respective GSA websites):

- **Individual GSA Meetings**: Each GSA in the Subbasin held regular, publicly-noticed, publicly accessible meetings, generally on a monthly schedule. From legal inception to date and as consistently compliant with the Brown Act:
  - The CGA has held 43 GSA Board Meetings.
    - The CGA has also held 9 Long-Term Funding Committee Meetings.
  - The GGA has held 54 GSA Board Meetings.
- **GSA Executive Committee Meetings**: Consistent with their respective by-laws, each GSA formed and then regularly convened an Executive Committee to address high-level administrative decisions. To date and as consistently compliant with the Brown Act:
  - The CGA has held 10 Executive Committee Meetings.
  - The GGA has held 36 Executive Committee Meetings.
  - The CGA and GGA have held 4 joint Executive Committee Meetings.
- **Joint GSA meetings:** The GSAs convened 4 times for publicly-noticed, publicly accessible joint meetings. The intent of the joint GSA meetings was to provide a forum for representatives from each GSA to share perspectives and information about GSP development and SGMA implementation, and near the end of the GSP development process, to ensure shared expectations and approvals of the GSP.
- **Inter-basin SGMA Coordination Meetings:** On a regular basis, inter-basin meetings of representatives from the Colusa Subbasin met with representatives from the adjacent Corning, Butte, Sutter and Yolo Subbasins (and other non-adjacent subbasin representatives) to discuss interconnected groundwater conditions, potential impacts and other factors related to groundwater management across the larger Sacramento Valley Basin.
- **GSA-specific and Joint Technical Advisory Committee Meetings:** As previously described, GSA-specific TACs were formed to review technical content, work with the technical consultant team and advise their respective GSA Boards on GSP development. The TACs generally met on a monthly basis and always in publicly-noticed, publicly accessible meetings.
  - The CGA and GGA have held 19 Joint TAC Meetings.
  - The CGA has held 1 GSA-Specific TAC Meeting.
  - The GGA has held 1 GSA-Specific TAC Meeting.
- **GSA Formation Working Group Meetings:** As described above, in the initial stages of GSA formation, close to 40 separate, eligible GSA organizations noticed the DWR of their intent to form separate GSAs. Using funding provided through DWR's FSS program, all said parties convened into two Subbasin Working Groups which convened every 4 to 8 weeks for close to two years to negotiate mutual governance agreements that became the basis for the two JPAs to be formed as the respective CGA and GGA. The meetings took place in person; always as publicly-noticed and publicly accessible events held in Colusa and Willows, California.

- **Public Meetings and Workshops**: In 2015, three initial meetings were held to discuss general SGMA information and were co-sponsored by the Glenn County Water Advisory Committee, the Glenn County Farm Bureau, and the University of California Cooperative Extension. In January 2016 (including in advance of the CGA and GGA being legally formed), Subbasin representatives started public events to inform beneficial users about SGMA.
  - **General Education / Information: January and March 2016** - A series of 2 kickoff public meetings were held respectively at the Colusa County Fairgrounds and Orland Memorial Hall to describe SGMA requirements and background, early governance and implementation steps, anticipated methods for public engagement and to provide an opportunity for public question and answer sessions with a panel of eligible GSA leaders actively involved in the governance development process.
  - **GSA Financing – Proposition 218 Public Information Meetings: January and April 2019 -** In support of the respective GSA's efforts to establish long range funding, 4 public information meetings were held respectively at the Colusa Indian Community Events, the Glenn Success Square Conference Center, the City of Willows City Council Chambers and the Ord Bend Community Hall. The meetings included background about SGMA implementation and compliance, presentations about Proposition 218, discussion of associated financing options and requirements, and opportunities for questions and answers.
  - **GSA Financing – Proposition 218 Public Ballot Hearings: June and July 2019** - In support of the respective GSA's efforts to establish long range funding, 2 final Proposition 218 ballot hearings were held respectively at the Colusa Industrial Properties and the City of Willows Council Chambers. Meetings were held as formal GSA Board meetings with an allowance for public feedback on the ballot process, followed by a formal counting of submitted ballots and a final determination of election outcomes.
  - **SGMA General Information, Basin Setting and Sustainable Management Criteria Workshops: 2019** - The GSAs sponsored a series of public workshops in 2019. Two GSA-specific events were held respectively at the Colusa Veterans of Foreign Wars Hall and the Glenn Success Square Conference Center. The purpose of each workshop was to provide an update on Basin Setting conditions, Subbasin Water Budget, modelling efforts, conduct small group exercises about potential significant and unreasonable conditions associated with sustainability indicators, and to conduct question and answer sessions. Individual and small group worksheets were prepared by workshop participants providing collective beneficial user input to the GSAs about potential groundwater sustainability problem areas in the Subbasin.
    - **Town Hall Meetings 2019:** The CGA in partnership with the Colusa County Groundwater Commission sponsored 3 locally focused Town Hall meetings in March 2019 to informally update them on GSA and GSP status and how they could participate. Appendix 2D-4 included example materials from these meetings. These meetings were focused respectively on the following communities:
      - Arbuckle / Williams / College City
      - Colusa / Princeton / Grimes
      - Maxwell / Williams

- **SGMA Series** – Beginning in February 2020 and extending in virtual and then virtual and in-person formats through October 2021, the GSAs sponsored a series of 8 paired public meetings (one in daytime / one in evening). These meetings focused on the following:
  - **February 2020** – On-Farm, Groundwater Recharge Workshop (co-sponsored with The Nature Conservancy)
  - **December 2020** – (2 workshops) Status of Basin Setting conditions, education on Sustainable management Criteria terms, requirements and processes; Projects and Management Actions terms and next steps
  - **January 2021** – Well Monitoring Program Public Workshop to inform the public about and solicit applicants for the program
  - **July 2021** – (2 workshops) Current and Historical Groundwater Conditions, Historical, Current, and Projected Water Budgets, Draft Sustainability Goal, Draft Significant and Unreasonable Conditions
  - **October 2021** – (2 workshops) Public Draft GSP Review and Public Discussion

2.7.2.2 Soliciting Written Comments

In addition to soliciting feedback at all meetings described above, opportunities were provided to offer written comments on the GSP via an online comment form, email or letter. A series of chapter-specific review periods was initiated in April 2021, providing beneficial users the opportunity to provide iterative feedback. Table 2-9 presents the schedule used for this process. All comments received during these periods were admitted into the Administrative Record and the associated comment tracking system for subsequent review by the GSA Boards and beneficial users. The written comments and responses can be found in Appendix 2B and its associated subsections.

Table 2-9. GSP Review Schedule

GSP Chapter/Activity	Start Date	End Date	Duration, days
Public Draft Review	4/7/2021	5/5/2021	28
Chapter 1 – Introduction Chapter 2 – Plan Area Chapter 3 – Basin Setting Chapter 4 – Monitoring Networks			
Public Draft Review	7/16/2021	8/13/2021	28
Chapter 5 – Sustainable Management Criteria Chapter 6 – Projects and Management Actions			
Public Draft Review	9/13/2021	10/31/2021	48
Preface Executive Summary Revised Chapters 1 through 6 Chapter 7 – Plan Implementation Chapter 8 – References and Technical Studies			
Technical Team Finalize GSP	11/1/2021	12/3/2021	33
Complete GSP			
GSP Adoption by Agencies and Submittal to DWR	12/3/2021	1/31/2022	59
Final Submitted Colusa Subbasin GSP			

2.7.3 Informing the Public about GSP Development Progress

2.7.3.1 Interested Parties List

Email distribution lists of GSA-specific beneficial users were developed for outreach supporting the GSP planning process. The lists are maintained and updated by the CGA and GGA Program Managers, respectively, and are summarized in Appendix 2C. (To protect sensitive information, actual contact information of interested parties is not appropriate to publish as part of this GSP). Any interested member of the public could be added to the lists by signing up via online entry options located on the CGA website and through email sign up options or requesting by phone for each GSA.

Tribal Engagement

As noted in the C&E Plan (Appendix 2E) and in Table 2-8 above, the Cachil DeHe Band of Wintun Indians of the Colusa Indian Community of the Colusa Rancheria is a federally recognized tribe of Wintun Indians from central California. The Tribe has been consistently identified as an Interested Party since the preliminary days of Subbasin governance (2015 – 2017) and has similarly, been a consistent entity on the Interested Parties list for both GSAs since their respective inception. A Tribal representative attended CGA and GGA meetings regularly from 2015 through December 2019, at which time, said representative departed Tribal employment. The CGA and GGA have continued their inclusive communication of all SGMA information to the Tribe; however, Tribal participation has been limited since January 2020. Likewise, the GSAs' inclusive communication of all SGMA information has been available to the Cortina Rancheria of Wintun Indians of California (Kletsel Dehe Wintun Nation); however, there has been no participation by a representative from the Cortina Rancheria in the GSP process.

2.7.3.2 Distribution of Meeting Information

Before each public meeting and workshop, agenda-based flyers were created in English and Spanish with key information provided. The flyers were emailed out to the Interested Party list, traditional media as well as to key outreach leads with various organizations and the member agencies of each GSA to ensure maximum distribution to the widest range of beneficial users feasible (Appendix 2C). Meeting and workshop flyers are presented in Appendix 2D.

2.7.3.3 Outreach and Branding

To provide Subbasin outreach materials with a consistent look and feel that ensure user awareness of messaging and a sense of organizational cohesion, the respective GSA Boards jointly recommended the development and ultimate approval of a Colusa Subbasin Logo and associated graphics standards to be used consistent on all outreach collateral and online materials. The new Colusa Subbasin logo has been included on this GSP and is also presented in Appendix 2D.

2.7.3.4 Traditional Media Outreach

In advance of each public meeting and workshop, press releases were issued to a local media contact list (Appendix 2C). Local media proved to be highly responsive and the Subbasin efforts collectively received media coverage for most public events described above. Related to this, the GSA Chairpersons wrote and the GSA's jointly approved, the release of an Op-Ed Piece for regional distribution regarding the nexus of the 2021 drought and SGMA planning and implementation (Appendix 2D).

2.7.3.5 Social Media Outreach

Based on a comprehensive outreach proposal submitted to and approved by the respective GSA Boards in October 2020, GSA staff launched social media sites on Facebook and Twitter:

- Facebook Page - https://www.facebook.com/search/top?q=Colusa%20Subbasin%20SGMA
- Twitter - https://twitter.com/colusasubbasin?lang=en

Through these sites, regular content updates were then conducted on average of a bi-monthly basis to ensure user interest and readability and to avoid information on said sites getting "stale." In addition to photographic images and SGMA / GSA / GSP content being regularly updated, the GSAs used Facebook Live to simulcast all events in the SGMA Series to ensure maximum availability for members of the public to view all outreach events from late 2020 through and including public review and subsequent GSA approval of the GSP.

2.7.3.6 GSA Websites

Throughout the planning process, the GSAs have maintained respective websites (as presented above).

These websites are populated with information about Subbasin-wide SGMA planning efforts. While the layout of these websites vary, in general, each includes the following:

- Reference documents regarding GSA creation, incorporation, governance and similar
- Reference documents regarding SGMA background information
- Calendar of public meetings and other upcoming events
- GSA Board, Executive Committee and TAC meeting agendas and materials including post meeting summaries and Zoom recordings (when available after March 2020)
- Information about past public meetings, including relevant meeting materials
- Links to external sites and research (e.g., Department of Water Resources SGMA portal, DWR Subsidence Studies) and other resources
- GSP Chapters, Appendices, Figures, Tables, Comment Forms and related materials
- Links to submit contact information into the Interested Parties Lists
- Reference and submission information for associated voluntary programs such as the Multi-benefit On-farm Managed Aquifer Recharge Program, and the Colusa Subbasin Well Monitoring Program and OpenET, an evapotranspiration data access project
- A link to the website of the respective other GSA
- Colusa Subbasin Social Media links
- Media links and strategy documents including press-releases and Op-Ed materials
- Information about other interbasin efforts
- GSP background documents
- Fact sheets and Subbasin maps

2.7.3.7 Beneficial User Input and Responses

As referred to above, the engagement opportunities described above provided various avenues for beneficial users to provide input on GSP development for the GSAs to be informed thereof. Appendices 2B and 2D present the input received and supports how this input influenced decision-making in GSP development.

CHAPTER 3
Basin Setting

Chapter 3 describes the basin setting, including the hydrogeologic conceptual model (HCM), current and historical groundwater conditions, and water budget information describing the movement of surface water and groundwater into, through and out of the Colusa (Subbasin). This chapter was prepared through a coordinated effort between the CGA and the GGA, the GSAs responsible for managing the Subbasin.

3.1 HYDROGEOLOGIC CONCEPTUAL MODEL

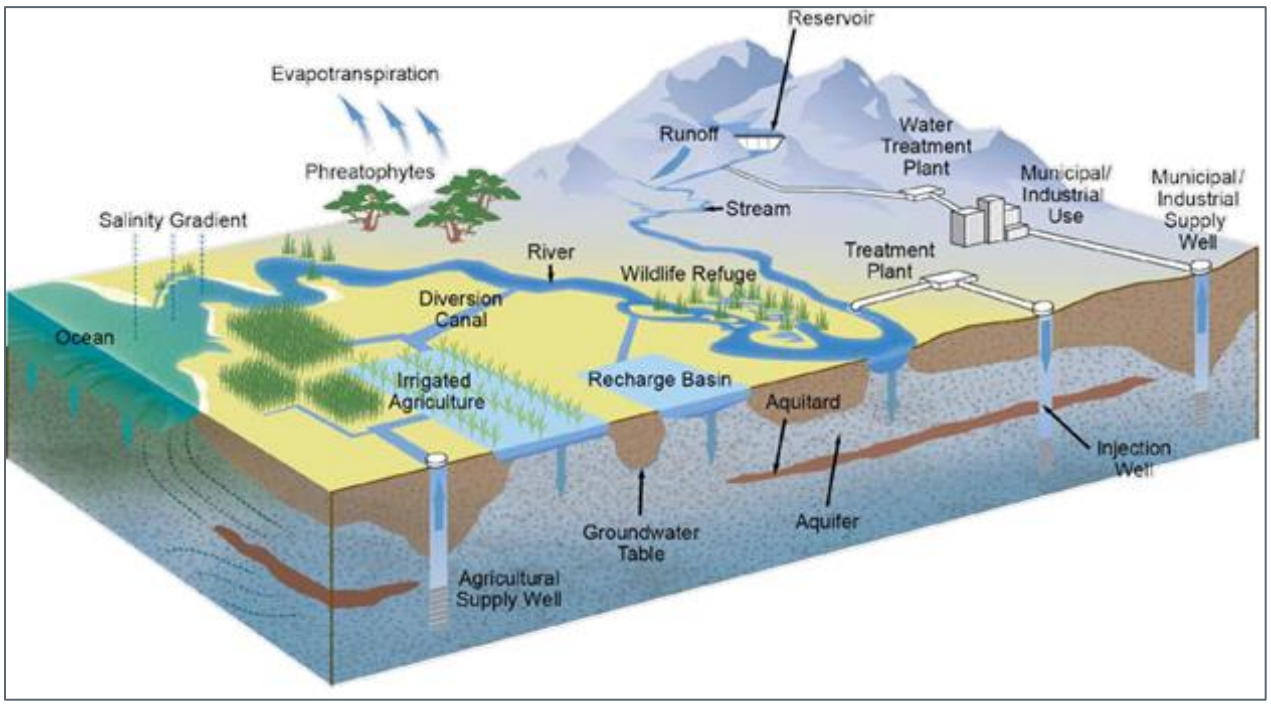
This section describes the Subbasin HCM. The HCM supports development and implementation of a GSP pursuant to the requirements of SGMA.

3.1.1 Regulatory Requirements

Title 23 Section 354.14 of the California Code of Regulations (23 CCR §354.14) requires that each GSP "*shall include a descriptive hydrogeologic conceptual model of the basin based on technical studies and qualified maps that characterizes the physical components and interaction of the surface water and groundwater systems in the basin*" and shall include written descriptions for the following HCM components:

- Regional geology and structure (Section 3.1.7)
- Lateral basin boundaries (Section 3.1.8.1)
- Definable bottom of the basin (Section 3.1.8.2)
- Principal aquifers and aquitards, including formation names, vertical and lateral extent, aquifer properties, restrictions to flow, water quality, and primary uses (Section 3.1.10)
- Any data gaps and uncertainties identified in the previously listed topics (Section 3.1.12)

In accordance with 23 CCR §354.14, the HCM shall also include maps of each of the following physical components of the HCM. All maps shall be informative, labeled, and include the datum (23 CCR §352.4(d)). Information regarding key data sources is also included on each of the maps.



- Topography
- Surface geology and a minimum of two cross sections
- Soil properties
- Recharge and discharge areas
- Surface water features
- Sources and points of delivery of imported water

This section addresses the requirements using currently available data and information in accordance with the Department of Water Resources (DWR) Best Management Practice (BMPs) for the Sustainable Management of Groundwater: Hydrogeologic Conceptual Model BMP (DWR, 2016a). Additionally, components of this HCM have been compared to and updated based on information included in the California Central Valley Groundwater-Surface Water Simulation Model – Fine Grid (C2VSimFG), the selected integrated hydrologic model (IHM) chosen to support the Colusa Subbasin GSAs. This section provides a comparison of the HCM and IHM. Data gaps, uncertainties, and recommended actions are also presented in this section (Section 3.1.12).

3.1.2 Background Information

The HCM provides the general understanding of the hydrogeologic physical setting, characteristics, and processes that occur within the Subbasin and provides the foundation upon which the IHM and components of the water budget are based.

Figure 3-1 depicts a generalized HCM (DWR, 2016a). The main components of the HCM include surficial and subsurface features. Surficial features include topography, hydrology, water supply features, land use, soil types, and geologic outcrops. Subsurface features of the HCM include geologic formations and structures and the presence and characteristics of aquifers and aquitards. These HCM components, except for land use, are discussed in this chapter. Land use is discussed in both Chapter 2 Plan Area, and Section 3.3 Water Budget sections of this Colusa Subbasin GSP.

(a) California Division of Mines and Geology is now the California Geological Survey.

3.1.3 Climate and Precipitation

The Subbasin has a Mediterranean climate with cool, wet winters and hot, dry summers. Regionally, temperature and precipitation vary with elevation, with lower temperatures and higher precipitation typically occurring at higher elevations. The region is subject to wide variations in annual precipitation, and experiences periodic dry periods. Summers can be hot, with temperatures commonly exceeding 100 degrees Fahrenheit.

Based on the historical data obtained from Western Regional Climate Center (WRCC) National Oceanic and Atmospheric Administration (NOAA) Cooperative Observer Network (COOP) stations in Colusa (Station 041948) and Orland (Station 046506), the recorded average monthly temperatures within the subbasin range from 46 to 80 degrees Fahrenheit, but the extreme low and high daily temperatures have been 15 and 120 degrees Fahrenheit, respectively (WRCC, 2020).

The average annual precipitation varies from about 21 inches in the northern portion of the subbasin to about 15 inches in the south. Due to the variable topographic relief of the subbasin, temperature and precipitation can vary greatly with location.

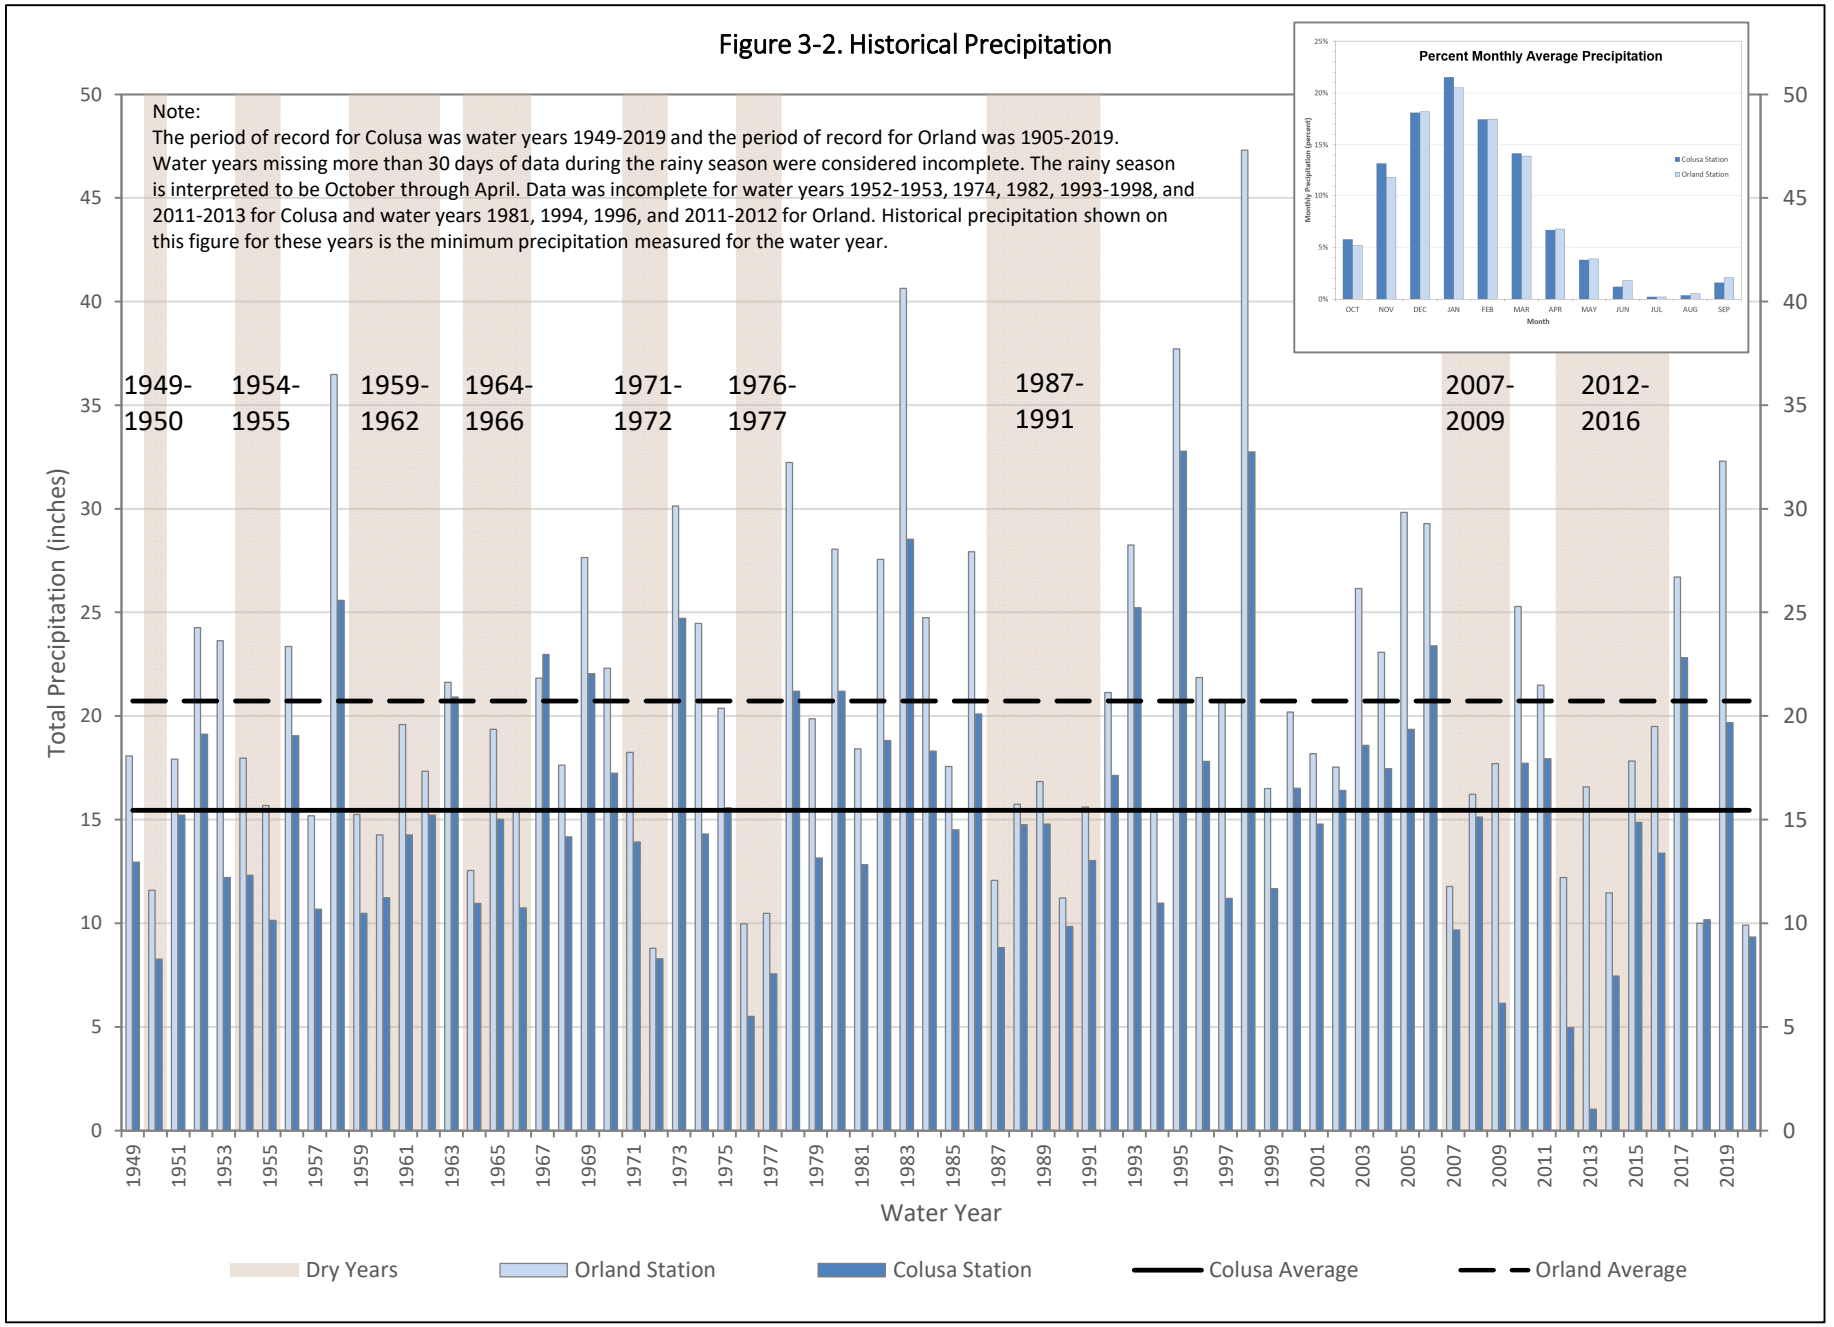
The Colusa station has recorded precipitation for water years 1949 through 2019 and the Orland station for 1905 through 2019. The water year starts October 1, ends on September 30, and is denoted by the calendar year of its end date. Figure 3-2 shows the annual water year precipitation measured at Colusa and Orland for water years 1949 through 2020. Water years missing more than 30 days of data during the rainy season were considered incomplete and were not included in this evaluation. The rainy season is interpreted to be October through April (Figure 3-2). Data was incomplete for water years 1952-1953, 1974, 1982, 1993-1998, and 2011-2013 at Colusa and water years 1906-1907, 1910, 1914, 1916-1920, 1941, 1981, 1994, 1996, and 2011-2012 at Orland. Historical precipitation shown on Figure 3-2 for these years is the minimum precipitation measured for the water year.

Multiple-year dry periods experienced in the Subbasin roughly correspond with state-wide multiple-year droughts. Multiple-year dry periods recorded within the Subbasin area include:

- 1949-1950
- 1954-1955
- 1959-1962
- 1964-1966
- 1971-1972
- 1976-1977
- 1987-1991
- 2007-2009
- 2012-2016

Figure 3-3 shows the exceedance curves for the Colusa and Orland precipitation data. The entire period of record except for water years with incomplete data was used for each station's exceedance curve. The figure shows the frequency at which a given level of annual precipitation was met or exceeded. The curve can be used to gauge how frequently the precipitation recorded in any given year was equaled or exceeded in the past. For example, the minimum historical precipitation of 8.15 inches recorded in Orland occurred in 1924 and was met or exceeded in 100 percent of years throughout Orland's period of record. Similarly, 90 percent of water years over Orland's period of record met or exceeded the 11.5 inches of precipitation measured in 2014.

Figure 3-2. Historical Precipitation



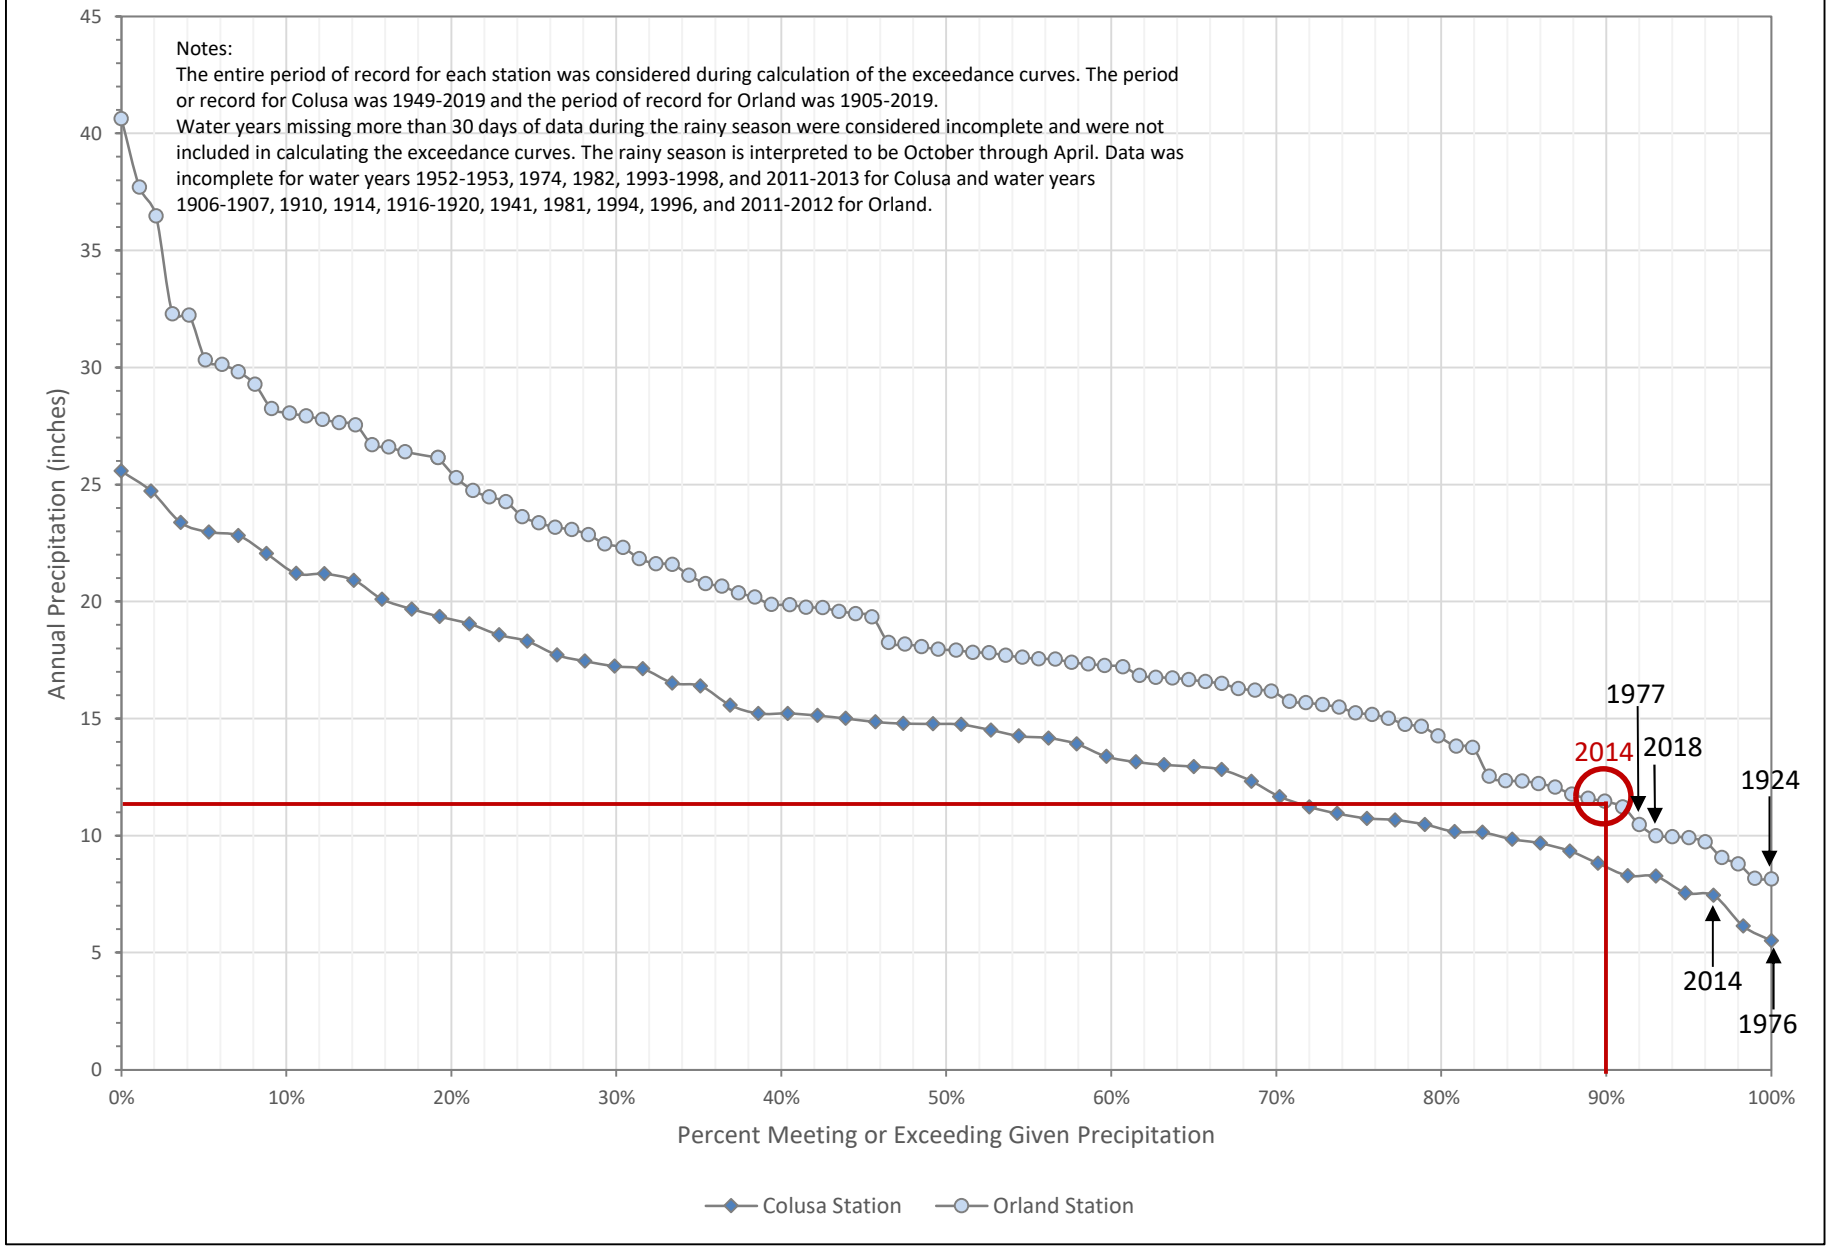


Figure 3-3. Precipitation Exceedance Curve

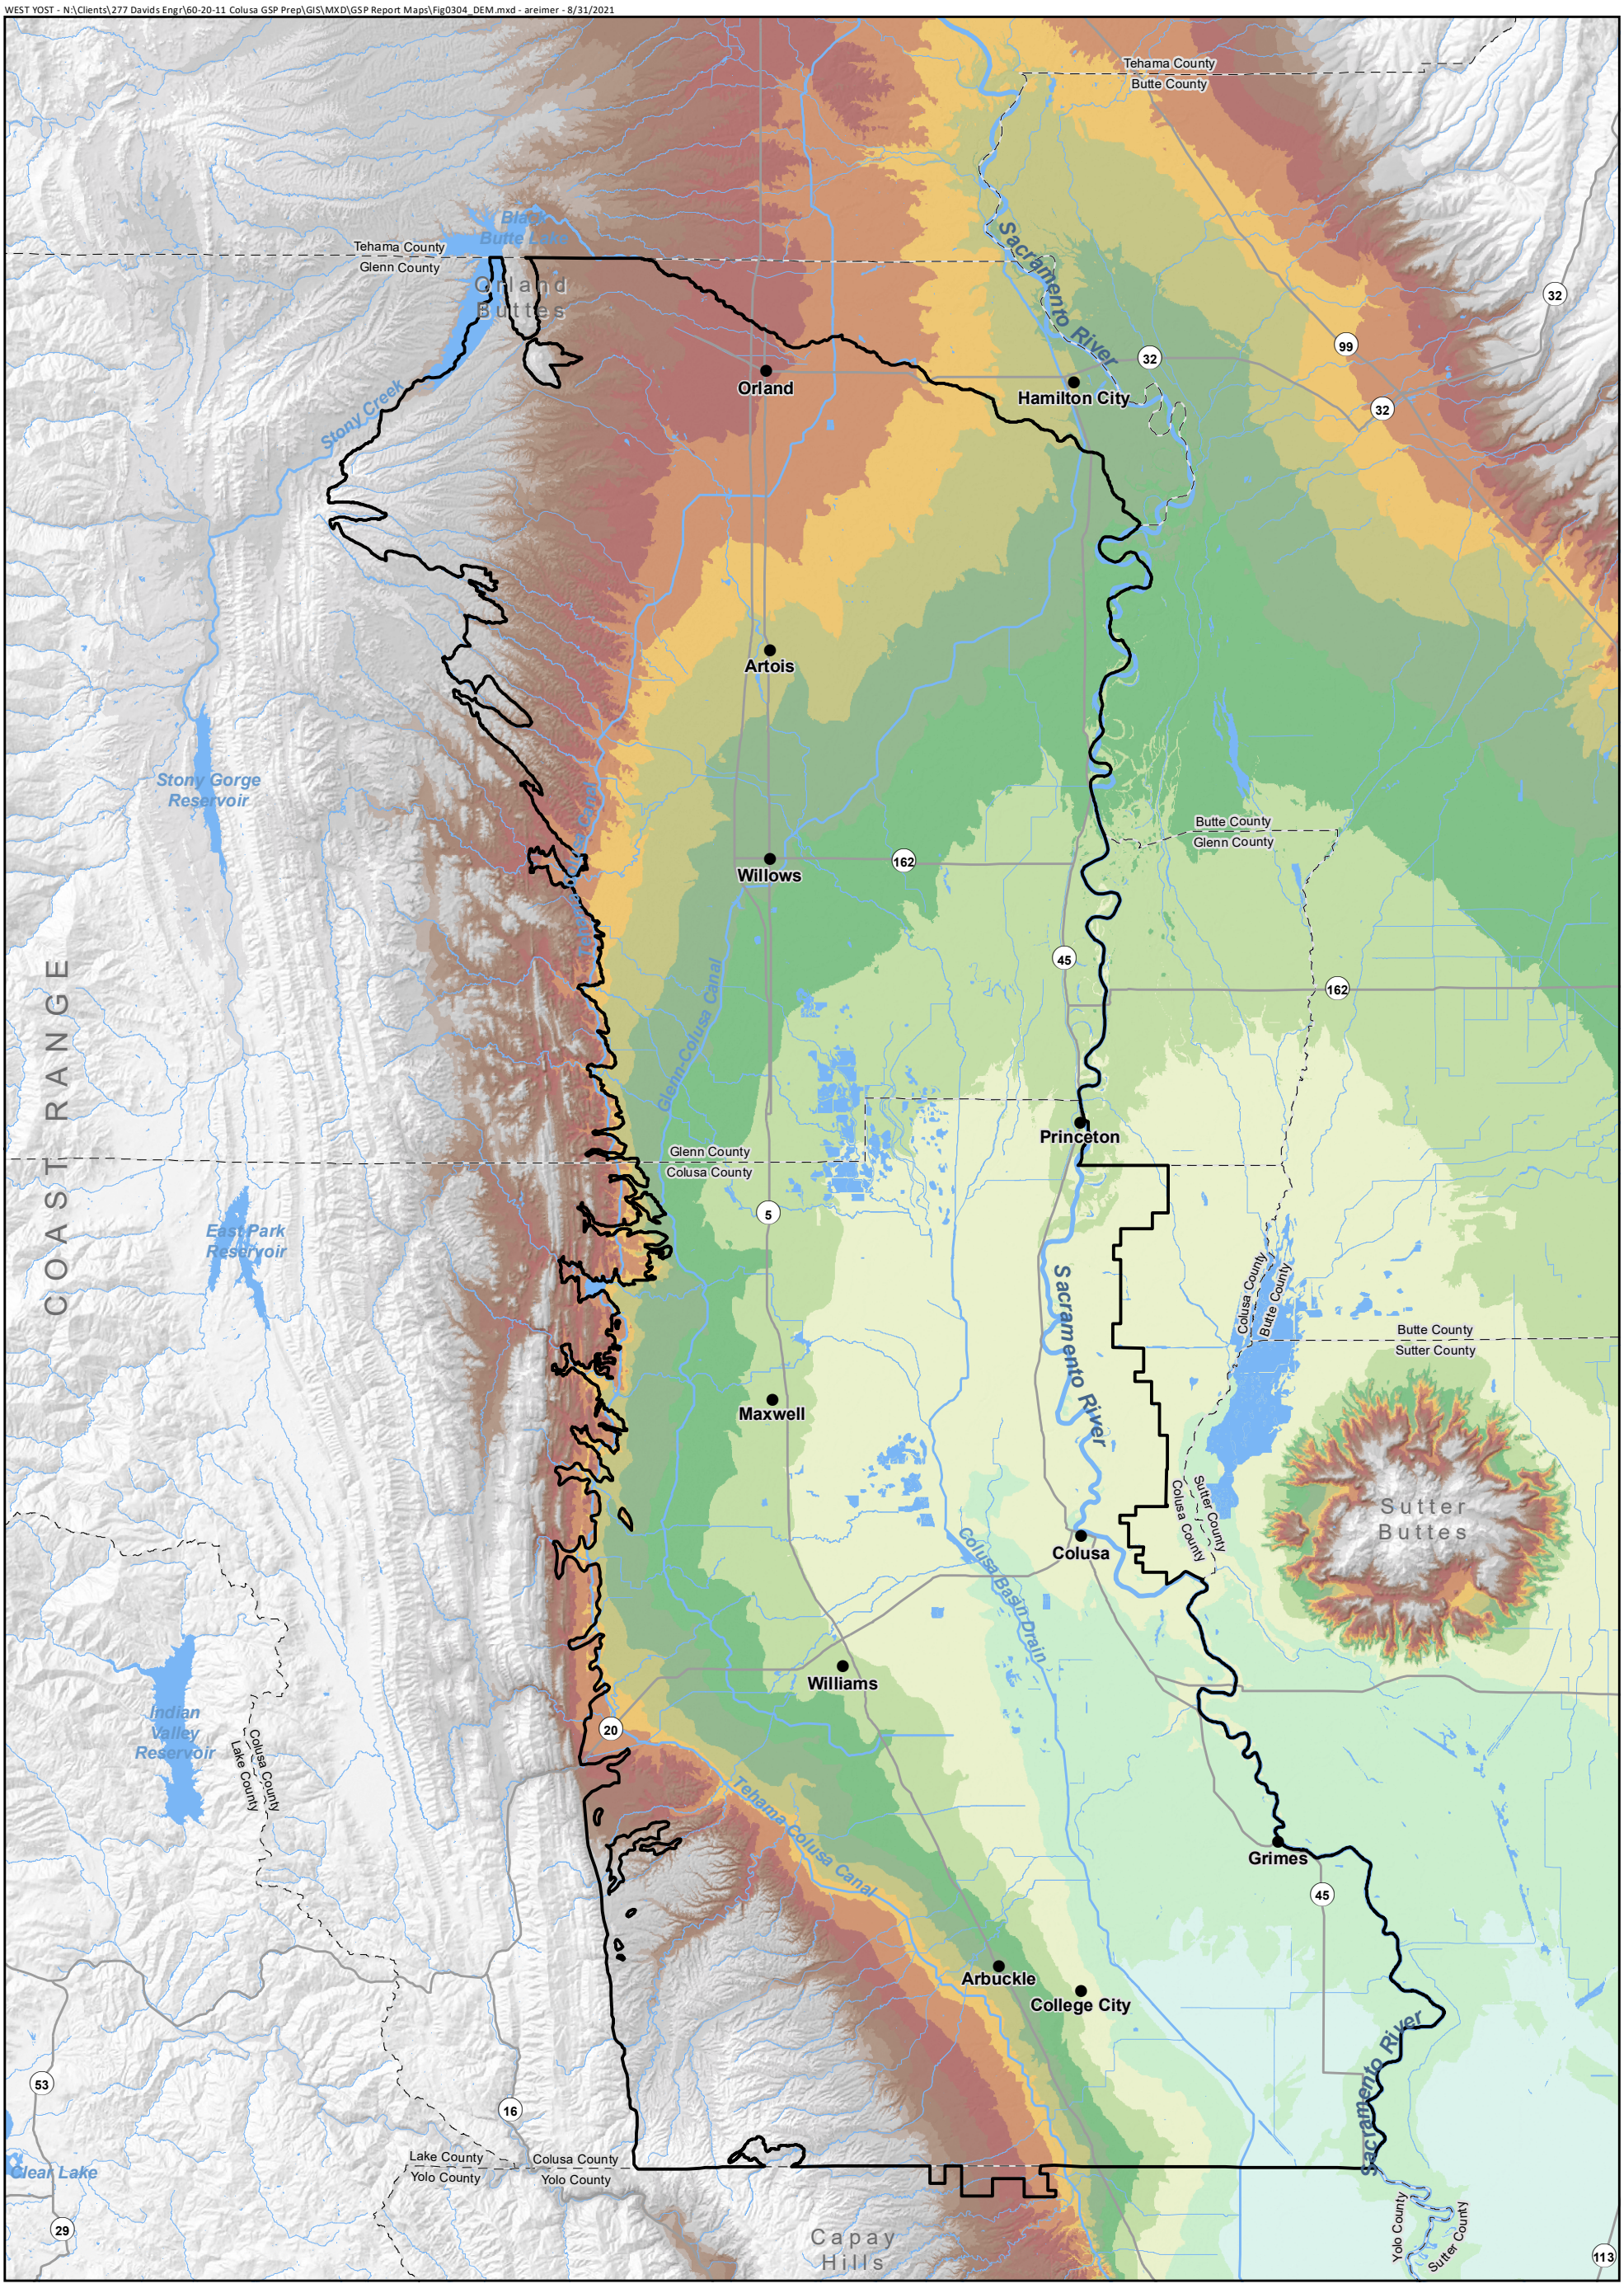
3.1.4 Topography

Figure 3-4 shows the topography of the Subbasin. The topography throughout the subbasin encourages drainage east towards the Sacramento River and south towards the San Joaquin-Sacramento River Delta (Delta). The western side of the subbasin is elevated and includes low foothills that transition to the higher elevation Coast Range. Streams from the Coast Range drain eastward through low alluvial plains towards the Sacramento River.

Elevations greater than 1,000 feet North American Vertical Datum of 1988 (NAVD 88) occur within the northwestern and the southwestern portion of the subbasin. These areas of high terrain are associated with the Coast Range foothills near Black Butte Lake and the northernmost extent of the Capay Hills. Minimum land surface elevations of less than 30 feet NAVD 88 occur in the southern portion of the subbasin between the Colusa Basin Drainage Canal System (Colusa Drain) and the Sacramento River. Elevations along the Sacramento River range from about 150 feet NAVD 88 at the northeast boundary of the subbasin to about 40 feet NAVD 88 near the southeast boundary of the subbasin.



3.1.5 Hydrology

The physical hydrology of the Subbasin is influenced by the underlying geology, geomorphology and topography of the region and the Sacramento Valley's large agriculture industry. Chemical hydrology of waters within the Subbasin are similarly impacted by geology, lithology, and geomorphology, as different geologic and lithologic sediments can leach or filter chemicals into or out of groundwater solution. Hydrogeologic structures can also impact flow paths of waters within the subsurface and up to stream beds, allowing or impeding mixing of waters with different chemical signatures. Physical surface water hydrology is discussed in this section. Stratigraphic features that can impact water flow regime are discussed in Section 3.1.9. Groundwater quality is discussed in Section 3.1.10.3 and Section 3.2.5.

Figure 3-5 shows watersheds and natural waterways in the Subbasin. The Sacramento River is the principal stream in the subbasin and contributes significantly to the statewide water supply. Most of the streams within the region drain the Sierra Nevada to the east and the Coast Ranges to west and are tributary to the Sacramento River.

The drainage watersheds of these tributary streams within or adjacent to the Colusa Subbasin include:

- Big Chico Creek Sacramento River watershed (hydrologic unit code 08 [HUC08] 18020157), which drains into the Sacramento River at the northern boundary of the Subbasin;
- Upper Stony Creek watershed (HUC08 18020104), which drains into Stony Creek along the northern boundary of the Subbasin;
- Butte Creek watershed (HUC08 18020158), which drains into the west-central portion of the Subbasin, east of the Sacramento River;
- Honcut Headwaters – Lower Feather River watershed (HUC08 18020159), which drains into the Sacramento River south of the City of Colusa and flows along the Subbasin boundary; and
- Sacramento Stone Corral watershed (HUC08 18020104), which drains the Coast Range foothills west of the Subbasin, as well as the majority of the Subbasin, itself.

Colusa Subbasin

Groundwater Sustainability Plan

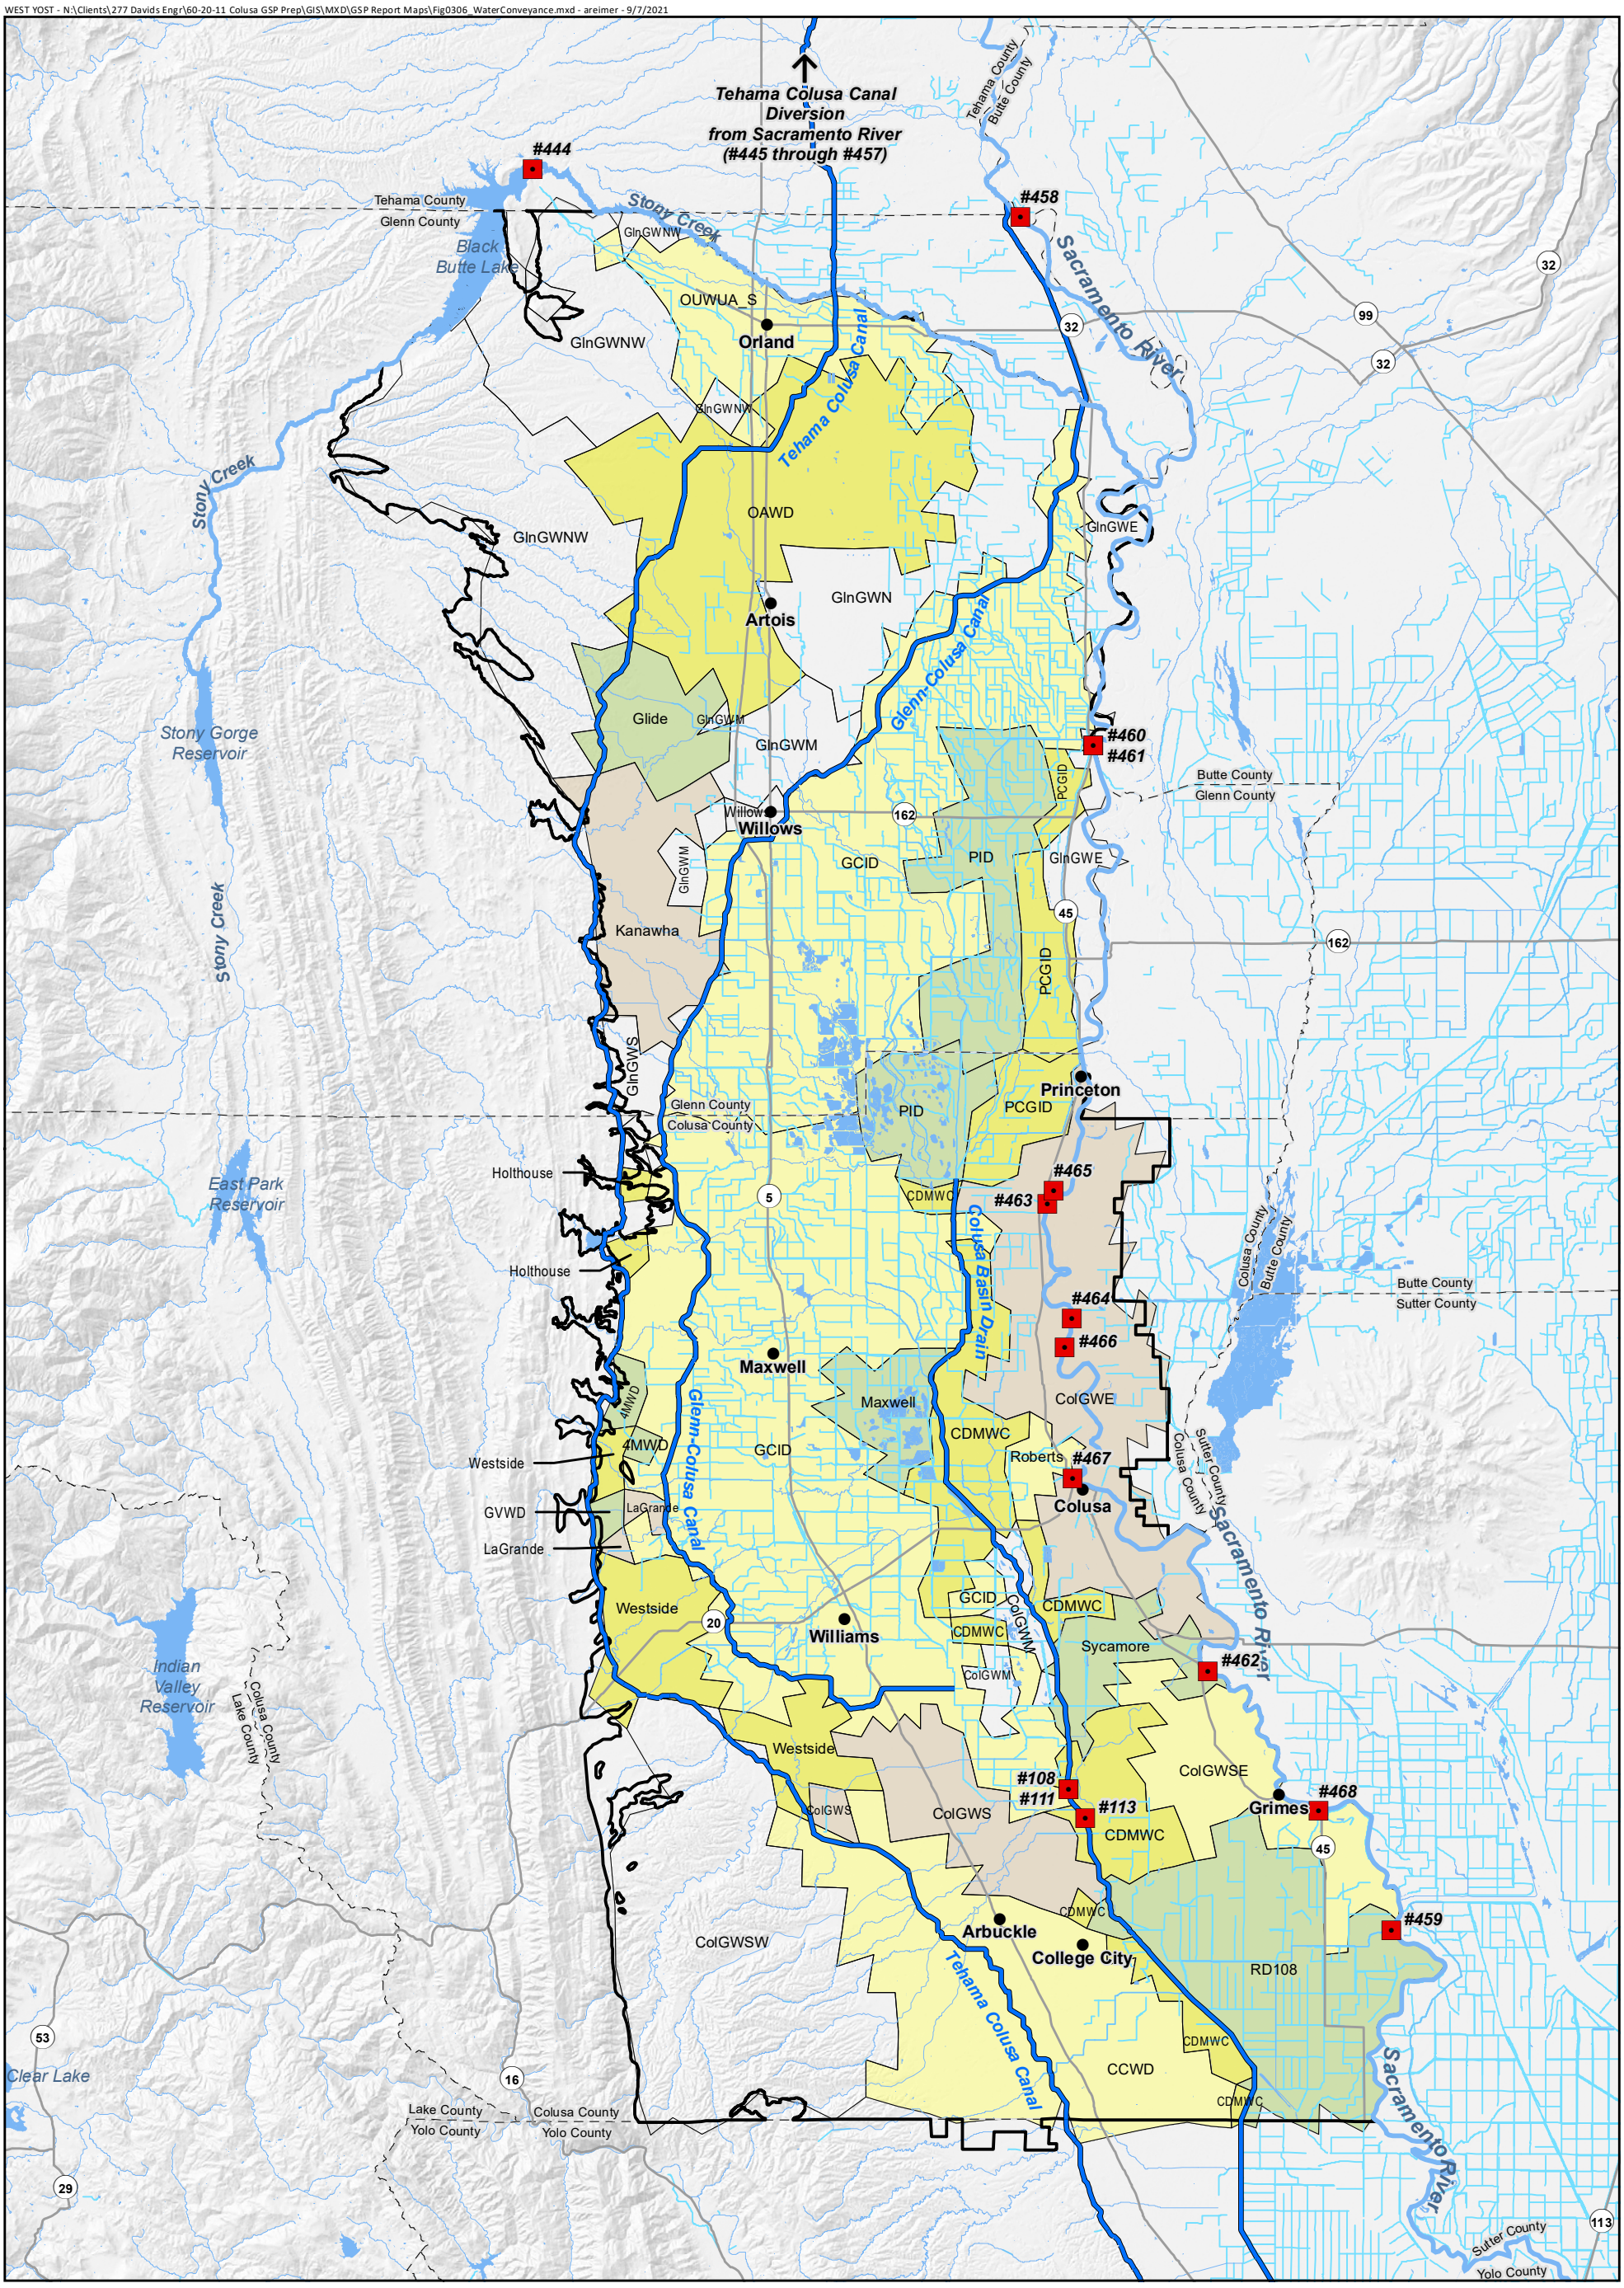
The dominant north-northwesterly south-southeasterly structural trends in the Coast Range west of the Subbasin result in long narrow valleys and ridges. These topographic features have produced a drainage network that routes most of the Coast Range runoff to the Subbasin via Stony Creek, which flows north in the Coast Range through Stony Gorge Reservoir to Black Butte Lake before entering the Subbasin along its northern boundary and discharging into the Sacramento River. To the southwest in the Coast Range, similar geologic, geomorphic and topographic influences route most of the runoff through the Upper Cache Creek watershed in a southeasterly direction where it contributes to flows in Cache Creek. Cache Creek enters the Sacramento Valley south of the Subbasin in the Yolo Subbasin. As a consequence of the dominance of the Upper Stony and Upper Cache Creek watersheds in capturing most of the runoff from the higher elevations in the Coast Range, the remainder of the other Coast Range streams influent to the subbasin have relatively small catchment areas in low elevation areas of the Coast Range. These streams are intermittent and drain the foothills that border the Coast Ranges to the west.



Canals and drains intersect streams and creeks to provide a water supply and drainage network, which is shown on Figure 3-6. Major water features and conveyance infrastructure that serve agencies within the Subbasin include the Sacramento River, Stony Creek, Black Butte Lake, the Tehama-Colusa Canal, Glenn-Colusa Canal, and the Colusa Drain. The major water features and conveyance infrastructure are discussed in the following section. More detailed information regarding flows and volumes are discussed in the water budget chapter.

3.1.5.1 Natural Surface Waters and Conveyance Infrastructure

The regional watersheds and natural waterways are shown on Figure 3-5. The major natural waterways flowing into, through, or along the boundary of the Subbasin include the Sacramento River and Stony Creek. Many smaller intermittent streams drain the foothills that abut the Coast Ranges west of the Subbasin. Three major water conveyance infrastructures also exist within the subbasin. These are the Tehama-Colusa Canal, the Glenn-Colusa Canal, and the Colusa Drain. Smaller canal and channel systems transport water between the natural waterways and conveyance infrastructure. The natural and man-made water channels within the Subbasin are interconnected. Figure 3-5 and Figure 3-6 show the surface hydrology of the Subbasin. The major waterways are discussed in the following subsections.

3.1.5.1.1 Black Butte Lake and Stony Creek

The Upper Stony Creek watershed drains an approximately 770 square mile area of the Coast Range, foothills, and uplands, most of which is situated west of the Subbasin. Stony Creek south of the Glenn-Tehama County line defines the boundary between the Colusa and Corning Subbasins. The Stony Creek headwaters are in the Coast Range terrain of western Colusa County. Stony Creek flows north toward Stony Gorge Reservoir, which was constructed in 1928. Water discharged from Stony Gorge Reservoir continues northeast to Black Butte Lake, where most of the drainage within the Stony Creek watershed is eventually captured. According to data listed on the CDEC website and shown on Figure 3-7, storage within Black Butte Lake has been between 1,200 af and 140,000 af since 1963, when it was constructed. The lowest lake storage was recorded in Fall 1977, a critically dry year. Releases from Black Butte Lake, monitored by the USBR and available on CDEC, from 1996 to 2020 fluctuated between 0 and 24,000 cubic feet per second (cfs) (CDEC, 2020). Discharges from Black Butte Lake flow into either Stony Creek or canals that irrigate agricultural lands of the Colusa and Corning Subbasins. Stony Creek eventually drains into the Sacramento River. Historical streamflow in Stony Creek near Hamilton City from 1941 to 1963, prior to the construction of Black Butte Lake, ranged between 0 and 30,000 cfs.

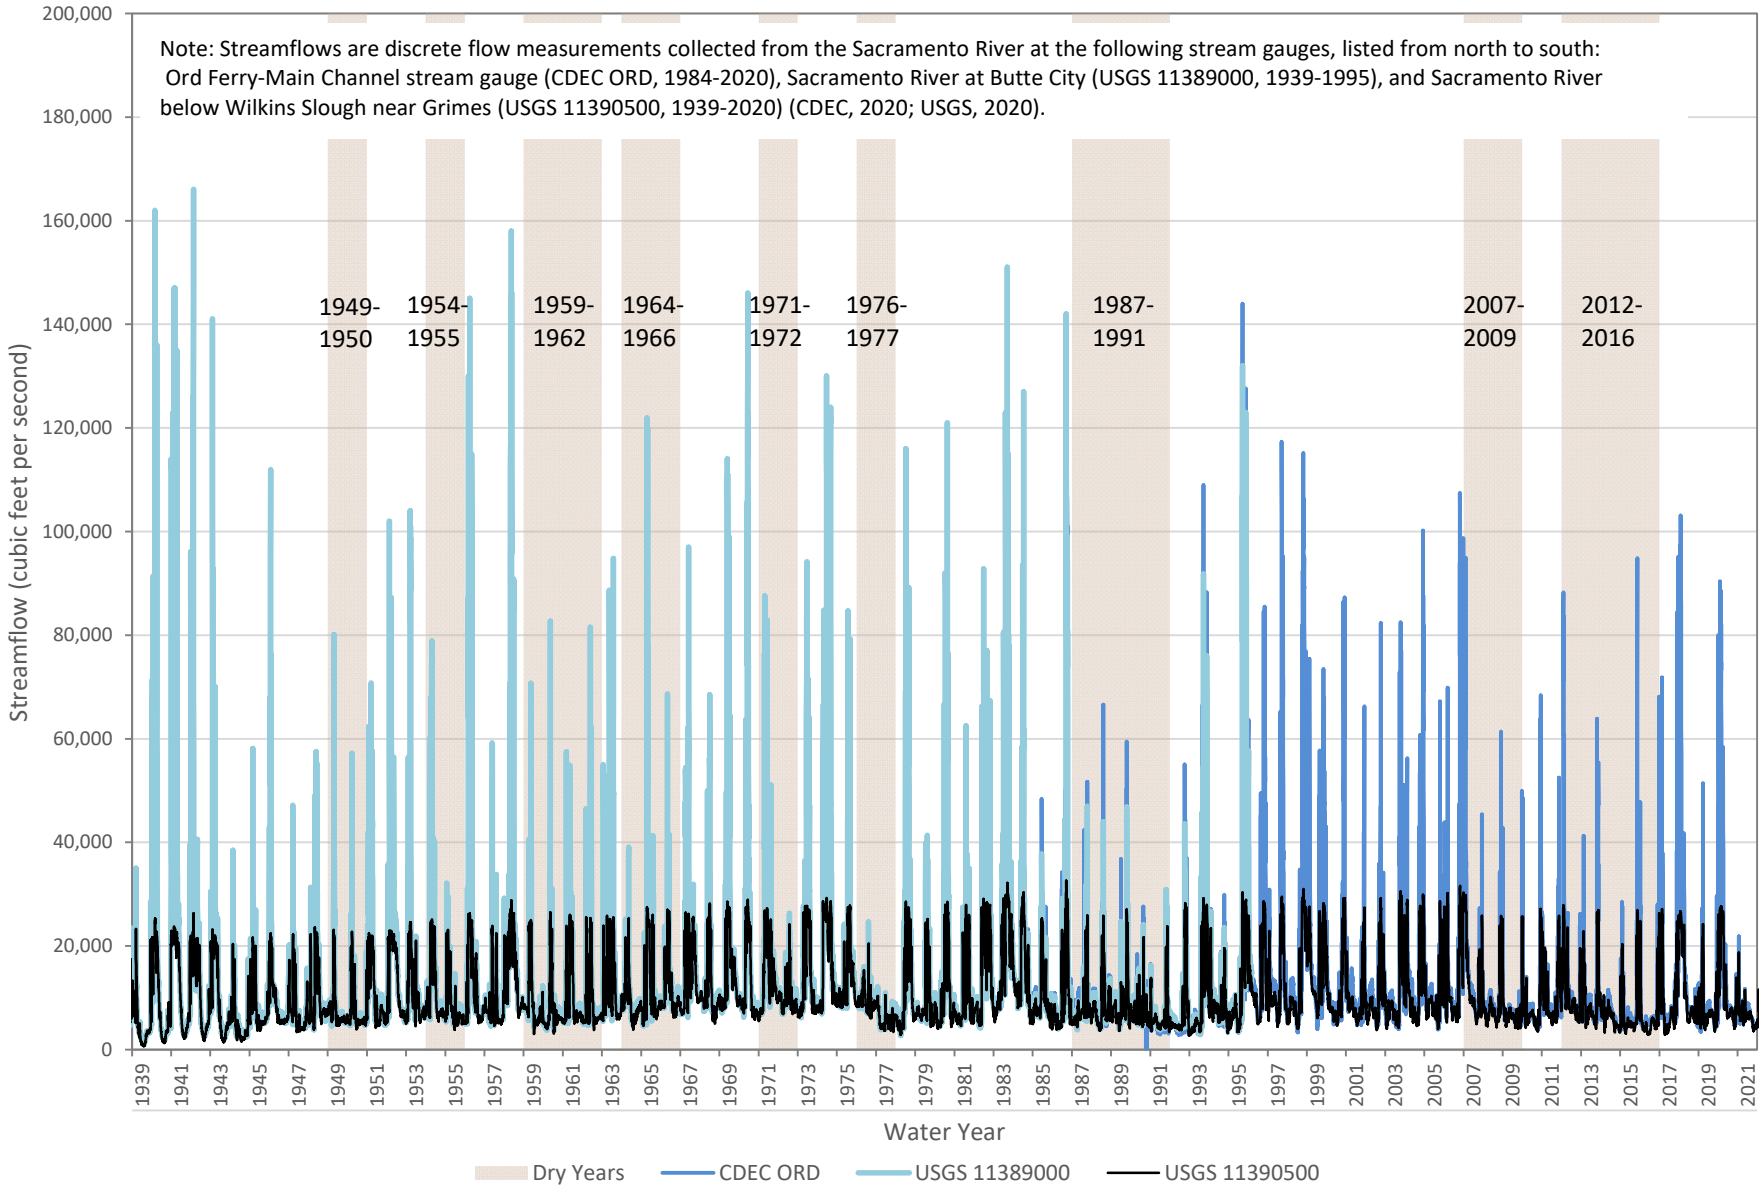
Figure 3-7. Black Butte Reservoir Storage

3.1.5.1.2 Sacramento River

The Sacramento River flows north to south along the eastern boundary of the Subbasin. The Sacramento River provides approximately 80 percent of the inflow to the Delta and is the largest and most important riverine ecosystem in the State of California (DWR, 2009a). In addition to providing flows to the Delta, the Sacramento River is the primary water source for irrigation water suppliers and certain landowners within the subbasin. Sacramento River stream flows measured at the Ord Ferry-Main Channel stream gage, in the northern part of the Subbasin, varied between 200 and 160,000 cfs during the 1984 to 2020 time period, with extreme low flows measured in the spring of 1990. River flows at Butte City (Station USGS 113890000) were record between 1939 and 2020 and ranged between 170,000 and 1,400 cfs. Stream flows measured at the stream gage below Wilkins Slough (Station USGS 11390500), south of Grimes, varied between 2,400 and 33,000 cfs for its entire period of record 1939 to 2020. Ord Ferry and Butte City are both located northwest of the Sutter Buttes and upstream of the confluence with Butte Creek, while Grimes is south of the Sutter Buttes. Figure 3-8 depicts the historical flows at these two locations. Flows at Wilkins Slough have historically remained fairly stable with the primary exceptions being critically dry years. Flows in the upstream stations are more seasonally and climatically variable and depict more of a response to dry years. Overall streamflows at all three stations have declined since 1995.

3.1.5.1.3 Tehama-Colusa Canal

The Tehama-Colusa Canal is operated and maintained by the Tehama-Colusa Canal Authority (TCCA), located near Willows, Glenn County. The TCCA service area covers approximately 150,000 acres and extends from Tehama County to Yolo County and provides irrigation water to farmers growing a variety of permanent and annual crops within the Subbasin. The Tehama-Colusa Canal originates north of the Subbasin at the Red Bluff Pumping Plant and Fish Screen in Tehama County, runs along the west side of the Colusa, and terminates south of the subbasin near Dunnigan Water District, Yolo County. Of the approximately 140 miles of TCCA water supply system, 75 miles of the Tehama-Colusa Canal traverses the Subbasin.



3.1.5.1.4 Glenn-Colusa Canal

The Glenn-Colusa Canal system is situated east of the Tehama-Colusa Canal and west of the Sacramento River. The Glenn-Colusa Canal originates on the Sacramento River north of the Subbasin and extends south of Williams, Colusa County, where it flows into the local canal system. The Glenn-Colusa Canal is operated by the Glenn-Colusa Irrigation District (GCID), located in Willows. GCID covers approximately 175,000 acres; of which, approximately 140,000 acres are farmed, making it the largest irrigation district in the Sacramento Valley (GCID, 2017). In addition to serving agricultural lands, GCID services approximately 1,200 acres of private habitat land and 20,000 acres of protected federal wildlife land. The main canal is approximately 65 miles long and conveys water into a complex system of nearly 1,000 miles of canals, laterals, and drains.

3.1.5.1.5 Colusa Basin Drainage Canal System

The Colusa Basin Drainage Canal System, or Colusa Drain, is a drainage system that transports rainfall runoff, agricultural runoff and return flows away from the agricultural lands in the Subbasin to the Sacramento River and the Tule Canal near Knights Landing, Yolo County. Many of the smaller natural streams of the region, including Willow Creek, drain into the Colusa Drain. Some of the water within the Colusa Drain is captured and reused prior to being discharged into the Sacramento River.

Figure 3-8. Sacramento River Streamflows

3.1.5.1.6 Other Streams

Walker Creek (near Artois) and Willow Creek (near Willows) are north-south trending streams largely contained within the subbasin (Figure 3-5). There are many ephemeral and intermittent streams that flow into or through the subbasin. These include ephemeral and intermittent streams that drain the foothills between the Subbasin and the higher elevation areas of the Coast Ranges. Historically, some of these streams were connected to springs at their headwaters or along their drainage reaches, where shallow groundwater would discharge into the channel. These foothill drainages and their tributaries are classified as part of the Sacramento-Stone Corral Watershed, as defined by the National Hydrology Dataset (NHD). The following streams comprise the Sacramento Stone Corral watershed, which bounds most of the Subbasin on its western side:

- Walker Creek
- Willow Creek
- French Creek
- Hayes Hollow Creek
- South Fork Willow Creek
- Logan Creek
- Hunters Creek
- Funks Creek
- Stone Corral Creek
- Lurline Creek
- Glenn Valley Slough
- Freshwater Creek
- Salt Creek (which flows past Williams, Colusa County)
- Spring Creek
- Manzanita Creek
- Cortina Creek
- Salt Creek (which flows past Arbuckle, Colusa County)
- Hambright Creek

Runoff in these ephemeral and intermittent streams generally begins in late fall when the rainy season starts and may continue until late spring. Inter-annual runoff patterns from streams such as these are highly variable, and many, if not all, of these streams flow into drainage canals within the subbasin. For example, Walker Creek and Willow Creek flow into the upstream end of the Colusa Drain, and other creeks, including Stone Corral Creek and both Salt Creeks, flow into the Colusa Drain's lower reaches (Figure 3-5).

3.1.5.2 Imported Water Sources and Points of Delivery

The primary surface water bodies through, or from, which imported waters are delivered to entities within the Subbasin include the Sacramento River and Stony Creek, with the Tehama-Colusa Canal and the Glenn-Colusa Canal being the primary conveyances of Sacramento River water. These surface water features, along with the regional and local water conveyance infrastructure, are shown on Figure 3-6. Water delivered via the Tehama-Colusa Canal, Sacramento River, Stony Creek, and other Central Valley Project contracts are managed by USBR.

Modeled points of surface water diversions included in the C2VSimFG-Colusa model and their delivery areas are shown on Figure 3-6 and listed in Table 3-2. The sources and delivery points for imported waters are described in more detail in the model development and calibration Technical Memorandum prepared by Woodard & Curran and Davids Engineering (2021) (Appendix 3D).

1

3.1.6 Soils

According to DWR (1978), which summarizes work performed by the USGS (Bertoldi, 1974), most soils in the Subbasin are either: 1) "soils containing hardpan or other consolidated horizons that restrict the vertical flow of water, including soils over bedrock", such as occurs in the western upland areas; or 2) "soils containing clay in sufficient quantities to impede the vertical flow of water", such as occurs in the former flood basins of the Sacramento River. Exceptions to this generalization are the soils in the vicinity of Stony Creek and stream channel deposits adjacent to the Sacramento River, which have "few barriers to the vertical flow of water" (DWR, 1978). These general patterns are supported by more recent soil surveys conducted by the Natural Resources Conservation Service (NRCS). Areas containing soils with few barriers to vertical flow have higher potential to recharge the underlying aquifers.

Figure 3-9 contains the NRCS Soil Survey Geographic Database (SSURGO) hydrologic soil group designations. Much of the Subbasin is classified as hydrologic groups C and D, which are defined as soils with slow or very slow infiltration rates when saturated (NRCS, 1986). Slow infiltration rates, as defined by NRCS, can be due to the presence of fine-textured layers, clays with high shrink-swell potential, shallow water tables, or shallow soil layers underlain by near-impervious layers. The Stony Creek alluvial fan, the Sacramento River historic channel, and runoff areas of northern Dunnigan Hills contain hydrologic soil groups A and B, which are defined as areas with high and moderate infiltration rates when saturated, respectively, occasionally mixed with soil group D (NRCS, 1986). Soils classified as mixed D soils (A/D, B/D, or C/D) typically correspond to soils near shallow water tables. These mixed D soils exhibit very low infiltration rates when undrained (characteristic of soil group D), and the alternate level of infiltration when drained (characteristic of soil group A, B, or C).

Source: Soil Survey Geographic Database (SSURGO) soils were downloaded via the 2014 SSURGO Downloader for the Big Chico Creek - Sacramento River, Butte Creek, Honcut Headwaters - Lower Feather, Sacramento Stone Corral, Upper Cache, and Upper Stony watershed subbasins.

Horizontal Datum: North American Datum of 1983, California State Plane Zone II, feet.

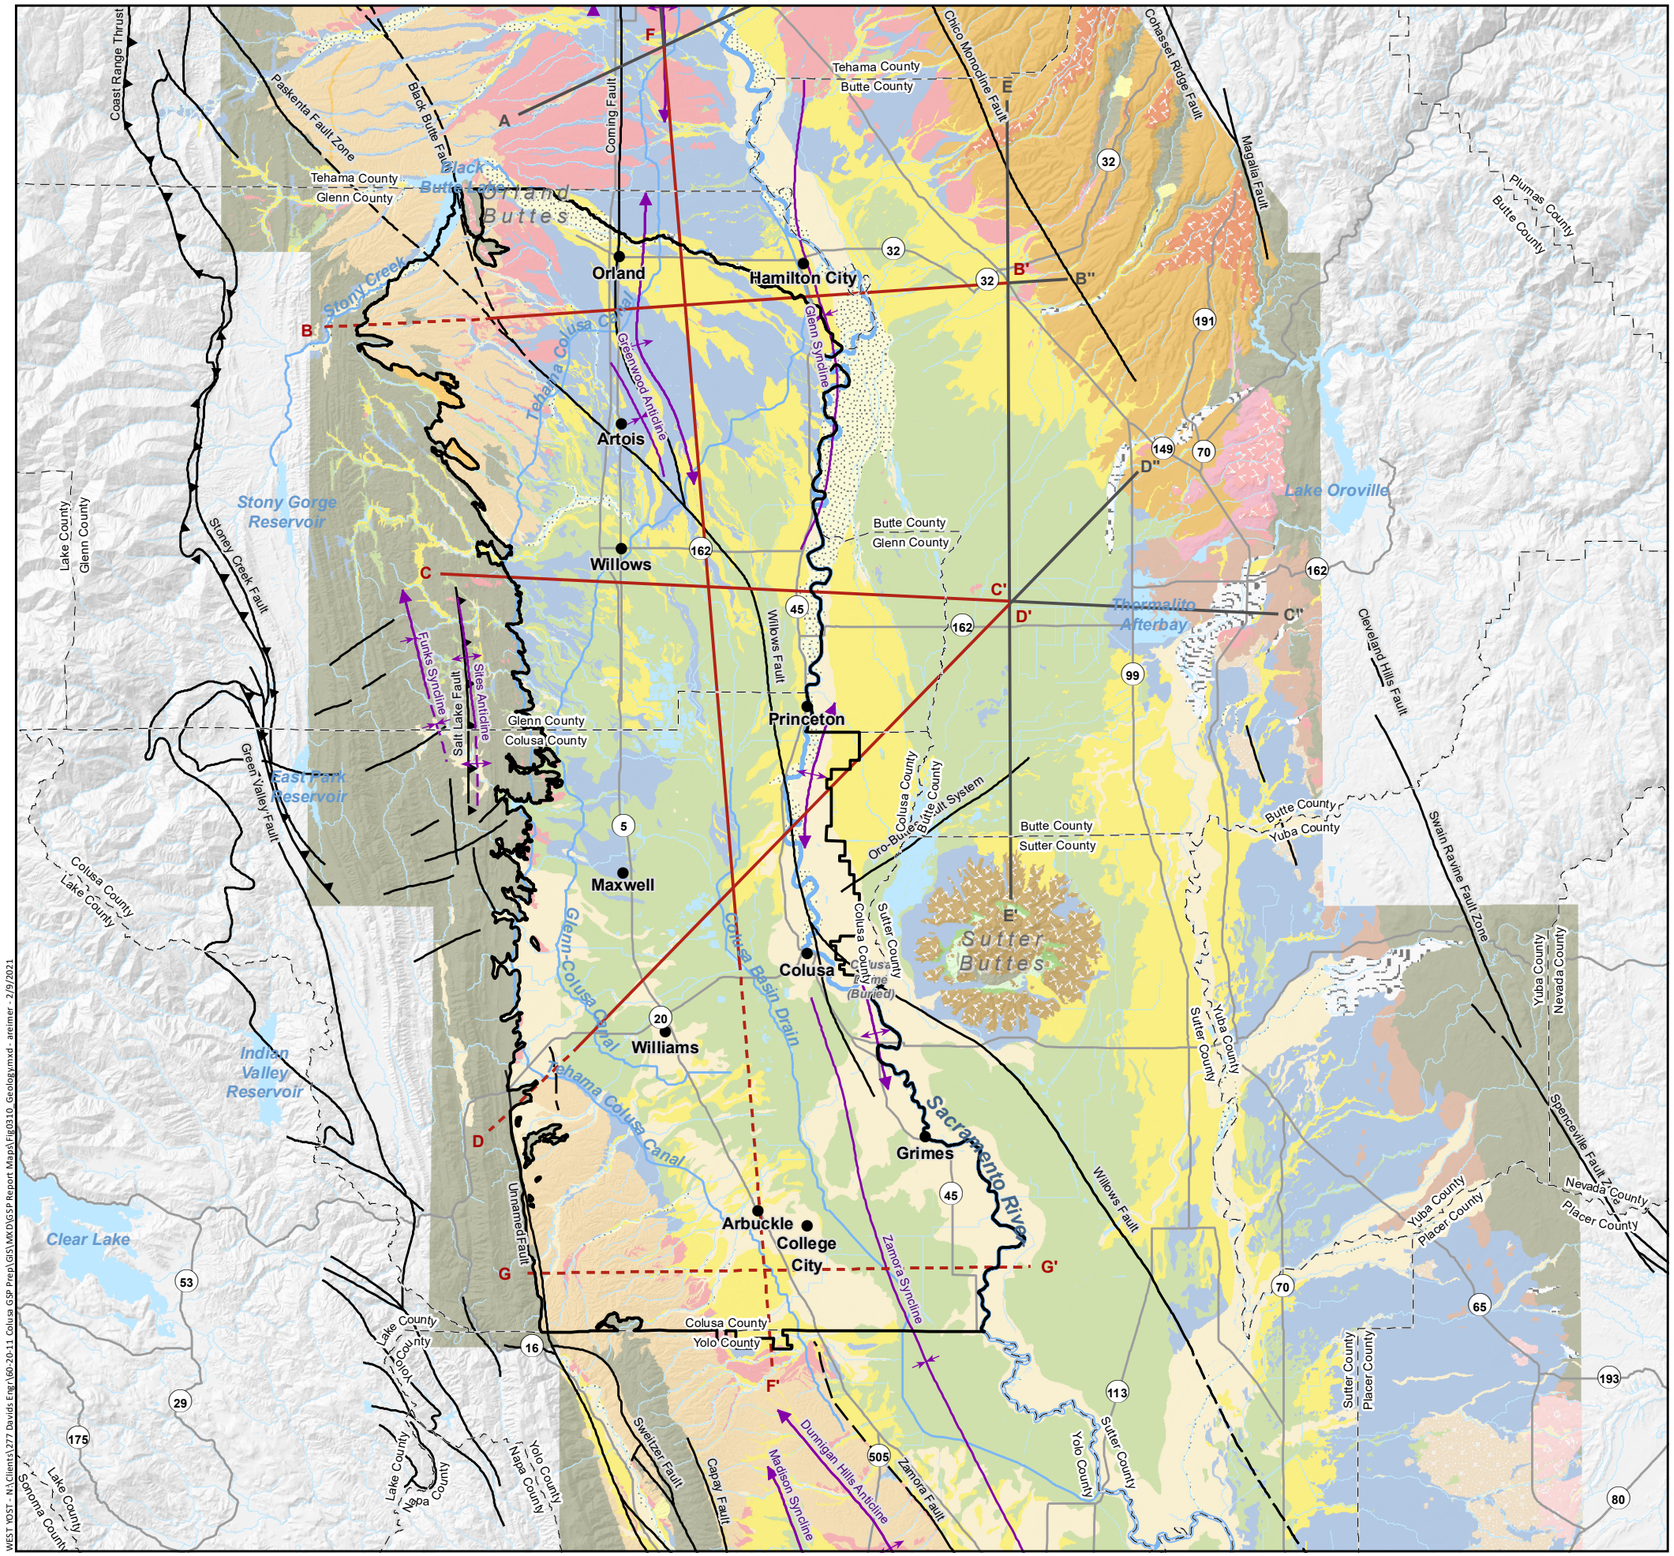
3.1.7 Geologic Framework

This section describes the geologic framework for the Subbasin, per the BMP (DWR, 2016a) and 23 CCR §354.14(b). The regional geologic and structural setting of the subbasin and surrounding area are described, including faults and other geologic structures that may influence groundwater flow and quality.

3.1.7.1 Regional Geologic History

Table 3-3 lists the geologic units within the Subbasin and characterizes their age, lithologic character, thickness, and water bearing character (WRIME, 2003a; WRIME, 2003b). Figure 3-10 shows detailed surface geologic mapping for the Subbasin and surrounding region, and the locations of five geologic cross sections through the Subbasin. Cross sections are provided on Figure 3-11 through Figure 3-13, and a three-dimensional (3D) representation of the HCM is provided on Figure 3-14. Figure 3-15 shows the Tehama and Tuscan Formation surficial outcrops and subsurface extents, including an approximation of the subsurface Tehama-Tuscan Transition Zone, in which Tehama and Tuscan Formation deposits are intermixed (DWR, 2009b). Figure 3-16 includes elevation contours for the top of the Cretaceous rocks. These contours represent the structural base of the freshwater aquifer system (Harwood and Helley, 1987).

The cross sections were developed based on DWR's Geology of the Northern Sacramento Valley report (DWR, 2014a). Some of the original DWR cross sections were expanded and new or extended cross sections were generated to provide a geologic representation of the subsurface throughout the entire Subbasin (Figure 3-10). The revised and new cross sections were based on land surface information, well completion reports, and other geologic references for the region. References to the data used to generate the cross sections are provided in Table 3-1 and Chapter 8. The cross sections were used to generate a 3D model of the post-Cretaceous water bearing formations, and for assessment of the groundwater monitoring network.



From the Late Jurassic (approximately 159 million years ago [Ma]) through the Miocene (approximately 23 Ma), much of what is now the Northern Sacramento Valley was a marine basin created in the forearc of the Pacific-North American plate subduction zone. The western boundary of the subbasin was formed by uplifting of volcanic, metamorphic and sedimentary rocks of marine origin, which would later become the Coast Ranges. This marine basin was bounded to the east by the Klamath-Sierran terrane formed during the Nevadan orogeny (approximately 155 Ma). Thick sequences of sediments eroded from the uplifted Klamath-Sierran terrane were deposited into the inland sea during the Cretaceous period. The resulting marine siltstones, sandstones, shales, and conglomerates comprise the Great Valley Sequence. Outcrops of the Great Valley Sequence define the western boundary of the Subbasin (Figure 3-10). The fresh groundwater-bearing formations overlie the Great Valley Sequence within most of the Subbasin, making it a major component of the structural base of the subbasin. The Great Valley Sequence is included in the pre-Paleogene and Cretaceous rocks referenced in the maps and within the report text. Figure 3-16 shows contours of the elevation of the top of the Cretaceous rocks in the Subbasin.

Table 3-3. Description of Geologic Units

Series		Unit	Lithologic Character	Thickness[a], ft	Water-Bearing Character
Quaternary	Holocene	Alluvium, Qa	Unconsolidated unweathered gravel, sand, silt, and clay[a].	80	Deposits are moderately to highly permeable with high permeability gravelly zones yielding large quantities to shallow wells[b]. Although deposits along Stony, Chico, and Thomes Creeks are important recharge areas[b], extensive water-bearing capacity is restricted by thickness and areal extent[a].
		Basin Deposits, Qb	Unconsolidated[e] fine-grained silts and clays, locally interbedded with stream and channel deposits along the Sacramento River[a].	150	Deposits are typically saturated nearly to the ground surface[b]. The low to moderate permeability results in yields of small quantity and poor groundwater quality to domestic wells[a,b].
	Pleistocene	Modesto Formation, Qm	Poorly sorted[e] unconsolidated weathered and unweathered gravel, sand, silt, and clay[c].	200	Moderately to highly permeable[a].
		Riverbank Deposits, Qr	Poorly sorted[e] unconsolidated to semi-consolidated[c] pebble and small cobble gravels interlensed with reddish clay, sand, and silt[a].	200	Water-bearing capability is limited by thickness. These poorly to highly permeable deposits supply moderate groundwater amounts to domestic and shallow irrigation wells. Deeper irrigation wells may be supplied if the wells contain multiple perforation zones[a].
		Red Bluff Formation, Qrb	Highly weathered, sandy gravels[g].	30[g]	Water-bearing capability is limited by thickness. Fresh groundwater may occur as a perched aquifer[g].
Neogene & Quaternary	Pliocene & Pleistocene	Tehama Formation, Tte	Fluviatile moderately consolidated pale green, gray, and tan sandstone and siltstone enclosing lenses of sand and gravel; silt and gravel; and cemented conglomerate derived from the Coast Ranges[a,c].	2,000	Local high permeability zones within this characteristically low to moderate permeability unit, widespread distribution, and deep thickness cause this formation to be the principal water bearing unit in the area. Deep well yields are typically moderate, but are highly variable[b].
Neogene	Pliocene	Tuscan Formation, Tt	This series of volcanic flows, consolidated tuff breccia, tuffaceous sandstone, and volcanic ash derived from the Cascade Range interfingers with the Tehama Formation as it westerly grades into volcanic sands, gravels, and clays[a,b]. The formation is divided by layers of thin tuff or ash units into four lithologically similar units A-D[a].	1,500	Within this formation, moderately to highly permeable volcanic sediments are hydraulically confined by layers of tuff breccias and clays[b]. Units A and B are the primary water-bearing zones and are composed of volcanic conglomerate, sandstone, and siltstone layers interbedded with lahars. Stratigraphically higher, the massive lahar deposits of unit C confine groundwater in the permeable beds of units A and B1.
		Nomlaki Tuff Member	Tuff breccias and white tuffs of dacitic composition. This member of the Tehama and Tuscan Formations serves as an important stratigraphical marker bed in northern Sacramento Valley[e].	60[e]	Poorly permeable.
	Miocene	Neroly Formation, Tn	Marine to non-marine tuffaceous andesitic sandstone interbedded with tuffaceous shales and tuff layers. Contains local conglomerate lenses[c].	500	This formation of variable permeability contains interstitial fresh water under confined conditions(d), however, deposits of the Neroly Formation are typically located below the base of fresh water.
		Upper Princeton Valley Fill, Tupg	Non-marine sandstone containing mudstone, conglomerate, and sandstone conglomerate interbeds[c].	1,400	Largely non-water bearing or contains interstitial confined fresh to brackish water[g].
		Lovejoy Basalt, Tl	Black, dense, hard microcrystalline basalt[c].	65	Largely non-water bearing.
Paleogene	Eocene	Ione Formation, Ti	Marine gravels[f], sandstone with claystone, and carbonaceous interbeds[g].	500(f)	Largely non-water bearing or contains interstitial confined fresh to brackish water.
		Lower Princeton Submarine Valley Fill, Tlpg	Marine conglomerate and sandstone interbedded with silty shale[c].	2,400	Largely non-water bearing or contains saline water.
Cretaceous		Great Valley Sequence, JKgvs	Marine siltstone, shale, sandstone, and conglomerate[c].	15,000	Largely non-water bearing or contains saline water[b].
Pre-Cretaceous		Basement Complex, pTb	Metamorphic and igneous rocks.	n/a	May contain groundwater, mainly saline, in fractures and joints.

Groundwater Sustainability Plan

The shoreline of the sea migrated westward throughout the Paleogene period due to continued subduction of the Pacific plate beneath the North American plate. During this period of regression, drainage from ancestral mountain ranges located north of the Subbasin eroded a submarine valley into the marine deposits (DWR, 2014a; Redwine, 1984). This valley, called the Princeton Submarine Valley, extends from the northern end of what is now the Sacramento Valley towards the City of Woodland in Yolo County, south of the Subbasin. Continued regression of the inland sea and ongoing drainage from the surrounding ancestral hills resulted in a mix of marine and continental deposits filling the Princeton Submarine Valley and surrounding basin. The incised nature of the Princeton Submarine Valley within the Great Valley Sequence can best be seen in the west to east trending Cross Sections B-B', C-C', and D-D' on Figure 3-11 and Figure 3-12. Cross Section F-F', on Figure 3-13, approximately follows the axis of the valley.

The lowest extents of the submarine valley were unconformably filled with Lower Princeton Valley Fill deposits during the Eocene. The Lower Princeton Valley Fill, deposited via turbidity flows, consists of interbedded sandstones and shale (DWR, 2014a; Springhorn, 2008). The Lower Princeton Valley Fill was conformably overlain by the Ione Formation in the Eocene (approximately 40 Ma) via stream drainage from the Sierra Nevada. The western extent of the Ione Formation is characterized by shallow marine deposition in the remnants of the inland sea, while the eastern extent of the formation is characterized by non-marine deltaic deposition (Redwine 1984; Springhorn, 2008). The Ione Formation unconformably overlies the Great Valley Sequence and crystalline and metasedimentary rocks near the eastern portion of the Sacramento Valley and is used as a marker bed to distinguish the Upper and Lower Princeton Valley Fill deposits.

Around this time, the tectonic regime of the northern Sacramento Valley began transitioning from a subduction zone to a transform zone as the Mendocino Triple Junction (composed of the Pacific, North America, and Juan de Fuca-Gorda plates) approached the Subbasin from the south. The transition from subduction to transform movement resulted in the creation of faults and folds, many of which are north-south trending due to the direction of compression applied by the transform system.

Volcanic activity during the Miocene resulted in the deposition of the Lovejoy Basalt (approximately 16.4 Ma), which unconformably overlies the Ione Formation and older formations, where they exist (Figure 3-11 and Figure 3-12). These basaltic flows originated near Honey Lake in the eastern Sierras and flowed westward, following channels towards and through what is now the northern Sacramento Valley (Helley and Harwood, 1985). Due to its distribution as flows in preexisting channels, the presence of Lovejoy Basalt is widespread but discontinuous.

Unconformably overlying the Lovejoy Basalt and older formations is the Upper Princeton Valley Fill. Upper Princeton Valley Fill was originally thought to have been deposited in Late Miocene to Oligocene, however age dating of the Lovejoy Basalt has constrained the age of the Upper Princeton Valley Fill to the Miocene epoch (approximately 16.4 Ma) (Springhorn, 2008). Upper Princeton Valley Fill consists of sandstone, with occasional interbeds of mudstone and conglomerate deposited in a fluvial floodplain system (Redwine, 1984). Because of its depositional history, groundwater within the Upper Princeton Valley Fill is fresh to brackish in quality.

Uplift of the Coast Ranges in the Pliocene epoch eventually gave form to the Sacramento Valley as it exists today. Alluvial, fluvial, and floodplain deposits derived from the Coast Ranges eventually accumulated as the Tehama Formation along the western side of the valley, while volcanic activity within the southern Cascade Ranges produced basalt and andesite flows that would eventually become reworked into the Tuscan Formation. The Tehama and Tuscan Formations were deposited concurrently during the late Pliocene to Pleistocene, interfingering with one another beneath the valley floor in what is referred to as the Tehama-Tuscan Transition Zone (Figure 3-15). The interlayering of the Tehama and Tuscan Formations can

be seen in Cross Sections B-B', C-C', D-D', and F-F' (Figure 3-11 through Figure 3-13). The Tuscan Formation appears as isolated lenses in north-south trending Cross Section F-F', but these lenses are integral with the main body of the Tuscan Formation, as depicted in the west-east trending cross sections. In the late Pliocene epoch, volcanic activity within the southern Cascade Range caused the widespread deposition of the Nomlaki Tuff across the northern Sacramento Valley. The Nomlaki Tuff has been radiometrically dated to 3.4 Million Years Ago (Ma) (Evernden, 1964) and provides an age constraint on the Tehama and Tuscan Formations because it is found in the basal deposits of both formations. The age of the upper boundary of the Tuscan Formation is further constrained to 1.5 Ma based on age dating of a rhyolite flow that overlies the Tuscan Formation near Mineral, Tehama County (Lydon, 1968).

Additional faults and folds were created as the Mendocino Triple Junction continued to move northward. These include the Corning Fault, Glenn Syncline, Greenwood Anticline, and an assortment of domes and buttes within the Subbasin. The Sutter Buttes are thought to have formed in part due to the compressional tectonics associated with the migration of the Mendocino Triple Junction (Hausback and Nilsen, 1999). The most recent Sutter Buttes volcanism occurred approximately 2 Ma (Hausback and Nilsen, 1999).

Quaternary geologic deposits are characterized by alluvial pediments and fans, and basin floodplain deposits of the Red Bluff Formation (an erosional surface, or pediment), Riverbank Formation, Modesto Formation, and basin deposits. These are collectively referred to as "Alluvium" on the cross sections found on Figure 3-11 through Figure 3-13 because of their limited thicknesses relative to the older formations (Table 3-3).

The Red Bluff Formation is a thin sand and gravel deposit resting on a pediment or erosional surface on the Tehama Formation (Figure 3-10). The Red Bluff Formation was formed when the Sacramento Valley was a closed drainage basin, which resulted in lacustrine depositional environments. The Red Bluff Formation is thought to represent the paleoshores of this ancient lacustrine system (DWR, 2014a; Springhorn, 2008). The age of the Red Bluff Formation is constrained to 0.6 to 1.09 Ma by radiometrically determined ages of the Rockland ash bed and the Deer Creek basalt, respectively (Harwood et. al., 1981; Harwood and Helley, 1987; Lanphere et. al., 1999). This constrains the age of the Tehama Formation to be no younger than 0.6 to 1.09 Ma.

Lacustrine environments resulting from the basin's internal drainage during deposition of the Red Bluff Formation also resulted in the deposition of diatomaceous clays similar to the Corcoran Clay of the San Joaquin Valley. This diatomaceous clay layer within the Sacramento Valley is referred to as the Turlock Lake Formation (Harwood and Jaworowski, 1985). This indicates that potentially subsidence-prone compressible sediments of approximately 0.6 to 1.09 Ma age are located near the top of the Tehama Formation. Boreholes east and south of the Sutter Buttes have encountered the Turlock Lake Formation. While similar sediment lithologies have been encountered in boreholes west of the Sutter Buttes, Turlock Lake Formation has not yet been identified in boreholes within the Subbasin. One borehole drilled near the Colusa Drain near Zamora in Yolo County, referred to as the USGS Zamora borehole, encountered a diatomaceous clay layer of about 10-feet thick at an approximate depth of 534 to 544 feet with properties similar to those of the diatomaceous clay from the Corcoran Clay of the San Joaquin Valley (Page, 1998; Page and Bertoldi, 1983).

The limited fresh groundwater found within the Red Bluff Formation tends to be present under perched conditions (DWR, 2014a). The Red Bluff Formation is therefore not further discussed in the following sections of this report.

Glacial activity during the Pleistocene epoch resulted in the Riverbank and Modesto Formations (Busacca et. al., 1989). The age of the Riverbank Formation ranges from 0.13 to 0.45 Ma and corresponds to the Illinoisan and older glacial stages. The age of the Modesto Formation ranges from approximately 0.01 to 0.042 Ma and correlates to the Wisconsin glacial stage.

The youngest deposits of the Subbasin consist of Holocene-aged basin deposits and stream channel deposits.

3.1.7.2 Primary Freshwater-Bearing Formations

The geologic formations forming the freshwater aquifer comprise a single aquifer system. The geologic formations comprising the freshwater aquifer system are discussed below.

3.1.7.2.1 Tuscan Formation

Tuscan Formation deposits are characterized by their Cascade Range origin and volcanic signature. This extensive series of basaltic and andesitic volcanic flows, consolidated tuff breccia, tuffaceous sandstone, and volcanic ash is primarily located on the northeastern portion of the Sacramento Valley. Figure 3-10 and Figure 3-15 show the approximate surface and subsurface extents of the Tuscan Formation in the vicinity of the Subbasin. The Tehama-Tuscan Transition Zone is also visible in the 3D hydrogeologic conceptual model shown on Figure 3-14. The Tuscan Formation comprises the oldest freshwater aquifer in the eastern half of the northern Sacramento Valley. The Tuscan Formation is exposed on the eastern side of the Sacramento Valley and occurs as interfingering layers with the Tehama Formation at depth near the center of the Sacramento Valley. This interfingering of the Tehama Formation with Tuscan Formation units is referred to as the Tehama-Tuscan Transition Zone (Figure 3-15). In the Subbasin, these deposits occur at depths greater than the depths of most existing domestic wells.

Moderately to highly permeable volcanic sediments are hydraulically confined by layers of tuff breccias and clays within the Tuscan Formation. The Tuscan Formation contains four map units, which are designated A through D, with A being the oldest (DWR, 2006a). The low permeability lahar, or mudflow, deposits of Unit C are confining beds for the underlying older Tuscan Units A and B. Although Unit C contains permeable volcanic sandstone and conglomerate interbeds, this unit is characterized by an overall low yield of water to wells within the Subbasin. Units A and B are much coarser-grained than the overlying Unit C, and they are the primary water-bearing zones of the eastern Sacramento Valley. The lower Tuscan Formation (Tuscan Units A and B) is present at depths below 700 feet in the northeastern part of the Subbasin and consists of volcanic conglomerate, sandstone, siltstone, and interbedded lahars overlain by tuffaceous breccias, sandstone and conglomerate. Tuscan Unit D is not present within the Subbasin.

The permeability of the Tuscan Formation varies, and irrigation wells range in well yield from 7 to 4,000 gallons per minute (gpm).

3.1.7.2.2 Tehama Formation

Figure 3-10 and Figure 3-15 show the approximate surface exposures and subsurface extents of the Tehama Formation. The Tehama Formation forms the oldest, deepest, and thickest part of the freshwater aquifer in the western half of the northern Sacramento Valley. The Tehama Formation consists of up to nearly 2,000 feet of moderately compacted silt, clay, and silty fine sand enclosing thin, discontinuous lenses of sand and gravel deposited in a fluvial (river-borne) environment (DWR, 2006a; Olmsted and Davis, 1961). Based on the mineralogy of surface exposures, the sediments were derived from erosion of the Coast Ranges and Klamath Mountains to the west and northwest. They were deposited under floodplain conditions on the west side of a broad valley of low relief (Brown and Caldwell, 2007; Russell, 1931).

The Tehama and Red Bluff Formations are exposed at the land surface on the western side of the Sacramento Valley, in the northwest, and the southwest. The outcrop of the Tehama and Red Bluff Formations and pinchout of the younger valley sediments coincide with an increase in terrain, as seen in Figure 3-4. There are few wells drilled in these areas and local residents report that existing wells yield little groundwater. Geologic mapping shows outcropping of older Cretaceous-aged sedimentary rocks in the northwestern portion of the subbasin near the Orland Buttes and west of the Tehama-Colusa Canal (Figure 3-10). Based on these observations, the Tehama Formation is relatively thin and has a low permeability where it outcrops. The Tehama Formation is buried beneath younger sediments to the east and interfingers with the Tuscan Formation throughout the Tehama-Tuscan Transition Zone in the northeast portion of the Subbasin (Figure 3-15).

The permeability of the Tehama Formation varies but is generally less than in the overlying unconsolidated alluvial deposits. Because of the thickness of the producing zones, production from the Tehama Formation can be up to several thousand gallons per minute per well (DWR, 2006a), but is typically less than that exhibited by the Tuscan Formation.

3.1.7.2.3 Riverbank and Modesto Formations

The late Pleistocene-aged Riverbank and Modesto Formations uncomfortably overlie the Tuscan and Tehama Formations. The thickness of the formation ranges from less than 10 feet to nearly 200 feet across the valley floor (DWR, 2006a; Helley and Harwood, 1985). These formations consist of loose to moderately compacted silt, silty clay, sand and gravel deposited in alluvial depositional environments during periods of world-wide glaciation (DWR, 2006a; Lettis, 1988; Weissmann et. al., 2002). The formations were deposited in response to changes in base level and increased precipitation during the glacial periods. The increased stream gradients and precipitation resulted in greater stream discharge and competency than observed today. The greater competency of the streams led to scouring of stream channels in preexisting geologic deposits, followed by transport, deposition and burial of sands and gravels in the channels as the glacial cycles progressed.

Figure 3-10 shows the spatial distribution of the Riverbank and Modesto Formation in the Subbasin. The formations are exposed at the land surface along the channels of creeks and along the western margin of the Subbasin, where they form a series of coalescing alluvial fans, emanating from the mouths of the creeks. The Riverbank and Modesto Formations typically form terraces along stream channels. The oldest terraces occur furthest from the channel and at the highest elevations. Successively younger terraces are incised into the next oldest deposit and, therefore, occur closer to the stream channel and at lower elevations. The Riverbank Formation forms the older terrace deposits that occur at a higher topographic level. In the Stony Creek Fan area, these terraces are well-defined, but they are absent or poorly defined along other minor streams in the Subbasin.

The Riverbank Formation consists of poorly to highly permeable pebble and small cobble gravels interbedded with reddish clay, sand, and silt. The Modesto Formation consists of moderately to highly permeable gravels, sands, and silts. The Riverbank Formation is distinguished from the Modesto Formation by interbedded clay layers. These formations contain fresh water (DWR, 2006a; Harwood and Helley, 1987).

Wells penetrating the sand and gravel units of the Riverbank and Modesto Formations produce up to about 1,000 gpm; however, the production varies depending on local formation thickness (DWR, 2006a). Wells screened in the Riverbank and Modesto Formations are generally domestic and shallow irrigation wells (DWR, 2006a).

3.1.7.2.4 Stream Channel and Basin Deposits

Holocene stream channel and basin deposits are the youngest sediments in Subbasin, with ages of roughly 10,000 years or younger (Helley and Harwood, 1985). The stream channel and basin deposits consist of up to 80-foot sections of unconsolidated clay, silt, sand, and gravel reworked from older formations by streams. According to DWR (2006a), which also refers to these deposits as younger alluvium, these deposits form a shallow, unconfined aquifer of moderate to high permeability, but with limited capacity due to the relatively restricted lateral and vertical extents of the deposits.

Holocene flood basin deposits are very young surficial deposits formed during flood events when streams overtopped their natural levees, flooding the surrounding area. As the flood water spread, the current velocity and stream competency decreased, resulting in deposition of silts, clays, and fine sands. Flood basin deposits reach thicknesses of up to 150 feet and may be interbedded with stream channel deposits (DWR, 2006a). Because of their low permeability, limited extent, and generally poor water quality, flood basin deposits are typically not used for groundwater production (DWR, 2006a).

3.1.7.3 Geologic Structures

Figure 3-16, from Harwood and Helley (1987), shows the structural contours in meters delineating the top of the Cretaceous marine sedimentary rocks in the vicinity of the Subbasin. The shaded color intervals on Figure 3-16 conform to the structural contours of the top of the Cretaceous rocks. The structural contours were based on the Cretaceous rocks because the resulting surface produces a single structural datum throughout the western Sacramento Valley. This datum helps reveal some of the geologic structures (folds and faults) that affect the Subbasin.

Figure 3-10 shows the significant structural features near the Subbasin, including, but not limited to the Willows Fault, Corning Fault, Glenn Syncline, and the Zamora Syncline in addition to other smaller unnamed geologic structures. These structural features affect geologic units at least as young as the Red Bluff Formation, which indicates that structural deformation was occurring as recently as 0.45 Ma – the oldest potential age of the overlying Riverbank Formation – and may be continuing at present (Harwood and Helley, 1987).

3.1.7.3.1 Faults

Faults may affect groundwater flow by bringing geologic materials with different hydraulic properties into contact across the fault plane or by fracturing the materials, which could either increase or decrease permeability, depending on the degree of fracturing and other geologic processes, such as mineralization, active within the fault zone. The fault might, therefore, act as a boundary or barrier affecting the lateral flow of groundwater between adjacent areas and might act as a conduit allowing vertical or lateral flow within the fault zone. The faults that were analyzed as part of this report include the Zamora Fault, Willows Fault, Corning Fault, Black Butte Fault, and the Paskenta Fault. These faults are shown on Figure 3-10 and discussed in the following subsections.

3.1.7.3.1.1 Zamora Fault

The Zamora Fault is a northwest-trending, east-dipping normal fault mapped along the eastern edge of Dunnigan Hills, south of the Subbasin. The Dunnigan Hills escarpment is partially attributed to the displacement along the Zamora Fault (Harwood and Helley, 1987). Local topography and geology indicate that the fault may extend further northward towards Arbuckle.

3.1.7.3.1.2 Willows Fault

The Willows Fault is a north-south trending reverse fault that dips 74 degrees to the east and extends from near Stockton, San Joaquin County to the north end of the Sacramento Valley (Harwood and Helley, 1987). The reverse movement of the fault juxtaposes Mesozoic-aged marine formations against the Tehama Formation, as seen in portions of Cross Sections B-B', C-C', and D-D', and the northernmost portion of Cross Section F-F' (Figure 3-11 through Figure 3-13). Additionally, there is evidence that the Willows Fault influenced not only the position of the Lower Princeton Valley Fill thalweg, but also offset the fill during deposition (Redwine, 1984). Displacement along the Willows Fault is approximately 1,600 feet at the top of the Cretaceous rocks and approximately 1,560 feet at the top of the Eocene formations (Harwood and Helley, 1987). The most recent activity along the Willows Fault affects the lower Tehama Formation. The slip rate on the Willows Fault is estimated to be 0.00055 inches per year (McPherson and Garven, 1999).

Groundwater elevations exhibit a localized lowering of the water levels where the northern extent of the Willows Fault splits into the Black Butte and Paskenta Fault zones. This is discussed more in the Existing and Historical Groundwater Conditions sections of the GSP (Section 3.2).

3.1.7.3.1.3 Corning Fault

The Corning Fault is an offshoot of the Willows Fault that extends north of Artois, Glenn County. It is a north-trending reverse fault of similar structure to the Willows Fault, which has no surface expression, but offsets the Pleistocene-age Red Bluff Formation and the underlying Tehama Formation (Harwood and Helley, 1987). Additionally, Late Cretaceous deposits in the region exhibit offsets of approximately 1,000 feet due to the Corning Fault (Helley and Hardwood, 1985), which can be seen in Cross Section B-B' (Figure 3-11). William Lettis and Associates (2002) concluded that "the Corning Fault is an active seismic source" with an estimated slip rate between 0.0008 and 0.002 inches per year.

3.1.7.3.1.4 Black Butte Fault

The Black Butte Fault is a northwest trending fault that separates the Orland Buttes from Black Butte Lake. Movement along the fault may have caused the uplift of the Orland Buttes (Russell, 1931). Mapping by Helley and Harwood (1985) included on Figure 3-10 depicts the Black Butte Fault as a northward offshoot of the Willows Fault, much like the Corning Fault.

3.1.7.3.1.5 Paskenta Fault

Displacement along the Paskenta Fault impacts the Cretaceous rocks but has not been observed within the Tehama and younger formations, constraining its most recent activity to approximately 3.3 Ma (DWR, 2014a). There are two main interpretations of the geologic nature of the Paskenta Fault zone. One interpretation is that the fault zone is a northwest trending, left lateral, transtensional strike slip fault (Moxon, 1990). The other interpretation is that the fault zone originated as an east-striking north-dipping normal fault zone that has been subjected to uplift and tilting to its current northwest trend (DWR, 2014a; Jones et. al., 1969; Moxon, 1990). Additionally, some studies represent the fault zone as truncating near Black Butte Lake or transitioning into an anticlinal form while others have mapped the fault as a splay fault from the Willows Fault, as shown on Figure 3-10 (DWR, 2014a).

3.1.7.3.2 Folds

Folds may affect groundwater conditions because folding causes the elevation and thickness of geologic units to vary from place to place. Synclines are typically characterized by thickening of younger units near the axis of the fold and potential exposure of older more consolidated units near the margins of the fold. Anticlines are the opposite and can expose less permeable rock formations along their axis and may

exhibit thickening of younger less consolidated formations near their margins. Additionally, the permeability and other material properties of sedimentary rocks, such as the Tehama Formation, are typically naturally anisotropic due to the alignment of mineral grains along bedding planes during deposition of the sediments. This alignment of the mineral grains results in higher permeability along rather than across bedding planes, which typically results in a maximum permeability horizontally and a minimum permeability vertically. Subsequent folding of bedding planes causes a reorientation of the direction of the mineral grains, and therefore a reorientation of the maximum and minimum permeability direction, which may affect groundwater flow rates and directions. The folds that were analyzed as part of this report include the Zamora Syncline, the Glenn Syncline, and the Greenwood Anticline. These folds are shown on Figure 3-10 and discussed in the following subsections.

3.1.7.3.2.1 Zamora Syncline

The Zamora Syncline is located in the subsurface east of Arbuckle, Colusa County and extends into Yolo County (Figure 3-10). The Zamora Syncline has no topographic expression, which means that the thickness of post-Cretaceous sediments, including the Tehama Formation, is greater along the axis of the syncline than on the limbs. This means that the aquifer thickness is greatest along the axis of the syncline. The effects of the Zamora Syncline on the older Cretaceous formations can be seen on Figure 3-16, where the elevation of the top of the Cretaceous formations is depressed west and south of College City, Colusa County.

3.1.7.3.2.2 Glenn Syncline

The Glenn Syncline is located near Hamilton City, Glenn County and was formed during the same compressional regime as the Corning Fault (DWR, 2014a). The Glenn Syncline roughly follows the direction of the Sacramento River (Figure 3-10). The effects of the Glenn Syncline on the Cretaceous formations can be seen in the elevation contours of the top of the Cretaceous rocks on Figure 3-10, where a depression in the top of the Cretaceous formations corresponds to the axis of the Glenn Syncline. Folding of the geologic formations along the Glenn Syncline can also be seen in Cross Section B-B' (Figure 3-11). Due to the vertical exaggeration of the cross section, folding is not as evident as the presence of the Princeton Submarine Valley, but a slight depression can be seen in the Great Valley Sequence and Upper Princeton Valley Fill near the Glenn Syncline.

3.1.7.3.2.3 Greenwood Anticline

The Greenwood Anticline and an unnamed syncline are located near Artois, Glenn County. These structures are on opposing sides of the Corning Fault and mimic the change in strike directions displayed by the Corning Fault (Helley and Harwood, 1985). It is believed that the Greenwood Anticline and the unnamed syncline coincided with the formation of the Corning Fault, under the same tectonic stress regimes (DWR, 2014a). Comparing Figure 3-10 and Figure 3-16, highs in the top of the Cretaceous formations are associated with the locations of the anticlines.

3.1.7.3.3 Orland Buttes

The Orland Buttes are located along the eastern shore of Black Butte Lake in Glenn County. The buttes are composed of Cretaceous rocks capped by Lovejoy Basalt, which were thought to have been uplifted due to movement along the Black Butte Fault (Russell, 1931). Seismic refraction data and a recent study by Williams Lettis and Associates (2002), however, suggest that the Orland Buttes were exposed via uplift and subsequent eastward tilting along a blind west-dipping thrust fault.

3.1.7.3.4 Sutter Buttes

The Sutter Buttes rise about 2,080 feet above the Sacramento Valley floor east of Colusa and are composed of igneous, metasedimentary and metavolcanic rocks about 2.4 to 1.4 Ma in age (Harwood and Helley, 1987). The formation of the Sutter Buttes occurred in two phases. The first phase caused Upper Cretaceous and Lower Paleogene formations to be arched into a dome rising above land surface during a period of magma injection. This was followed by rapid erosion and heavy faulting of the dome structure, causing the relatively older formations to be exposed prior to the second phase. The second phase consisted of explosive volcanism, producing the rampart tuffs and breccias surrounding the Sutter Buttes. Like many of the other geologic structures of the region, the Sutter Buttes express characteristics representative of the stress regime produced by the Mendocino Triple Junction (Harwood and Helley, 1987).

3.1.7.3.5 Colusa Dome

The Colusa Dome is a subsurface structure located approximately six miles west-southwest of the Sutter Buttes (Harwood and Helley, 1987). The dome is oblong in shape, approximately 12 miles long in the north-south direction and approximately 3 miles wide. Formation of the Colusa Dome, proposed by Harwood and Helley (1987), is due to both drag on the Willows Fault and/or a related south-trending fault splay and localized magmatic intrusion, potentially during the same period as the formation of the Sutter Buttes. The Colusa Dome is associated with uplift of Cretaceous to Eocene formations. Uplift of the Cretaceous rocks can be seen on Figure 3-16. The Cretaceous rocks have been uplifted to approximately 1,500 feet below ground surface (bgs) while the younger Eocene deposits have been uplifted to approximately 500 feet bgs (Springhorn, 2008; Williams and Curtis, 1977).

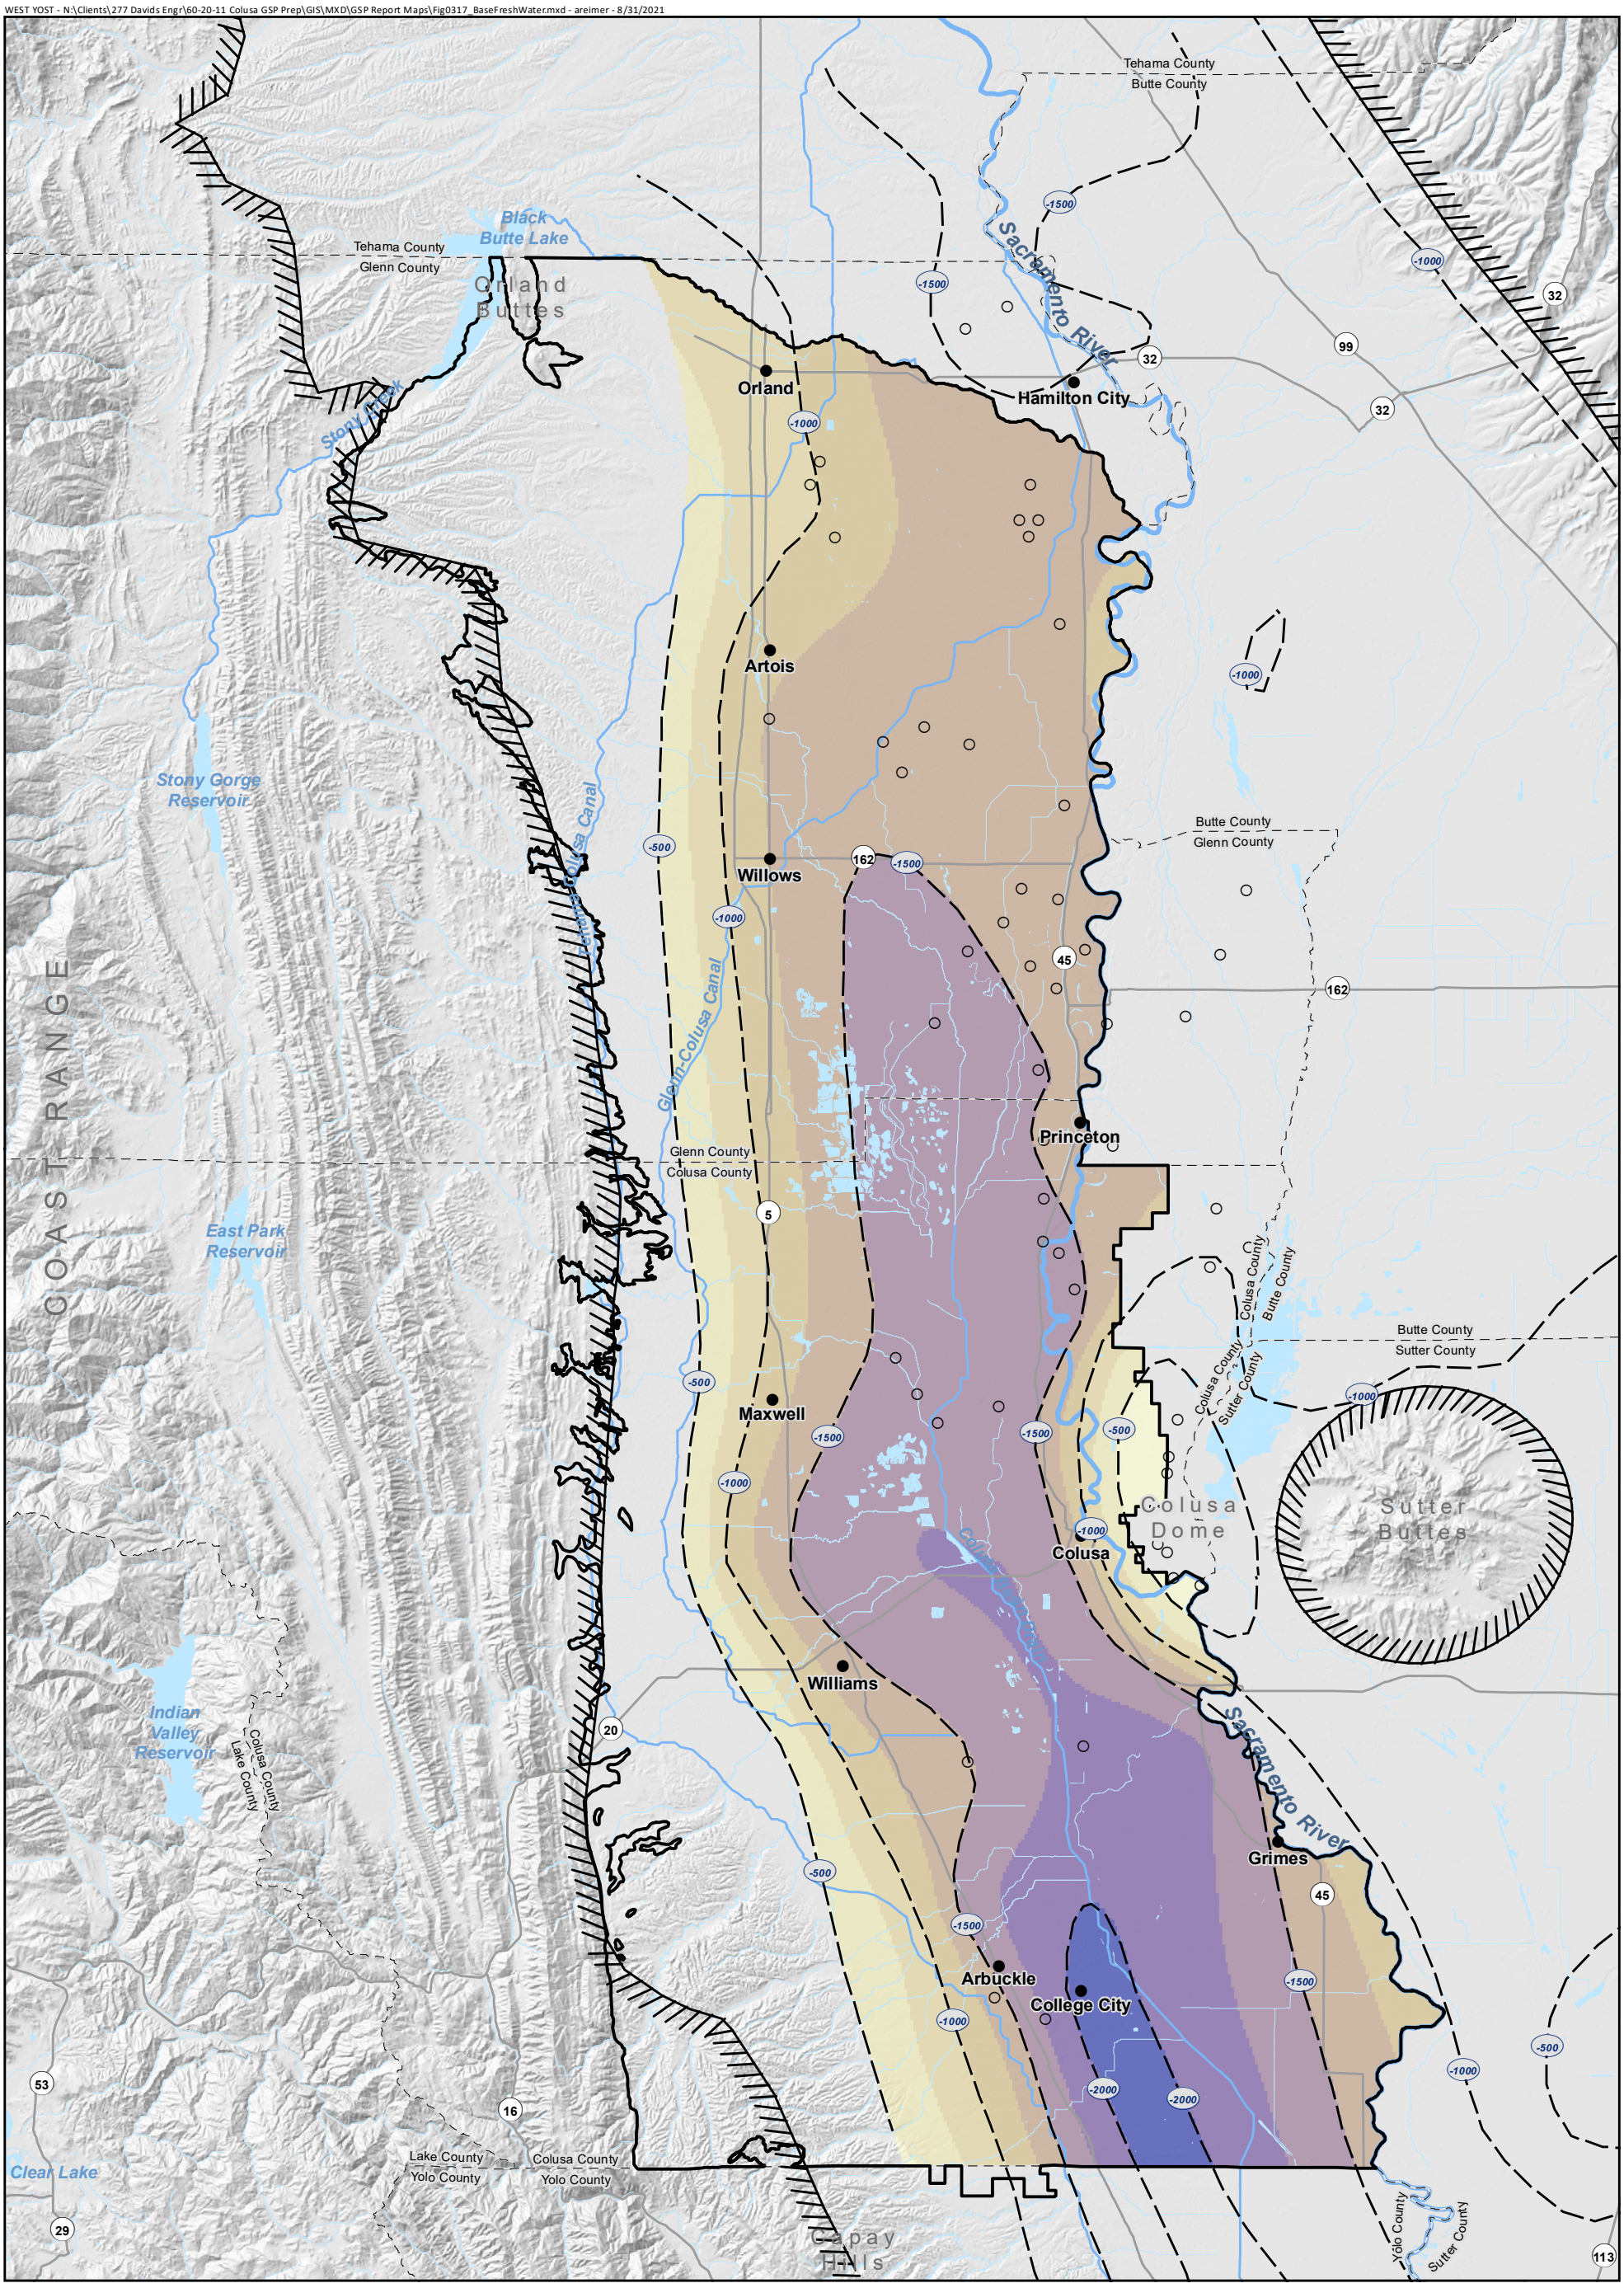
3.1.8 Basin Boundaries

Per the BMPs (DWR, 2016a) and 23 CCR §354.14(b), the lateral basin boundaries can be defined as geologic, hydrologic, or structural features that significantly affect groundwater flow. The lower boundary of the basin can be defined based on physical properties (such as depth to bedrock) or geochemical properties (such as base of fresh water).

3.1.8.1 Lateral Boundaries

Historically, the lateral boundaries of the Subbasin were defined hydrologically and consisted of Stony Creek to the north, the Sacramento River to the east, Cache Creek to the south, and the foothills of the North Coast Ranges to the west. The hydrologic rationale for these boundaries is that the streams are, or may be, coincident with groundwater divides (boundary zones of either converging or diverging groundwater flow) and the low-permeability Coast Ranges rocks create a barrier to groundwater flow at their contact with the alluvial sediments of the Subbasin.

The modified Subbasin extents have defined the southern boundary to be the Colusa-Yolo County line and the southern extent of the Colusa County Water District, both of which are jurisdictional boundaries (DWR, 2016d). The northern boundary is Stony Creek, where the Subbasin exists within Glenn County, and the Glenn-Tehama County line where Stony Creek exists in Tehama County. Stony Creek and the Coast Ranges comprise the western extent of the Subbasin. The Sacramento River demarks the eastern boundary of the Subbasin with the exception of lands within Colusa County east of the Sacramento River and west of Reclamation District 1004, which were added after the groundwater basin boundary modifications of 2018 (DWR, 2019).



3.1.8.2 Vertical Boundaries

Figure 3-16 provides elevation contours of the top of Cretaceous-age rocks within the Subbasin (Harwood and Helley, 1987). These contours provide one approximation of the physical base of the principal aquifer in the Subbasin (Harwood and Helley, 1987). Harwood and Helley (1987) contoured the top of the igneous crystalline and metasedimentary rocks where depth information was available and contoured the top of the Cretaceous rocks where wells were not deep enough to reach the crystalline and metasedimentary rocks. The contours on Figure 3-16 do not account for the post-Cretaceous Lower Princeton Valley Fill and Ione Formation, which were deposited in marine environments, or the Upper Princeton Valley Fill, which can contain fresh or brackish groundwater, and are therefore not considered part of the fresh groundwater aquifer system (Redwine, 1984). These formations lie above the elevation contours shown on Figure 3-16.

The base of the groundwater subbasins can also be defined chemically as the base of fresh water. The map in Figure 3-17 and the cross sections in Figure 3-11, Figure 3-12, and Figure 3-13 depict the base of fresh water as defined by USGS (Olmsted and Davis, 1961). According to Olmsted and Davis (1961), the base of fresh water is where specific conductance of the water exceeds 3,000 micromhos, or approximately 2,000 milligrams per liter (mg/L) total dissolved solids (TDS). DWR is preparing an updated map of the base of freshwater within the Central Valley, which will be based on a TDS concentration of 1,000 mg/L, as defined the SWRCB maximum contamination level (MCL) for TDS (DWR, 2016a). The base of fresh water defined by C2VSim is defined by a TDS concentration of 3,000 parts per million (ppm) (3,000 mg/L) and was based on available geophysical logs (DWR, 2020a). The differences in the definition of the “base of fresh water” is a data gap that will be addressed in future versions of the HCM, as more recent studies are issued, and an industry standard is adopted. Data gaps and uncertainties associated with the base of freshwater and recommendations to address them are discussed in Section 3.1.12.

The cross sections shown on Figure 3-11 through Figure 3-13 contain an approximate delineation of the vertical extent of the subbasin. The physical base of the subbasin was defined as the base of the Tuscan or Tehama Formations. This definition excludes Cretaceous-age formations, post-Cretaceous age sediments of marine origin (Lower Princeton Valley Fill and the Ione Formation). The post-Cretaceous, non-marine Upper Princeton Valley Fill is excluded because it can contain brackish groundwater, where saline waters from the marine deposits mix with freshwater from the continental deposits. This delineation is similar to the delineation based on the chemically defined basin extent, except near the western margins of the Subbasin where brackish groundwater occurs above the Upper Princeton Valley Fill in the Tehama Formation.

3.1.9 Stratigraphic and Structural Features Potentially Affecting Flow

Stratigraphic and structural features that could potentially impact groundwater flow were introduced in Section 3.1.7.3. The structures discussed below are not necessarily subbasin boundaries but may impede or enable groundwater flow within the aquifer system.

3.1.9.1 Topography

Topographic relief impacts flows at shallower depths in the aquifer system, for example where permeable beds pinch out on elevated topography and the older, less permeable units are exposed on the surface.

3.1.9.2 Faults

Geologic investigations have shown displacement of the hydrogeologic formations along the Willows and Corning Faults. This is evident in the cross sections of Figure 3-11 through Figure 3-13. These faults may act as barriers or conduits to fresh groundwater flows. Deep-seated faults that intersect base of freshwater boundary may impact water quality if the fault zone sediments are relatively permeable compared to the native formations. Fault zone sediments with higher permeability will encourage groundwater mixing of the deeper brackish or saline waters and shallower fresh groundwater.

Displacement along the Paskenta Fault zone has not been observed in the fresh groundwater bearing hydrogeologic formations, however, measured and interpolated water levels near the Paskenta and Willows Fault zones near Artois, Glenn County exhibit a consistent localized lowering of the groundwater elevations along the trace of the fault. Additional study of the groundwater conditions would be needed to determine if the fault is acting as a conduit for flow along the fault trace, is impeding flows traverse to the fault, or both. Faults that act as conduits to groundwater flow can lead to degradation of water quality if contaminated or low-quality waters are mixed with freshwater sources.

3.1.9.3 Folds

Synclines are the folding in of the stratigraphic formations, deepening younger formations along the axis of the syncline and potentially exposing the older formations along the margins. Synclines can indicate locations of increased permeability or aquifer connectivity. This is seen within the subbasin near the Zamora Syncline where the Tehama Formation is characterized by highly pervious, loose, and well bedded layers (DWR, 2006a). Folds can also cause reorientation of naturally anisotropic units causing decreased permeability within the aquifer; however, this effect on permeability has not yet been quantified within the subbasin.

3.1.9.4 Stratigraphic Pinchouts

Stratigraphic pinchouts can occur at different scales. At a geologic scale, pinchouts can be found at the lateral extents of the formation, where the formation thickness tapers out. Examples of this within the study include the overlapping fingers of the Tehama and Tuscan Formations throughout the transition zone (Figure 3-15) or where the alluvial and basin deposits truncate against the uplands of the Coast Ranges (Figure 3-10). Pinchout can also be seen in the cross sections on Figure 3-11 through Figure 3-13.

Pinchouts can also occur at a larger scale. Structured heterogeneity of a geologic formation can result in higher permeable sediment occurring within lower permeable material. The Tehama Formation is especially heterogeneous given its depositional history of alluvial and fluvial deposits and is composed of predominantly fine-grained sediments enclosing discontinuous lenses of sand and gravel, which by definition are pinchouts.

3.1.9.5 Manmade Features

Structural features that may impact groundwater flow are not limited to naturally occurring geologic structures. Subsurface manmade features can also act to impede or encourage groundwater flow. Sediment mixing or digging may inhibit shallow groundwater flows. Structures with leaky subsurface infrastructure, such as basements, may impede natural groundwater flow by trapping shallow groundwater within the structure. Conversely, manmade structures that can encourage groundwater flows include boreholes such as water wells, oil and gas wells, or exploratory drilling shafts. Groundwater can use unsealed or leaky boreholes to quickly move vertically through the aquifer system. This can impact not only groundwater levels, but also groundwater quality.

3.1.10 Principal Aquifers and Aquitards

The Subbasin is underlain by one principal aquifer with interconnected unconfined, semiconfined, and confined zones.

Shallow groundwater in the Subbasin occurs under unconfined conditions in the Holocene stream channel deposits, except where these units are overlain by Holocene basin deposits, creating semiconfined to confined conditions (DWR, 1978). At greater depths, groundwater occurs under semiconfined to confined conditions in a single heterogeneous aquifer system, composed of predominantly fine-grained sediments enclosing discontinuous lenses of sand and gravel. The aquifer properties, including hydraulic conductivity and degree of confinement are dependent on the properties of the fine-grained units (Bertoldi et. al., 1991; Williamson et. al., 1989). The physical, chemical, and hydraulic hydrogeologic properties of the principal aquifer are discussed in the following subsections.

Most of the fresh groundwater within the Subbasin is contained within the Tehama Formation. The fraction of fresh groundwater contained within the Tehama Formation decreases in the northeastern portion of the Subbasin, where sediments of the Tuscan Formation are more prevalent (Figure 3-15). The interface between the Tehama Formation and Tuscan Formation, referred to in this report as the Tehama-Tuscan Transition Zone, has been documented as mixed Tehama and Tuscan Formation sediments (DWR, 2009b). These mixed sediment zones grade into the Tehama and Tuscan Formations and probably result in continuity of flow between the Tehama and the Tuscan Formations.

There are no defined principal aquitards within the Subbasin, however, the formations deposited under alluvial conditions or volcanic flows with lahars, such as the Tehama and Tuscan Formations, respectively, tend to consist of thick low-permeability sediments interbedded with interconnected channels or lenses of higher-permeability sediment. The low-permeability sediments may impede vertical groundwater flows, but generally do not separate the aquifer system into separate, definable principal aquifers.

3.1.10.1 Physical and Structural Properties

The lateral extent of the principal aquifer is the same as the lateral extent of the subbasin and is discussed in Section 3.1.8.1.

The principal aquifer extends to the base of fresh water, which is discussed in Section 3.1.8.2.

The unconfined to semi-confined portion of the principal aquifer primarily consists of Riverbank and Modesto Formations, as well as the overlying Holocene stream channel and basin deposits. These sediments can be up to approximately 200 feet thick and are comprised of unconsolidated to semi-consolidated materials. These sediments are found throughout the subbasin but pinch out near the western margin of the Subbasin where the foothills and uplands of the Coast Ranges commence, and the Tehama Formation outcrops. Geologic mapping and well records support that the Tehama Formation is relatively thin where it outcrops and does not produce much groundwater. This is discussed more in Section 3.1.7.2.2.

The confined portion of the principal aquifer consists of the Tehama Formation, Tuscan Formation, and to a lesser extent, the Upper Princeton Valley Fill. The Tehama Formation is the primary water-bearing formation within the principal aquifer. The Tehama Formation is heterogeneous with discontinuous sand and gravel lenses. Thicknesses of the Tehama Formation can be as much as approximately 2,000 feet (Olmsted and Davis, 1961). The Tehama Formation exists throughout the Subbasin but pinches out along the western margin of the Subbasin with the Coast Ranges and also to the east within the Tehama-Tuscan Transition Zone (Figure 3-15). The Tuscan Formation is composed of interbedded lahars, conglomerate, volcanic sandstone, and volcanic ash layers and can be found at depths greater than 700 feet bgs. The Tuscan Formation within the subbasin exists almost solely within the Tehama-Tuscan Transition Zone but can be found as far east as the foothills of the Sierra Nevada Mountain Range. The Upper Princeton Valley Fill is located at depths greater than 1,000 feet bgs where it exists within the subbasin and is predominantly composed of sandstone. Table 3-4 contains the ranges of vertical and horizontal hydraulic conductivity, transmissivity, storativity, and specific yield values for the principal aquifer's unconfined and confined hydrogeologic units as listed in published reports on aquifer testing. Analytical models such as the Theis or Hantush-Jacob methods commonly enable the estimation of transmissivity and storativity from aquifer test data. Transmissivities can then be used to determine hydraulic conductivity of a water-bearing unit. Hydraulic conductivities are a measure of the aquifer's ability to transmit water horizontally or vertically. Aquifer materials generally have higher horizontal hydraulic conductivity than vertical hydraulic conductivity. Confining units are generally the limiting factor when evaluating vertical movement of water through the aquifer system.

Horizontal hydraulic conductivity of the unconfined to semi-confined zone ranges from 10 to 229 feet per day (ft/day).

A typical horizontal hydraulic conductivity of the Tehama Formation is approximately 27 ft/day. Within the permeable units of the Tuscan Formation (Units A and B), horizontal hydraulic conductivities range from 11 to 88 ft/day. One study estimated horizontal hydraulic conductivity within the confining unit of the Tuscan Formation (Unit C) to be 321 to 571 ft/day (Brown and Caldwell, 2013), an order of magnitude larger than those estimated within the more permeable units. Typically, the horizontal hydraulic conductivity of low-permeability strata is lower than that of its more permeable counterparts. This discrepancy in hydraulic conductivity values may be due to aquifer testing conducted within highly permeable zones within Unit C. More investigation into the discrepancy is recommended, as discussed in Section 3.1.12.2.

Vertical hydraulic conductivity for the confining unit in the Tehama-Tuscan Transition Zone was estimated to be 0.0036 ft/day based on data obtained during an aquifer test using a multiple completion observation well with separate completions perforated above and below the confining unit (West Yost, 2012).

Table 3-4. Hydraulic Properties

(b) Brown and Caldwell, 2013
(c) Montgomery Watson Harza (unpublished) via WRIME, 2003
(d) Olmsted and Davis, 1961

Water released from storage within confined aquifer systems is characterized by the storativity of the aquifer units. Storativity is estimated to range from 0.0003 to 0.001 for the Tehama Formation and 0.00004 to 0.003 for the Tuscan Formation. Storativity of Unit A of the Tuscan Formation (the deepest unit) is generally higher than that of Unit B (Brown and Caldwell, 2013), but still lower than that of the Tehama Formation. Storativity values are not reported for the unconfined portion of the Tuscan Formation.

Specific yield represents the water released from drainage from the pore space between the individual grains that comprise the aquifer sediment. Specific yield is only specified for the unconfined portion of the principal aquifer. Specific yield for the unconfined portion of the principal aquifer is approximately 0.034 to 0.185 (3.4 percent to 18.5 percent) (Olmsted and Davis, 1961).

Structural properties that could impact groundwater flows within the principal aquifer are discussed in more detail in Section 3.1.9.

3.1.10.2 Primary Uses

There are approximately 90 public water service agencies that provide potable water within the Subbasin (Figure 2-4). These stakeholders include municipalities, water agencies, irrigation districts, wildlife refuges, and reclamation districts. Not shown are private and domestic pumpers located in the "white-space" of the Subbasin and State small water systems. The primary uses of groundwater within the principal aquifer include agricultural, irrigation, domestic, industrial, and municipal supply (DWR, 2006a).

3.1.10.3 Water Quality

Historical groundwater quality concerns within the Subbasin include locally elevated levels of salinity, TDS, adjusted sodium absorption ratio, boron, nitrate, and manganese (DWR, 2006a; Wood Rodgers, 2008). Many of the entities within Glenn and Colusa Counties that monitor groundwater for quality either use wells that have multiple or long perforated intervals that access groundwater from both the unconfined and confined portions of the principal aquifer, or report water quality results from their wells collectively, without specifying what depth(s) the well was screened in. This data gap is discussed in more detail in Section 3.1.12 of this report.

Recent groundwater quality concerns within the Subbasin include salinity, boron, nitrate, heavy metals, including arsenic, and hexavalent chromium. High concentrations of sodium, chloride, and sulfate, all of which are related to salinity have been observed south of Maxwell (CH2MHILL, 2016a; RD 108, 2008) and could negatively impact agricultural applications. Elevated concentrations of boron within Colusa County have already impacted agricultural practices (GCID, 1995). In contrast, boron concentrations measured in select groundwater wells within Glenn County have not exceeded the United States Environmental Protection Agency (USEPA) agricultural water quality goal for boron of 750 micrograms per liter (µg/L) (USEPA, 1986; USGS, 2018). Elevated salinity levels throughout much of Colusa County, nitrates near Orland and Willows, arsenic near Grimes, and iron and manganese near Williams and Colusa are of concern with respect to drinking water MCLs (CH2MHILL, 2016a). Arsenic, especially, has been a constituent of concern for Grimes, Colusa, and the surrounding area. Local agencies have been working to mitigate arsenic contamination in groundwater in this area. Drinking water supply wells near Willows, Glenn County, have experienced high concentrations of hexavalent chromium (California Water Service, 2016).

There are also several active groundwater contamination cleanup sites in the Subbasin. These primarily include leaky storage tanks and unauthorized releases of contaminants such as petroleum hydrocarbons, nitrate, pesticides and herbicides including dicamba, and solvents. Most of these cleanup sites impact the unconfined portion of the principal aquifer, but there is a risk that the contamination could migrate into

the deeper, more heavily pumped portions of the aquifer. The largest contamination site is the Orland Dry Cleaner site, a tetrachloroethylene (PCE) plume that extends approximately two miles southeast of the source location in Orland, Glenn County (Department of Toxic Substances Control [DTSC], 2020; SWRCB, 2020b). In 2007, PCE contamination was recorded at depths of 127 feet bgs (DTSC, 2020).

More detail regarding existing and historical groundwater quality issues and trends is provided in Section 3.2 of this GSP.

3.1.11 Groundwater Inflows and Outflows

Groundwater inflows and outflows between the Subbasin and neighboring groundwater subbasins depend on fixed aquifer hydraulic properties and the prevailing groundwater gradients, which are influenced by time-dependent natural recharge and discharge patterns, aquifer interactions with streams, the effects of pumping, and the effects of managed and unmanaged recharge. These inflows and outflows are discussed further in the following subsections.

3.1.11.1 Groundwater Underflow

Groundwater underflow occurs as outflow across the boundary of the Colusa and Yolo Subbasins under the influence of the generally southeasterly to southerly groundwater flow gradient. The boundary between the Colusa and Yolo Subbasins is jurisdictional and has no influence on the flow of groundwater. Groundwater underflow as inflow occurs along the boundary of the Colusa and Corning Subbasins, along Stony Creek. Groundwater underflow may occur as either outflow or inflow across the eastern hydrologic border of the Subbasin, where the Subbasin is bound by either the Sacramento River or the jurisdictional boundary of R.D. 1004. How groundwater levels impact interconnected surface waters is discussed in Section 3.2.7.

The magnitude of these underflows is not currently quantified but is anticipated to be a relatively small component of the water budget for the Subbasin and neighboring groundwater subbasins. Significant influences on these inflows and outflows include groundwater gradients across subbasin boundaries, stream stage in the Sacramento River, Stony Creek and Butte Creek, and the timing, location, and magnitude of groundwater pumping, managed recharge, and unmanaged recharge, which includes recharge due to agricultural practices and precipitation.

Underflow across the western boundary of the Subbasin is negligible due to the low permeability of the Coast Range rocks.

3.1.11.2 Groundwater Recharge Areas

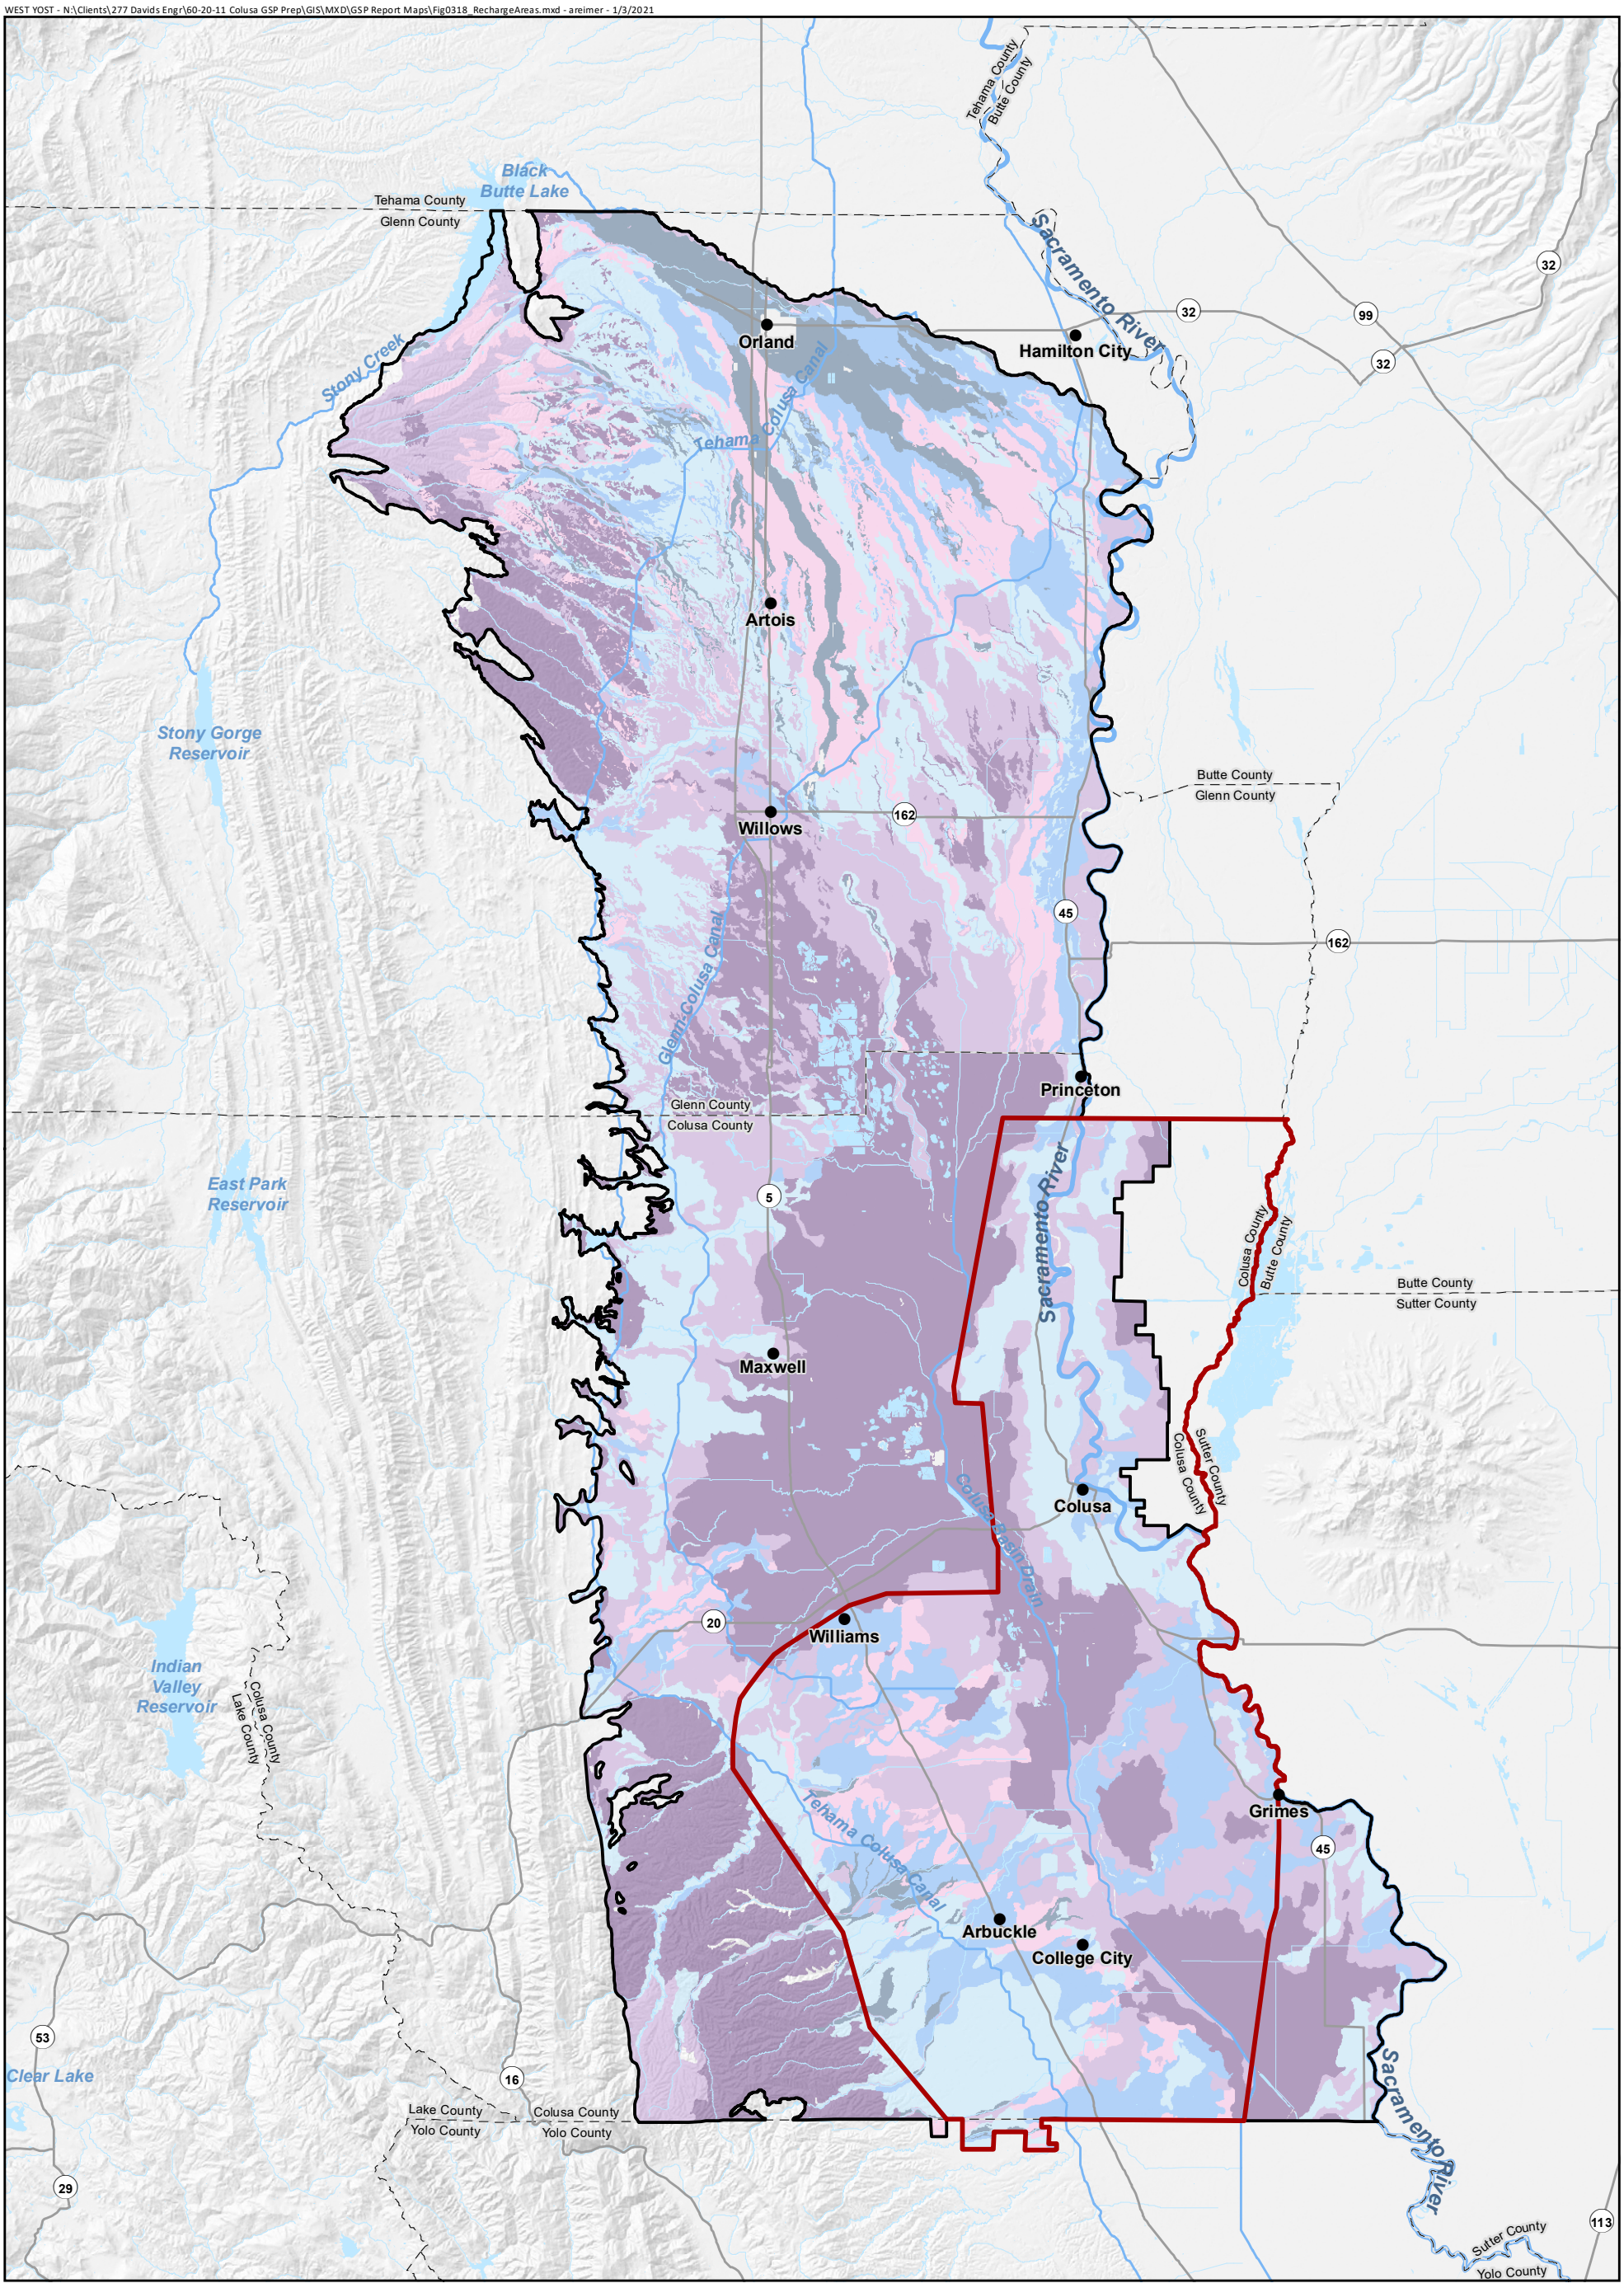
The primary sources of groundwater recharge in the Subbasin are deep percolation – the movement of water from land surface to the aquifer – of precipitation and applied water. Other volumetrically less important sources include deep percolation resulting from domestic and municipal uses.

3.1.11.2.1 Agricultural Recharge

Much of the Subbasin is devoted to agriculture; many of the agricultural fields are irrigated with surface water supplies from the Tehama-Colusa Canal, the Glenn-Colusa Canal, and other irrigation water supply systems, which provide Sacramento River water from outside of the subbasin boundaries (Figure 3-6). Water applied to agricultural lands has a significant contribution to groundwater recharge.

3.1.11.2.2 Soil Suitability for Groundwater Recharge

Recharge occurs throughout the Subbasin, but at variable rates depending on topography, soil properties and the underlying geology, as introduced in Sections 3.1.4, 3.1.6, and 3.1.7, respectively. Figure 3-18 shows potential recharge areas based on the Soil Agricultural Groundwater Banking Index (SAGBI) (O'Geen et. al., 2015). SAGBI was developed to provide a measure of soil suitability for recharge on agricultural lands while maintaining the viability of soils and crops, and groundwater quality. The index was developed considering five major factors (O'Geen et. al., 2015):



1. Deep percolation;
2. Root zone residence time;
3. Topography;
4. Chemical limitations; and
5. Soil surface conditions.

As depicted on Figure 3-18, the index also includes the assumption that soils with restrictive layers would be made more permeable through deep tillage. The index ranges from very poor to excellent over the Subbasin.

Soils with indices in the moderately good to excellent range correspond to hydrologic soil groups A through C, as discussed in Section 3.1.6, and are mostly located over younger alluvial fan and stream channel deposits, including those of Stony Creek and other small streams draining the Coast Ranges, and younger stream channel deposits located along the Sacramento River (Figure 3-9 and Figure 3-10).

3.1.11.2.3 On-Farm Multi-Benefit Managed Aquifer Recharge and Shorebird Habitat Program

In 2018, CGA in cooperation with The Nature Conservancy (TNC) implemented a pilot managed aquifer recharge program. During this program, farmers worked with TNC to create temporary wetlands using existing water conveyance infrastructure and available flows during fall and winter migration periods. The program sought to increase groundwater recharge in severely disadvantaged communities while providing habitat for migratory birds. Various factors including water availability, soil suitability, and farming practices were evaluated for participating farmers. The pilot project areas are delineated on Figure 3-18.

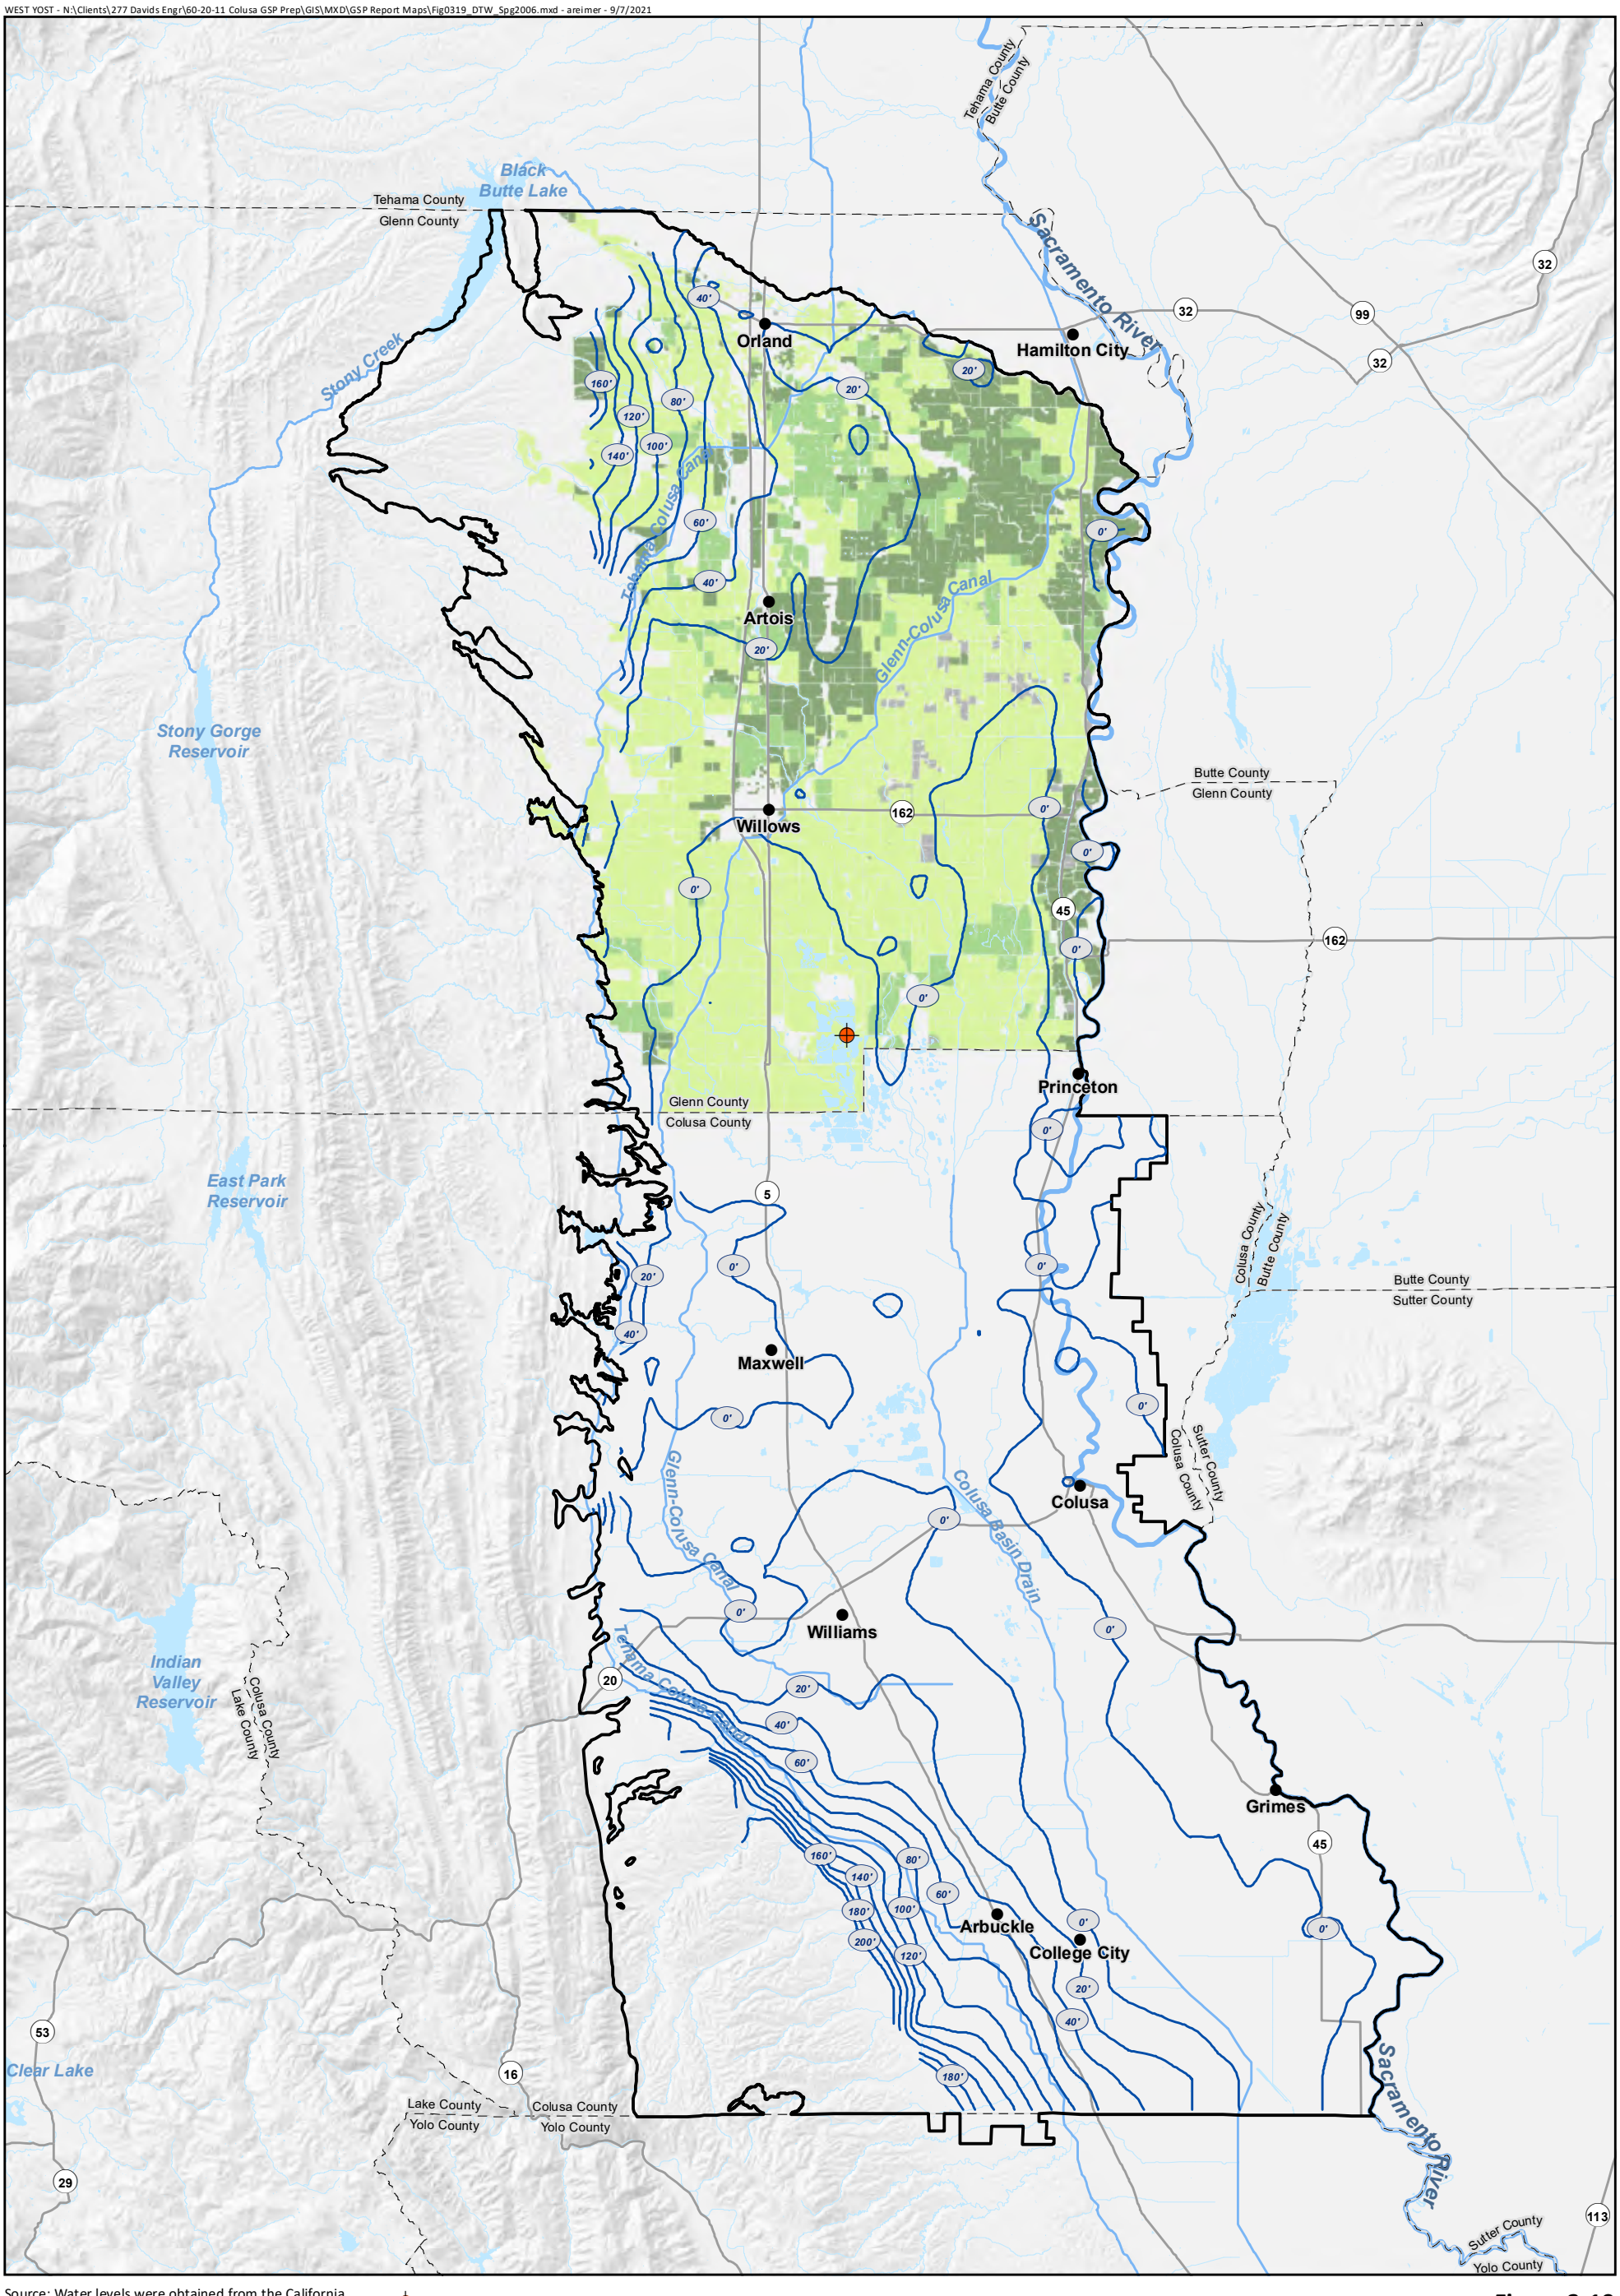
3.1.11.3 Groundwater Discharge Areas

Groundwater discharges in the Subbasin include:

- Discharges to streams, drains, seeps and springs;
- Losses to the atmosphere through uptake and consumption by wetland or riparian vegetation (phreatophytes), deeply rooted crops, and bare soil evaporation under shallow water table conditions; and
- Groundwater pumping.

Figure 3-19 and Figure 3-20 show depth to groundwater during the spring of 2006 (prior to the multiple year droughts of 2007-2009 and 2012-2015) and the spring of 2017 (after the multiple year droughts), respectively.



Areas with depth to groundwater close to land surface may indicate potential zones of groundwater discharge that can be expressed as flowing artesian wells, or through discharge to ponds, springs, wetlands, streams and canals. Discharges can also occur through evapotranspiration from riparian or phreatophytic vegetation, and from bare soil evaporation.

Approximately 25 springs can be identified from historical USGS topographic maps of the subbasin. Most of these springs are unnamed and located in the Subbasin occur near the western boundary. Location indicates that the springs historically discharged from the Tehama, Riverbank, or Modesto Formations and stream channel alluvium. A number of these springs have been developed for agricultural use by landowners locally (apparent on satellite imagery). Data regarding discharge and water quality was not found for incorporation into this GSP.

In the spring of 2006, the largest of these potential discharge zones was in a low elevation area of the Subbasin aligned along a north-northwesterly trend extending from the Colusa-Yolo County line into the southern half of Glenn County (Figure 3-19). The axis of the southerly part of this zone was aligned with the Colusa Drain, which is an indication that the Colusa Drain received groundwater discharge in spring 2006. Shallow depths to water in spring of 2006 also were evident along the Sacramento River, indicating that some reaches of the Sacramento River may have received groundwater discharges in spring 2006. The extent of potential groundwater discharge areas in the spring of 2017 was similar but more limited.

Comparison of the depth to groundwater contours to land use shows that many areas with shallow depths to groundwater correspond to the areas of rice cultivation and wildlife refuges. Ponded agricultural fields tend to be in areas that contain a high percentage of silts and clays, which restrict, yet do not negate the vertical flow of water into or out of the groundwater system. A portion of the groundwater would therefore discharge into the ponded water and a portion would discharge into unlined irrigation canals, drains, or ephemeral stream channels.

Groundwater Sustainability Plan

The potential for flowing artesian conditions is evident in the historical groundwater level measurements for some monitoring wells in the Subbasin. Figure 3-21 is a hydrograph for a multiple completion well located north of the Sacramento National Wildlife Refuge, west of Princeton. As seen on the hydrograph, the groundwater within the deep completion (18N02W18D001) historically has a higher potentiometric head than the groundwater within the shallower completions. This indicates a potential for upward flow of groundwater from the deeper confined water-bearing units to the shallower confined water-bearing units. Starting in 2014 and continuing through the first half of 2020, however, the depth to groundwater within the deepest completion has decreased significantly, indicating a reversal in the vertical flow direction. This period corresponds to the multiple year droughts of 2007 to 2009 and 2012 to 2016. Although the overall depths to groundwater were greater in the latter half of 2020, the vertical flow direction quickly reverted back to pre-2014 conditions. Generally speaking, groundwater pumping increases during periods of drought, when surface water deliveries are diminished. This causes a lowering of groundwater levels and may result in cones of depression surrounding the groundwater extraction wells. When sufficient surface water supplies exist, pumping decreases, and the groundwater levels revert to their previous vertical gradient regime, as evidenced in the hydrographs. Groundwater levels can take much longer to recover than the vertical gradient regime.

Groundwater pumping within the subbasin serves municipal, domestic, irrigation, commercial, and environmental needs. Figure 3-19 and Figure 3-20 show the irrigation districts, reclamation districts, municipal water agencies, and wildlife refuges within the Subbasin and the water supply source identified by DWR in 2014 (DWR, 2014b). DWR surveys of groundwater extraction for the Subbasin reported approximately 310,000 af for agricultural applications, 14,000 af for municipal and industrial consumption, and 22,000 af for environmental wetland use (DWR, 2006a). There are also many unmetered domestic and small agricultural wells located throughout the Subbasin. Colusa County estimates approximately 1,200 af of groundwater extraction from domestic wells (Wood Rodgers, 2008) across the entire County. A more detailed discussion of the water budget is discussed in Section 3.3 of this GSP. For GSP development, groundwater pumping by rural residential wells was estimated using the C2VSimFG-Colusa model, and was calculated based on residential demand after accounting for any other available water supplies and separately accounting for agricultural demand (see Appendix 3D for additional information). More detailed discussion of the GSP water budget and groundwater pumping estimates is provided in Section 3.3 of this GSP.

While the municipalities rely on groundwater to serve their residents, much of the agricultural lands within the Subbasin divert surface water supplies for irrigation. Some of the farmlands use a mix of surface water supplies and groundwater (Figure 3-19 and Figure 3-20). The primary groundwater pumping areas for irrigation correspond to farmlands that do not receive surface water supplies. An example of this includes farmlands that are not part of an existing irrigation district.

Figure 3-21. Hydrograph for Well 18N02W18D001-004M

3.1.12 Data Gaps, Uncertainty, and Recommended Actions

BMPs for the HCM (DWR, 2016a) state that "the HCM should be developed and periodically updated as part of an iterative process as data gaps are addressed and new information becomes available". The different components of the HCM were evaluated for data gaps, uncertainty, and unresolved discrepancies identified through comparison with the C2VSimFG. These topics and recommended future actions are discussed in more detail in the following subsections. More information regarding C2VSimFG and how it was used for the Subbasin can be found in Appendix 3D.

The data gaps in the HCM and some recommended actions to address the data gaps are discussed in the following sections. The following data gaps have been identified:

- Lateral and vertical extent of geologic units and the principal aquifer, specifically with regard to the Tehama-Tuscan transition zone, volcanic and plutonic formations related to the Colusa Done and Sutter Buttes, Turlock Lake Formation or similar highly compressible clayey deposits, and thickness of the Tehama Formation in the upland areas of western Colusa Subbasin and near the Zamora Syncline.
- Vertical extent of the base of fresh water.
- Hydraulic parameters of the principal aquifer.
- Groundwater quality of the principal aquifer, specifically with regard to the source and vertical migration of contaminated waters.
- Groundwater levels within the principal aquifer, specifically pertaining to the western margins of the Subbasin where there is a lack of monitoring locations and the unconfined shallow water table (e.g., near Orland where an increase of drying shallow domestic wells is currently occurring).
- Location and discharge of springs.

3.1.12.1 Extent of Geologic Units, Principal Aquifer, and Base of Fresh Water

Uncertainties in the thickness and extent of the principal aquifer, geologic formations, and base of fresh water have been identified in the following areas of the subbasin:

1. Tehama-Tuscan Transition Zone;
2. West and south of the Sutter Buttes;
3. Northwestern upland area, west of Orland;
4. Southwestern upland area, west of Arbuckle; and
5. Near the Zamora Syncline, east of Williams and College City.

There is uncertainty regarding the extent and depths of the Tehama and Tuscan Formations within the Tehama-Tuscan Transition Zone. Previous geologic mapping shown on the cross sections (Figure 3-11 through Figure 3-13) and Figure 3-15 depict thick depositions of Tehama and Tuscan within the Transition Zone, but the borehole data delineating the thickness and extent of units and the degree to which Tehama and Tuscan Formation sediments are intermixed is limited.

Springhorn (2008) identified the lands west and south of the Sutter Buttes, along the Sacramento River and surrounding area, as an area with gaps in information regarding subsurface lithologic extent and how it impacts groundwater quality, primarily arsenic. The investigations conducted for this GSP agree that the area is a data gap.

Additionally, there is some concern regarding the extent and thickness of the Turlock Lake Formation or a similar diatomaceous clay layer within or near the Subbasin. The compressible Turlock Lake Formation sediments may lead to land subsidence and reduction in aquifer storage. The Turlock Lake Formation and a similar diatomaceous clay layer is present in boreholes east and south of the Sutter Buttes and was encountered in a borehole near Zamora in Yolo County. Additional subsurface investigations in the areas west and south of the Sutter Buttes is recommended to better understand the extent of these sediments.

The base elevation of the uppermost three C2VsimFG model layers is overlain on the cross sections (Figure 3-11 through Figure 3-13). The modeled layers for C2VSimFG are based on groundwater conditions and pumping, not geologic units, but can be compared with the extent of the geologic units comprising the principal aquifer. The principal aquifer is also characterized by the extent and thickness of the freshwater-bearing geologic formations within the subbasin. Therefore, the extent of the geologic formations, principal aquifer, mapped base of freshwater and extent of the model layers are all related. Discrepancies between these datasets highlight uncertainty in the underlying datasets, the methods used to interpolate the base of fresh water, and the methods used to interpolate the thicknesses of geologic formations between locations with known data. Available information in the northwest uplands indicate that the Tehama Formation in that area is relatively thin compared to the rest of the subbasin and has low groundwater yield. The geologic mapping and cross section B-B' shown on Figure 3-10 and Figure 3-11 support this theory. The modeled base of fresh water, however, shows the principal aquifer as approximately 1,000 feet thick. This contradicts the available geologic data and verbal reports from residents of the area. Olmsted and Davis (1961) did not map the base of fresh water in this area. Table 3-5 provides a comparison of the four model layers with the principal aquifer and geologic formations.

Table 3-5. Comparison of Modeled Layers with Principal Aquifer and Geologic Units

C2VSimFG Model Layer Number	C2VSimFG Model Layer Description	Principal Aquifer	Geologic Formation
1	Unconfined Freshwater Aquifer Zone with Pumping	Unconfined Zone	Holocene Basin Fill and Stream Channel Deposits Modesto Formation Riverbank Formation Tehama Formation (minimal)
2	Confined Freshwater Aquifer Zone with Pumping	Confined Zone	Tehama Formation Tuscan Formation
3	Confined Freshwater Aquifer Zone with Little Pumping	Confined Zone	Tehama Formation Tuscan Formation Upper Princeton Valley Fill (partial)
4	Confined Saline Aquifer	--	Upper Princeton Valley Fill (partial) Ione Formation Lower Princeton Valley Fill

Uncertainty is even greater in the southwestern upland area than the northwest upland area. In addition to minimal available well logs, there are no mapped isolated outcrops of older Cretaceous-aged rocks within the southern uplands to indicate uplift of older bedrock formations. Cross sections D-D' and G-G', which cut through the southwestern upland area, show the reverse discrepancy along the west margin of the Subbasin (Figure 3-12). Cross sections D-D' and G-G' show the modeled base of the aquifer to be much shallower than the mapped freshwater-bearing geologic units.

The Tehama Formation thickens near the Zamora Syncline, however available data that identifies the base of the Tehama Formation in this area is scarce. The modeled based of fresh water from C2VSimFG and the mapped base of fresh water from Olmsted and Davis (1961) both indicate that fresh water exists at depths greater than those shown on cross section G-G' (Figure 3-12).

Other locations where the modeled or mapped base of fresh water does not coincide with the freshwater-bearing formations can be seen on the cross sections (Figure 3-11 through Figure 3-13). For example, near the Corning Fault on cross section B-B', near Sacramento River on cross section D-D', or between Cortina Creek and the Tehama-Colusa Canal on cross section F-F'. Additionally, input from residents and additional groundwater quality studies support that the base of fresh water is shallower than reported along fault zones (e.g., Willows Fault) and near the Sutter Buttes, where the freshwater-bearing geologic formations are thinner and shallower.

Additional subsurface data will be collected to help delineate the base of the geologic formations in the aforementioned areas. The vertical extents of these geologic units will be updated through evaluation of DWR's forthcoming texture model developed as part of the Sacramento Valley Simulation Model (SVSim); inspection of geophysical logs from oil and gas wells; aeromagnetic surveys; passive seismic or other geophysical investigation surveys, such as controlled source audio-frequency magnetotellurics (CSAMT); in-depth evaluation of available well completion reports (most of which may not be deep enough to characterize the base of the Tehama and Tuscan Formations, but may be sufficient to better define the Tehama-Tuscan Transition Zone); information from new boreholes; and/or other methods or data sources that may characterize the subsurface stratigraphy.

Different agencies have chosen different TDS concentration thresholds to define the base of fresh water. These different threshold concentrations used to classify fresh water versus saline water is a contributing factor in the discrepancy between all of the mapped depth to base of fresh water. Olmsted and Davis (1961) used a threshold of approximately 2,000 mg/L while C2VSimFG assumes a threshold of 3,000 ppm (approximately 3,000 mg/L of TDS, DWR, 2020a), and DWR is preparing an updated analysis of the base of freshwater within the Central Valley, which will be based on a TDS concentration of 1,000 mg/L, the MCL for TDS (DWR, 2016a). The new DWR analysis will be used to update the HCM and the freshwater threshold concentration used by that analysis will supersede all previous mapped thresholds.

Once additional, more recent information is evaluated the geologic and base of freshwater extents in the HCM can be updated and the relevant C2VSimFG model inputs can be adjusted to better represent the principal aquifer in these areas. Further improvements to the HCM can be conducted using oil and gas well logs, the proposed future DWR airborne electromagnetic survey data (AEM), and any new theses or studies regarding hydrogeology or geochemistry in the greater Colusa Subbasin area.

3.1.12.2 Hydraulic Parameters

Hydraulic parameter estimates will be updated and refined by performing additional pumping tests, and reanalyzing existing test data in cases in which parameter estimates are outside of expected ranges. Pumping tests will use pumping wells and dedicated monitoring wells discretely screened in either the

unconfined or confined portion of the principal aquifer in order to better quantify hydraulic parameters per the principal aquifer's unconfined or confined condition.

The hydraulic properties of Tuscan Formation Unit C will be further investigated to verify the high hydraulic conductivities reported for Unit C and their applicability in the Subbasin.

3.1.12.3 Groundwater Quality

23 CCR §354.14(b)(4)(D) states that "general water quality of the principal aquifers" shall be included in the HCM. Future groundwater quality characterization efforts will utilize wells with known construction. The wells used to characterize groundwater quality discussed in this plan are all drilled within the principal aquifer but have not been identified as representing the unconfined or confined conditions. Identifying well depths and construction information would be beneficial in order to better understand groundwater quality and the potential spatial trends and movement of contaminants within the principal aquifer. GSAs should keep in mind the Human Right to Water and how it could be managed via water quality degradation projects implemented under the Colusa Subbasin GSP.

Coordination with local agencies, public water systems and domestic pumpers west and south of the Sutter Buttes and near Williams is encouraged to better understand the extent and potential movement of arsenic and salinity concentrations. Further investigation regarding the potential for mobilization of brackish waters or naturally occurring constituents of concern is recommended. The proposed DWR AEM survey is anticipated to be able to characterize shallow freshwater-saline water interface(s).

3.1.12.4 Groundwater Level Measurements

Groundwater elevation contours shown on Figure 3-19 and Figure 3-20 imply that the faulting could be impacting the localized groundwater flow regime. Additional water level measurements collected from the greater Artois area and westward would allow better evaluation of groundwater conditions in the area. More data could shed light on if the localized groundwater lows are due to the fault zone or some other factor such as localized pumping. The same applies to the Willows Fault near Colusa and the Sutter Buttes, where uncertainty exists regarding how the fault zone could impact migration of deep brackish to saline water into the freshwater aquifer system.

Most of the wells monitored for groundwater elevations are greater than 100 feet deep. This presents a data gap in understanding the shallow, unconfined groundwater elevations that many domestic and agricultural irrigation supply wells extract from. Recent conversations with domestic pumpers near the greater Orland area have indicated that many domestic wells have gone and are going dry as a result of the ongoing drought. DWR has recently started mapping and recording reports of drying wells and more published data is being made available. Glenn County and Colusa County are also recording reports of wells that have gone dry or have other issues. Maps of reported wells in Glenn County are regularly updated and available to the public at: https://arcg.is/10nmyT2. Coordination between the GSAs, public monitoring agencies, public water systems, domestic pumpers, and other stakeholders that depend on shallow groundwater wells has already started and evaluation of shallow water levels is currently ongoing. Regular monitoring of shallow wells and recording of drying wells will provide information to better characterize the extent and magnitude of groundwater lowering within the shallow portion of the principal aquifer.

3.1.12.5 Springs

According to historical USGS topographical maps, springs exists throughout the western margin of the Subbasin. However, their location, if they still exist, and their characteristics such as source waters, use, and flow discharge and frequency are not well reported. Better understanding the spring flows from the

Coast Range foothills will help shed light on the shallow groundwater regime of the western area of the Subbasin, as well as provide insight into the ephemeral and intermittent streams and potentially help delineation of groundwater dependent ecosystems and habitats. Additional evaluation, potentially including field survey of the spring locations, communication with local residents and stakeholders, and monitoring of surface discharge is recommended.

3.2 EXISTING AND HISTORICAL GROUNDWATER CONDITIONS

This section describes the existing and historical groundwater conditions of the Subbasin to support development and implementation of the GSP pursuant to the requirements of SGMA. This plan section was prepared through a coordinated effort between the GSAs responsible for managing the Subbasin.

3.2.1 Regulatory Requirements

Title 23 Section 354.16 of the California Code of Regulations (23 CCR §354.16) requires that the GSP "*shall provide a description of current and historical groundwater conditions in the basin, including data from January 1, 2015, to current conditions, based on the best available information*" and shall include descriptions for conditions related to the six undesirable results listed under SGMA:

- Groundwater elevations (Section 3.2.2)
- Groundwater storage (Section 3.2.3)
- Seawater intrusion (Section 3.2.4)
- Groundwater quality issues (Section 3.2.5)
- Land subsidence (Section 3.2.6)
- Interconnected surface water systems (Section 3.2.7)
- Groundwater-dependent ecosystems (Section 3.2.8)

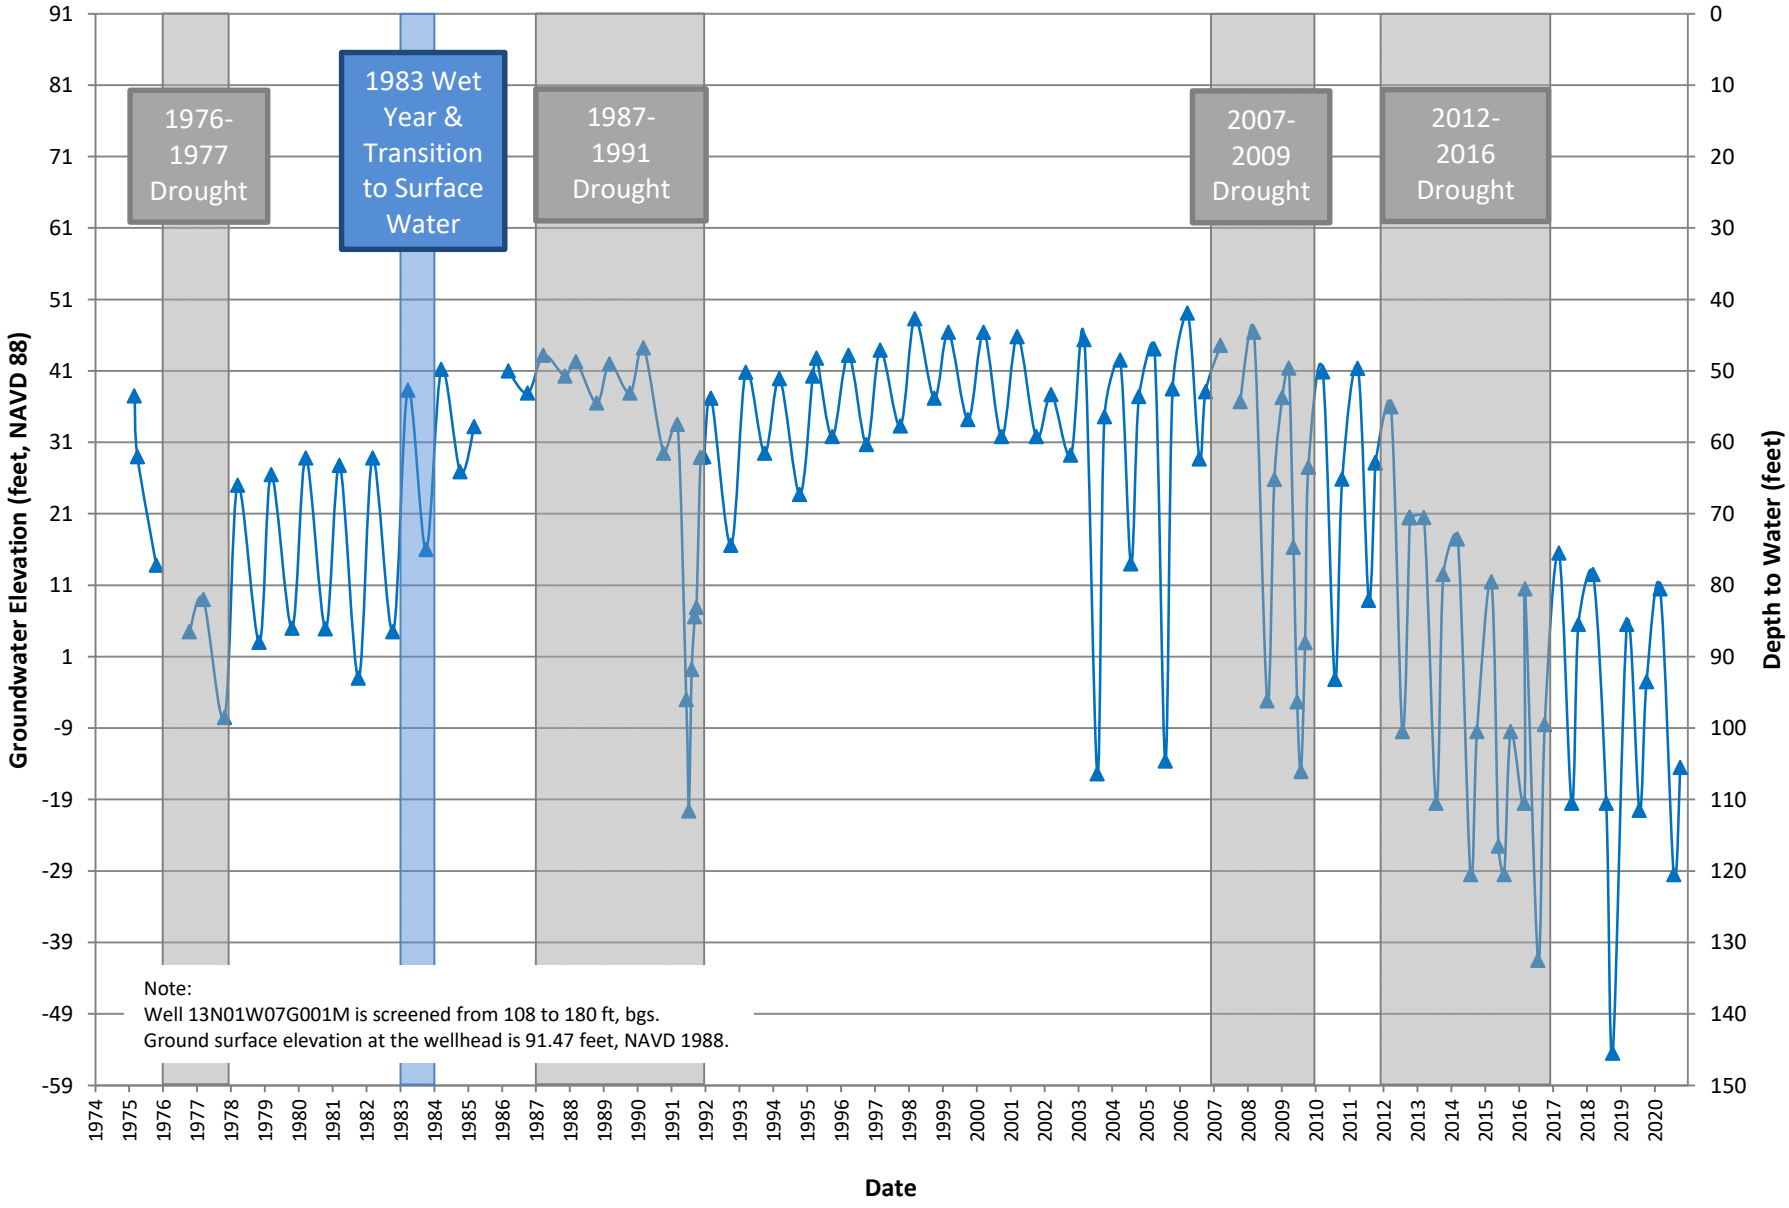
This section addresses these requirements using currently available data and information in accordance with the information provided by DWR and listed in the California Code of Regulations.

3.2.2 Groundwater Elevations

Appendix 3A contains the location map and historical hydrographs for the 50 wells within the Subbasin. The hydrograph wells contain a mix of active water supply wells and dedicated observation wells. The hydrograph wells are constructed to different depths within the principal aquifer and represent conditions within the unconfined to confined zones. Appendix 3B contains historical groundwater elevation contour maps for spring and fall of calendar years 2006 (wet conditions), 2015 (critical conditions), 2017 (wet conditions), and 2020 (dry conditions). Most of the wells used in contouring are screened at depths greater than 100 feet and represent groundwater levels in the semiconfined to confined part of the principal aquifer. This presents a data gap in mapping shallow groundwater elevations that would impact domestic and agricultural irrigation supply wells, discussed in Section 3.1.12, and would potentially impact environmental water users.

3.2.2.1 Temporal and Spatial Trends

Figure 3A-1 of Appendix 3A shows the locations of historical monitoring wells within the subbasin. A hydrograph representative of typical historical and seasonal groundwater level trends within the Subbasin is shown on Figure 3-22. Historical water levels, measured between approximately 1975 and 2005, were overall increasing or stable from year to year. Since about 2007, however, there has been a general decline in water levels. Many wells with historical measurements (Appendix 3A) recovered to pre-2006 conditions after the 2012 to 2016 multiple-year drought but are still below their historical average. With the current ongoing dry years, it is expected that water levels will continue to decline.



The Subbasin has a Mediterranean-type climate with wet winters and dry summers. Seasonal trends in groundwater elevations reflect these seasonal climatic changes. During the dry season when there is an increase in groundwater pumping, depth to groundwater increases, and during the rainy season when there is a decrease in demand and groundwater recharge rates are higher, depth to groundwater decreases. These seasonal fluctuations in groundwater elevations can be seen in the hydrograph on Figure 3-22 as the "peaks" and "valleys", respectively, of the water level line. The magnitude of the seasonal drawdown and recovery depends on hydrologic conditions (e.g., dry or wet years) and human influence such as demand and available water supply sources.

Well 13N01W07G001M (Figure 3-22) is screened in the unconfined to semi-confined portion of the principal aquifer. Groundwater levels declined during the droughts of 1976 to 1977, 1987 to 1991, 2007 to 2009, and 2012 to 2016 and either stabilized or recovered after these dry years. The most notable recovery periods occurred around 1983, which was both a wet year and when water users added more surface water to their supply portfolios, and after the 1987 to 1991 drought. Groundwater recharge increased after the introduction of surface waters due to a decrease in groundwater pumping and the addition of applied surface waters for agricultural use. Event signatures such as these are less notable in shallow wells located near surface waters, where flows in perennial streams or irrigation canals may smooth out impacts to groundwater levels.

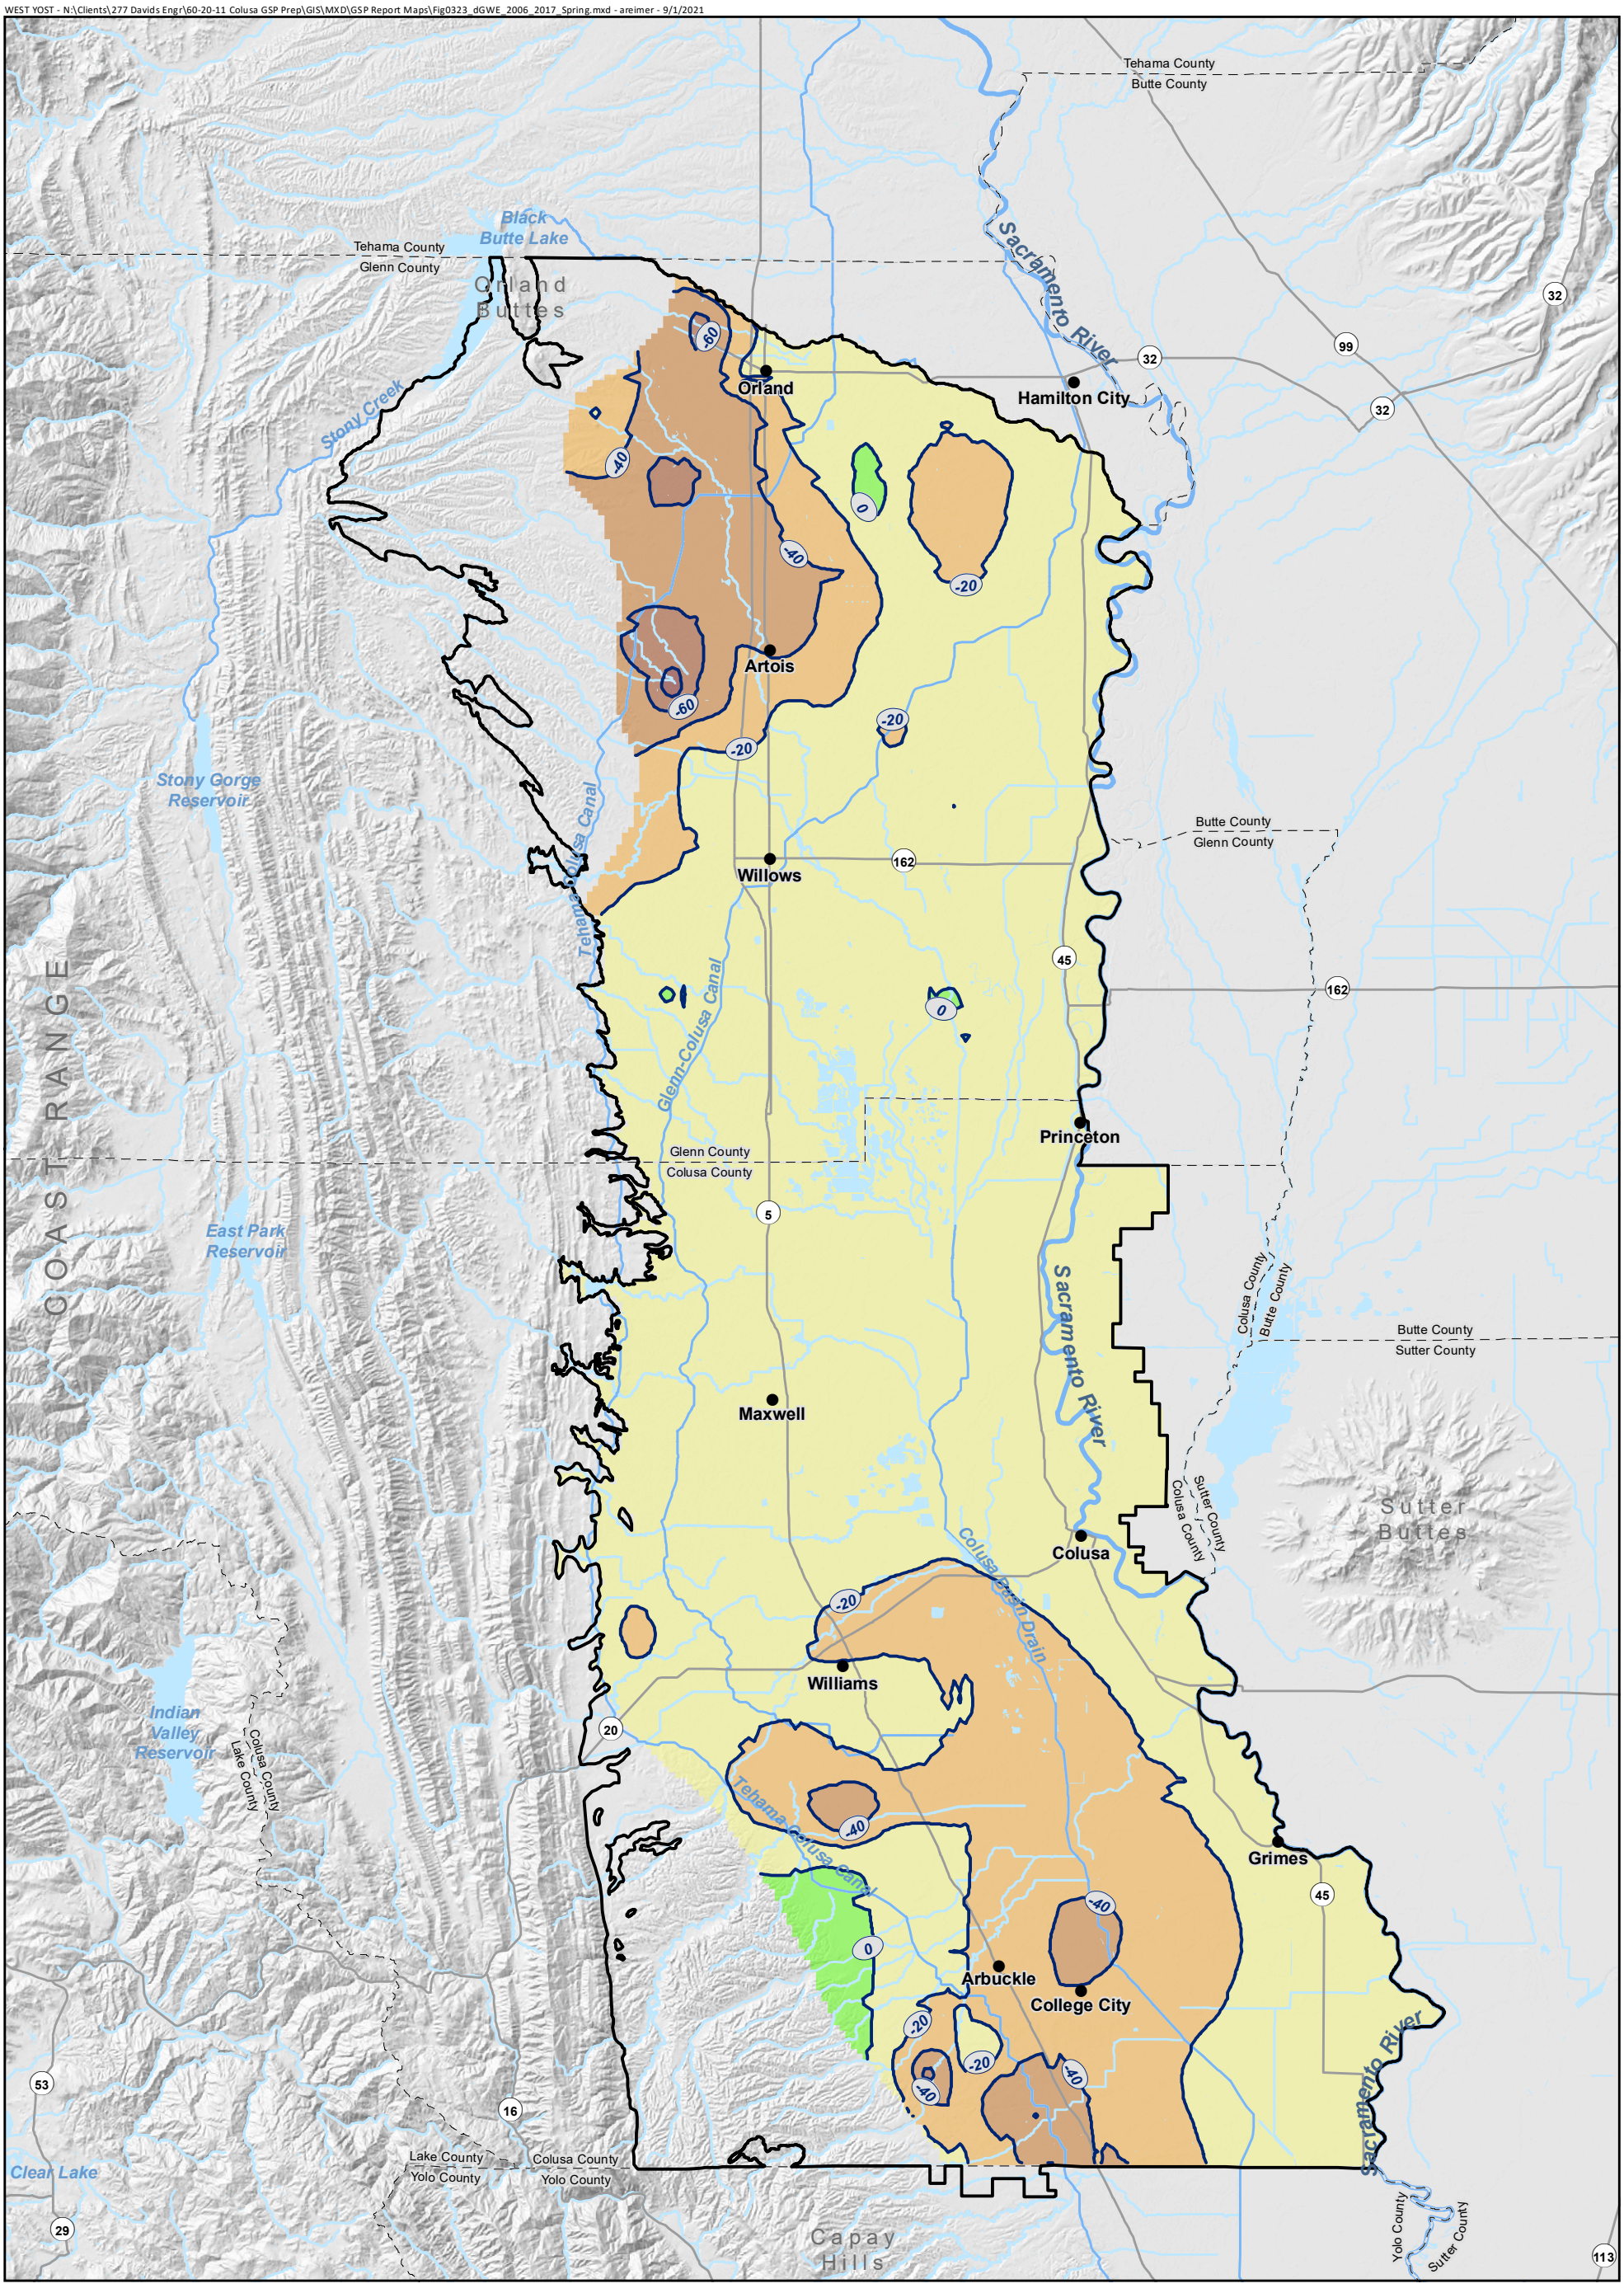
Regional groundwater flow within the Subbasin is generally eastward from the margins of the Sacramento Valley toward the Sacramento River and southward towards the Sacramento-San Joaquin Delta. The regional groundwater flow trends are typified by groundwater conditions in 2006. Figures 3B-1 and 3B-2 of Appendix 3B shows the groundwater elevations in spring and fall of 2006, before the onset of the multiple-year droughts of 2007 to 2009 and 2012 to 2016. For most of the subbasin, the groundwater flows in a southeasterly direction, consistent with typical regional trends. South of Arbuckle, however, groundwater flows northeast down from the uplands before turning southeast and down the valley. This flow pattern is repeated in spring and fall 2015, which represent conditions during a multiple-year drought period (Figure 3B-3 of Appendix 3B).

Groundwater pumping has resulted in localized cones of depression that disrupt the regional groundwater flow trends. Changes in land use and multiple-year droughts have led to increased groundwater pumping. These changes in groundwater pumping have created new cones of depression and enlarged existing cones of depression. The regional groundwater gradient and direction were affected by cones of depression in areas of heavy groundwater pumping, which can be seen on the spring and fall 2015 contour maps (Figures 3B-3 and 3B-4 of Appendix 3B).

Figure 3-22. Hydrograph for Well 13N01W07G001M

Groundwater elevations throughout the Subbasin declined over the prolonged dry period after 2006 but recovered in 2017. Figure 3-23 is a groundwater elevation change map that compares spring 2006 (pre-drought) to spring 2017 (post-drought) conditions. Negative changes in groundwater elevations indicate decreases in the spring groundwater elevations from 2006 to 2017, which highlights areas that had not fully recovered from the multiple-year drought between 2007 and 2016. The primary areas with groundwater declines were in the northwestern part of the Subbasin near, and west of, the Glenn County communities of Orland and Artois, and in the southern part of the Subbasin near the Colusa County communities of Williams, Arbuckle, and College City.

Current groundwater elevations are shown on Figure 3-24 and Figure 3-25 for spring and fall 2020, respectively. Current groundwater levels are similar to those measured in 2017, indicating that regional groundwater levels have been relatively stable since the end of the previous multiple-year drought. However, since the end of the previous multiple-year drought, the Subbasin has experienced alternating years of average or dry conditions. These climatic patterns are starting to have an impact on groundwater levels. Shallow groundwater levels are of particular concern. Many shallow domestic and agricultural irrigation wells in Glenn County have been going dry. Monitoring of shallow wells and coordination with public water systems, domestic pumpers and monitoring agencies is in-progress to characterize the magnitude and rate of shallow groundwater level decline. Data gaps and recommendations are discussed in Section 3.1.12.



3.2.2.2 Lateral and Vertical Flow Gradients

The lateral groundwater gradient has historically been relatively stable over time and typically increases with increasing terrain slope. Typical lateral flow gradients within the Subbasin are approximately 0.001 in the valley and approximately 0.01 in the uplands. Impacts due to pumping are the exception to the typical gradients and disrupt both local and regional gradients. Changes in hydraulic parameters due to reduction in storage or compression of aquifer materials to land subsidence can result in long-term impacts to the lateral and vertical hydraulic gradients.

The vertical groundwater gradients within the principal aquifer provide insight into pumping stresses within the aquifer. Vertical groundwater gradient also helps in the identification and assessment of areas where groundwater discharge and recharge may occur and supports the understanding of interconnections between the surface water features and the groundwater system. Figure 3-26, Figure 3-27, and Figure 3-28 contain hydrographs for multiple-completion nested monitoring wells in order from north to south. The well locations are shown on Figure 3A-1 of Appendix 3A. Well 22N03W24E001-003M is located just south of Stony Creek near the Tehama-Colusa Canal. A downward vertical gradient has consistently been observed at 22N03W24E001-003M (Figure 3-26), indicating that there is potential groundwater recharge from surface sources. This is consistent with other multiple-completion wells in the area.

Well 18N02W18D001-004M, shown on Figure 3-27, is located just north of the Glenn and Colusa County border. Before 2014, the well exhibited an upward flow gradient, with potential for upward groundwater from the deeper confined aquifer zone towards a shallower semi-confined aquifer zone. After 2014, in the midst of the prolonged dry period, the gradient began to transition. The vertical gradients in 18N02W18D001-004M after 2014 show potential for downward flow during the rainy season and upward flow during the dry season.

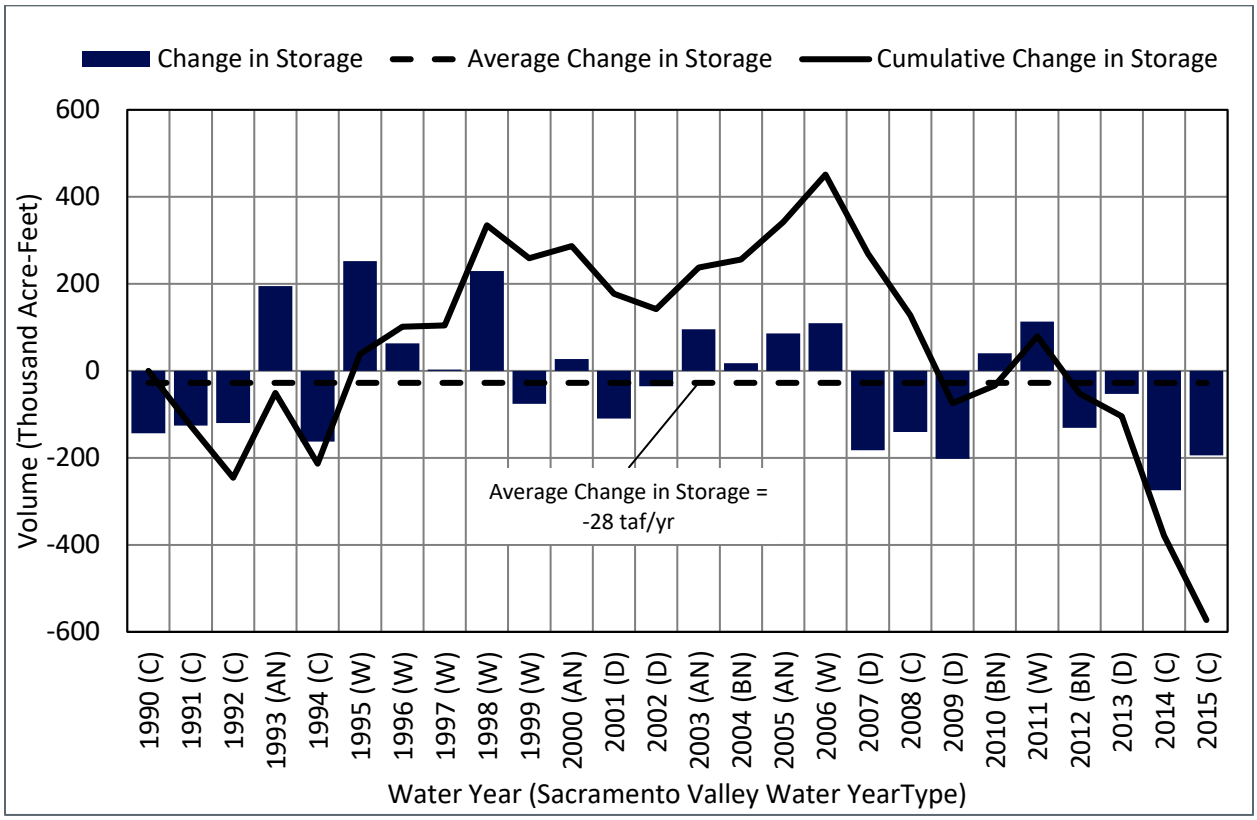
Variable vertical gradients also occurred in well 12N01E06D002-004M (Figure 3-28), located on the Colusa and Yolo County line. Prior to the prolonged dry period between 2007 and 2016, the vertical gradients and groundwater elevations measured in the well showed potential for seasonal flowing artesian conditions. The potentiometric head of the confined aquifer system rose above land surface during the wet season. During the start of the multiple-year drought, the vertical gradient was upward from the deep zone and downward from the shallow zone towards the middle zone. This may have been due to the majority of groundwater pumping occurring at depths similar to the middle completion of the monitoring well. During the latter half of the multiple-year drought, the vertical gradient reversed during the wet season, with vertical gradients showing potential for flow from the shallow towards the deeper zones. After 2016, the vertical gradients returned to pre-drought conditions, but at generally lower groundwater elevations.



3.2.3 Estimate of Groundwater Storage

The current groundwater storage volume within the Subbasin, above the crystalline basement rocks and base of freshwater, is estimated to be between about 26 million acre-feet (maf) and 140 maf based on an analysis using contouring of Spring 2020 groundwater levels, an average saturated thickness, and an assumed average specific yield range of 0.034 to 0.185, taken from Olmsted and Davis (1961). This range in groundwater storage volume reported in this GSP is low due the lack of groundwater elevation data within the upland areas of the subbasin and uncertainty regarding the depth to the base of freshwater. Recent groundwater modeling conducted to support development of this GSP suggests average specific yield values for the full saturated thickness in the subbasin (i.e., from the regional water table to the base of fresh water) fit within the range provided by Olmsted and Davis (1961).

Prior to the groundwater basin boundary modification process concluded by DWR in 2019, DWR Bulletin 118 estimated the aquifer storage capacity within the upper 200 feet of the Subbasin to be approximately 13 maf (DWR, 2006a). The Subbasin at the time was bounded by Stony Creek to the north, Sacramento River to the east, Cache Creek to the south, and the uplands of Dunnigan Hills and the foothills of the Coast Ranges to the west. Currently, the Subbasin excludes the areas south of the Colusa-Yolo County boundary and includes a portion of the former West Butte Subbasin east of the Sacramento River within Colusa County. Taking into account the area of the current Subbasin extent and a specific yield estimate of 0.071 within the unconfined zone, as reported in Bulletin 118 (2006a), approximately 10.3 maf of storage capacity is estimated within the upper 200 feet of the current subbasin extent.

The average annual change in storage was -28 thousand acre-feet per year (taf/yr) over the historical water budget period of 1990 to 2015. This indicates that, on average, more groundwater has left the Subbasin than entered, resulting in an average net reduction in groundwater stored in the Subbasin. Figure 3-29 summarizes the annual change in storage and the cumulative change in storage in the Subbasin aquifer system over the historical water budget period. A decrease in groundwater storage occurred during critically dry (C), dry (D), and below normal (BN) water years. This is most evident between 2007 and 2015, when the region experienced a series of consecutive, multiple-year droughts. While critically dry, dry, and below normal water years almost always correspond with a decrease in storage, above normal (AN) and wet (W) water years do not always result in an increase in groundwater storage. On average, the Subbasin's storage volume is influenced more by dry years than wet years. This is likely due to both a greater reliance on groundwater supply during dry years when surface water is less readily available and the relatively slow nature of deep percolation to recharge the groundwater system during wet years. Most of the groundwater inflows and outflows within the Subbasin are exchanged directly with the land and surface water system overlying the Subbasin groundwater system. More information regarding the groundwater storage calculations can be found in the water budget section of this GSP

(Section 3.3) and the model development and calibration Technical Memorandum prepared by Woodard & Curran and Davids Engineering (2021) (Appendix 3D).

Reference: Woodard & Curran and Davids Engineering. 2021. C2VSimFG-Colusa Model Development and Calibration Technical Memorandum: (Appendix 3D).

Figure 3-29. Change in Groundwater Storage

3.2.4 Seawater Intrusion

The Subbasin is located approximately 30 miles from the legal Sacramento-San Joaquin River Delta boundary, and even farther from the brackish delta estuaries. Additionally, the 2019 Basin Prioritization study by DWR found that the Subbasin has not exhibited any impacts of seawater intrusion within the past 20 years (DWR, 2020b). Seawater intrusion is neither occurring nor anticipated to occur in the subbasin over the planning horizon and thus further discussion of seawater intrusion is not included in this GSP.

3.2.5 Groundwater Quality

Groundwaters within the subbasin are mixed calcium, magnesium, and sodium bicarbonate waters (DWR, 2004a, 2006a, 2006b). The northern portion of the subbasin is dominated by calcium bicarbonate water, while increased sodium content has been observed near the Sutter Buttes and west towards Williams, resulting in localized occurrences of mixed sodium and magnesium bicarbonate waters south of Princeton, near Williams, Colusa, Grimes, and Arbuckle, and south towards Yolo County (DWR, 2006a).

Groundwater quality concerns within the Subbasin include locally elevated levels of salinity, TDS, adjusted sodium absorption ratio, arsenic, boron, hexavalent chromium, iron, manganese, and nitrate (DWR, 2006a; Wood Rodgers, 2008; California Water Service, 2016; SWRCB, 2020a). The following subsections discuss the occurrence of these constituents of concern within the subbasin.

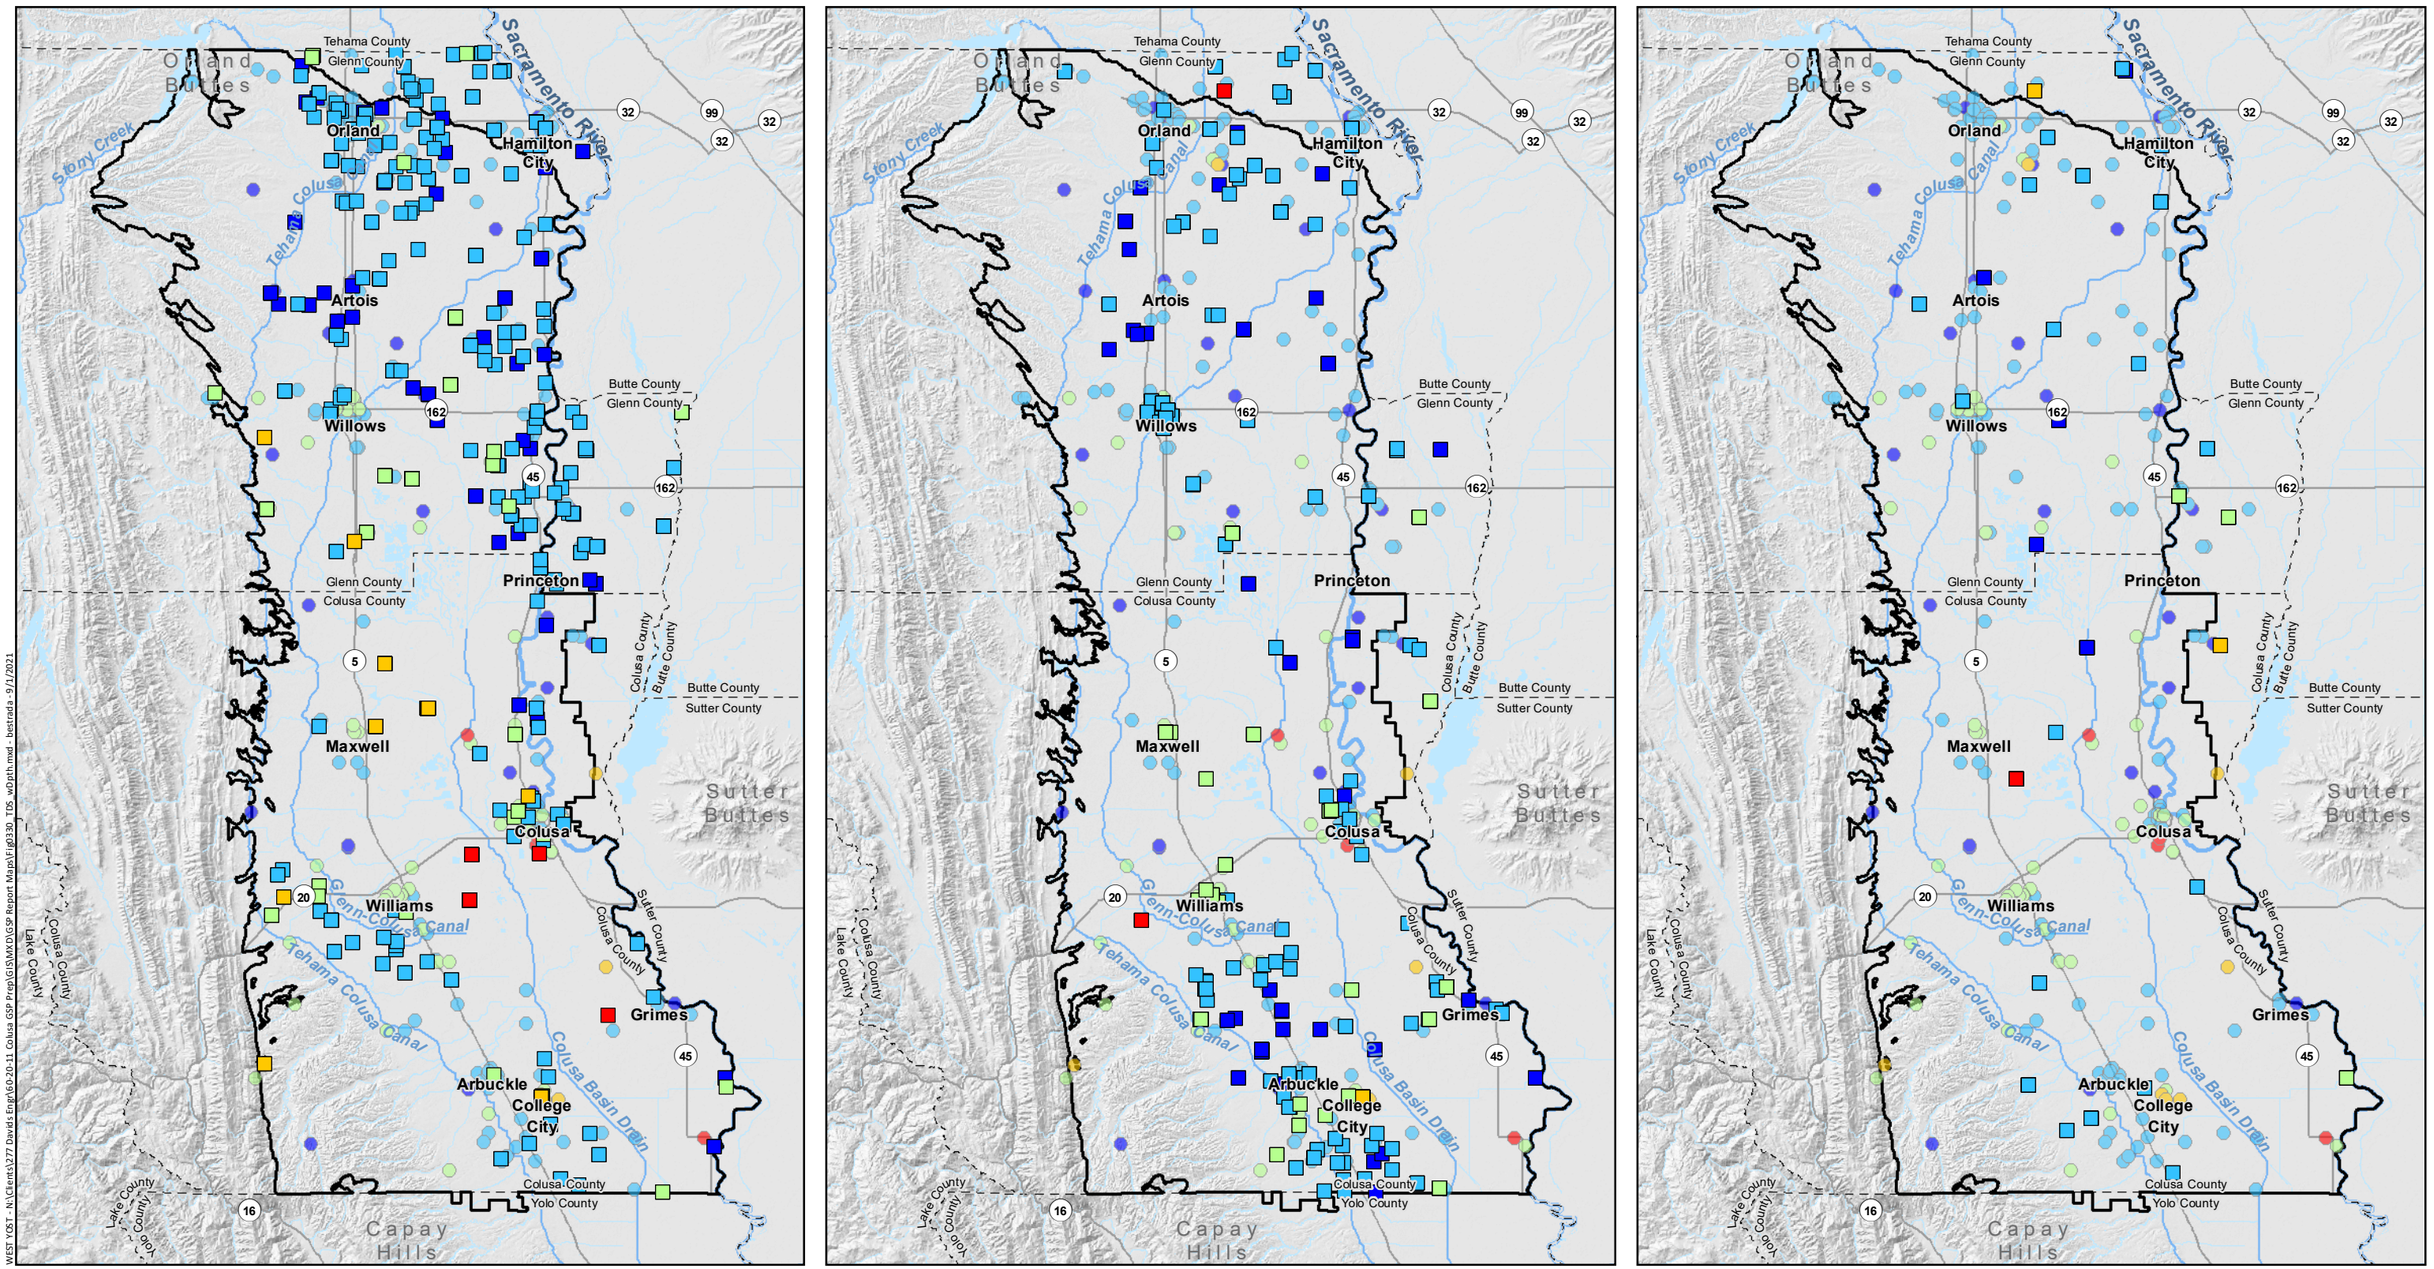
Monitoring and regulatory programs exist for the major constituents of concern within the Subbasin. These include programs managed by the U.S. Geological Survey, State of California Department of Water Resources and the State Water Resources Control Board, Central Valley Salinity Coalition, and Central Valley Regional Water Quality Control Board. This section summarizes groundwater quality information from these existing programs. The California Safe Drinking Water Act addresses the regulation and control of public water systems in the State of California, including enforcing provisions of the federal Safe Drinking Water Act. The federal government first granted primary enforcement responsibility to the State in 1978. The State Water Resources Control Board Division of Drinking Water (DDW) is the agency responsible for enforcement in Colusa and Glenn Counties, including the entire Subbasin.

Chapter 4 describes the proposed monitoring network for monitoring the potential mobilization of brackish or saline water from below the freshwater aquifer or along faults in the vicinity of the Sutter Buttes.

3.2.5.1 Major Naturally Occurring Constituents

All groundwater contains dissolved constituents that are products of natural processes of the hydrologic cycle. Rainfall contains only small concentrations of dissolved constituents. Upon reaching the land surface, dissolution of minerals contributes dissolved ions to the water. Calcium, magnesium, and sodium are the major cations (positively charged ions) typically found in groundwater, and sulfate and chloride, which, along with bicarbonate, are the major anions (negatively charged ions). The bicarbonate ion is formed by dissolution of carbon dioxide from the atmosphere and released by organic processes in the soil. Dissolved carbon dioxide contributes to the dissolution of minerals as water is recharged. The quantity of dissolved salts depends on the specific surface area of the aquifer material, the solubility of the minerals present, the pH and oxidation-reduction potential (Eh) of the system, and the residence time of the water in the subsurface aquifer.

3.2.5.1.1 Salinity



Salinity of groundwater can be characterized by the measured TDS concentration and/or the electrical conductivity (EC) value, which is easily measured in the field and can be used as a proxy for TDS. TDS has three secondary drinking water MCLs, which are established for aesthetic consumer acceptance: recommended limit (500 mg/L), upper limit (1,000 mg/L), and short-term limit (1,500 mg/L). The recommended MCL is the threshold for a “higher degree of consumer acceptance”, the upper MCL indicates the limit for which it is reasonable to provide an alternate water source, and the short-term MCL water is “acceptable only for existing community water systems on a temporary basis pending construction of treatment facilities or development of acceptable new water sources” (22 CCR §64449).

TDS concentrations throughout the subbasin range from less than 100 mg/L to more than 1,500 mg/L, the short-term secondary MCL defined by Title 22 California Code of Regulations (SWRCB, 2018b). Figure 3-30 shows TDS concentrations detected in wells of varying depths. Wells with unknown depth and construction information are shown on all three panels of Figure 3-30. TDS concentrations of more than 500 mg/L, the recommended secondary MCL, have been detected in wells throughout the subbasin, but mostly in wells south of Artois. The highest concentrations of TDS have been measured in the area surrounding the cities of Maxwell, Colusa, and Williams.

Wells screened in the unconfined to semi-confined zone of the aquifer (i.e., in wells less than 200 feet deep) in the central and southern portion of the Subbasin had the highest number of wells with elevated TDS concentrations. TDS concentrations in the shallow wells southwest of Colusa have consistently been greater than 2,000 mg/L over a 20-year period. The wells southwest of Colusa with unknown depth have historically had TDS concentrations between 649 mg/L and 1,820 mg/L between 1957 and 2011. The wells northeast of Maxwell have consistently had TDS concentrations above 1,000 mg/L over a 20-year period.

Wells with depths greater than 200 feet near Maxwell, Colusa, and Williams have historically had TDS concentrations less than 1,000 mg/L, with the exception of the deep well southeast of Maxwell. This well is a multiple-completion nested monitoring well with completions set at 378 feet, 775 feet, 1,236 feet, and 1,481 feet deep. In 2011, TDS concentrations in the deepest completion had the lowest TDS concentration (approximately 260 mg/L) while the second-deepest completion well had the highest TDS detection (approximately 930 mg/L). The two shallowest completions in the well had TDS concentrations of approximately 520 mg/L. In 2016, the second-shallowest completion well had the highest TDS concentration (approximately 1,640 mg/L), while the shallowest completion well had the lowest concentration (approximately 530 mg/L). The deepest completion was not measured in 2016.

The shallow well west of Grimes shown in Figure 3-30 is shown with an elevated TDS symbol because of a single TDS measurement of 2,040 mg/L taken in 1975. This older measurement may not be representative of current conditions in the area. Similarly, the wells near College City and other locations with TDS detections greater than 1,000 mg/L tend to be wells with a single measurement and may not represent current or consistent TDS concentrations for those locations.

Many of the wells located in or near urban areas exhibit TDS concentrations above the 500-mg/L recommended secondary MCL. This includes wells with unknown depths in the areas of Williams, Maxwell, Williams, Colusa, Arbuckle, and College City. Public supply wells deeper than 200 feet near Williams and Willows exhibited an increasing trend in TDS concentrations (Dupuy, et. al., 2019; Jurgens, et. al., 2020).

3.2.5.1.2 Major Cations and Anions

The primary cations within the Subbasin are calcium, magnesium, and sodium. The highest calcium concentrations within the Subbasin have been measured in wells between Colusa and Williams, where concentrations have been recorded above 100 mg/L. Elevated sodium concentrations have been detected in wells throughout the Subbasin but tend to be higher in the area surrounding Williams and Colusa. In Colusa, sodium concentration levels are often an order of magnitude greater that of magnesium or calcium. Magnesium concentrations are typically between 10 and 30 mg/L. Wells near Willows, Williams, and Arbuckle have shown an increasing trend in magnesium concentrations over the past decade (DWR, 2021b; SWRCB, 2020a; USGS, 2020).

The ratio of calcium to sodium is much higher in the northern part of the subbasin compared to the southern part of the subbasin. This aligns with the spatial trend in water type, with calcium bicarbonate waters being characteristic of northern Glenn County and sodium bicarbonate waters generally characterizing Colusa County.

As a general rule, the ratio of sodium to calcium and magnesium concentrations in groundwater increases with residence time. This is due to cation exchange, which can be thought of as a natural water softening process that occurs when groundwater containing calcium and magnesium comes in contact with clay containing exchangeable sodium. The longer the water is in contact with the aquifer, the higher the ratio of sodium to calcium and magnesium, and the softer the water. This relationship may be obscured by

other factors, including geologic heterogeneities that may cause variation in the sodium concentrations, independent of the residence time of the groundwater, and saline water intrusion. These factors, notwithstanding the relative concentrations of sodium, calcium and magnesium in the wells, may also help to delineate recharge and discharge zones, and potential mobilization of brackish or saline water.

The subbasin waters are mixed bicarbonate waters. Other major anions distributed throughout the subbasin include chloride and sulfate. The spatial distribution of the high concentrations of chloride and sulfate is similar to that of elevated concentrations of TDS and sodium, with the highest concentrations detected in the general Maxwell-Colusa-Williams area and south towards Arbuckle (Figure 3-30). Sulfate concentrations in this area have been measured above the 250-mg/L recommended secondary MCL, with the southern wells showing a long-term increasing trend in sulfate concentrations (SWRCB, 2020a). Groundwater samples in the past decade have generally contained chloride concentrations below the 250-mg/L recommended secondary MCL throughout the Subbasin (DWR, 2021b; SWRCB, 2020a). Anthropogenic sources of chloride and sulfate include wastewater effluent, septic discharge, industrial use, landfill leachate, and agricultural runoff.

3.2.5.2 Other Naturally Occurring Constituents

Naturally occurring constituents that could constrain the use of groundwater within the Subbasin for potable supply, and which have been detected in wells regionally throughout the Sacramento Valley, include arsenic, boron, iron, manganese, and hexavalent chromium. Boron can also be detrimental to plants.

3.2.5.2.1 Arsenic

Arsenic is a naturally occurring constituent in groundwater and commonly occurs at concentrations ranging from 10 to 50 µg/L in the western United States, where it is typically associated with alluvial-lacustrine basin-fill deposits and volcanic rocks and sediments (Welch, et. al., 1988). The primary MCL for arsenic in drinking water is 10 µg/L (SWRCB, 2018a).

Grimes and Princeton have had violations of the 10 µg/L drinking water MCL, which is both the State of California and federal standard. Arsenic has been detected near Grimes at concentrations as high as about 28 µg/L (measured in 2012). A federal program was initiated to install filters on water connections and reduce the arsenic concentration (Glenn County, 2005). Recent concentrations of arsenic in wells near Grimes have been less than 20 µg/L, however, there have been detections of high levels of arsenic in wells near the Sutter Buttes. The elevated arsenic concentrations near Grimes were determined to be due to natural conditions (Glenn County, 2005), potentially including proximity to the Sacramento River stream channel, Sutter Buttes, Willows Fault, and the Colusa Dome.

3.2.5.2.2 Boron

Boron is a naturally occurring element that is associated with the marine deposits of the Coast Ranges. Anthropogenic sources of boron include industrial waste discharges, municipal wastewater, and agricultural practices (SWRCB, 2017). Fire retardant manufacturing, storage, and use throughout Glenn and Colusa Counties could be an anthropogenic source of boron in the aquifer system. Boron in groundwater is most likely in the form of boric acid. Boron is a necessary component to plant growth in small amounts, but some plants are sensitive to the presence of boric acid in waters and may exhibit adverse effects if exposed to boron concentrations higher than the plant's tolerance.

Elevated concentrations of boron reported by GCID within Colusa County have impacted agricultural practices (GCID, 1995). According to GCID (1995), groundwater underlying the northern portion of the GCID service area has boron concentrations suitable for irrigation. Additionally, boron measured in select groundwater wells within Glenn County has not exceeded the USEPA agricultural water quality goal for boron of 750 µg/L (USEPA, 1986; USGS, 2020). In contrast, elevated levels of boron have been detected in the southern portion of the GCID service area (GCID, 1995).

3.2.5.2.3 Iron and Manganese

Iron and manganese in groundwater are naturally occurring via weathering from subterranean sediment. Anthropogenic sources include landfill leachate, sewage discharge, and industrial effluent. Iron concentrations exceeding the 300-µg/L secondary MCL have been reported in water supply wells near Orland, Willows, Delevan, Williams, Colusa, and Arbuckle within the past decade (DWR, 2021b; SWRCB, 2020a). Williams and Colusa have experienced long-term increasing trends in iron concentrations, although the most recent concentrations have been lower than during previous years (USEPA, 2020; CH2MHILL, 2016a).

Elevated manganese concentrations above the 50-µg/L secondary MCL have been reported near the cities of Williams and Colusa, and northeast of Artois, near the Sacramento River (USEPA, 2020). According to the Northern Sacramento Valley (Four Valley) Drinking Water Strategy Document (Glenn County, 2005), there have been customer complaints near Williams and Colusa related to iron and manganese in drinking water.

3.2.5.2.4 Hexavalent Chromium

Chromium typically occurs in in the trivalent state, which is nearly insoluble. Geochemical conditions in recharge zones or the aquifer can oxidize trivalent chromium to hexavalent chromium, which is soluble, mobile in groundwater, and a carcinogen. Naturally occurring chromium minerals are associated with serpentinite and other Coast Range rocks. Over geologic time, these rocks have been eroded, transported by streams, and incorporated in the basin fill sediments of the Subbasin. Anthropogenic sources of hexavalent chromium are mostly related to industrial use and waste.

There is currently no MCL for hexavalent chromium. The SWRCB implemented a 10-µg/L primary MCL for hexavalent chromium on July 1, 2016. On May 31, 2017, the Sacramento Superior Court ruled that the SWRCB must withdraw the 10-µg/L hexavalent chromium MCL and develop a new MCL after assessing the economic feasibility of compliance, especially for smaller public water systems. The 10-µg/L hexavalent chromium MCL was withdrawn on September 11, 2017. The SWRCB has not published a timeline for issuing the new MCL, but the new MCL is anticipated to be announced in late 2021.

Drinking water supply wells near Willows have experienced high concentrations of hexavalent chromium (California Water Service, 2016). Hexavalent chromium in a well west of Willows has not been detected at concentrations below 20 µg/L since 2016 and was detected at 40.1 µg/L in July 2020 (SWRCB, 2020a). Hexavalent chromium concentrations greater than 20 µg/L have also been detected in wells midway between Williams and Arbuckle, and near Colusa, within the past decade (DWR, 2021b; SWRCB, 2020a).

3.2.5.3 Non-Point Sources of Groundwater Pollution

Non-point sources of groundwater pollution are diffuse discharges that occur over a wide area. The major non-point source groundwater constituent of concern in the Subbasin is nitrate.

3.2.5.3.1 Nitrate

Nitrate is a naturally occurring compound that forms when nitrogen and oxygen combine in the soil. Nitrate occurs naturally in groundwater or can be introduced through a variety of land uses, including row crop agriculture, irrigated agriculture, and various waste disposal practices. Typical waste materials resulting in nitrate pollution include animal manures from commercial poultry, dairy, hog and beef operations; wastewater treatment plant effluent applied to land; household wastes disposed of in septic systems; and landfill leachate.

Small amounts of nitrate in groundwater are normal, but larger concentrations can result in serious health problems. The 45-mg/L MCL for nitrate (quantified as nitrate) is considered by the State and Federal governments to be the maximum concentration that can be safely consumed from a public water system. Excessive nitrate consumption can lead to health problems, including irritation of gastrointestinal tract and bladder, and methemoglobinemia, or blue baby syndrome, so named because affected infants take on a bluish tinge. Blue baby syndrome is caused when nitrate is converted to nitrite by bacterial activity in the stomach. Typically, in adults, these bacteria are destroyed by stomach acid. The stomachs of infants (especially less than 3 months of age in humans) are not fully developed and do not produce strong acids. This allows the bacteria to survive, leading to the buildup of nitrite in the blood. The nitrite oxidizes the ferrous iron in the blood to ferric iron, thereby limiting its ability to carry oxygen to the cells. The syndrome is readily treated if diagnosed.

Nitrate detections are widespread in the Subbasin but are mostly low concentrations, typically meeting drinking water standards, with the exception of the northern portion of Glenn County and the area near Willows (CH2MHILL, 2016a; Wood Rodgers, 2008). According to the Sacramento Valley Water Quality Coalition Groundwater Quality Report (CH2MHILL, 2016a), only 2 percent of the 359 total wells analyzed within Glenn and Colusa Counties had nitrate concentrations above the 45-mg/L MCL and the average nitrate concentration was 8.3 mg/L.

3.2.5.4 Point Sources of Groundwater Pollution

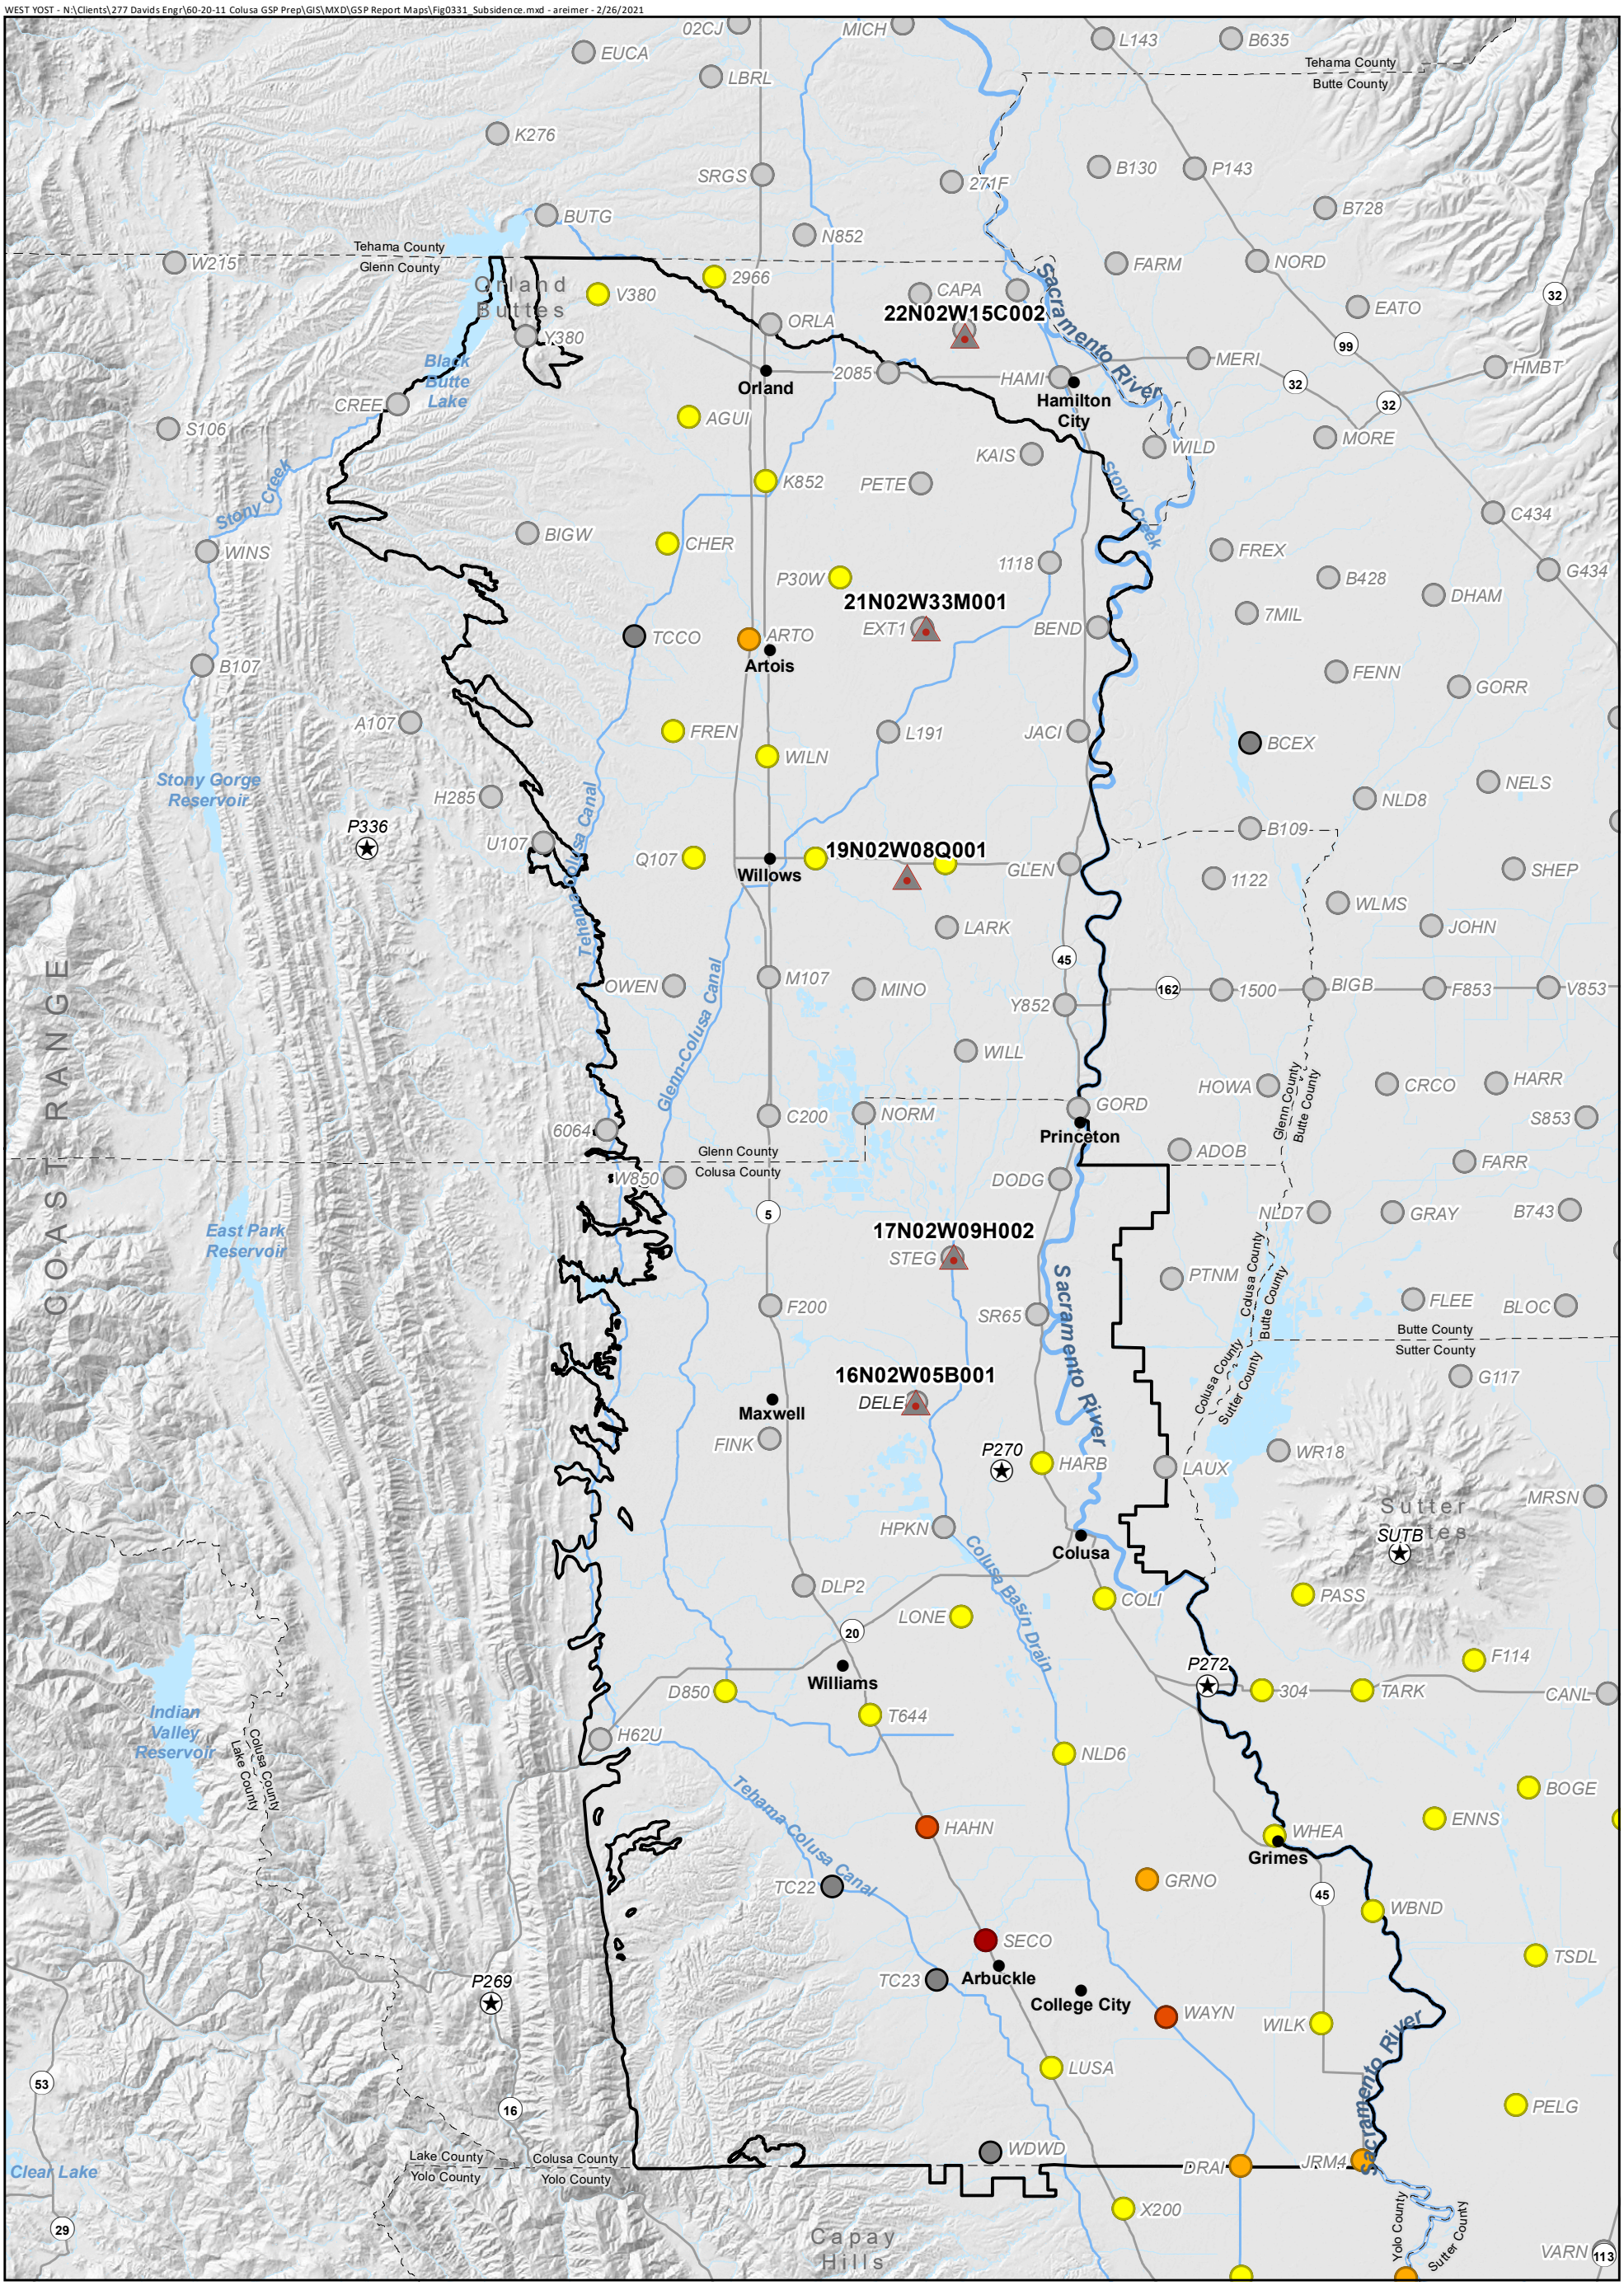
Point sources of groundwater pollution are discrete discharges that occur at a single identified location. Discharges from point sources can be either a single discharge event or have occurred continuously over a period of time. Point sources of groundwater pollution often require monitoring and cleanup programs.

There are several active groundwater contaminant cleanup sites in the Subbasin. These mostly include leaky storage tanks and unauthorized releases of contaminants such as petroleum hydrocarbons, nitrate, pesticides and herbicides. The largest contamination site is the Orland Dry Cleaner site, a perchloroethylene (PCE) plume within the Subbasin that extends approximately two miles southeast of the source location in Orland (DTSC, 2020; URS Corporation Americas, 2020). PCE is a dense non-aqueous phase liquid, meaning it is denser than water, with a moderate to high mobility rating (SWRCB, 2017). Long-term temporal trends of PCE concentrations in most of the monitoring wells show concentrations stabilizing or decreasing since the start of sampling in 2003 (URS Corporation Americas, 2020).

3.2.6 Land Subsidence

Differential land subsidence and associated earth fissuring resulting from groundwater withdrawal have had significant consequences in several California groundwater basins. Land subsidence can cause structural damage to wells, foundations, roads, bridges, and other infrastructure, as well as impacting surface water flows by reducing conveyance capacity and potentially changing flow gradients within canals, natural streams, and floodplains. Inelastic land subsidence may also negatively impact groundwater storage capacity. Land subsidence has been measured within the Subbasin, however, it is yet to be determined if the subsidence measured within the Subbasin has measurably impacted storage capacity.

The 1976-1977 drought was the first time that more groundwater than surface water was used for agricultural irrigation in the Sacramento Valley. Drilling and pump contractors reported that in the summer of 1977 many wells were discovered to have broken casings, and the demand for new and replacement wells could barely be met (Borchers, et. al., 1998).



The risk of significant land subsidence impacts depends on a complex array of variables including: the degree of new groundwater development, especially in areas or at depths not previously exploited; changing land use, which could bring to light an effect that would otherwise go unnoticed; and the mineral composition and consolidation history of the aquifer skeleton.

Land subsidence due to groundwater withdrawal is triggered by decreases in pore pressure in a confined aquifer system containing clay layers (typically, montmorillonite clay). The decrease in pore pressure increases the effective stress on the aquifer skeleton. If this effective stress exceeds the maximum stress to which the aquifer skeleton has been subjected in the past, the clay layers will undergo permanent compaction. Highly compressible clays, such as montmorillonite, have not been reported within Subbasin boreholes. They have, however, been encountered in boreholes south of the Sutter Buttes (see discussion regarding lacustrine deposits and the Turlock Lake Formation in Section 3.1.7.1). Additionally, a borehole drilled near the Colusa Drain, near Zamora in Yolo County (south of the Subbasin), at 12N1E34Q1 contained a silty, diatomaceous, kaolinitic clay with a compression index of 1.22 and coefficient of consolidation of 4.98 square feet per year. These values are comparable to samples of diatomaceous clay from the Corcoran Clay of the San Joaquin Valley, and indicate a high susceptibility to compaction (Page, 1998). The core sample was collected at a depth of 534 to 544 feet.

Figure 3-31 shows the measured land surface displacement from resurvey of Sacramento Valley benchmarks between 2008 and 2017 (DWR, 2018a). Figure 3-32 includes the annual rate of subsidence from 2018 to 2019, as calculated from interferometric synthetic aperture radar (InSAR) imagery surveys (TRE ALTAMiRA, 2020). Appendix 3C contains the location map and ground surface displacement charts measured in five extensometers located within the counties of Colusa and Glenn.

Land subsidence has been reported and measured in the Arbuckle area of Colusa County. A 2015 NASA report based on InSAR survey evaluation showed isolated land subsidence of up to approximately 0.5 feet west of Arbuckle (Farr et. al., 2015). Data from a repeat survey of the Sacramento Valley Height-Modernization Project benchmarks also indicates a decrease in land surface elevation by as much as 2 feet between 2008 and 2016 near Arbuckle (Ehorn, 2016). A resurvey of those benchmarks conducted in 2017 showed a total displacement of 2.14 feet since 2008. This equates to approximately 0.24 feet, or approximately 3 inches, of subsidence per year between 2008 and 2017, on average. Subsidence calculated by TRE ALTAMiRA from InSAR imagery showed up to more than 2 inches of subsidence occurring between 2018 and 2019 within the greater Arbuckle area (Figure 3-32).

Land subsidence is not exclusive to the Colusa County portion of the subbasin; repeat surveys of benchmarks in Glenn County showed small amounts of land subsidence southwest of Orland occurring between 2008 and 2017 (Ehorn, 2016; DWR, 2018a). One benchmark located near Artois had a measured displacement of 0.59 feet, or approximately 7 inches. InSAR imagery from 2018 to 2019 showed approximately 1.5 inches of subsidence occurring between Orland and Artois.

Extensometer measurements have also recorded ground displacement in the Subbasin. Appendix 3C contains a map of the extensometer locations (Figure 3C-1 of Appendix 3C) and ground displacement measured within extensometers in or near the subbasin. Seasonal displacements of ±0.3 inches have been recorded in these extensometers. Most of the subsidence measured in the extensometers has been elastic, meaning the aquifer materials are not permanently compressed. Potential inelastic displacement may have occurred in extensometers 21N02W33M001M, northeast of Artois, and 16N02W05B001M, east of Maxwell, during the multiple-year droughts (Figure 3C-5 and Figure 3C-2 of Appendix 3C, respectively). Potential inelastic subsidence occurred in 21N02W33M001M between 2007 and 2010, and between 2008 and 2016 in 16N02W05B001M. Measured seasonal fluctuations in displacement within both of these boreholes have since stabilized.

3.2.7 Interconnected Surface Waters

Traditionally, water resource managers have tended to address surface water and groundwater systems as distinct and separate. However, most surface water bodies (e.g., rivers, streams, drains and lakes) are connected to the groundwater system to some degree so that changes to surface water bodies (either gains or losses) can affect flows in aquifer systems, and vice versa. Additionally, changes in land use, irrigation methods, and management of surface water storage and conveyance infrastructure can impact surface water and groundwater systems.

Figure 3-33 illustrates the typical range of groundwater-surface water interactions in the absence of groundwater pumping. Streams interact with groundwater in three basic ways: streams gain water from inflow of groundwater through the streambed (gaining stream); they lose water to groundwater by outflow through the streambed (losing stream); or they do both, gaining in some reaches and losing in other reaches (Winter, et. al., 1998). Also, whether a given reach is gaining or losing can vary with time in response to changing hydrological conditions. The upper, high elevation reaches of a stream may tend to be losing while the lower reaches may tend to be gaining. If the stream is connected to the groundwater system, meaning that it is physical contact with the groundwater system, then the gains and losses depend on the stage of the stream, the groundwater level, and the streambed conductance. If the stream is disconnected from the groundwater system, meaning that the stream is separated from the groundwater system by an unsaturated zone, then the gains and losses are independent of the groundwater level.

Reference: U.S. Geological Survey. 2021.

Figure 3-33. Conceptual Example of Gaining and Losing Streams

Groundwater pumping can lead to streamflow depletion, potentially reducing supplies for human and ecosystem water uses (USGS, 2012). When groundwater is pumped, the water table near the well declines, forming a cone of depression. Initially the decline is accounted for by a change in aquifer storage surrounding the well. As pumping continues, the cone of depression expands, and begins to capture groundwater that would have otherwise discharged to the stream. The pumping may lower groundwater levels enough to cause induced infiltration from the stream, changing the once gaining reach of the stream to a losing reach. The streamflow depletion is the sum of the captured groundwater discharge that would otherwise have reached the stream, plus the induced infiltration caused by the groundwater pumping (Barlow and Leake, 2012).

After pumping is stopped, groundwater levels will not recover immediately. Instead, groundwater will flow towards the cone of depression at a rate dictated by the hydraulic properties of the aquifer and the hydraulic gradient directed radially inward towards the well. The rate will gradually decline with the hydraulic gradient. The existence of residual drawdown in the aquifer after pumping ceases means that streamflow depletion can continue after pumping stops.

The duration of streamflow depletions caused by pumping depends on the spatial scale: the greater the distance between groundwater pumping and affected stream, the longer the timescale. As a consequence, the ultimate effects of pumping can occur significantly after pumping starts, or even after pumping has ceased. The timescales involved in aquifer responses to pumping and other stresses can be on the order of decades, making it difficult to associate cause with effect. Monitoring for potential impacts may be ineffective because, by the time effects are observed, it may be too late to take in action, and the effects may persist for decades. In general, the longer the timeframe for effects to be observed at a given monitoring point, the longer those effects will persist, if the pumping resulting in the effects is halted immediately. Also, the effects of pumping on stream depletions are cumulative, with the effects of each pumping cycle in each well imposed on the next.

3.2.7.1 Simulated Stream Gains and Losses

The Subbasin integrated hydrologic model, C2VSimFG-Colusa, was used to analyze historical stream gains (water that enters the stream from the groundwater system) and losses (water that enters the groundwater system from the stream; also referred to as seepage) in waterways that flow within or along the boundaries of the Subbasin. The modeled streams include the Sacramento River, Stony Creek, and the Colusa Drain.

Table 3-6 includes the breakdown of the modeled net stream gain (stream gains minus stream losses) for each stream by water year type. Table 3-7 includes stream gain and loss statistics for the modeled streams. Simulated Sacramento River conditions were mostly net gaining, with the exception of 1998, where the Sacramento River experienced net loss of approximately 13 taf. The median net gain along the Sacramento River was approximately 72 taf/yr. The net stream gain in the Sacramento River was lower during wet years, when there would be more surface flow, and higher in the dry years, when surface waters would be in short supply. Simulated conditions in the Colusa Drain indicate net stream gain of approximately 115 taf/yr on average between 1990 and 2015, with net gains occurring in all years including critically dry years. Contrary to simulated Sacramento River conditions, net stream gain in the Colusa Drain were higher during wet years than during dry conditions. Stony Creek always experienced annual net losses between 1990 and 2015. Stream losses were greatest during critically dry and dry years.

A detailed assessment of projected stream gains and losses is presented in Appendix 3G. The analysis considers the Sacramento River, Stony Creek, and the Colusa Drain individually and collectively, and

evaluates temporal patterns of gain and loss over the 50-year projected (future) water budget period (described in Section 3.3, below). Under projected future conditions without climate change, average net stream gains (stream gains minus stream losses) are projected to be approximately 125 taf/yr in aggregate for the Sacramento River, Stony Creek, and the Colusa Drain combined. With the potential effects of climate change[1], net stream gains are projected to remain positive but to decrease by about 48 taf/yr, or by 38 percent, with respect to the projected future conditions without climate change. However, viewed in the relation to the average Sacramento River flow above the Feather River confluence of approximately 11,700 taf/yr the projected change is roughly one half of one percent. These simulated net stream gains are less than the typical ±2.5% accuracy of annual volume measurements when calculated from current meter-based stage-discharge functions (Clemmens and Wahlin, 2006). Consequently, these simulated net stream gains are not significantly different than the uncertainty of average annual streamflows along these waterways, and cannot be measured directly from stream gage measurements with certainty. This will continue to be evaluated and addressed as part of continued work to fill data gaps and part of ongoing monitoring to be reported in annual reports.

Table 3-6. Modeled Net Stream Gain 1990-2015 by Water Year Type

Water Year Type	Number of Years Evaluated	Net Stream Gain, taf		
		Colusa Drain	Stony Creek	Sacramento River
Critical Dry	7	109	-38	91
Dry	5	109	-30	86
Below Normal	3	104	-31	57
Above Normal	4	121	-33	47
Wet	7	127	-28	26

Note: Total gains, losses and net stream gains will not exactly match values reported elsewhere in this GSP due to different methods of extracting data from C2VSimFG-Colusa.

Table 3-7. Modeled Net Stream Gain 1990-2015 Statistics

	Colusa Drain		Stony Creek		Sacramento River

Median	115	1997	-31	2011	72	2000
Average	115	--	-32	--	62	--

Note: Total gains, losses and net stream gains will not exactly match values reported elsewhere in this GSP due to different methods of extracting data from C2VSimFG-Colusa.

[1] Results are from the C2VSimFG-Colusa model "Projected Future Conditions with 2070 Climate Change and without Projects" scenario, in which projected precipitation, evapotranspiration, and surface water supplies are adjusted to reflect the estimated effects of climate change based on the 2070 Central Tendency climate change datasets provided by DWR to support GSP development. Climatological, hydrological, and water operations datasets, change factors, and the DWR Climate Change Resource Guide are available at: https://data.cnra.ca.gov/dataset/sgma-climate-change-resources.

3.2.7.2 Stony Creek Thalweg Analysis

A thalweg analysis was conducted for Stony Creek, where local historical water level measurements were compared to streambed elevation of Stony Creek's thalweg to evaluate for stream-aquifer connectivity and to compare those results with results of the *Interconnected Surface Water in California's Central Valley* (ICONS) study (TNC, 2021). Shallow wells less than 200 feet deep and within 5 miles of surface water features are the criteria used to identify representative groundwater level wells to be used as a proxy for surface water depletion and stream-aquifer interaction monitoring, discussed in Chapter 4 and Chapter 5. Figure 3-34 shows a cross section, A-A', that follows the thalweg of Stony Creek. Superimposed onto the cross section are the spring and fall 2006, 2015, and 2020 groundwater level measurements from 31 shallow wells (less than 200 feet deep) within 5 miles of the creek. Also shown in the cross section are the ICONS datasets:

- Minimum groundwater elevation measured between 2011 and 2018: depicted as a light blue interpolated potentiometric water surface.
- Maximum groundwater elevations measured between 2011 and 2018: depicted as a medium blue interpolated potentiometric water surface.
- Stream likelihood of connectivity based on the average groundwater elevations measured between 2011 and 2018: depicted as a graded rainbow-colored horizontal line above land surface where red indicates disconnected stream reaches, yellow are reaches with uncertain connectivity, green indicates connected and potentially losing reaches, and dark blue are connected and potentially gaining stream reaches.

The measured groundwater levels roughly match the interpolated surface of the ICONS minimum and maximum groundwater elevation datasets. The most notable discrepancies occur just southeast of Orland, where measured groundwater levels appear deeper than the interpolated minimum groundwater elevation, and just northwest of Orland, where measured groundwater levels appear shallower than the maximum interpolated groundwater elevation. None of the measured groundwater levels are at higher elevation than the streambed land surface which suggests that no part of Stony Creek is gaining. This, however, could be due to the spatial density of the shallow groundwater wells. Additionally, there is no active stream gage on Stony Creek below Black Butte Lake.

Further evaluation of locations, quantity and timing of stream depletions through additional monitoring and/or construction of additional shallow or multiple-completion monitoring wells near surface waters (e.g., Stony Creek, Sacramento River, and the Colusa Drain) comparing observed groundwater levels with stream discharge or river stage information would provide more insight into stream-aquifer interactions and a subsequent detailed analysis of potential impacts to beneficial users and uses.

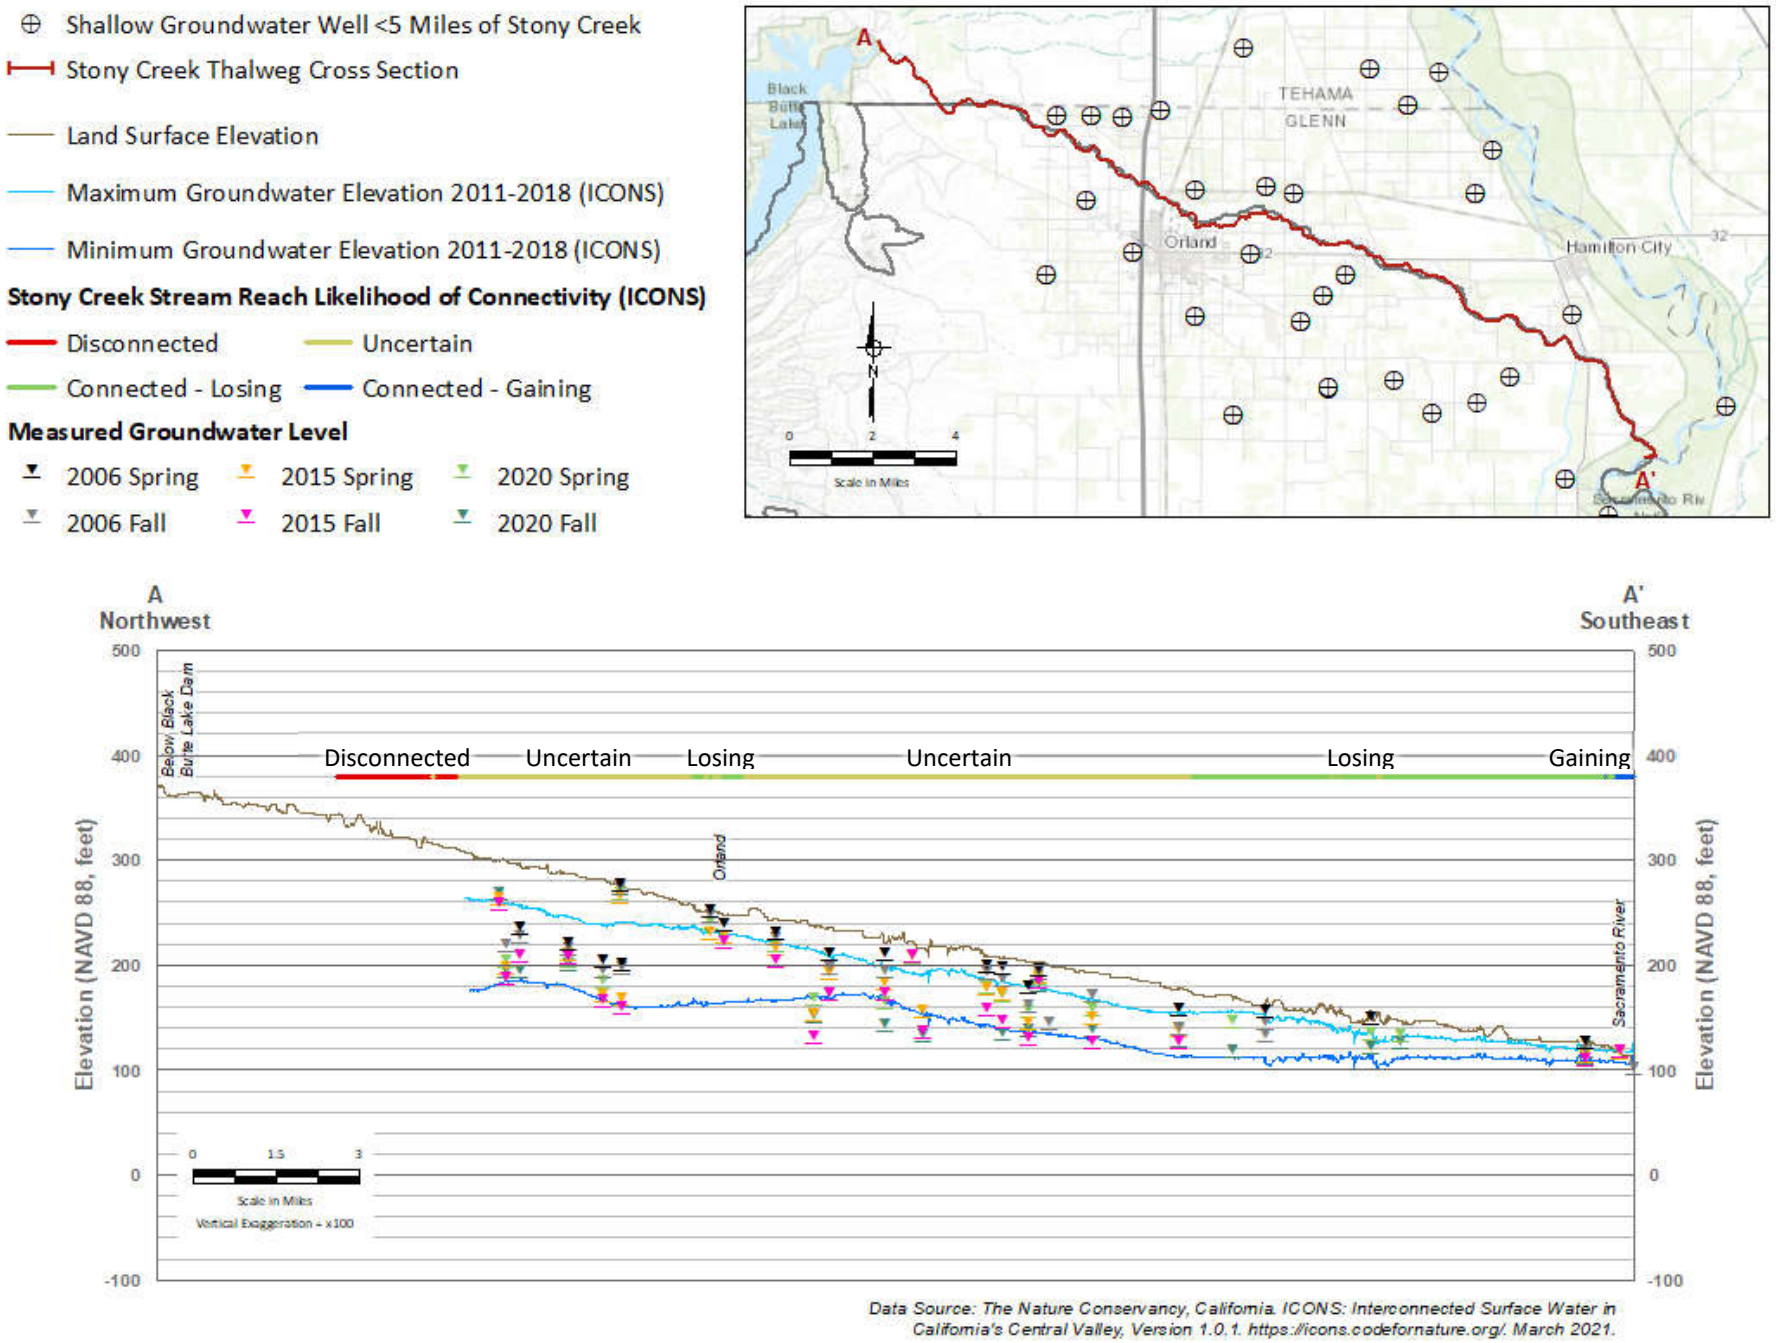

Figure 3-34. Thalweg Analysis

3.2.8 Groundwater Dependent Ecosystems

GDEs are defined as "ecological communities of species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" (23 CCR § 351(m)). As described in TNC's guidance for GDE analysis (Rohde et al. 2018), a GDE's dependence on groundwater refers to reliance of GDE species and/or communities on groundwater for all or a portion of their water needs. TNC has identified hundreds of freshwater species that are located in the Subbasin, based on analysis of the California Freshwater Species Database version 2.0.9 within the Subbasin boundary (Appendix 2B-2). While there are data gaps in understanding how many of these species utilize or depend on groundwater, the GSAs conducted an initial evaluation of potential GDEs in the Subbasin using the best available information at the time of GSP development. As described in Chapter 7 of this GSP, the GSAs have also planned several studies that will expand monitoring of GDEs and help to increase understanding of the potential impacts of land use planning and well permitting on GDEs in the Subbasin.

Natural communities commonly associated with groundwater (NCCAG) within the State of California were mapped by TNC (2018b) and Klausmeyer, et. al. (2018). The NCCAG mapping provided an initial indication of the location, habitat type, and impacted vegetation for potential GDE areas within the Subbasin. The majority of the potential GDE vegetation areas include cottonwood (31 percent), bulrush (21 percent), willow (15 percent), and oak (13 percent) habitat areas. Arundo, or giant reed, accounts for four percent of NCCAGs initially identified within the Subbasin.

Preliminary screening of the potential GDEs within the Subbasin was conducted to help prioritize areas for further mapping, evaluation, and monitoring of GDEs during implementation of the Colusa Subbasin GSP. The preliminary screening supported the assessment of data gaps, evaluation of existing monitoring networks, which could potentially be used for GDE monitoring, and development of PMAs.

The GSAs will seek to work with resource agencies, stakeholders, beneficial users and the public to refine the understanding of GDEs in the Subbasin, fill data gaps, and develop PMAs with consideration of GDEs.

Under the preliminary screening, a score of 1 (less likely to be a GDE) to 4 (more likely to be a GDE) was applied to the NCCAG areas based on depth to groundwater, proximity to surface waters, and proximity to irrigated croplands. Figure 3-35 shows the relationship between the score and ranking criteria.

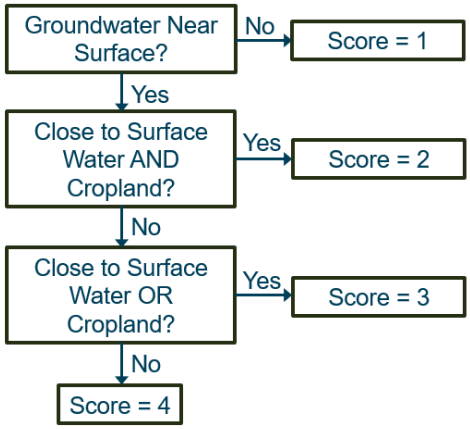

Figure 3-35. GDE Scoring Criteria

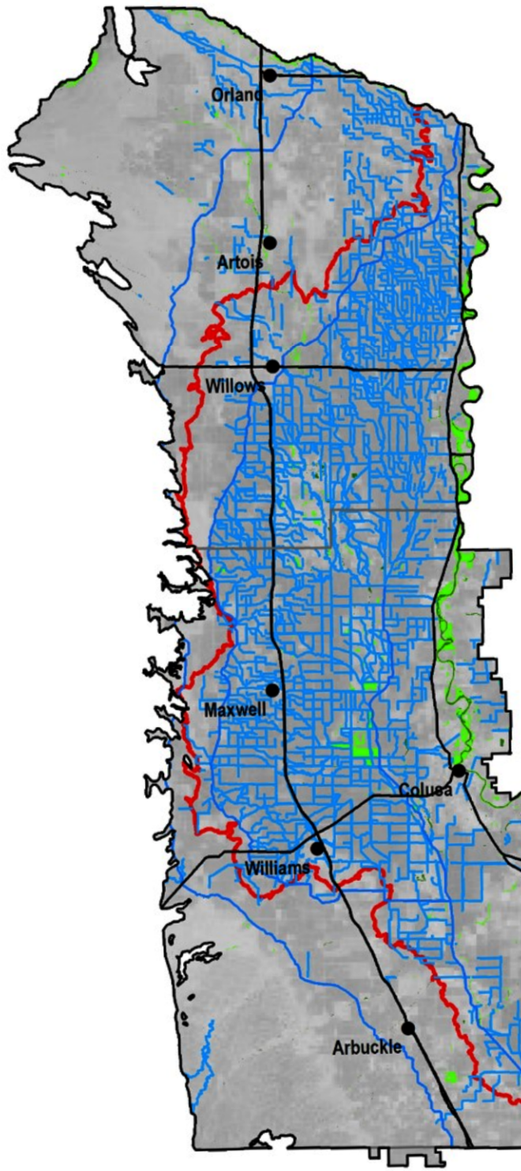
Average spring groundwater level data from 2014 to 2018 indicates that shallow groundwater levels (i.e., within 30 feet of ground surface) exists throughout most of the subbasin. A depth to water (DTW) of 30 feet based on the average DTW for 2014 to 2018 was used as one of the primary criteria in the initial

screening of potential GDEs. The use of a 30-foot DTW criterion to screen potential GDEs is based on reported maximum rooting depths of California phreatophytes and is consistent with guidance provided by TNC (Rohde et al., 2018) for identifying GDEs. The use of shallow groundwater data over the 5-year 2014 to 2018 time period was deemed appropriate because it provided a more conservative (i.e., more inclusive) indicator of potential GDEs than the use of a data from a single year. The 30-foot DTW contour is shown on Figure 3-36. Depths to shallow groundwater east of the contour are less than 30 feet. Based on the scoring criteria presented in Figure 3-35, east of the 30-foot contour line is shallow groundwater and so will be evaluated using the next criteria while land west of the contour line receives a score 1 (less likely to be a GDE) and is not evaluated with additional criteria.

Areas within 150 feet of surface waters, including canals, ditches, and perennial streams, were considered to have access to surface waters. Additionally, areas within 150 feet of irrigated rice paddies and 50 feet of other irrigated croplands were considered to have access to surface waters. The leftmost and middle panels of Figure 3-36 include the areas within 150 feet of surface waters, 150 feet of rice croplands, and 50 feet of other irrigated croplands. Vegetation within these areas is assumed to have access to surface water and/or agricultural runoff and percolation and therefore receive a score of 2 if they are close to both surface water and agricultural lands (i.e., they are more likely to be a GDE than lands without shallow groundwater, but still not very likely) or a score of 3 if they are close to either surface waters or agricultural lands (i.e., they only have one source of water from surface practices or natural flows). GDEs include vegetation and habitat that are wholly dependent on groundwater. Closer proximity to available surface waters decreases the likelihood that a vegetated wetland or potential GDE habitat area is a GDE. The exception to this could be locations where surface waters gain a significant amount of water from groundwater. The Sacramento River and the Colusa Drain are both under net-gaining conditions, where surface waters annually gain water from the aquifer system (Section 3.2.7). These net-gaining conditions along surface water corridors could increase the likelihood of GDEs regardless of the scoring exercise results presented here.



Vegetated lands that have access to shallow groundwater and not near either surface waters or irrigated agricultural lands receive a score of 4 (i.e., the only water source available for vegetation consumption is groundwater).

The rightmost panel of Figure 3-36 shows the scores for the potential GDE areas within the Subbasin. Table 3-8 includes the acreages per GDE score. Most of the NCCAG lands within the Subbasin were designated a score of 2, which is on the lower end of likelihood of being classified as a GDE due to proximity to both surface waters and irrigated croplands. The majority of the high scores (i.e., score of 3 or 4, or a high likelihood of being a GDE) occur along the Sacramento River corridor, within the wildlife refuges, and in non-agricultural lands surrounding some of the streams, such as along Willows Creek and south of Delevan Wildlife Refuge. Groundwater level data is lacking in the uplands west of Orland and west of Arbuckle. There is potential for GDEs to be present in these areas, especially near seeps and springs, but the data is lacking in order to determine their existence. This data gap is discussed in Section 3.1.12

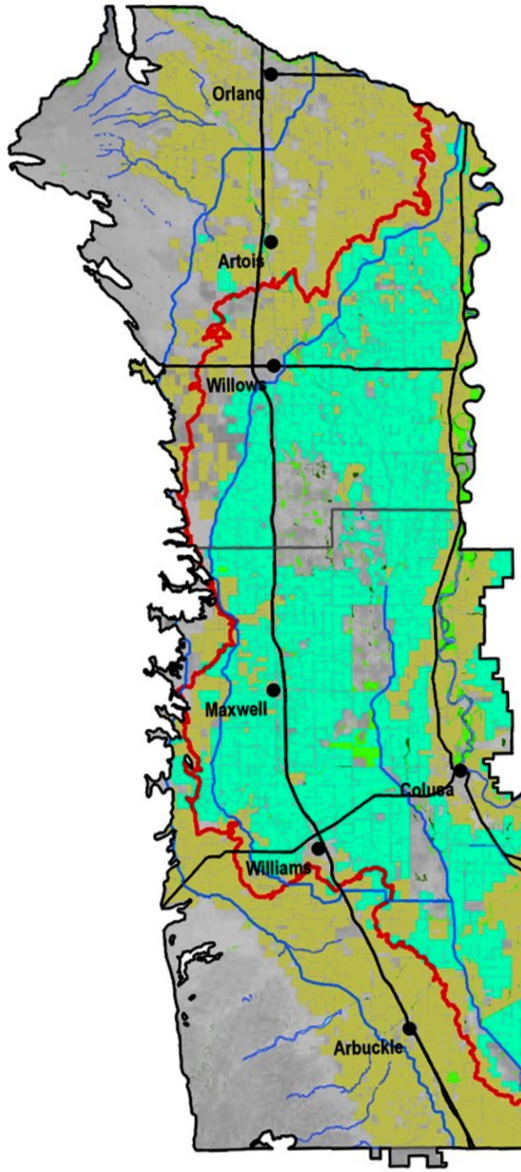


Table 3-8. GDE Likelihood Scores

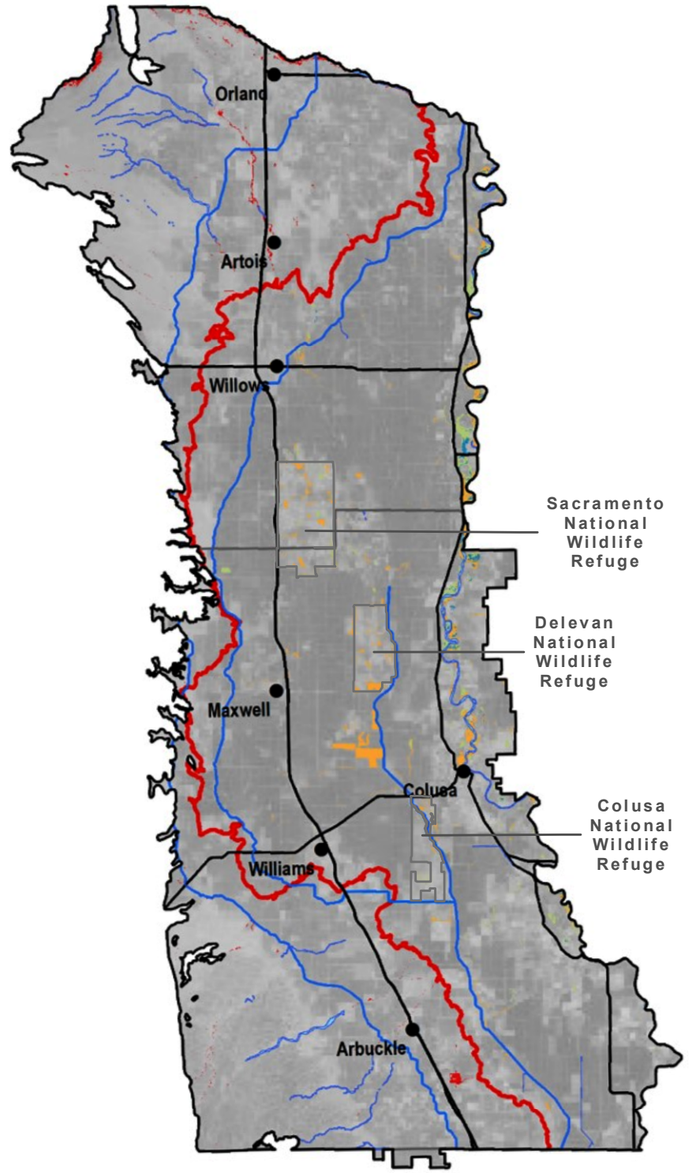
Score	Score Description	Approximate Acreage
1	Less Likely	2,540
2	--	8,710
3	--	5,580
4	More Likely	920



Within 150 ft of Surface Waters

3.3 WATER BUDGET INFORMATION

This section describes historical, current, and projected water budgets developed for the Subbasin in accordance with §354.18 of the GSP Emergency Regulations. According to §354.18, the water budgets were prepared using the best available information and best available science to quantify and provide an understanding of historical and projected hydrology, water demands, water supplies, land use, population, climate change, groundwater and surface water interaction, and subsurface groundwater flow. The water budgets support GSP development in a number of ways, including assessing the sustainable yield of the subbasin, development of sustainable management criteria, and evaluating the need for projects and management actions to ensure sustainable operation of the Subbasin. Components of the water budgets are depicted in Figure 3-37.

Notes: Boundary fluxes are shown as solid blue arrows, with inflows and outflows indicated by blue and red captions, respectively. Internal fluxes are indicated by dashed blue arrows. The two primary storage mechanisms are the surface water storage and groundwater storage systems.

Figure 3-37. Water Budget Components (DWR 2016)

Water budgets were developed considering hydrology, water demand, water supply, land use, population, climate change, surface water - groundwater interaction, and subsurface groundwater inflows and outflows to and from neighboring groundwater basins. Water budget results are reported on a water year basis spanning from October 1 of the prior year to September 30 of the current year. All water budget values are expressed in average annual volumes, with annual volumes presented in tabular form in Appendix 3E (for the entire Subbasin) and in Appendix 3F (for 32 subareas within the Subbasin).

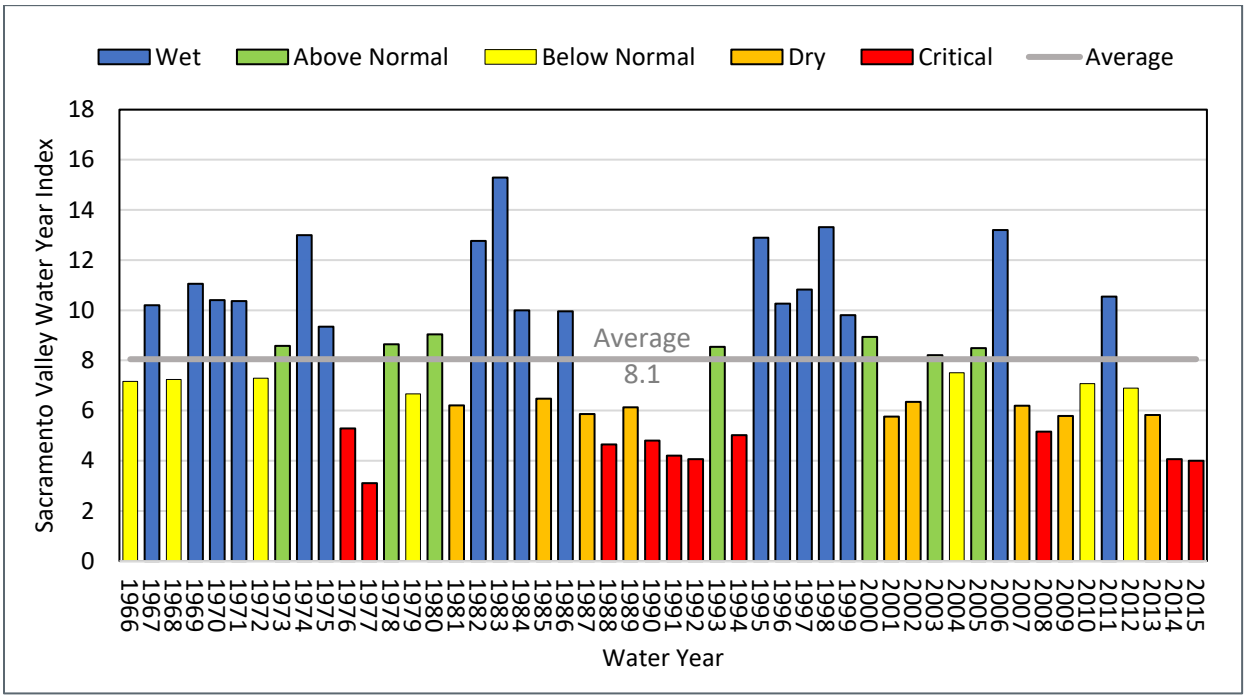
3.3.1 Selection of Hydrologic Periods

The GSP Emergency Regulations require evaluation of water budgets over a minimum of 10 years for the historical water budget, using the most recent hydrology for the current water budget, and 50 years of hydrology for the projected water budget. Hydrologic periods were selected for each water budget category listed below based on consideration of the best available information and science to support water budget development and consideration of the ability of the selected periods to provide a representative range of wet and dry conditions:

- **Historical** – The 26-year period from water years[2] 1990 to 2015 was selected based on the level of confidence in historical input data and information to support water budget development considering land use, surface water availability, hydrology, and other factors.
- **Current Conditions** – Historical water budget information for 2015 represents the most recent hydrology developed for GSP analysis (i.e., precipitation, evapotranspiration, stream inflows). To provide a broader basis for understanding current water budget conditions, a water budget scenario combining most recently available land use (2013 and 2015, representing non-curtailment [Shasta Non-Critical] and curtailment [Shasta Critical] years[3], respectively) and urban demands (average of 2006-2015) over 50 years of historical hydrology was developed. The period selected was 1966 to 2015. An advantage of evaluating the current conditions water budget over a representative 50-year period is that the results provide a baseline for evaluation of the projected water budgets.
- **Future Conditions** – Consistent with the current conditions water budget, the hydrologic period selected as the basis for the projected water budgets was 1966 to 2015.

Selection of the 50-year hydrologic period for the current and projected water budget scenarios was based primarily on three considerations:

- C2VSimFG, the primary tool used to develop the water budgets, has hydrologic information from water years 1922 to 2015.
- The average Sacramento Valley Water Year Index[4] values for the 50-year period from 1966 to 2015 and the 104-year period from 1906 to 2019 (1906 is the first year for which the index is available) are both 8.1. This indicates that the selected 50-year period is similar on average to the entire period of record for the Sacramento Valley watershed. (Figure 3-38). This is important because the major source of surface water in the Subbasin is the Sacramento River.



[2] A water year is defined as the period from October 1 of the prior year to September 30 of the current year. For example, water year 2000 refers to the period from October 1, 1999, to September 30, 2000.

[3] In general, Shasta Critical conditions are declared when the forecast inflow to Lake Shasta for a particular water year is equal to or less than 3.2 million acre-feet. In Shasta Critical years, the Sacramento River Settlement Contractors in the Colusa Subbasin (and elsewhere in the Sacramento Valley) are subject to 25% water supply reductions, significantly reducing surface water supplies available to the subbasin in those years. In turn, the reduction of surface water supplies results in a reduction of cropped farmland.

[4] The Sacramento Valley Water Year Index classifies water years as wet, above normal, below normal, dry, or critical based on Sacramento River unimpaired flows. Additional details describing the Sacramento Valley Water Year Index are available from the California Data Exchange Center .

- The selected period includes a combination of wet and dry cycles, including relatively wet periods in the early 1970's, mid 1980's, and late 1990's and dry periods in the late 1970's, early 1990's, and from approximately 2007 to 2015.

Additionally, annual precipitation for the 1966 to 2015 period averaged approximately 19.4 inches per year, as compared to 18.0 inches for the 1906 to 2018 period indicating slightly wetter conditions than the entire period of record for the Sacramento Valley Index.

Notes: The average index is 8.1, which is the same as the average for the entire period of record from 1906 through 2019.

Figure 3-38. Sacramento Valley Water Year Index and Water Year Types for a 50-year Period from 1966 to 2015

3.3.2 Use of the C2VSimFG Integrated Hydrologic Model

Development of the Integrated Water Flow Model (IWFM) began under the direction and funding of the DWR in 2001. The fine-grid application of IWFM, the California Central Valley Groundwater-Surface Water Simulation Model (C2VSimFG), became publicly available in 2012. The model has been updated over time to simulate historical conditions through water year 2015. The model performs calculations on a monthly time step with monthly input data (i.e., precipitation, stream inflow, surface water diversions) and some annual input data (i.e., land use). Refinements to the model over time include additional crop types to better represent ponded crops (i.e., rice and wetlands), recalibrated soil parameters, and elemental land use. Development and calibration of the C2VSimFG-Colusa[5] model used for water budget analyses in the Subbasin are described in more detail in Appendix 3D.

[5] Version BETA2 of C2VSimFG was used for C2VSimFG-Colusa.

To prepare water budgets for this GSP, historical C2VSimFG-Colusa results for water years 1990 to 2015 have been relied upon, and four additional baseline scenarios have been developed to represent current and projected (future) conditions utilizing 50 years of hydrology (described previously). Specific assumptions associated with these scenarios are described in the following section.

3.3.3 Water Budget Assumptions

Assumptions utilized to develop the historical, current, and projected water budgets are described below and summarized in Table 3-9. Assumptions are listed for the analysis period, hydrology (including stream inflows and precipitation), land use, and water supplies (including surface water diversions and water demands).

In the historical simulation, surface water supplies implicitly reflect historical surface water transfers and any effects of transfers on groundwater pumping. In the current conditions and future conditions scenarios, possible future water transfers (unrelated to GSP projects) were considered but not simulated, as they were considered to be highly speculative. GSP implementation will follow the principle of adaptive management, with continued monitoring and refinement of the basin setting, and with implementation of projects and/or management actions in response to changes in Subbasin conditions that may occur depending on future water transfers and other factors potentially affecting surface water supplies and groundwater pumping.

Table 3-9. Summary of Water Budget Assumptions Used for Historical, Current Conditions, Future Conditions, and Future Conditions with Climate Change at Two Times in the Future (i.e., 2030 and 2070)

Water Budget	Analysis Period	Hydrology	Land Use	Water Supplies
Historical Simulation	1990-2015	Historical	Historical	Historical
Current Conditions Baseline	2016-2065	Historical (1966-2015)	Current (2013 and 2015) used for Shasta Non-Critical and Shasta Critical, respectively	Current (2013 and 2015) used for Shasta Non-Critical and Shasta Critical, respectively, for water diversions; 2006-2015 average for urban demands
Future Conditions, No Climate Change Baseline	2016-2065	Historical (1966-2015)	Current (2013 and 2015) used for Shasta Non-Critical and Shasta Critical, respectively	Current (2013 and 2015) used for Shasta Non-Critical and Shasta Critical, respectively, for water diversions; 2006-2015 average for urban demands
Future Conditions, 2030 Climate Change Baseline	2016-2065	Historical (1966-2015), adjusted based on 2030 climate change with central tendency	Current (2013 and 2015) used for Shasta Non-Critical and Shasta Critical, respectively	Same as Current (see above), adjusted for 2030 climate change

Table 3-9. Summary of Water Budget Assumptions Used for Historical, Current Conditions, Future Conditions, and Future Conditions with Climate Change at Two Times in the Future (i.e., 2030 and 2070)

Water Budget	Analysis Period	Hydrology	Land Use	Water Supplies
Future Conditions, 2070 Climate Change Baseline	2016-2065	Historical (1966-2015), adjusted based on 2070 climate change with central tendency	Current (2013 and 2015) used for Shasta Non-Critical and Shasta Critical, respectively	Same as Current (see above), adjusted for 2070 climate change

3.3.3.1 Historical

A historical water budget was developed to support understanding of past aquifer conditions, considering surface water and groundwater supplies utilized to meet demands. The historical water budget was developed using C2VSimFG-Colusa and incorporates the best available science and information. Historical water supplies and aquifer response have been characterized by water year type based on DWR's Sacramento Valley Water Year Index.

As described previously, water years 1990 to 2015 were selected to provide a minimum of ten years across a range of hydrologic conditions. This period includes relatively wet years in 1995, 1998, 2006, and 2011 as well as dry conditions between 1990 and 1992, in 1994, between 2007 and 2009, and between 2013 and 2015.

Development of the historical water budget is described in greater detail in Appendix 3E. Model inputs and historical water budget results were summarized for 32 distinct subareas within the Subbasin. These subareas, described in Appendix 3F, approximately represent regions of the subbasin that share a common water supplier (e.g., an irrigation or water district service area), a common governing agency (e.g., a county or city), and a common primary water supply source (e.g., areas with access to surface water or areas with access to only groundwater, i.e., "groundwater" areas). Subareas were delineated within the C2VSimFG-Colusa model to support development of model inputs and to support quality control and calibration of model outputs. Specific data and information used to create model inputs are summarized in Appendix 3D.

Information utilized to develop the historical water budget includes:

- **Analysis Period** – Water years 1990 to 2015
- **Stream Flows** – Data from C2VSimFG-Colusa were used as best-estimates for inflows and outflows from rivers, streams, and other waterways traversing the Subbasin or along the boundary. The Sacramento River is the major surface water inflow to the subbasin. Stony Creek also provides inflow to the region along the northern boundary. Flows were estimated using C2VSimFG-Colusa which simulates the Sacramento River, Stony Creek, and Colusa Drain in the Subbasin.

- **Land Use** – Land use characteristics for agricultural, native, and urban (including rural residential) lands were estimated annually based on a combination of DWR land use surveys and county agricultural commissioner cropping reports. DWR land use data were available for 1993, 1998, 2003, 2009, and 2014. Urban land use areas were also verified against urban spheres of influence identified from city and county planning documents.
- **Agricultural Water Demand** – Agricultural irrigation demands were estimated using C2VSimFG-Colusa, which simulates crop growth and water use on a monthly basis, considering crop type, evapotranspiration, root depth, soil characteristics, and irrigation practices. For ponded land uses (rice and managed wetlands), pond depths and pond drainage are also considered to simulate demands.
- **Urban and Industrial Water Demand** – Urban and industrial demands and per capita water use over time were estimated based on a combination of pumping data provided by the State Water Resource Control Board (Small Supplier Conservation Reports) and Urban Water Management Plans (UWMPs). Estimates of population were based on data from the Department of Finance and from UWMPs.
- **Surface Water Diversions** – Surface water diversions were estimated based on a combination of reported diversions by water suppliers and Bureau of Reclamation records. In some cases, agricultural water demand was estimated for areas known to receive surface water but for which reported diversion data were not available. Deliveries of surface water supplies were configured to simulate actual surface water deliveries, to the extent possible with available data, and thus implicitly reflect historical surface water transfers and any effects of transfers on groundwater pumping.
- **Groundwater Pumping** – For urban water suppliers, historical pumping was estimated from reported pumping volumes over time. Pumping for large irrigation districts was developed from reported data and private pumping for landowners was calculated automatically within the model by first estimating the total demand and then subtracting surface water deliveries to calculate estimated groundwater pumping required to meet the remaining demand.

3.3.3.2 Current Conditions

The current conditions water budget was developed as a baseline to evaluate projected water budgets considering future conditions and is based on 50 years of hydrology along with the most recent information describing land use, urban demands, and surface water supplies. The 50-year hydrologic period was selected rather than the most recent year for which historical water budget information is available to allow for direct comparison of potential future conditions to current conditions. The use of a representative hydrologic period containing wet and dry cycles supports the understanding of variability and uncertainty in groundwater conditions over time, establishment of sustainable management criteria, and development of projects and management actions to avoid undesirable results.

The current water budget estimates current inflows, outflows, and change in storage for the subbasin using 50 years of representative hydrology and the most recent water supply, water demand, and land use information.

Information utilized to develop the current conditions baseline water budget include:

- **Analysis Period** – The 2016-2065 analysis period was simulated based on 50 years of historical hydrology representing the period from 1966 to 2015. Table 3-10 identifies the projected water years and corresponding historical water years and water year types that

were assigned for mapping historical hydrologic data to the current conditions scenario. Hydrologic model inputs for years 2016-2065 were based on these historical water year assignments to achieve a future hydrologic period of that is representative and consistent with historical hydrology over the 1965-2015 period.

- **Stream Inflows** – Inflows of surface water into the subbasin were estimated utilizing the same information as for the historical water budget.
- **Land Use** – Land use for agricultural, native, and urban (including rural residential) lands was estimated annually using the most recent land use information. Specifically, 2013 and 2015 land use were mapped to the 50-year analysis period, with 2015 land use applied to critically dry years corresponding to Shasta Critical years and 2013 land use applied to all other years. Shasta Critical years were identified based on annual inflow to Shasta Lake. Annual inflow to Shasta Lake is a reasonable indicator of surface water supplies and associated changes in diversion curtailments within the subbasin, which are primarily from the Sacramento River.
- **Agricultural Water Demand** – Agricultural irrigation demands were estimated using C2VSimFG-Colusa, in the same manner as the historical water budget. The same general assumptions used for simulating all crops (including rice and managed wetlands) in the historical water budget were also used in the current conditions baseline water budget.
- **Urban and Industrial Water Demand** – Urban and industrial demands were estimated based on recent per capita water use and projected 2050 population. Specifically, average per capita water use for recent years (2006 to 2015) was reduced based on projected 2050 values in the Willows UWMP.
- **Surface Water Diversions** – For the current conditions scenario, historical diversions were applied to the future, with 2015 diversions used in Shasta Critical years and 2013 diversion used in Shasta Non-Critical years. Shasta Critical Conditions were simulated for the following five years throughout the 50-year simulation period: 2026, 2027, 2041, 2064, and 2065. Simulated diversions in the Subbasin in those Shasta Critical years were on average approximately 30 percent less than the simulated diversions in Shasta Non-Critical years.
- **Groundwater Pumping** – Pumping to meet urban demands was estimated based on an average of recent years, as described above. Pumping to meet agricultural and managed wetlands demands was estimated using C2VSimFG-Colusa as described previously for the historical water budget.

Table 3-10. Summary of Projected Water Years and Assigned Historical Water Year

Projected Water Year	Assigned Historical Water Year	Sacramento Valley Water Year Type	Projected Water Year	Assigned Historical Water Year	Sacramento Valley Water Year Type
2016	1966	BN	2041	1991	C
2017	1967	W	2042	1992	C
2018	1968	BN	2043	1993	AN
2019	1969	W	2044	1994	C
2020	1970	W	2045	1995	W
2021	1971	W	2046	1996	W
2022	1972	BN	2047	1997	W
2023	1973	AN	2048	1998	W
2024	1974	W	2049	1999	W
2025	1975	W	2050	2000	AN
2026	1976	C	2051	2001	D
2027	1977	C	2052	2002	D
2028	1978	AN	2053	2003	AN
2029	1979	BN	2054	2004	BN
2030	1980	AN	2055	2005	AN
2031	1981	D	2056	2006	W
2032	1982	W	2057	2007	D
2033	1983	W	2058	2008	C
2034	1984	W	2059	2009	D
2035	1985	D	2060	2010	BN
2036	1986	W	2061	2011	W
2037	1987	D	2062	2012	BN
2038	1988	C	2063	2013	D
2039	1989	D	2064	2014	C
2040	1990	C	2065	2015	C

Note: Sacramento Valley Water Year Type is based on the Sacramento Valley Water Year Index and is classified into five types: Wet (W), Above Normal (AN), Below Normal (BN), Dry (D), and Critical (C).

3.3.3.3 Future Conditions Scenarios

Three projected (future conditions) baseline water budgets were developed considering a range of future conditions that may occur. The scenarios consider future planned land use changes (i.e., development), along with changes in climate, including precipitation, surface water inflows, and evapotranspiration. These baselines provide information regarding changes in subbasin conditions (e.g., groundwater storage) that may occur in the future over a series of wet and dry cycles.

The projected water budget estimates potential future inflows, outflows, and change in storage for the subbasin using 50 years of representative hydrology (including modifications based on climate change projections), the most recent water supply and water demand, and planned future land use information.

Information utilized to develop the future conditions baseline water budgets include:

- **Analysis Period** – The 2016-2065 analysis period was simulated based on 50 years of historical hydrology representing the period from 1966 to 2015. Table 3-10 identifies the projected water years and corresponding historical water years and water year types that were assigned for mapping historical hydrologic data to the future conditions scenarios. Hydrologic model inputs for years 2016-2065 were based on these historical water year assignments to achieve a future hydrologic period of that is representative and consistent with historical hydrology over the 1965-2015 period.
- **Stream Inflows**
  - Future Conditions, No Climate Change – Inflows of surface water into the subbasin were estimated utilizing the same information as for the historical water budget.
  - Future Conditions, 2030 Climate Change – Precipitation, evapotranspiration, and surface water supplies were adjusted to reflect climate change based on the 2030 Central Tendency climate change datasets provided by DWR to support GSP development.
    - For precipitation and evapotranspiration, monthly change factors were applied to historical values to estimate potential future conditions.
    - For stream flows, DWR estimates of stream inflows were utilized where available; for streams without direct estimates of inflows, inflows were estimated using streamflow change factors applied at the watershed scale.
  - Future Conditions, 2070 Climate Change – Precipitation, evapotranspiration, and surface water supplies were adjusted to reflect climate change based on the 2070 Central Tendency climate change datasets provided by DWR to support GSP development.
    - For precipitation and evapotranspiration, monthly change factors were applied to historical values to estimate potential future conditions.
    - For stream flows, DWR estimates of stream inflows were utilized where available; for streams without direct estimates of inflows, inflows were estimated using streamflow change factors applied at the watershed scale.
- **Land Use** – Land use for agricultural, native, and urban (including rural residential) lands was estimated annually using the most recent land use information and modified based on planned development according to County General Plan documents.
  - Future Conditions, No Climate Change – Land use was assumed to be similar to the current conditions water budget scenario.
  - Future Conditions, 2030 Climate Change – 2013 and 2015 land use data were mapped to the 50-year analysis period considering 2030 central tendency climate change projections. 2015 land use was applied to extreme dry years and 2013 land use applied to all other years. 2013 and 2015 land use data were modified to reflect planned development, generally resulting in an increase in urban land through development of previously undeveloped (i.e., native) lands.
- **Future Conditions, 2070 Climate Change** – 2013 and 2015 land use data were mapped to the 50-year analysis period considering 2070 central tendency climate change projections. 2015 land use was applied to Shasta Critical years and 2013 land use applied to all other (Shasta Non-Critical) years. 2013 and 2015 land use data were modified to reflect planned development, generally resulting in an increase in urban land through development of previously undeveloped (i.e., native) lands.

- **Agricultural Water Demand** – Agricultural irrigation demands were estimated using C2VSimFG-Colusa and modified from the current conditions scenario as described below.
  - Future Conditions, No Climate Change – Agricultural water demand was assumed to be similar to the current conditions water budget scenario.
  - Future Conditions, 2030 Climate Change – Agricultural water demand was increased from current conditions based on 2030 central tendency climate change projections.
  - Future Conditions, 2070 Climate Change – Agricultural water demand was increased from current conditions based on 2070 central tendency climate change projections.
  - Besides these modifications, the same general assumptions used for simulating all crops (including rice and managed wetlands) in the historical water budget were also used in the future conditions water budgets.
- **Urban and Industrial Water Demand** – Urban and industrial demands were estimated based on projected urban demands. Specifically, future urban demands were estimated based on preliminary draft demands for 2050 provided as part of the 2020 Urban Water Management Plan (UWMP) for Willows. Estimates for other urban demand areas were based on population growth rates and per capita water use similar to Willows.
- **Surface Water Diversions** – Climate change estimates are based on current diversions with reduced diversions in some years to simulate drought periods. For both the 2030 and 2070 central tendency scenarios, reductions occurred in eight years within the 50-year simulation period: 2016, 2026, 2027, 2028, 2041, 2042, 2064, 2065. Diversions were on average about 25 percent less than full supply years.
- **Groundwater Pumping** – Pumping to meet urban demand was estimated based on draft projections from UWMPs currently under development, as described above. Pumping to meet agricultural and managed wetlands demand was estimated using C2VSimFG-Colusa as described previously for the historical water budget.

3.3.4 Water Budget Estimates

As described previously, water budget estimates were developed using the C2VSimFG-Colusa model. Primary components of the land and surface water system water budget include the following:

- **Inflows**
  - Surface Water Inflows – Inflows at the land surface through rivers, streams, canals, or other waterways, including Sacramento River diversions, Stony Creek diversions, Sacramento River inflows, and inflows from boundary streams. These inflows may also include overland flow from upslope areas outside of the Subbasin. Note that although interactions with streams along the boundary of the subbasin (i.e., diversions and stream-aquifer interaction) are accounted for, the flow in the stream is not considered an inflow to the Subbasin. Inflows from streams that traverse the Subbasin, primarily the Sacramento River near the eastern edge of the subbasin where the river is within the subbasin, are accounted for explicitly. All surface water that enters the Subbasin that does not flow out of the Subbasin or evaporate may be used or available for use for groundwater recharge or in-lieu use, whether through seepage or deep percolation to the groundwater system, or irrigation or other consumptive use that offsets groundwater demand.

- Precipitation – Rainfall on the land surface within the Subbasin boundary.
- Groundwater pumping – Extraction of groundwater to meet agricultural, urban and industrial, managed wetlands, or other beneficial uses.
- Stream Gains from Groundwater (Accretions) – Gains in streamflow from shallow groundwater occurring when the water level in the aquifer adjacent to the stream is greater than the water level in the stream.

- **Outflows**
  - Evapotranspiration – Consumptive use of water including both evaporation and transpiration components occurring on agricultural, urban, industrial, managed wetland, native vegetation lands, and evaporation from canals and other water surfaces. Native vegetation includes riparian corridors along streams and rivers.
  - Deep Percolation – Recharge of the groundwater system through the vertical movement of precipitation and applied irrigation water (surface water and groundwater) below the root zone.
  - Seepage (also referred to as losses or leakage) – Recharge of the groundwater system from streams, canals, drains or other water bodies.
  - Surface Water Outflows – Outflows at the land surface through rivers, streams, canals, or other waterways, including runoff or precipitation, runoff of surface water and groundwater applied for irrigation, and outflows from the Sacramento River, Colusa Drain, the Colusa Weir (to the Sutter Bypass) and other boundary streams. These outflows may also include overland flow to downslope areas outside of the subbasin.
- **Change in Storage** – Changes in soil moisture storage within the upper several feet of soil in the root zone, as well as changes in storage in surface water bodies within the subbasin, calculated as Total Inflow minus Total Outflow. These changes vary over the course of a year based on precipitation and irrigation patterns and other factors, but are generally negligible on an annual basis.

Primary components of the groundwater system water budget include the following:

- **Inflows**
  - Subsurface Water Inflows – Groundwater inflows from adjacent subbasins or from the Coast Range foothills on the west side of the subbasin.
  - Deep Percolation (from the overlying land surface and surface water system) – Described above.
  - Seepage (from streams, canals, and drains) – Described above.
- **Outflows**
  - Groundwater Pumping – Described above.
  - Subsurface Outflows – Groundwater outflows to adjacent basins.
  - Accretions – Described above.
- **Change in Storage** – Changes in water storage in the aquifer system, calculated as Total Inflow minus Total Outflow. These changes tend to be large compared to changes in root zone soil moisture storage and can vary substantially from year to year.

Many components of the water budget can be estimated based on measured data (e.g., precipitation, diversions, evapotranspiration, etc.) and are used to develop inputs to C2VSimFG-Colusa to support water budget development. Other components are more difficult to measure or do not have measured values readily available (e.g., deep percolation, subsurface flows, groundwater pumping, surface water-groundwater interaction, etc.) and are estimated using C2VSimFG-Colusa. Additional detail describing the C2VSimFG is available in DWR Technical Memorandum entitled Integrated Water Flow Model: IWFM-2015 Theoretical Documentation[6].

Average annual water budget estimates for the historical water budgets and for the current and projected water budget scenarios are summarized in Table 3-11 for the land and surface water system and in Table 3-12 for the groundwater system. Additional information and discussion regarding the water budgets is provided in the following subsections. It is anticipated that the water budgets will be refined and updated over time as part of GSP implementation in the subbasin.

Table 3-11. Average Annual Land and Surface Water System Inflows, Outflows, and Changes in Storage in taf/yr for the Water Budget Analysis Periods Listed in Table 3-9

Component	Historical Simulation	Current Conditions Baseline	Future Conditions, No Climate Change Baseline	Future Conditions, 2030 Climate Change Baseline[(a)]	Future Conditions, 2070 Climate Change Baseline[(a)]
Inflows					
Surface Water Inflows	11,747	12,556	12,556	12,597	12,715
Sacramento River Diversions[(b)]	1,076	1,192	1,196	1,196	1,196
Stony Creek Diversions[(b)]	92	95	91	91	91
Sacramento River Inflows[(c)]	10,500	11,188	11,188	11,228	11,335
Other Inflows from Boundary Streams	78	81	81	81	92

3.3.4.1 Historical Simulation

The historical water budget provides a foundation for understanding how the subbasin has behaved, including insight into historical groundwater conditions (e.g., observed water levels). Also, in accordance with the GSP Emergency Regulations, the historical water budget covers a period of at least ten years (26-year period from 1990 to 2015). The historical water budget is used to evaluate the availability and reliability of historical surface water supplies and provides insight into the ability to operate the subbasin sustainably. Note that the historical analysis period experienced slightly more precipitation than the long-term average and included historic drought conditions from approximately 2007 to 2015.

Average annual inflows to and outflows from the Subbasin for the historical land and surface water system water budget were estimated to be 13,825 taf/yr (13.8 maf/yr). Average annual values were presented previously in Table 3-11 and are shown graphically in Figure 3-39.

Primary inflows to the land and surface water system include surface water inflows (11,747 taf/yr), precipitation (1,210 taf/yr), groundwater pumping (502 taf/yr), and stream gains from groundwater[7] (366 taf/yr). Surface water inflows include the Sacramento River, other inflows from boundary streams including Stony Creek, as well as overland runoff of precipitation and applied water from upslope lands. Additionally, diversions from the Sacramento River and from Stony Creek are major sources of surface water inflows.

Primary outflows from the land and surface water system include evapotranspiration (1,740 taf/yr), deep percolation (441 taf/yr), seepage (345 taf/yr), and surface water outflows (11,302 taf/yr). Evapotranspiration is primarily from agricultural lands but also from managed wetlands, canal evaporation, native vegetation, and urban and industrial lands. Deep percolation is primarily from precipitation, but also from applied water. Seepage includes a combination of stream seepage and seepage from canals and drains.

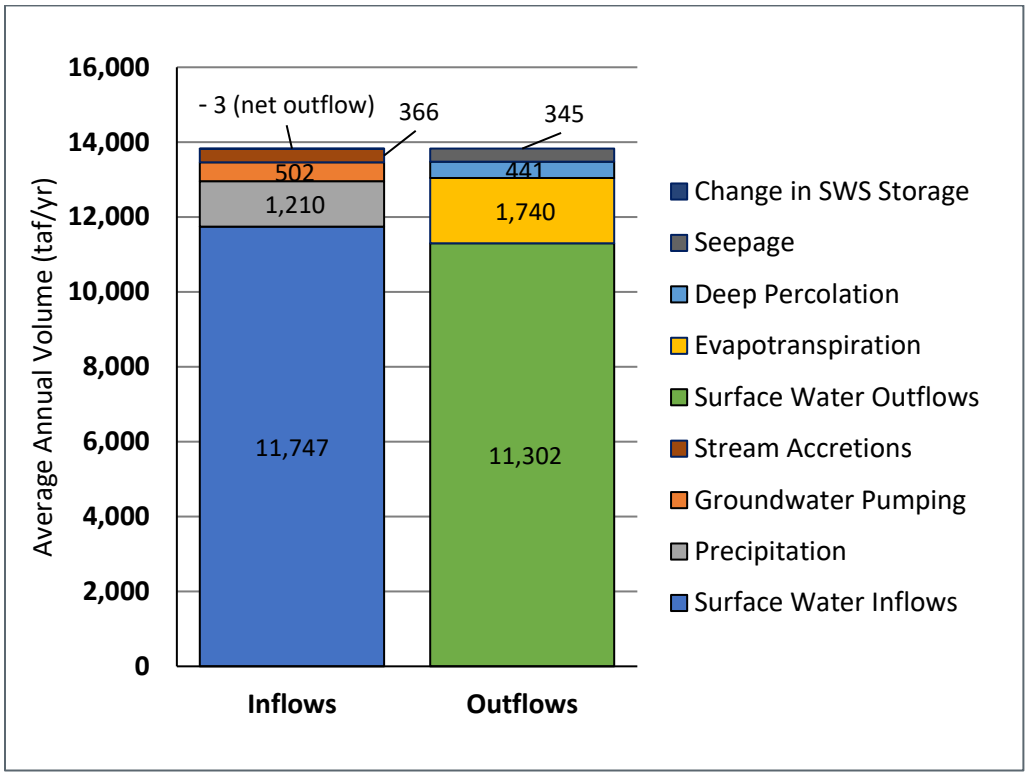

Figure 3-39. Average Annual Historical Land and Surface Water System Water Budget Summary (1990-2015, rounded to nearest taf/yr)

The average annual change in storage in the land and surface water system (3 taf/yr) is negligible due to similar soil moisture content in the root zone, on average, across water years.

Annual historical land and surface water system water budgets for 1990 to 2015 are provided in Table 3E-1 of Appendix 3E for the entire Subbasin.

[7] i.e., stream accretions

Average annual historical inflows to and outflows from the groundwater system were estimated to be 986 taf and 1,014 taf, respectively. Average annual values were presented previously in Table 3-12 are shown graphically in Figure 3-40 Inflows to the groundwater system include deep percolation (441 taf/yr), subsurface inflows from the Corning, Butte, Sutter, and Yolo Subbasins (200 taf/yr), seepage (345 taf/yr), and changes in groundwater storage (28 taf/yr). Outflows from the groundwater system include groundwater pumping (502 taf/yr), subsurface outflows to the Corning, Butte, Sutter, and Yolo Subbasins (146 taf/yr), and stream gains from groundwater (366 taf/yr).

Annual historical groundwater system water budgets for 1990 to 2015 are provided in Table 3E-2 of Appendix 3E for the entire Subbasin.

Historical water budget values are also presented in Appendix 3F for 32 distinct subareas defined within the Subbasin. Each subarea approximately represents a region of the Subbasin that shares a common water supplier (e.g., an irrigation or water district service area), a common governing agency (e.g., county or city), and a common primary water supply source (e.g., areas with access to surface water or areas with access to only groundwater, i.e., "groundwater" areas).

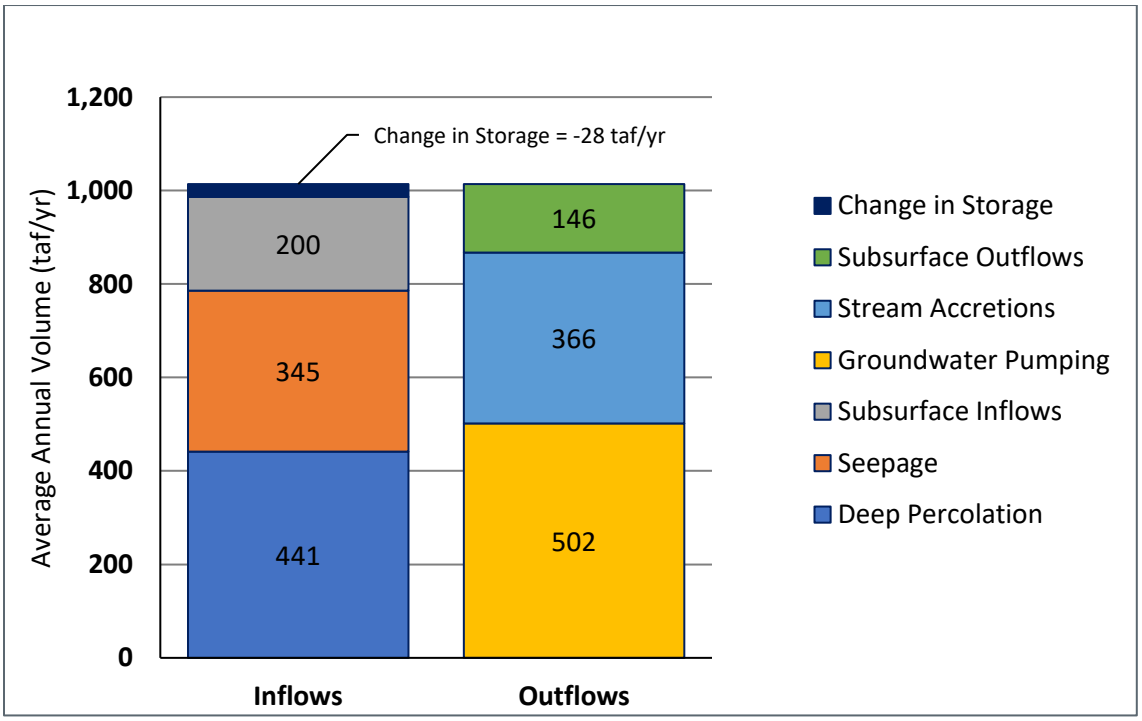

Figure 3-40. Average Annual Historical Groundwater System Water Budget Summary (1990-2015, rounded to nearest taf/yr)

Historical water supplies and change in groundwater storage are summarized by water year type in Table 3-13 based on the Sacramento Valley Water Year Index. Between 1990 and 2015, there were seven wet years, four above normal years, three below normal years, five dry years, and seven critical years. Historical surface water deliveries were greatest in dry years, when agricultural demands tend to be relatively high and surface water supplies tend to be available, and least in critical years, when surface water supplies tend to be constrained despite relatively high agricultural demands. Groundwater pumping was greatest in dry years and least in wet years. Historically, groundwater storage in the subbasin has tended to increase in wet and above normal years and to decrease in below normal, dry, and critical years,

with reductions in storage in below normal years less than reductions in dry and critical years. The average annual change in storage over the 1990-2015 historical period was -28 taf.

Table 3-13. Historical Water Supplies and Change in Groundwater Storage by Hydrologic Water Year Type, taf/yr (1990-2015)

Water Year Type	Surface Water Deliveries[(a)]	Groundwater Pumping	Total Supply	Change in Groundwater Storage
Wet	1,381	435	1,814	99
Above Normal	1,474	435	1,909	101
Below Normal	1,592	546	2,138	-24
Dry	1,598	570	2,168	-116
Critical	1,228	540	1,768	-166
Average	**1,420**	**502**	**1,922**	**-28**

(a) Surface Water Deliveries represents the volume of water delivered to agricultural and urban lands. It is an internal flow path and is different than Surface Water Inflow in the Subbasin boundary balance summarized in Table 3-11.

3.3.4.1.1 Availability or Reliability of Historical Surface Water Supplies

As indicated in Table 3-13, historical surface water supplies for delivery to agricultural land vary based on water year type. The primary sources of surface water in the subbasin are the Sacramento River and Stony Creek Diversions. Surface water supplies are relatively reliable in the Subbasin and represent approximately 70-percent of the total water supplies (Sacramento River and Stony Creek diversions plus Groundwater Pumping). This average percentage reflects all of the supply curtailments or shortages experienced by the surface water suppliers in the subbasin over the 1990-2015 historical period, including the 25 percent curtailments to Sacramento River settlement contractors in Shasta Critical years, less than 100 percent allocations to Tehama-Colusa Canal CVP contractors in certain years, and Stony Creek water shortages experienced by the Orland Unit Water Users Association. Under 2030 and 2070 climate change conditions there may be an increase in the availability of surface water for irrigation in the Subbasin due to increased precipitation from climate change effects. Potential effects of these changes are evaluated as part of the projected water budgets in the following sections.

Under diversion agreements between Sacramento River Settlement Contractors and the State, Sacramento River diversions can be reduced under the following conditions:

- DWR forecasted annual inflow into Lake Shasta is less than 3,200 taf[8], or
- There is a cumulative deficit of inflows below 4,000 taf of greater than 800 taf for any year or consecutive series of years.

Another source of uncertainty in the availability or reliability of historical surface water supplies is Phase 2 of the San Francisco Bay/Sacramento-San Joaquin Delta Estuary Water Quality Control Plan (Bay-Delta Water Quality Control Plan). Standards within the Bay-Delta Water Quality Control Plan are being updated by the State Water Resources Control Board in two phases. Phase 2 of this effort will include a

[8] The final, official forecast must be made by April 10 of each year.

comprehensive update to the plan, creating new inflow requirements for the Sacramento River and its tributaries. While Phase 2 is not yet complete, the requirements proposed in this phase have the potential to constrain the volume and/or timing of surface water diversions by water users along the Sacramento River and its tributaries. GSP annual reports and periodic evaluations will address specific impacts of the Bay-Delta Water Quality Control Plan, when known.

3.3.4.1.2 Suitability of Tools and Methods for Planning

The water budgets presented herein have been developed using the best available information and best available science and structured in a manner consistent with the hydrogeologic conceptual model of the Subbasin. The IWFM application C2VSimFG-Colusa, which is used to organize information for the water budgets, develop water budget scenarios, and perform water budget calculations, is currently the best available tool and is suitable for GSP development for the subbasin. The IWFM has been developed over the past several decades and updated over time to use updated model code, updated datasets, and updated input parameters through a series of efforts by DWR. Refinements to C2VSimFG specific to the Subbasin are described Appendix 3D.

The water budgets developed using C2VSimFG-Colusa support the development of sustainable management criteria, evaluation of the monitoring network, and development of projects and management actions as part of GSP development. It is anticipated that the C2VSimFG-Colusa will continue to be updated and refined in the future as part of GSP implementation. Additional information describing C2VSimFG is available in DWR's Theoretical Documentation and User's Manual[9].

3.3.4.1.3 Ability to Operate the Subbasin within the Sustainable Yield

Sustainable yield refers to the maximum quantity of water, calculated over a base period representative of long-term conditions in the Subbasin, and including any temporary surplus that can be withdrawn annually from a groundwater supply without causing an undesirable result. As a result, determination of sustainable yield requires consideration of SGMA's six sustainability indicators. Historical water budget estimates indicate an average annual decrease in storage of 28 taf/yr for the period from water year 1990 to 2015. Operation of the subbasin within the sustainable yield will likely require implementation of projects and management actions over the 20-year SGMA planning and implementation horizon. Projects and management actions are discussed in Chapter 6. The estimated sustainable yield of the subbasin is described in greater detail in Section 3.3.7.

3.3.4.2 Current Conditions Baseline

The current conditions baseline water budget provides a foundation to understand the behavior of the subbasin considering current land use and urban demands over a broad range of hydrologic conditions as well as a basis for evaluating how groundwater conditions may change in the future based on comparison of water budget results to projected water budgets presented in the following section. A 50-year hydrologic period was selected, rather than a single, recent year to improve the basis for estimation of sustainable yield under current conditions (along with consideration of other sustainability parameters).

[9] https://data.cnra.ca.gov/dataset/c2vsimfg_beta2

Average annual inflows to and outflows from the subbasin for the current conditions land and surface water system baseline water budget were estimated to be 14,587 taf/yr. Average annual values were presented previously in Table 3-11 and are shown graphically in Figure 3-41.

Primary inflows to the land and surface water system include surface water inflows (12,556 taf/yr), precipitation (1,183 taf/yr), groundwater pumping (499 taf/yr), and stream gains from groundwater (349 taf/yr). Surface water inflows include the Sacramento River, other inflows from boundary streams including Stony Creek, as well as overland runoff of precipitation and applied water from upslope lands. Additionally, diversions from the Sacramento River and from Stony Creek are primary sources of surface water inflows.

Primary outflows from the land and surface water system include surface water outflows (12,002 taf/yr), evapotranspiration (1,790 taf/yr), deep percolation (416 taf/yr), and seepage (379 taf/yr). Surface water outflows include outflows through Sacramento River, Colusa Drain, Colusa Weir to Sutter Slough, and outflows to boundary streams including Stony Creek, as well as overland runoff of precipitation and applied water to downslope lands. Evapotranspiration is primarily from agricultural lands but also from managed wetlands, canal evaporation, native vegetation, and urban and industrial lands. Deep percolation is primarily from precipitation, but also from applied water. Seepage includes a combination of stream seepage and seepage from canals and drains.

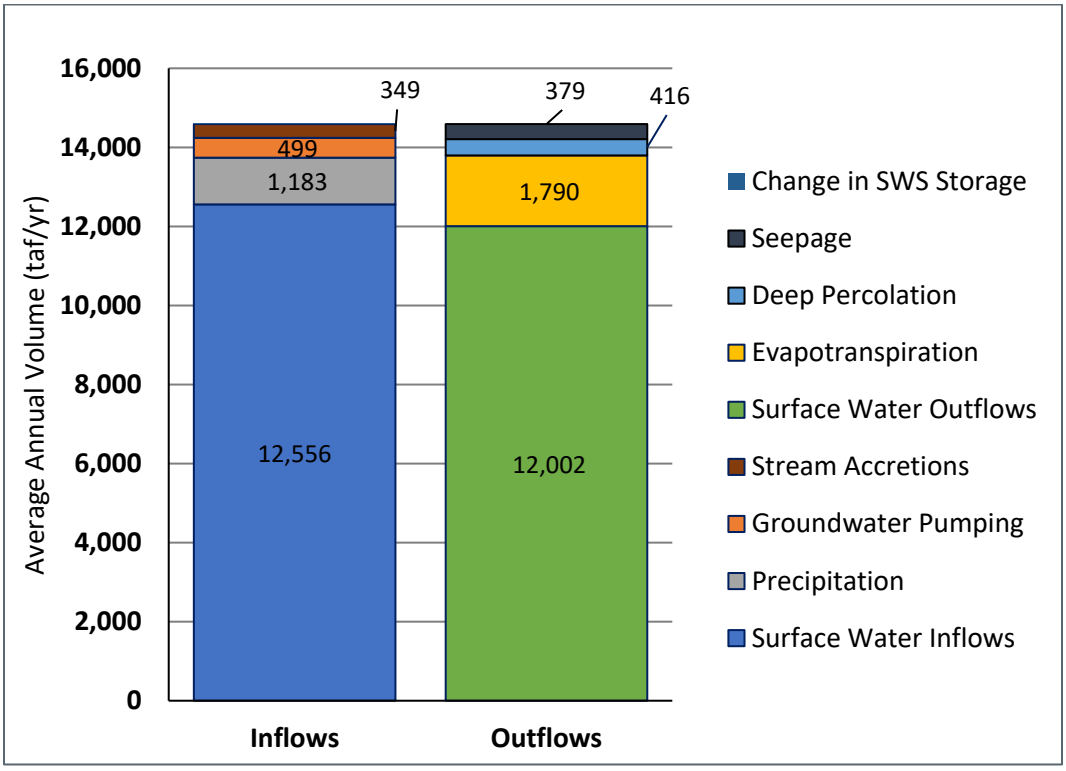

Figure 3-41. Average Annual Current Conditions Baseline Land and Surface Water System Water Budget Summary (2016-2065, rounded to nearest taf/yr)

The average annual change in storage in the land and surface water system (0.1 taf/yr) is negligible due to similar soil moisture content in the root zone, on average, across water years.

Average annual inflows to and outflows from the groundwater system were estimated to be 997 taf/yr during the current conditions baseline simulation period. Average annual values were presented previously in Table 3-12 and are shown graphically in Figure 3-42.

Inflows to the groundwater system include deep percolation (416 taf/yr), seepage (379 taf/yr), and subsurface inflows from the Corning, Butte, Sutter, and Yolo Subbasins (203 taf/yr). Outflows from the groundwater system include groundwater pumping (499 taf/yr), stream gains from groundwater (349 taf/yr), subsurface outflows to Corning, Butte, Sutter, and Yolo Subbasins (149 taf/yr), and change in groundwater storage (1 taf/yr).

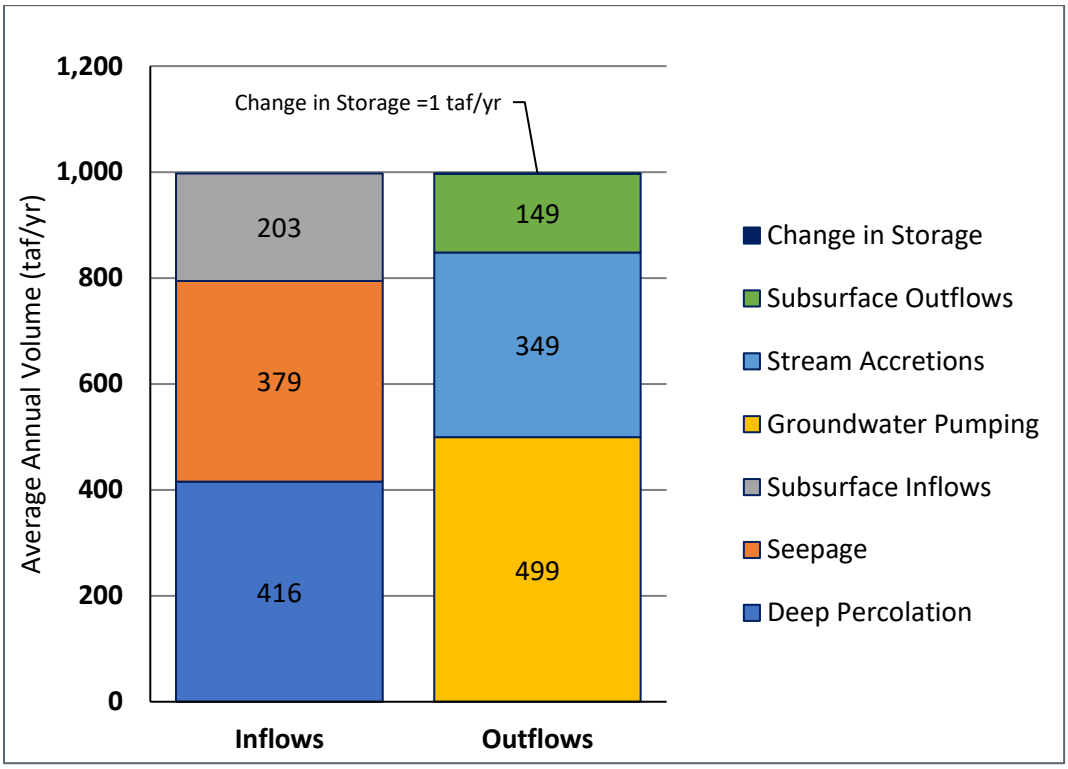

Figure 3-42. Average Annual Current Conditions Baseline Groundwater System Water Budget Summary (2016-2065, rounded to nearest taf/yr)

3.3.4.3 Future Conditions Scenarios

Three projected water budgets were developed for the subbasin to provide baseline scenarios representing potential future conditions considering planned development under the Colusa County 2030 General Plan and climate change centered around 2030 and 2070 based on central tendency climate change datasets provided by DWR. The projected water budget scenarios provide a foundation to understand the behavior of the subbasin considering potential future land use and urban demands over a broad range of hydrologic conditions, modified based on climate change projections. Use of a 50-year hydrologic period provides a basis for estimation of sustainable yield under potential future conditions.

3.3.4.3.1 Future Conditions, No Climate Change Baseline

Average annual inflows to and outflows from the subbasin for the future conditions without climate change projected land and surface water system baseline water budget were estimated to be 14,587 taf/yr. Average annual values were presented previously in Table 3-11 and are shown graphically in Figure 3-43.

Primary inflows to the land and surface water system include surface water inflows (12,556 taf/yr), precipitation (1,183 taf/yr), groundwater pumping (499 taf/yr), and stream gains from groundwater (349 taf/yr). Surface water inflows include the Sacramento River, other inflows from boundary streams including Stony Creek, as well as overland runoff of precipitation and applied water from upslope lands. Additionally, diversions from the Sacramento River and from Stony Creek are a primary source of surface water inflows. Surface water inflows include the Sacramento River, other inflows from boundary streams including Stony Creek, as well as overland runoff of precipitation and applied water from upslope lands. Additionally, diversions from the Sacramento River and from Stony Creek are a key source of surface water inflows.

Primary outflows from the land and surface water system include surface water outflows (12,003 taf/yr), evapotranspiration (1,790 taf/yr), deep percolation (415 taf/yr), and seepage (379 taf/yr). Surface water outflows include outflows through Sacramento River, Colusa Drain, Colusa Weir to Sutter Slough, and outflows to boundary streams including Stony Creek, as well as overland runoff of precipitation and applied water to downslope lands. Evapotranspiration is primarily from agricultural lands but also from managed wetlands, canal evaporation, native vegetation, and urban and industrial lands. Deep percolation is primarily from precipitation, but also from applied water. Seepage includes a combination of stream seepage and seepage from canals and drains.

The average annual change in storage in the land and surface water system (0.1 taf/yr) is negligible due to similar soil moisture content in the root zone, on average, across water years.

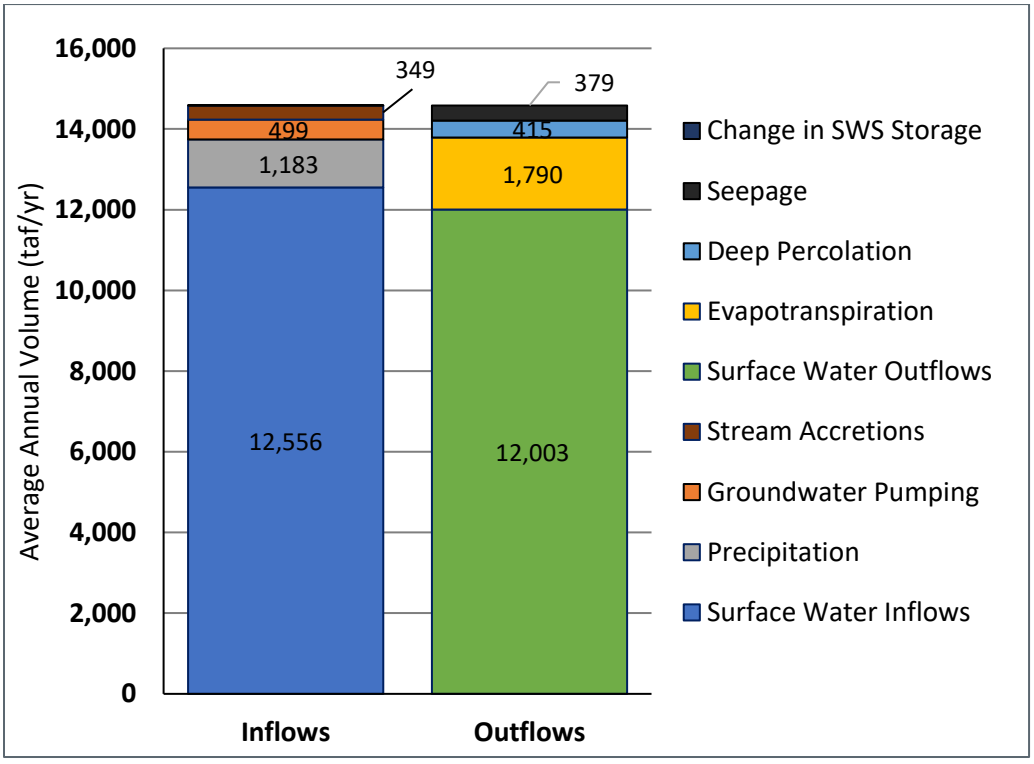

Figure 3-43. Average Annual Future Conditions, No Climate Change Baseline Land and Surface Water System Water Budget Summary (2016-2065, rounded to nearest taf/yr)

Average annual inflows to and outflows from the groundwater system were estimated to be 997 taf/yr for the future conditions without climate change simulation. Average annual values were presented previously in Table 3-12 are shown graphically in Figure 3-44**.**

Inflows to the groundwater system include deep percolation (415 taf/yr), seepage (379 taf/yr), and subsurface inflows from the Corning, Butte, Sutter, and Yolo Subbasins (203 taf/yr). Outflows from the groundwater system include groundwater pumping (499 taf/yr), stream gains from groundwater (349 taf/yr), and subsurface outflows to the Corning, Butte, Sutter, and Yolo Subbasins (149 taf/yr).

There is negligible change (+1 taf/yr) in groundwater storage under the future condition, no climate change baseline water budget.

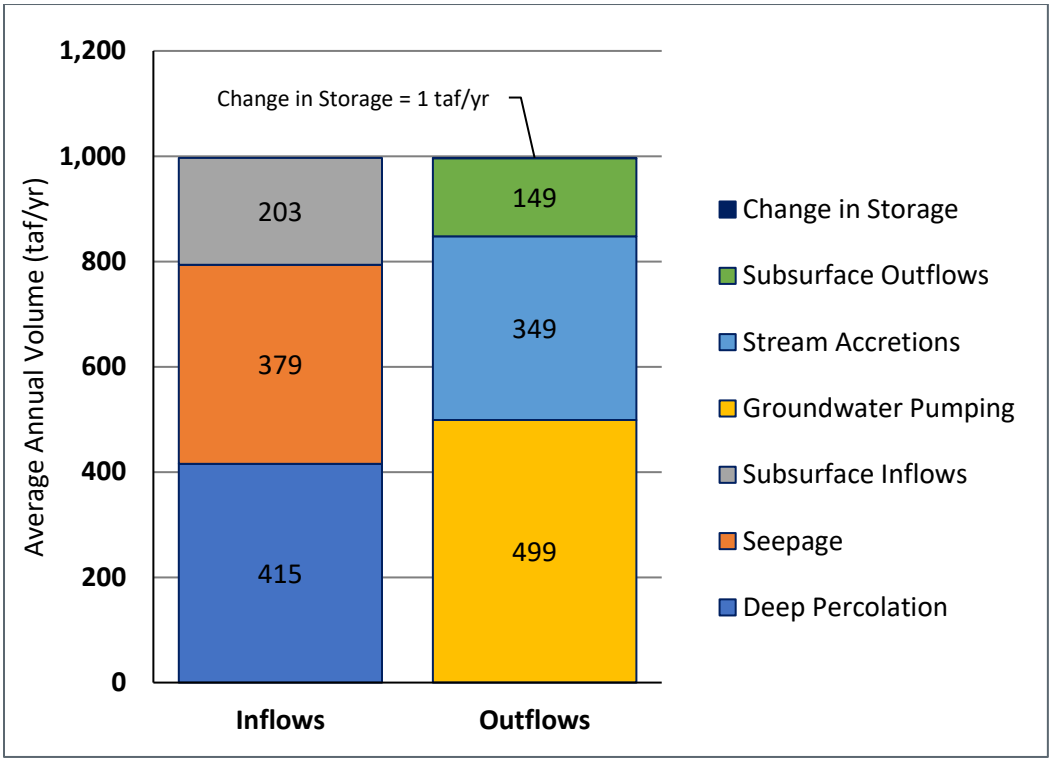

Figure 3-44. Average Annual Future Conditions, No Climate Change Baseline Groundwater System Water Budget Summary (2016-2065, rounded to nearest taf/yr)

3.3.4.3.2 Future Conditions, 2030 Climate Change Baseline

Average annual inflows to and outflows from the subbasin for the future conditions with 2030 climate change projected land and surface water system baseline water budget were estimated to be 14,657 taf/yr. Average annual values were presented previously in Table 3-11 and are shown graphically in Figure 3-45.

Primary inflows to the land and surface water system include surface water inflows (12,597 taf/yr), precipitation (1,198 taf/yr), groundwater pumping (525 taf/yr), and stream gains from groundwater (337 taf/yr). Surface water inflows include the Sacramento River, other inflows from boundary streams including Stony Creek, as well as overland runoff of precipitation and applied water from upslope lands.

Additionally, diversions from the Sacramento River and from Stony Creek are a key source of surface water inflows.

Primary outflows from the land and surface water system include surface water outflows (12,015 taf/yr), evapotranspiration (1,841 taf/yr), deep percolation (415 taf/yr), and seepage (387 taf/yr). Surface water outflows include outflows through Sacramento River, Colusa Drain, Colusa Weir to Sutter Slough, and outflows to boundary streams including Stony Creek, as well as overland runoff of precipitation and applied water to downslope lands. Evapotranspiration is primarily from agricultural lands but also from managed wetlands, canal evaporation, native vegetation, and urban and industrial lands. Deep percolation is primarily from precipitation, but also from applied water. Seepage includes a combination of stream seepage and seepage from canals and drains.

The average annual change in storage in the land and surface water system (0.1 taf/yr) is negligible due to similar soil moisture content in the root zone, on average, across water years.

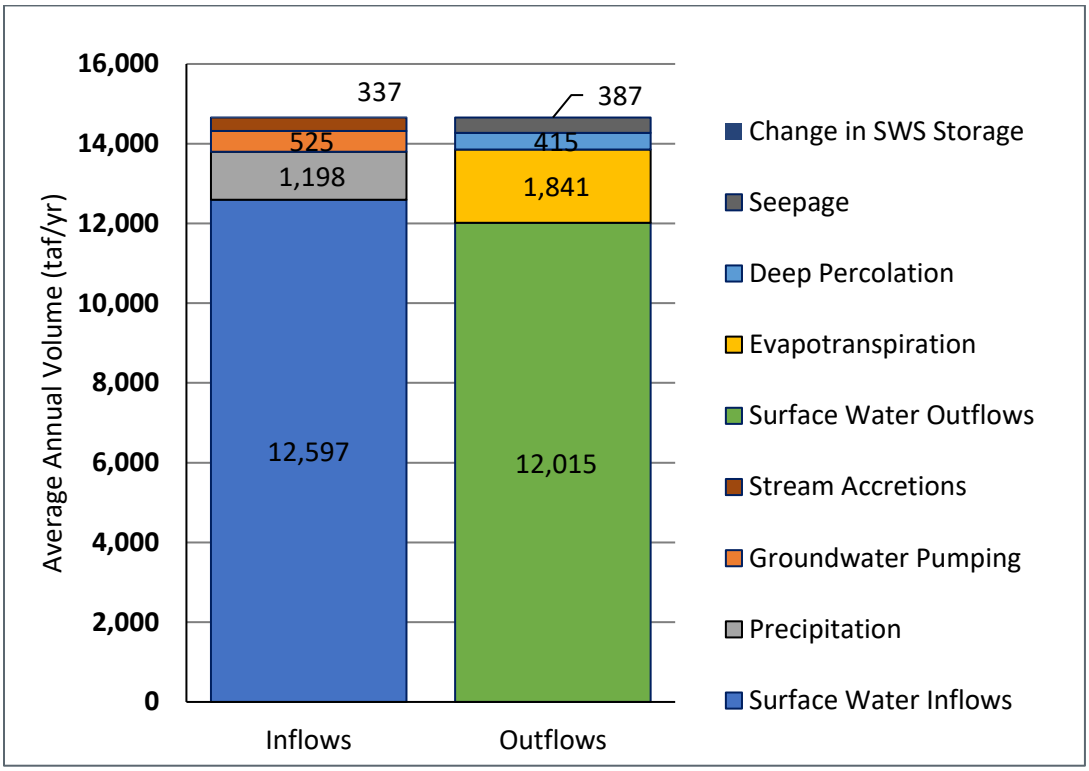

Figure 3-45.Average Annual Future Conditions, 2030 Climate Change Baseline Land and Surface Water System Water Budget Summary (2016-2065, rounded to nearest taf/yr)

Average annual future conditions 2030 climate change baseline groundwater system inflows and outflows were estimated to be 1,010 taf/yr during the 50-year simulation period. Average annual values were presented previously in Table 3-12 are shown graphically in Figure 3-46.

Inflows to the groundwater system include deep percolation (415 taf/yr), seepage (387 taf/yr), subsurface inflows from the Corning, Butte, Sutter, and Yolo Subbasins (205 taf/yr), and change in storage (3 taf/yr). Outflows from the groundwater system include groundwater pumping (525 taf/yr), stream gains from

groundwater (337 taf/yr), and subsurface outflows to the Corning, Butte, Sutter, and Yolo Subbasins (148 taf/yr).

There is a very small (-3 taf/yr) change in groundwater storage under the Future Condition, 2030 Climate Change water budget.

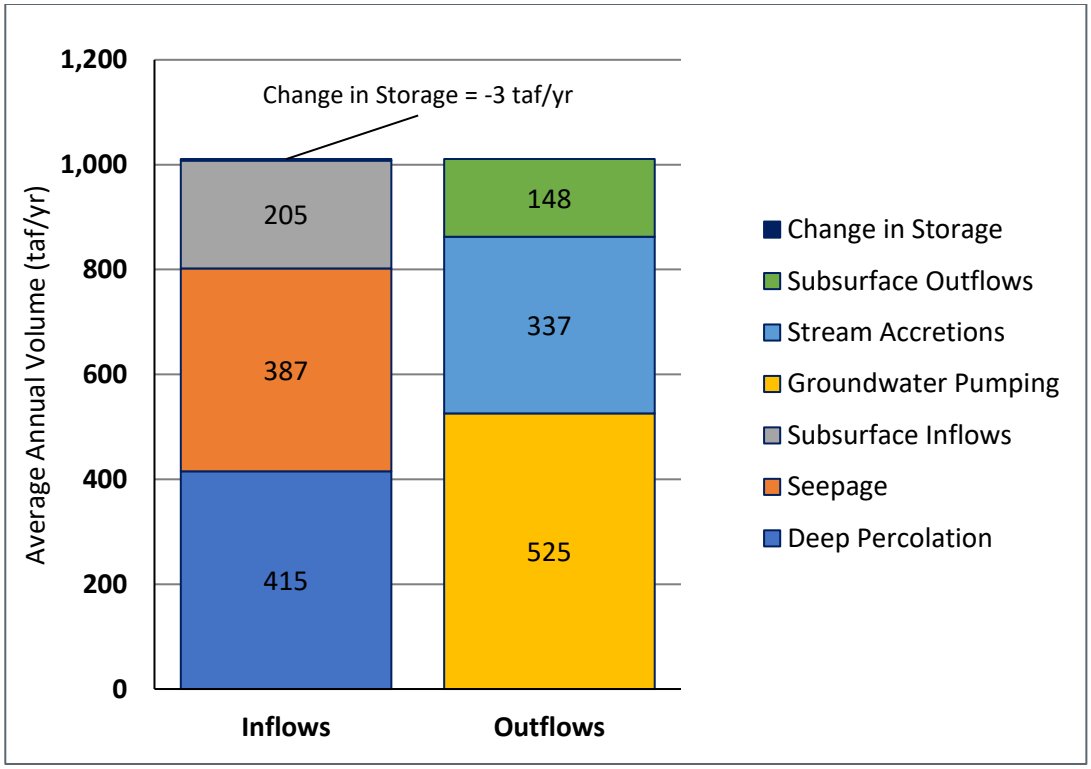

Figure 3-46. Average Annual Future Conditions, 2030 Climate Change Baseline Groundwater System Water Budget Summary (2016-2065, rounded to nearest taf/yr)

3.3.4.3.3 Future Conditions, 2070 Climate Change Baseline

Average annual inflows to and outflows from the Subbasin for the future conditions with 2070 climate change projected land and surface water system baseline water budget were estimated to be approximately 14,855 taf/yr. Average annual values were presented previously in Table 3-11 and are shown graphically in Figure 3-47.

Primary inflows to the land and surface water system include surface water inflows (12,715 taf/yr), precipitation (1,258 taf/yr), groundwater pumping (559 taf/yr), and stream gains from groundwater (323 taf/yr). Surface water inflows include the Sacramento River, other inflows from boundary streams including Stony Creek, as well as overland runoff of precipitation and applied water from upslope lands. Additionally, diversions from the Sacramento River and from Stony Creek are a key source of surface water inflows.

Primary outflows from the land and surface water system include surface water outflows (12,141 taf/yr), evapotranspiration (1,901 taf/yr), deep percolation (411 taf/yr), and seepage (401 taf/yr). Surface water outflows include outflows through Sacramento River, Colusa Drain, Colusa Weir to Sutter Slough, and

outflows to boundary streams including Stony Creek, as well as overland runoff of precipitation and applied water to downslope lands. Evapotranspiration is primarily from agricultural lands but also from managed wetlands, canal evaporation, native vegetation, and urban and industrial lands. Deep percolation is primarily from precipitation, but also from applied water. Seepage includes a combination of stream seepage and seepage from canals and drains.

The average annual change in storage in the land and surface water system (0.1 taf/yr) is negligible due to similar soil moisture content in the root zone, on average, across water years.

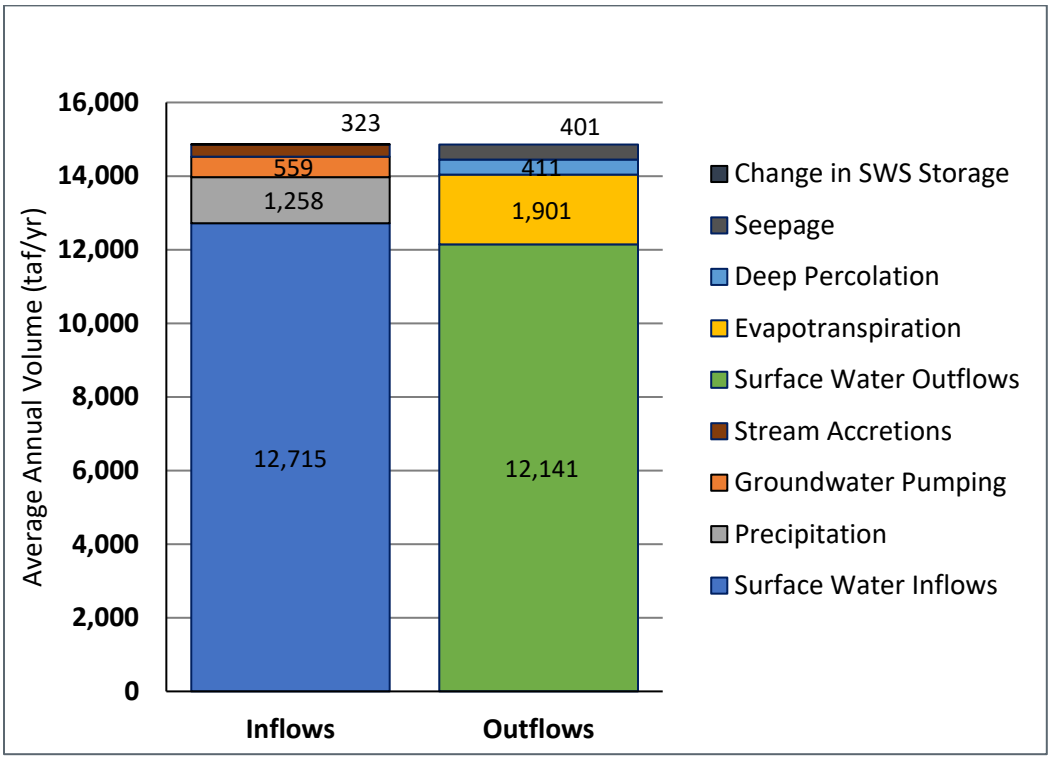

Figure 3-47. Average Annual Future Conditions, 2070 Climate Change Baseline Land and Surface Water System Water Budget Summary (2016-2065, rounded to nearest taf/yr)

Average annual inflows to and outflows from the groundwater system were estimated to be approximately 1,020 to 1,030 taf/yr during the 50-year simulation period. Average annual values were presented previously in Table 3-12 are shown graphically in Figure 3-48.

Inflows to the groundwater system include deep percolation (411 taf/yr), seepage (401 taf/yr), subsurface inflows from the Corning, Butte, Sutter, and Yolo Subbasins (209 taf/yr), and change in groundwater storage (-7 taf/yr). Outflows from the groundwater system include groundwater pumping (559 taf/yr), stream gains from groundwater (323 taf/yr), and subsurface outflows to the Corning, Butte, Sutter, and Yolo Subbasins (147 taf/yr).

There is a very small (-7 taf/yr) change in groundwater storage under the Future Condition, 2070 Climate Change water budget.

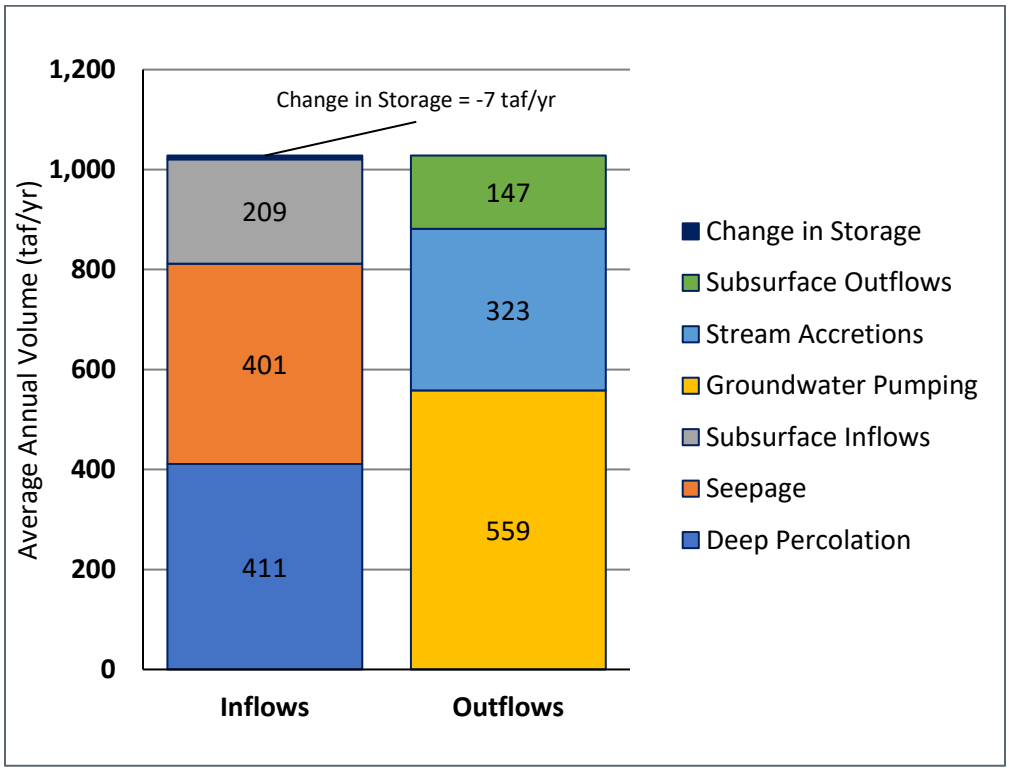

Figure 3-48. Average Annual Future Conditions, 2070 Climate Change Baseline Groundwater System Water Budget Summary (2016-2065, rounded to nearest taf/yr)

3.3.4.3.4 Comparison of Water Budget Scenarios

A figure depicting cumulative change in storage for the current conditions and three future conditions baseline scenarios is provided on the following page (Figure 3-49). In the figure, the cumulative change in groundwater storage is shown for the 50-year hydrologic period. The x-axis (horizontal axis) is labeled with the historical reference year along with the corresponding water year type based on the Sacramento Valley Water Year Index. Years are identified as wet (W), above normal (AN), below normal (BN), dry (D), or critical (C).

Estimated changes in storage are practically zero for the current conditions and future conditions without climate change scenarios. Current conditions and future conditions with no climate change are identical, except for minor urban growth represented in the future scenario without climate change. For the two future with climate change scenarios, there are small decreases in groundwater storage over the 50-year period, due primarily to increased groundwater pumping needed to meet increasing agricultural water demands resulting from climate change. For all scenarios, the changes in groundwater storage are substantial across wet and dry cycles, with the total range in storage change for all scenarios exceeding 800 taf over the 50-year period.

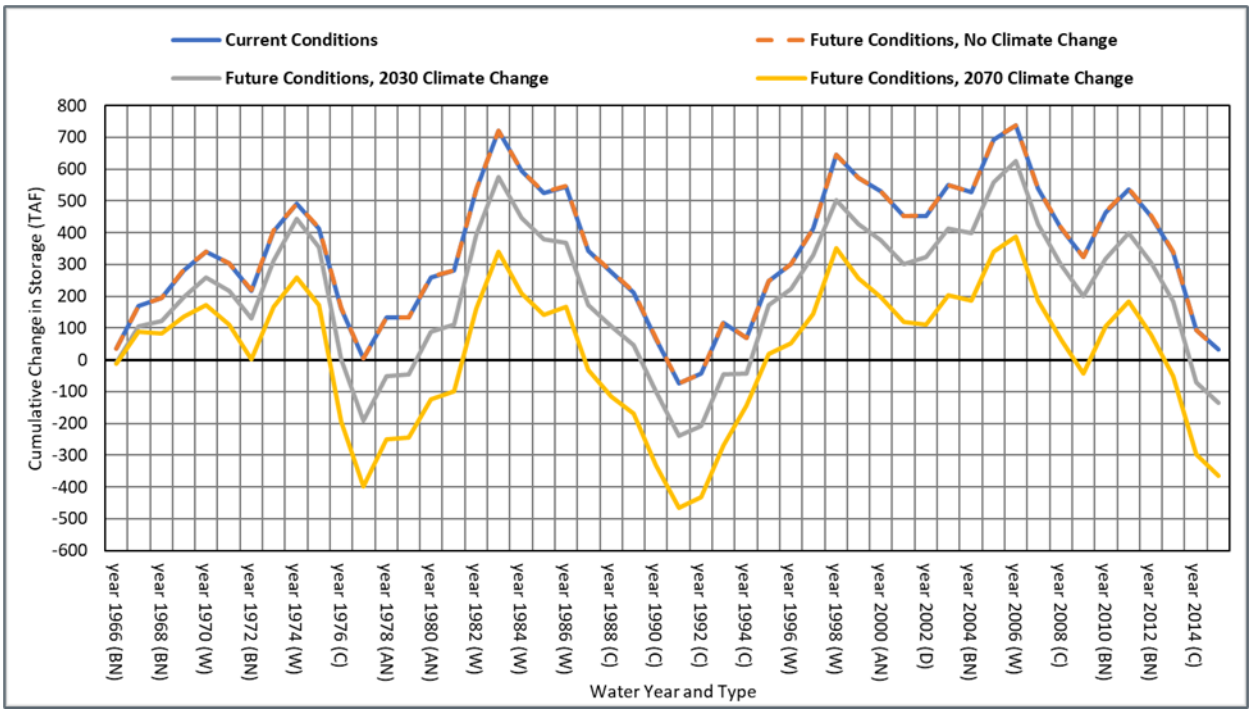

Figure 3-49. Cumulative Change in Groundwater Storage for Current and Future Conditions Baseline Scenarios

3.3.5 Water Budget Uncertainty

Water budget uncertainty refers to a lack of understanding of the subbasin setting that significantly affects an Agency's ability to develop sustainable management criteria and appropriate projects and management actions in a GSP, or to evaluate the efficacy of plan implementation, and therefore may limit the ability to assess whether a subbasin is being sustainably managed. Substantial uncertainty exists in all components of each water budget component. Substantial uncertainty also exits in the assumptions used to project potential future conditions related to planned development and associated urban demands, as well as projections of climate change. Consequently, the estimated negligible or very small changes in groundwater storage for current and future water budgets, calculated as total subbasin inflows minus outflows, are highly uncertain. It is anticipated that confidence in model results will be increased over time through additional monitoring and data collection, refinements to C2VSimFG-Colusa input, and coordination with neighboring subbasins.

However, the uncertainties that currently exist do not substantially limit the ability to develop and implement a GSP for the subbasin including the ability to develop sustainable management criteria and appropriate projects and management actions, including improved monitoring, nor the ability to assess whether the subbasin is being sustainably managed over time. GSPs are by nature iterative, and each opportunity will allow for improvements that will (1) lower uncertainty and (2) facilitate more refined analyses of sustainable management criteria and projects and management actions, and (3) refine the GSP implementation.

3.3.6 Overdraft Conditions

Overdraft refers to a negative average annual change in storage for the groundwater system over time. Based on the current conditions and future conditions with no climate change scenarios, which represent long-term average conditions in the subbasin, overdraft is expected to be negligible or very small in the Subbasin. An average annual change in storage of approximately 0.6 taf/yr is expected, as presented in Table 3-11 previously and Table 3-14 in the following section. However, based on the future condition scenarios with climate change, modest overdraft is expected to occur. Average annual overdraft is approximately 2.7 taf/yr in the 2030 scenario and 7.3 taf/yr in the 2070 scenario, corresponding to cumulative overdraft volumes of 135 taf and 365 taf, respectively, over the 50-year simulation of future conditions.

3.3.7 Sustainable Yield Estimate

As described previously, sustainable yield refers to the maximum quantity of water, calculated over a base period representative of long-term conditions in the subbasin, and including any temporary surplus that can be withdrawn annually from a groundwater supply without causing an undesirable result. Provisional estimates of sustainable yield have been calculated from water budget parameters for each scenario as the long-term annual average groundwater pumping, minus the average annual decrease in groundwater storage, as summarized in Table 3-14**.** Sustainable subbasin operation is expected to be achievable in current and future conditions scenarios, but modest overdraft is expected in future conditions with 2030 climate change and future conditions with 2070 climate change. Ultimately, it is anticipated that other factors will be considered in refining these sustainable yield estimates as part of development of sustainable management criteria for the subbasin, and as monitoring is improved and operational experience is gained during GSP implementation.

Table 3-14. Estimated Groundwater Pumping, Change in Groundwater Storage, and Sustainable Yield by Baseline Scenario, in taf/yr for the Water Budget Analysis Periods Listed in Table 3-9

Baseline Scenario	Groundwater Pumping	Change in Groundwater Storage	Sustainable Yield
Current	499	1	500
Future, No Climate Change	499	1	500
Future, 2030 Climate Change	525	-3	522
Future, 2070 Climate Change	559	-7	552
Future, 2070 Climate Change with Simulated Projects and Management Actions[(a)]	510	0	510

(a) Simulated projects and management actions are described in Appendix 6D.

3.4 MANAGEMENT AREAS

The GSP emergency regulations (at §354.20) provide that GSAs "may define one or more management areas with a basin if the Agency has determined that creation of management areas will facilitate implementation of the Plan". Both the CGA and the GGA boards considered defining management areas for purposes of developing and implementing the initial GSP. Both boards reached the conclusion that defining management areas is premature at this time because clear, compelling advantages could not be identified. However, both boards are receptive to the concept of management areas and will give them further consideration during GSP implementation.

CHAPTER 4
Monitoring Networks

Monitoring networks are required to better understand and evaluate changing conditions within the groundwater, surface water, and land surface systems. To optimize data collection and analysis, the network should be easily accessible, spatially and temporally relatable to other monitoring networks, sufficient for demonstrating spatial and temporal trends, and representative of actual conditions. The following sections discuss the Subbasin monitoring network objectives, requirements, monitoring protocols, network sites, data gaps, and proposed actions.

4.1 MONITORING NETWORK OBJECTIVES

Title 23 Section §354.34b of the California Code of Regulations (23 CCR §354.34(b)) states that the monitoring network objectives shall be implemented to:

> *(1) "Demonstrate progress toward achieving measurable objectives described in the [Groundwater Sustainability] Plan.*
>
> *(2) Monitor impacts to the beneficial uses or users of groundwater.*
>
> *(3) Monitor changes in groundwater conditions relative to measurable objectives and minimum thresholds.*
>
> *(4) Quantify annual changes in water budget components."*

Monitoring network objectives for the Subbasin were designed to address the requirements of five sustainability indicators (not including seawater intrusion, which is neither occurring nor anticipated to occur in the subbasin over the planning horizon) in support of the future measurable objectives and minimum thresholds. The overarching goals of the monitoring networks are to: (1) characterize current and historical conditions within the groundwater, surface water, and land surface systems, and (2) evaluate future conditions within the groundwater, surface water, and land surface systems due to water management practices, climatic influence, and GSP implementation within the Subbasin.

The monitoring network objectives are to characterize:

- Groundwater levels, availability, and flow characteristics, including impacts to groundwater storage;
- Surface water availability and interactions with groundwater, including impacts to native riparian land and groundwater dependent ecosystems (GDEs);
- Quality of groundwater; and,
- Extent and rate of land subsidence.

4.2 MONITORING NETWORKS

The following sections describe the monitoring sites included in the Subbasin groundwater level, groundwater quality, land subsidence, and surface water monitoring networks. Most of the networks consist of existing monitoring and reporting programs and are reliant on data collected and provided by other agencies. The Subbasin GSAs will continue to coordinate and collaborate with the other agencies regarding their monitoring programs, including changes to monitoring sites, monitoring protocols or frequencies, and management actions. Data acquisition is not anticipated to be an issue. If necessary, the

GSAs will consider implementing their own monitoring programs to address concerns over undesirable results, data gaps in the monitoring networks, or GSP project needs.

4.2.1 Groundwater Level Monitoring

Groundwater levels are and will continue to be monitored to evaluate groundwater elevations (GWE), reduction in groundwater storage, and stream-aquifer interactions throughout the subbasin. The GSP groundwater level monitoring network is based on the pre-existing groundwater monitoring networks of Colusa and Glenn Counties.

4.2.1.1 Requirements

The groundwater monitoring network should have sufficient density to represent spatial and temporal trends through the Subbasin:

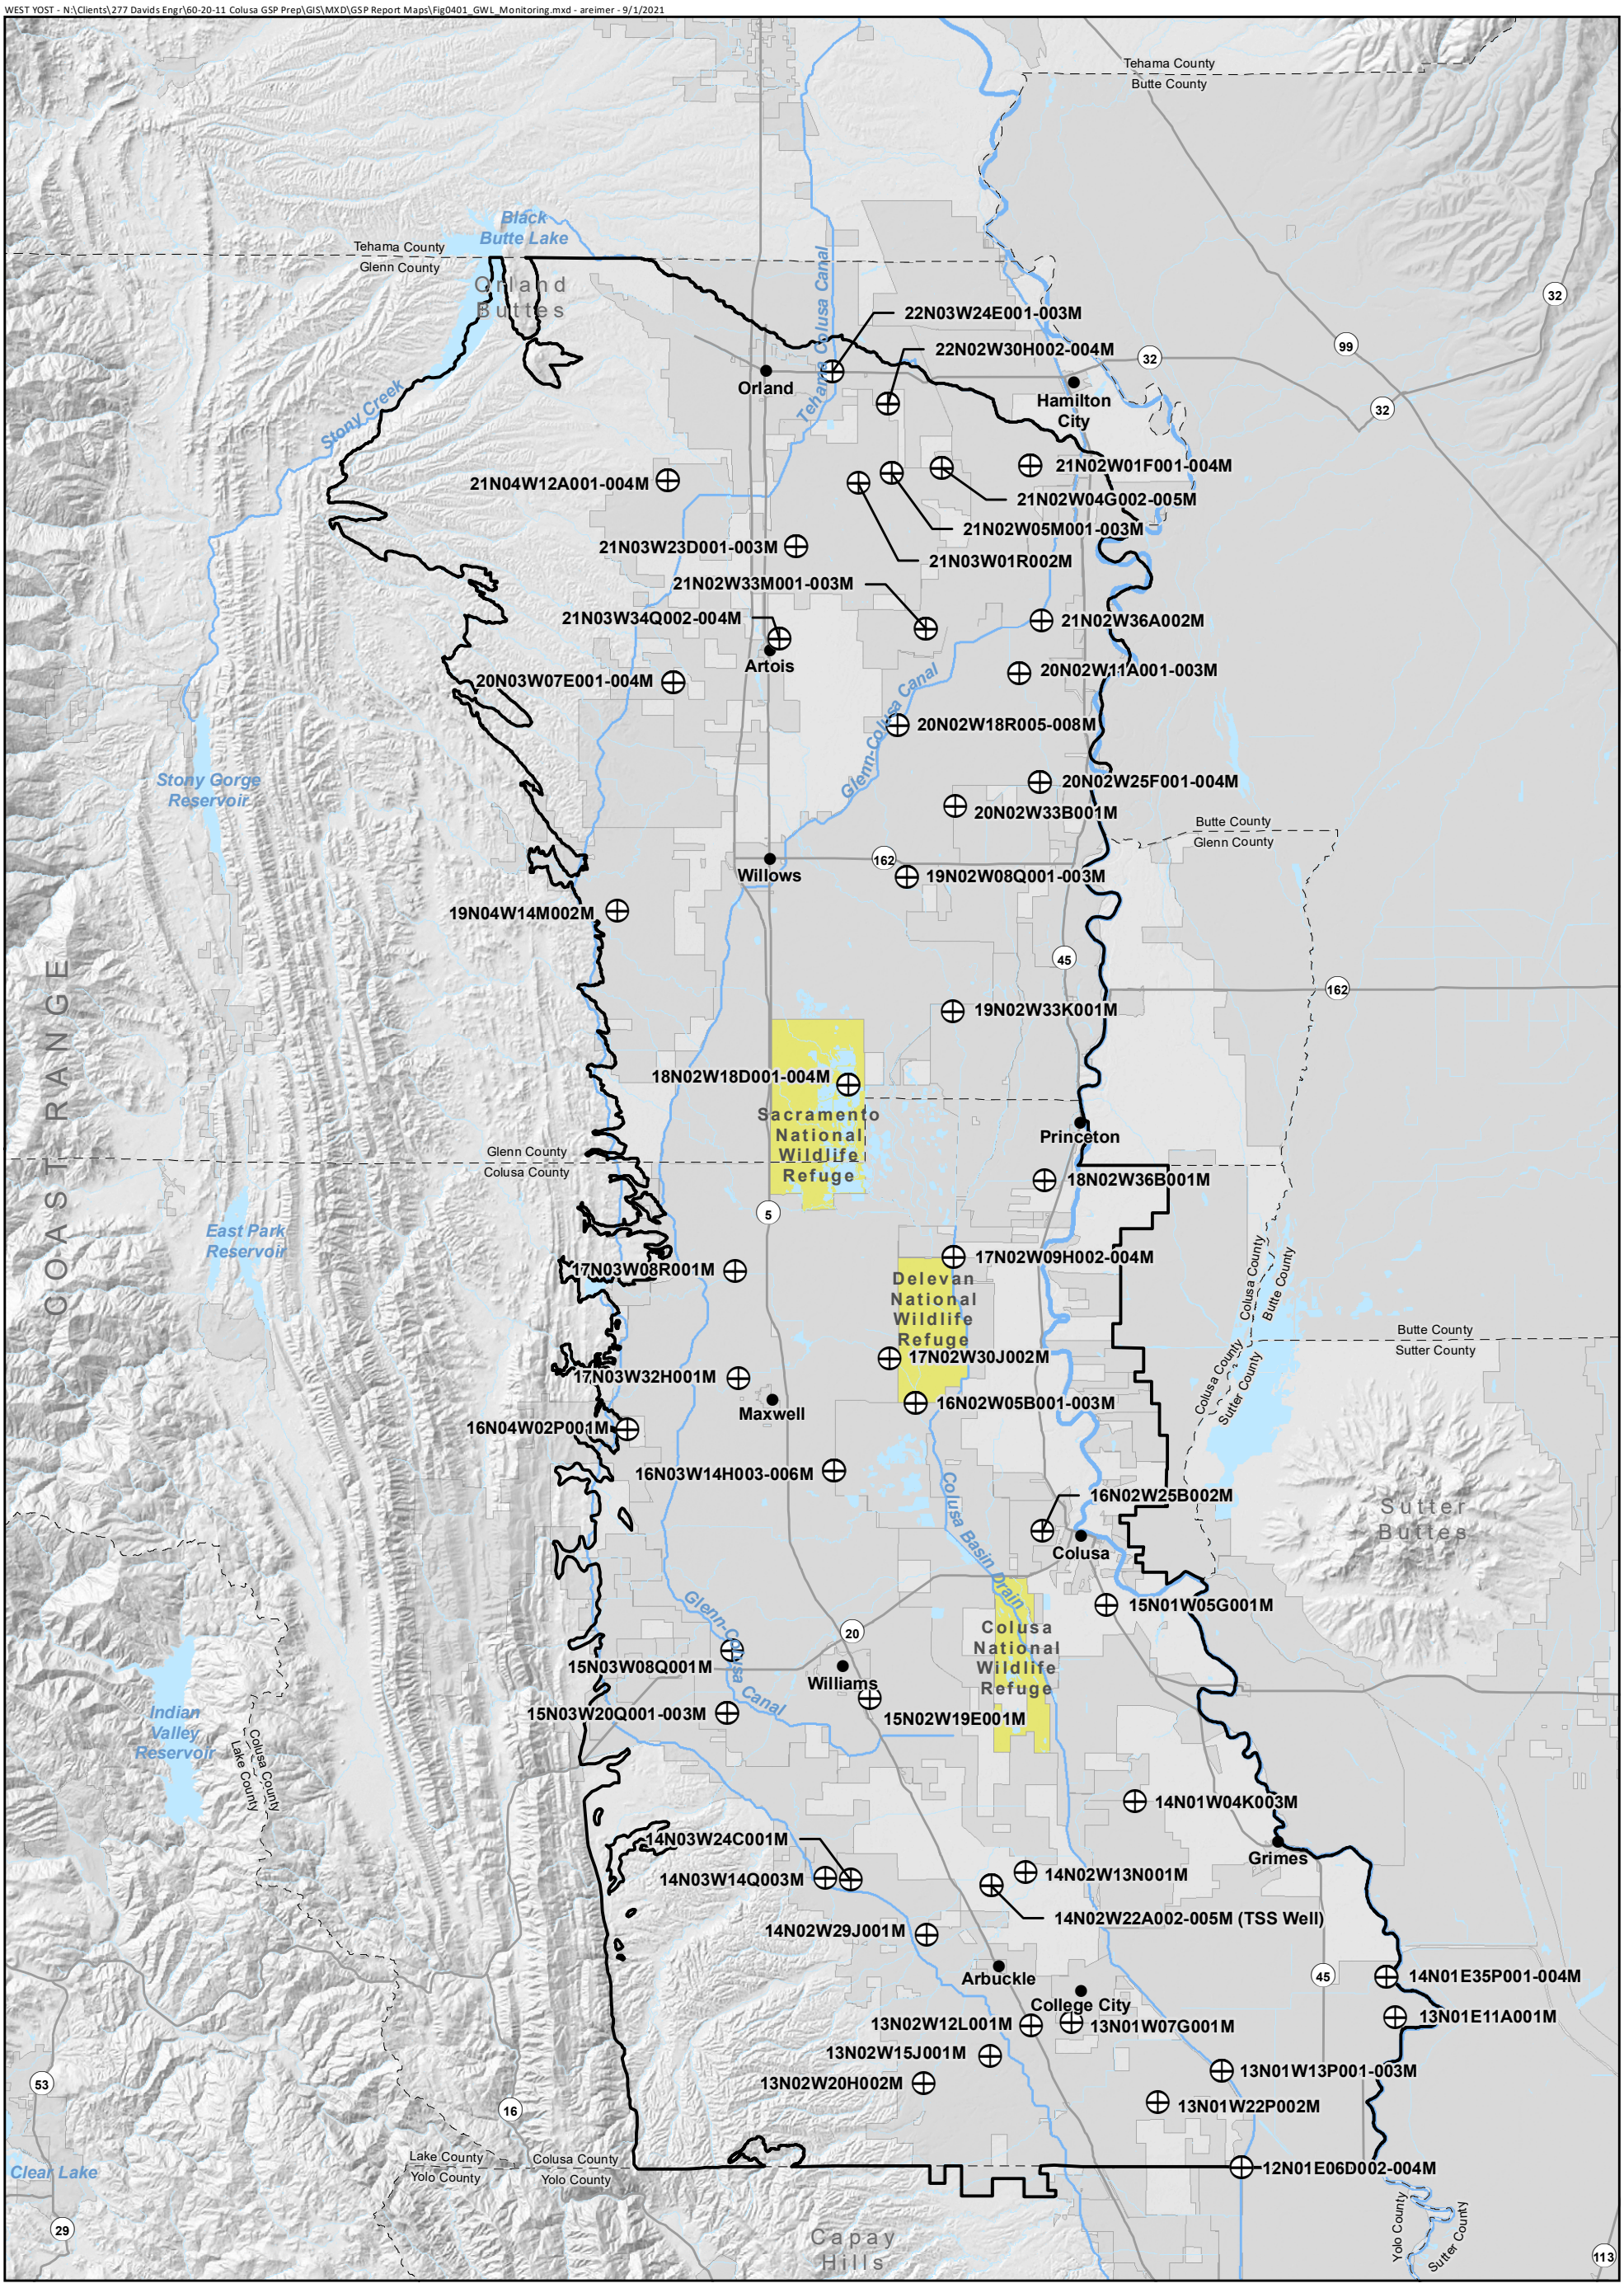
- Spatial densities should sufficiently represent both lateral and vertical extents of the groundwater subbasin.
  - The quantity and density of groundwater monitoring wells should be sufficient to evaluate overall static groundwater conditions for each principal aquifer and sufficiently support evaluation of impacts from GSP implementation and water and land management practices.
  - The quantity and density of groundwater monitoring wells shall be sufficient to evaluate groundwater conditions for the subbasin (23 CCR §354.34(d)).
- Groundwater monitoring network shall be designed such that the sustainability indicators are adequately covered, not just over the entire groundwater basin, but also within any specific GSP-defined management areas (23 CCR §354.34(d)), of which there are none currently defined within the Subbasin. The sustainability indicators supported by the groundwater level monitoring network include:
  - **Chronic lowering of groundwater levels**
    - 23 CCR §354.34(c)(1) specifies that the groundwater monitoring network shall be sufficient to represent the seasonal occurrence, flow direction, and hydraulic gradients of groundwater within and between the principal aquifer and surface waters.
    - The representative groundwater level monitoring network is discussed in Section 4.2.5.1.
  - **Reduction in groundwater storage**
    - Data from the groundwater monitoring network shall be sufficient to enable calculations of annual changes in groundwater storage over time (Monitoring Network Best Management Practice [BMP], California Department of Water Resources [DWR], 2016b).
    - The representative groundwater quality monitoring network is discussed in Section 4.2.5.
  - **Depletion of interconnected surface water**
    - The groundwater monitoring network shall be sufficient to represent the seasonal occurrence, flow direction, and hydraulic gradients of groundwater between the principal aquifer and surface waters (23 CCR §354.34(c)(6)). Per the Monitoring Network BMP (DWR, 2016b), shallow groundwater monitoring wells should be appropriately located with respect to connected streams to enable characterization

of the groundwater levels adjacent to connected stream channels. The groundwater monitoring network should extend away from and along the stream course at appropriate intervals and be monitored on a frequency to capture seasonal pumping conditions (DWR, 2016b).

- The representative groundwater quality monitoring network is discussed in Section 4.2.5 and the surface water monitoring network is discussed in Section 4.2.4.

The Monitoring Network BMP states that the groundwater monitoring network should be able to provide data sufficient to:

- Represent the unconfined and confined parts of the principal aquifer.
- Support evaluation of groundwater level data to support evaluation of stream-aquifer interactions, impacts to GDEs, declining GWE, reduction in groundwater storage, and impacts to land subsidence.
- Support delineation of areas with declining GWE, recharge areas, and conditions at subbasin boundaries.
- Groundwater level monitoring frequencies shall be capable of representing:
  - Short-term, seasonal, and long-term trends (i.e., minimum of twice-annually to represent seasonal high and low groundwater conditions) per 23 CCR §354.34(c)(1)(b)).
  - Groundwater conditions, as necessary, to evaluate the progress of GSP implementation (23 CCR §354.34(a)).



The Subbasin groundwater level monitoring network meets these requirements. Data gaps in the network are discussed in Section 4.2.1.4.

4.2.1.2 Groundwater Level Monitoring Network

The Subbasin groundwater monitoring network wells shown on Figure 4-1 are a combination of pre-SGMA Colusa County groundwater monitoring wells and pre-SGMA Glenn County dedicated groundwater monitoring wells (Glenn County wells that are dedicated observation wells and not used for supply). For the Glenn County wells, these exclude the Basin Management Objective (BMO) water supply wells and the wells included in the Glenn County annual water quality monitoring program discussed in Section 2.2. The Colusa County groundwater monitoring network includes active water supply wells as part of the County's groundwater level monitoring program.

All of the wells originally used for monitoring purposes by Colusa and Glenn Counties were assessed for their suitability as a groundwater monitoring network well. Table 4-1 lists the criteria used for evaluating the groundwater monitoring wells in the Subbasin groundwater monitoring network. These criteria were identified based on the groundwater monitoring network requirements discussed in the Monitoring Network BMP and 23 CCR §354.34.

There are 104 completions in 48 wells in the Subbasin groundwater level monitoring network. All of these wells are currently included in the California Statewide Groundwater Elevation Monitoring Program (CASGEM) database and monitored by DWR. Table 4-2 contains the entire current groundwater monitoring network with State Well Numbers (SWNs), CASGEM IDs, well completion report IDs, well status and use, location information, reference point information, construction, principal aquifer designations, and quality assessment categories. Well completion reports for the current Subbasin groundwater monitoring network wells, if available, are included in Appendix 4A.

Groundwater Sustainability Plan

Table 4-1. Assessment Categories of the Groundwater Monitoring Network Wells

Characteristic	Importance
Known Construction Characteristics	Known well construction characteristics will enable evaluation of groundwater conditions at specific depths within the principal aquifer. Examples of construction characteristics include borehole depth, screened intervals, and the presence of seals within the annular fill.
Nested Multiple Completion Wells	Nested, multiple completion wells allow the measurement of water levels at discrete depths within the aquifer system. The degree of confinement of the aquifer increases with depth. Multiple completion wells can provide insight into how the aquifer system is connected and allow estimates of vertical gradients and vertical hydraulic conductivity to be made.
Non-Dedicated Monitoring Wells	Pumping causes cones of depression that impact the water levels at and near the pumping well. Pumping water levels are not indicative of the static condition of the aquifer system and can skew estimates of groundwater storage. Pumping wells included in the groundwater monitoring network should be verified as inactive when measurements are made.
Proximity to Streams and Interconnected Surface Waters	Wells, including multiple completion wells, near streams or interconnected surface waters are useful for evaluating interaction between the aquifer and interconnected streams and surface waters. Vertical hydraulic gradients measured in wells near stream gages can provide insight regarding the direction of flow into or away from the surface water feature.
Lateral and Vertical Density	To characterize groundwater levels throughout the Subbasin, accessible monitoring sites should be spatially distributed throughout the area of interest. Not only should the monitoring sites be distributed laterally, but their screened intervals should also be set at representative depths within the principal aquifer.
Accessibility and Usability	The monitoring sites need to be easily accessible by field staff. Additionally, well completions should be clear down-hole to allow access of water level measuring equipment.

Known Construction. Construction details are known for all but one of the groundwater monitoring wells (Table 4-2 and Figure 4-1). Colusa County monitoring well 13N02W12L001 is a U.S. Bureau of Reclamation (USBR) well without well construction information. This well is listed in Table 4-2 and shown on Figure 4-1 because there is historical groundwater level data available for the well.

Nested Multiple Completion Wells. Of the 48 groundwater monitoring sites (104 separate completions) shown on Figure 4-1 and listed in Table 4-2, over 20 are nested multiple completion wells. These nested wells are screened at discrete depths up to a maximum depth of 1,180 feet below ground surface. The nested wells enable measurement of vertical head gradients within the principal aquifer. Additionally, the nested wells support monitoring of the groundwater system and interconnected surface waters. The current groundwater monitoring network contains wells that provide a lateral and vertical density sufficient to enable characterization of groundwater within the principal aquifer.

Non-Dedicated Monitoring Wells. The majority of the active domestic, irrigation, and stock water wells included in the current groundwater monitoring network are located in Colusa County. The Monitoring Network BMP allows the temporary inclusion of water supply wells in the groundwater monitoring network if the wells are screened within a single water-bearing unit. Of these wells, three were identified to be perforated across broad depth intervals, potentially with different degrees of confinement, but all still zoned within the principal aquifer. These three wells are 18N02W36B001 (near Princeton), 15N03W08Q001 (west of Williams), and 14N02W13N001 (north of Arbuckle).

Proximity to Streams and Interconnected Surface Waters. The subbasin is bounded and traversed by irrigation canals and drains, as well as perennial, ephemeral, and intermittent streams. Many of the surface waters are near wells included in the current groundwater monitoring network, except for surface waters in the following areas:

- Within the Colusa National Wildlife Refuge, east of Williams (Figure 4-1). There are no network groundwater monitoring wells near the Colusa National Wildlife Refuge.
- North and northwest of Orland near Stony Creek.
- Northwest of Artois along the middle reaches of Walker Creek.
- Northwest of Willows along the middle reaches of Willow Creek.

Lateral and Vertical Density. The groundwater monitoring network has a lateral density of approximately 9.2 completions per 100 square miles and 4.2 well boreholes per 100 square miles in the principal aquifer, averaged over the entire subbasin. These well densities are sufficient to evaluate groundwater level trends throughout the subbasin, in accordance with the recommendations listed in the Monitoring Network BMP (DWR, 2016b). Additionally, there are sufficient depth-specific wells located throughout the subbasin to evaluate groundwater elevation trends, groundwater storage, surface water connectivity, and aquifer characteristics with depth.

Accessibility and Usability. Five completions within three wells included in the Glenn County or Colusa County monitoring networks were determined to be unusable due to damaged casings. These include 13N02W04G001, -003, -004, 16N03W35N002, and 22N03W28P002 (shown on Figure 4-2). These wells are not included in the Subbasin groundwater level monitoring network but are shown on Figure 4-2 along with one suggested replacement well. The suggested replacement well is an existing well with known construction. All of the Subbasin groundwater monitoring network wells listed in Table 4-2 are accessible for field investigations. However, the accessibility of these sites should be verified via site visits.

Groundwater Sustainability Plan

4.2.1.3 Monitoring Protocols

Data will either be obtained from the agencies that are responsible for managing the monitoring sites within the groundwater quality monitoring network or downloaded from dataset host websites. The Subbasin GSAs will continue to coordinate and collaborate with other agencies regarding their monitoring programs and data acquisition. Issues with obtaining data is not anticipated to occur and the GSAs will consider implementing their own monitoring programs, if necessary. Water levels measured in the Subbasin groundwater monitoring network wells can be found in multiple online state websites including:

- CASGEM website: https://www.casgem.water.ca.gov
- DWR Water Data Library (WDL) website: https://wdlbeta.water.ca.gov/Map.aspx
- California Natural Resources Agency (CNRA) website: https://data.cnra.ca.gov/dataset/periodic-groundwater-level-measurements

Since all of the wells identified as part of the Subbasin groundwater monitoring network are included in existing DWR monitoring programs, water levels being collected comply with existing regulatory protocols. These protocols also comply with those required in the Monitoring Protocols BMP (DWR, 2016c), which are summarized below for both methodology and frequency.

4.2.1.3.1 Methodology

The Monitoring Protocols, Standards, and Sites Best Management Practices (Monitoring Protocols BMP, DWR, 2016c) recommends the following monitoring conditions:

- Groundwater levels should be measured from a pre-established and recorded reference point.
- Groundwater levels should be measured using approved measurement equipment. Equipment should be operated, calibrated, maintained in accordance with the manufacturer's instructions.
- When well caps are removed, signs of pressure release should be noted. If pressure release is noted, an appropriate time should be allowed for the water surface to equilibrate to aquifer conditions. Multiple measurements may be taken to assess whether equilibration has been reached.
- Questionable measurements should be appropriately noted at time of monitoring.
- All salient conditions should be recorded at time of monitoring.
- Water levels shall be measured to the nearest 0.1 foot, at a minimum (23 CCR §352.4(a)(3)).
- Water level equipment should be decontaminated after each use.
- Measurements should be collected from all monitoring sites within as short a time period as possible; in general, one to two weeks is acceptable. All data should be entered into the data management system as soon as possible.

In addition to manual measurements, pressure transducers connected to data loggers may be used to monitor groundwater levels (DWR, 2016). Pressure transducers should be installed in conjunction with manual depth to water measurements; it is recommended that GWE be calculated after data have been downloaded to prolong the battery life of the unit. The Monitoring Protocols BMP identifies the following requirements when using data loggers:

- All transducers should be installed, operated, and maintained in accordance with the manufacturer's specifications.
- Unvented pressure transducers should be corrected for barometric pressure with continuous data from a barometric transducer.
- Groundwater levels should be recorded to the nearest 0.1 foot, at a minimum.
- The pressure transducers should be assessed to determine if the unit is capable of recording data to an appropriate precision and accuracy. Instrument drift due to groundwater conditions, battery life, and storage capacity should be taken into consideration when GWE are being calculated.
- Manual groundwater levels should be measured to maintain data logger integrity.

4.2.1.3.2 Frequency

Manual water level measurements shall be collected twice annually, at a minimum, to ensure seasonal trends are well accounted for (23 CCR §354.34(c)(1)(B)). Manual measurements for all network wells should be collected in the spring and fall, at a minimum, unless more frequent measurements are required to characterize changes in groundwater levels.

4.2.1.4 Data Gaps in Groundwater Level Monitoring Network

23 CCR §354.38(b) defines data gaps as occurring where there is an insufficient number of monitoring sites, insufficient monitoring frequency, or unreliable monitoring sites. Data gaps can also occur when collected data are of insufficient quality or quantity to support evaluation of the sustainability indicators (Monitoring Network BMP, 2016b).

The groundwater monitoring network was assessed based on requirements listed in the Monitoring Network BMP and 23 CCR §354.34. Spatial or temporal density and quality of monitoring sites were then assessed to identify potential data gaps. Data gaps within the groundwater monitoring network were evaluated for all criteria and categorized as follows:

- Usability of the monitoring site due to:
  - Wells screened across multiple water-bearing units and principal aquifers
- Spatial distribution of monitoring sites with regard to:
  - Presence near a surface water body
  - Full lateral and vertical extent of coverage
  - Areas and depths with known groundwater level decline (e.g., near Orland where an increase of drying shallow domestic wells is currently occurring).

Many of the surface waters are near wells included in the current groundwater monitoring network, except for surface waters in the following areas:

- Within the Colusa National Wildlife Refuge, east of Williams (Figure 4-1). There are no network groundwater monitoring wells near the Colusa National Wildlife Refuge.
- North and northwest of Orland near Stony Creek.
- Northwest of Artois along the middle reaches of Walker Creek.
- Northwest of Willows along the middle reaches of Willow Creek.

4.2.1.5 Proposed Actions to Address Data Gaps

Figure 4-2 shows the Subbasin groundwater monitoring network and recommended revisions. The recommended revisions include:

- Potential "replacement" wells that would replace historical monitoring wells that have been removed from the groundwater monitoring network due to well destruction or damage. The "replacement" wells are existing wells that could be added to the Subbasin groundwater monitoring network.
- Potential existing wells to add to the Subbasin groundwater monitoring network to address data gaps in spatial coverage.

Existing wells proposed to be added to the groundwater monitoring network and the rationale for selection are listed in Table 4-3.

Table 4-3. Existing Wells Proposed to be Added to the Groundwater Monitoring Network

State Well Number	Location	Existing Groundwater Monitoring Network	Rationale for Selection
15N04W11G001	Colusa County	DWR CASGEM/WDL[(a)]	Expand lateral monitoring network coverage towards the subbasin's western margin.
16N03W35M001	Colusa County	DWR CASGEM/WDL	Replacement for 16N03W35N002M, an inaccessible caved-in well. Similar location and construction characteristics.

(a) California Department of Water Resources (DWR) California Statewide Groundwater Elevation Monitoring (CASGEM) and/or Water Data Library (WDL).

It is recommended that a field survey be conducted of all current groundwater monitoring network sites to verify latitude and longitude coordinates, well depths, ground surface elevations, reference point elevations, and descriptions in accordance with the requirements described in 23 CCR §352.4(a) through (c). Monitoring frequencies should also be verified for compliance with requirements set forth in 23 CCR §354.34(c)(1)(B).

Additional monitoring sites are recommended for urban areas, near surface waters, and within areas with reported occurrences of drying shallow domestic wells. New monitoring sites would require a well siting study or public survey, as well as continued coordination with local stakeholders and DWR, to determine existing wells to include as monitoring sites or determine land suitable for the construction of new

monitoring wells. Evaluation of the shallow unconfined portion of the principal aquifer is ongoing by DWR and the Colusa Subbasin GSAs and will impact scope of work to address this data gap.

Annual reports and future revisions to the GSP will provide updates on actions taken to address data gaps over the reporting period.

4.2.2 Groundwater Quality Monitoring

The primary groundwater quality constituent of concern within the Subbasin is salinity, specifically the upwelling of brackish connate water into the principal aquifer. There are many existing programs that monitor for and manage salinity (e.g., total dissolved solids or electrical conductivity) in groundwater. In lieu of managing and monitoring a groundwater quality monitoring program of its own, the Colusa Subbasin GSAs will utilize data collected via existing groundwater quality monitoring programs. The GSAs will continue to coordinate and collaborate with other agencies regarding their monitoring programs, including changes to monitoring sites, monitoring protocols or frequencies, and management actions. Data acquisition is not anticipated to be an issue. If necessary, the GSAs will consider implementing their own monitoring programs to address concerns over undesirable results, data gaps in the monitoring networks, or GSP project needs. A discussion of recommendations to address any data gaps within the existing monitoring networks is provided in this section.

4.2.2.1 Requirements

In accordance with the Monitoring Network BMP (DWR, 2016b), the groundwater quality monitoring network shall be designed such that the sustainability indicators are adequately covered not just over the entire subbasin, but also within any specific GSP-defined Management Areas, of which there are none defined within the Subbasin. The groundwater quality monitoring network shall be designed to collect sufficient spatial and temporal data from the principal aquifer to enable determination of groundwater quality trends and to address known water quality issues (23 CCR §354.34(c)(4)).

Data collected from the groundwater quality monitoring network should be sufficient to:

- Enable definition of the three-dimensional extent of impacts;
- Enable mapping of transient water quality degradation;
- Facilitate assessment of groundwater quality impacts to beneficial uses and users;
- Enable evaluation of management practice impacts to groundwater quality degradation;
- Support evaluation of movement and concentration of brackish or saline waters.

The Subbasin groundwater quality monitoring network mostly meets these requirements. Data gaps within the groundwater quality monitoring network are mostly regarding mapping of three-dimensional impacts and migration of poor-quality waters. Data gaps in the network are discussed in Section 4.2.2.4.

4.2.2.2 Groundwater Quality Monitoring Network

Groundwater quality monitoring network locations for the Subbasin include wells identified and currently being monitored for salinity under existing regulatory programs. These include groundwater monitoring conducted by coalitions formed under Irrigated Lands Regulatory Program (ILRP) and public drinking water supply communities regulated by the State Water Resources Control Board (SWRCB) Division of Drinking Water. The Subbasin representative groundwater quality monitoring network includes 54 monitoring sites. Table 4-4 includes the Subbasin groundwater quality monitoring network programs. The

wells included in those programs as of 2020 are listed in Appendix 4B. Their locations are shown on Figure 4-3.

(c) ILRP = Irrigated Lands Regulatory Program.
(d) Central Valley Regional Water Quality Control Board. 2016.
(e) Luhdorff and Scalmanini. 2019.

Active community water system wells regulated under SWRCB Division of Drinking Water from each municipal or community water system within the Subbasin were selected for the Subbasin groundwater quality monitoring network. Community water systems are defined as "public water systems that serve at least 15 service connections used by yearlong residents or regularly serves at least 25 yearlong residents of the area served by the system" and may include municipalities, community services districts, and mobile home and trailer parks. These public supply wells are constructed at varying depths throughout the subbasin and are sampled and monitored by their respective water supply agency. As of the issuance of this Colusa Subbasin GSP, there are 40 active wells being monitored by 19 public water supply agencies included in the SWRCB Division of Drinking Water.

Figure 4-3

Groundwater Quality Monitoring Network Wells

Colusa Groundwater Authority and Glenn Groundwater Authority

Colusa Subbasin

Groundwater Sustainability Plan

The California Rice Commission ILRP groundwater quality trend network includes USGS-managed wells within and surrounding the California Rice Commission management area (CH2MHILL, 2016a). Ten of these wells are within the Subbasin (CVRWQCB, 2016) and are included in the Subbasin groundwater quality monitoring network. All ten of the wells are relatively shallow (less than 40 feet deep) and located near rice ponds, irrigation canals, and other agricultural fields and infrastructure. Water chemistry within these wells will provide information regarding shallow instances of increased salinity within agricultural areas.

The Sacramento Valley Water Quality Coalition Groundwater Quality (SVWQC) Trend Monitoring Program, formed under ILRP, includes four wells within the Subbasin (Luhdorff and Scalmanini, 2019). One well is in Glenn County, just south of Stony Creek, one well is near the intersection of the Sacramento River and the Glenn-Colusa County boundary line, and the other two are near Arbuckle, Colusa County. The SVWQC wells are public or domestic water supply wells of moderate depths (100 to 300 feet deep). SVWQC's monitoring program started in 2020 and is relatively new. As such, there is not much information available for these wells as of the writing of this GSP.

The groundwater quality monitoring network will be re-evaluated and updated in annual reports and future revisions of the Subbasin, as necessary to address the needs and concerns of the GSAs and local stakeholders. The Colusa Subbasin GSAs will continue to coordinate with the existing monitoring agencies to account for any changes in well status or sampling frequencies. Additionally, water quality data from wells included in other groundwater quality monitoring programs discussed in Chapter 2, but not yet included in the Subbasin groundwater quality monitoring network, will be evaluated during future groundwater condition investigations for the Subbasin.

4.2.2.3 Monitoring Protocols

Data will either be obtained from the agencies that are responsible for managing the monitoring sites within the groundwater quality monitoring network or downloaded from dataset host websites. A listing of the websites is provided below:

- SWRCB Division of Drinking Water wells:
  - SWRCB Drinking Water Watch website: https://sdwis.waterboards.ca.gov/PDWW/
  - CNRA website: https://data.cnra.ca.gov/dataset/ground-water-water-quality-results
- California Rice Commission (CRC) wells:
  - California Rice Commission contact: https://calrice.org/
  - USGS National Water Information System (NWIS) website: https://waterdata.usgs.gov/nwis
  - GeoTracker Groundwater Ambient Monitoring & Assessment Program (GAMA) website: http://geotracker.waterboards.ca.gov/gama/
- Sacramento Valley Water Quality Coalition wells:
  - SVWQC contact: https://www.svwqc.org/
  - GeoTracker ESI website: https://geotracker.waterboards.ca.gov/

Most recent data will be more easily obtained directly from the responsible agency instead of via the alternate host websites. The GSAs will continue to coordinate and collaborate with other agencies regarding their monitoring programs, including changes to monitoring sites, monitoring protocols or frequencies, and management actions. Data acquisition is not anticipated to be an issue. If necessary, the GSAs will consider implementing their own monitoring programs to address concerns over undesirable

results, data gaps in the monitoring networks, or GSP project needs. A discussion of recommendations to address any data gaps within the existing monitoring networks is provided later in this section.

Since all of the wells identified as part of the Subbasin groundwater quality monitoring network are included in existing monitoring programs, water quality samples being collected must comply with existing regulatory sampling and testing protocols. Water quality samples collected from public drinking water wells and reported to SWRCB comply with SWRCB sampling and testing protocols for drinking water. Water quality samples collected from the California Rice Commission and SVWQC wells comply with sampling and testing protocols required by the Regional Water Quality Board for compliance under ILRP and CV-SALTS. These protocols also comply with those required in the Monitoring Protocols BMP (DWR, 2016c), which are summarized below:

- All water quality analyses should be performed by a State Environmental Laboratory Accreditation Program certified laboratory.
- Groundwater quality sampling protocols should follow USGS National Field Manual for the Collection of Water Quality Data (Wilde, 2005 or more recent).
- Groundwater sampling protocols should ensure that salient data are recorded and all data are handled such that integrity is maintained.
- Samples from pumping wells should be collected near the wellhead.
- All sampling equipment and ports should be free of contaminants and decontaminated between sampling locations.
- Wells not equipped with low-flow sampling taps should be purged prior to sampling to ensure sampling is of ambient groundwater conditions and not borehole storage conditions. Typically, three casing volumes purged is adequate.
- If purging or pumping causes a well to be evacuated, allow 90 percent recovery prior to sampling.
- Samples should be collected under laminar flow conditions.
- Samples should be collected according to appropriate standards. The sample collection procedure should reflect the type of analysis being performed.
- Samples should be preserved at the time of sampling. Samples should be filtered, as appropriate.
- Samples should be chilled after collection to prevent degradation.
- Chain of custody forms should be used to track procession of the samples.
- Analytical laboratories should utilize reporting limits that are equal to or less than the regional water quality objectives and screening levels.

4.2.2.4 Data Gaps in Groundwater Quality Monitoring Network

Potential data gaps have been identified within the proposed groundwater quality monitoring network:

- The current California Rice Commission groundwater monitoring plan to collect groundwater quality samples every two years and the varying sampling frequency of public water supply wells may not be sufficient to satisfy the requirements set forth in the Monitoring Network BMP (DWR, 2016b) or to satisfy the Colusa Subbasin GSAs' goal of tracking salinity concentrations.

- The existing groundwater quality monitoring network does not provide full monitoring coverage in areas with salinity concerns. Specifically, sites may not be sufficient to monitor the movement of brackish or saline waters in the area west and south of the Sutter Buttes and near the City of Williams.
- It is possible that the existing groundwater quality monitoring networks may not be sufficient to adequately allow differentiation between upwelling or intrusion of deeper brackish/connate waters or percolation recharge of waters with elevated salinity into the freshwater aquifer system.
- Existing monitoring networks are managed by other agencies. Monitoring locations and frequencies are subject to change based on the needs of the existing monitoring programs.

4.2.2.5 Proposed Actions to Address Data Gaps

Groundwater quality data collected under existing regulatory programs may not be sufficient for SGMA compliance. The Colusa Subbasin GSAs will consider coordinating with the SVWQC, Northern California Water Association (NCWA), and the California Rice Commission in the establishment and ongoing evaluation of these groundwater quality monitoring network sites with the goal of using data collected under the ILRP for SGMA compliance.

The wells included in the groundwater level monitoring network (discussed in Section 4.2.1) provide ample spatial coverage throughout the Subbasin. These wells, shown on Figure 4-1, would be good potential sites to add to the groundwater quality monitoring network in areas with identified salinity and upwelling concerns. The wells could be sampled regularly, at varying frequencies, in accordance with the needs of the Colusa Subbasin GSAs and local stakeholders.

The SWRCB GeoTracker and GeoTracker GAMA databases include information from a variety of monitoring and public wells, including domestic and agricultural irrigation wells. The GeoTracker sites are continuously being updated with new data and should be evaluated for all future Subbasin water quality projects and studies.

Annual reports and future revisions to the GSP will provide updates on actions taken to address data gaps over the reporting period.

4.2.3 Land Subsidence Monitoring

Land subsidence has been measured within the Subbasin. There are several existing programs in place to monitor and measure ongoing land subsidence. Many of these existing programs are included in the Subbasin land subsidence monitoring network so that the GSAs and local stakeholders can best determine the rate and extent of subsidence within the subbasin boundaries.

4.2.3.1 Requirements

In accordance with the Monitoring Network BMP (DWR, 2016b), the land subsidence network shall be designed such that the sustainability indicators are adequately covered, not just over the entire subbasin, but also within any specific GSP-defined Management Areas, of which there are none defined within the Subbasin. The land subsidence monitoring network shall be designed to enable the characterization of the rate and extent of subsidence by providing consistent, accurate, and reproducible results (23 CCR §354.34(c)(5); DWR, 2016).

Monitoring sites shall be compliant with requirements listed in 23 CCR §352.4(a) through (b).

The Subbasin land subsidence monitoring network meets these requirements. Data gaps in the network are discussed in Section 4.2.3.4.

4.2.3.2 Land Subsidence Monitoring Network

The Subbasin land subsidence monitoring network is comprised of survey benchmarks, benchmarks, continuous GPS stations, extensometers, and remote sensing data. Table 4-5 lists the benchmarks, continuous GPS stations, and extensometers included in the land subsidence monitoring network. Figure 4-4 shows these locations relative to the subbasin. All of the land subsidence monitoring network sites and remote sensing programs are managed and monitored through the following agencies and programs.

California DWR Ground Surface Displacement - Land Subsidence Monitoring

Extensometers are land surface displacement sensors that are installed inside of groundwater monitoring wells. A cable or pipe attached to the bottom of the well is connected to a sensor at the top of the well. Subsidence or land displacement due to compaction of sediment between the bottom of the well and the top can be detected to the nearest 0.01 foot by installed extensometers.

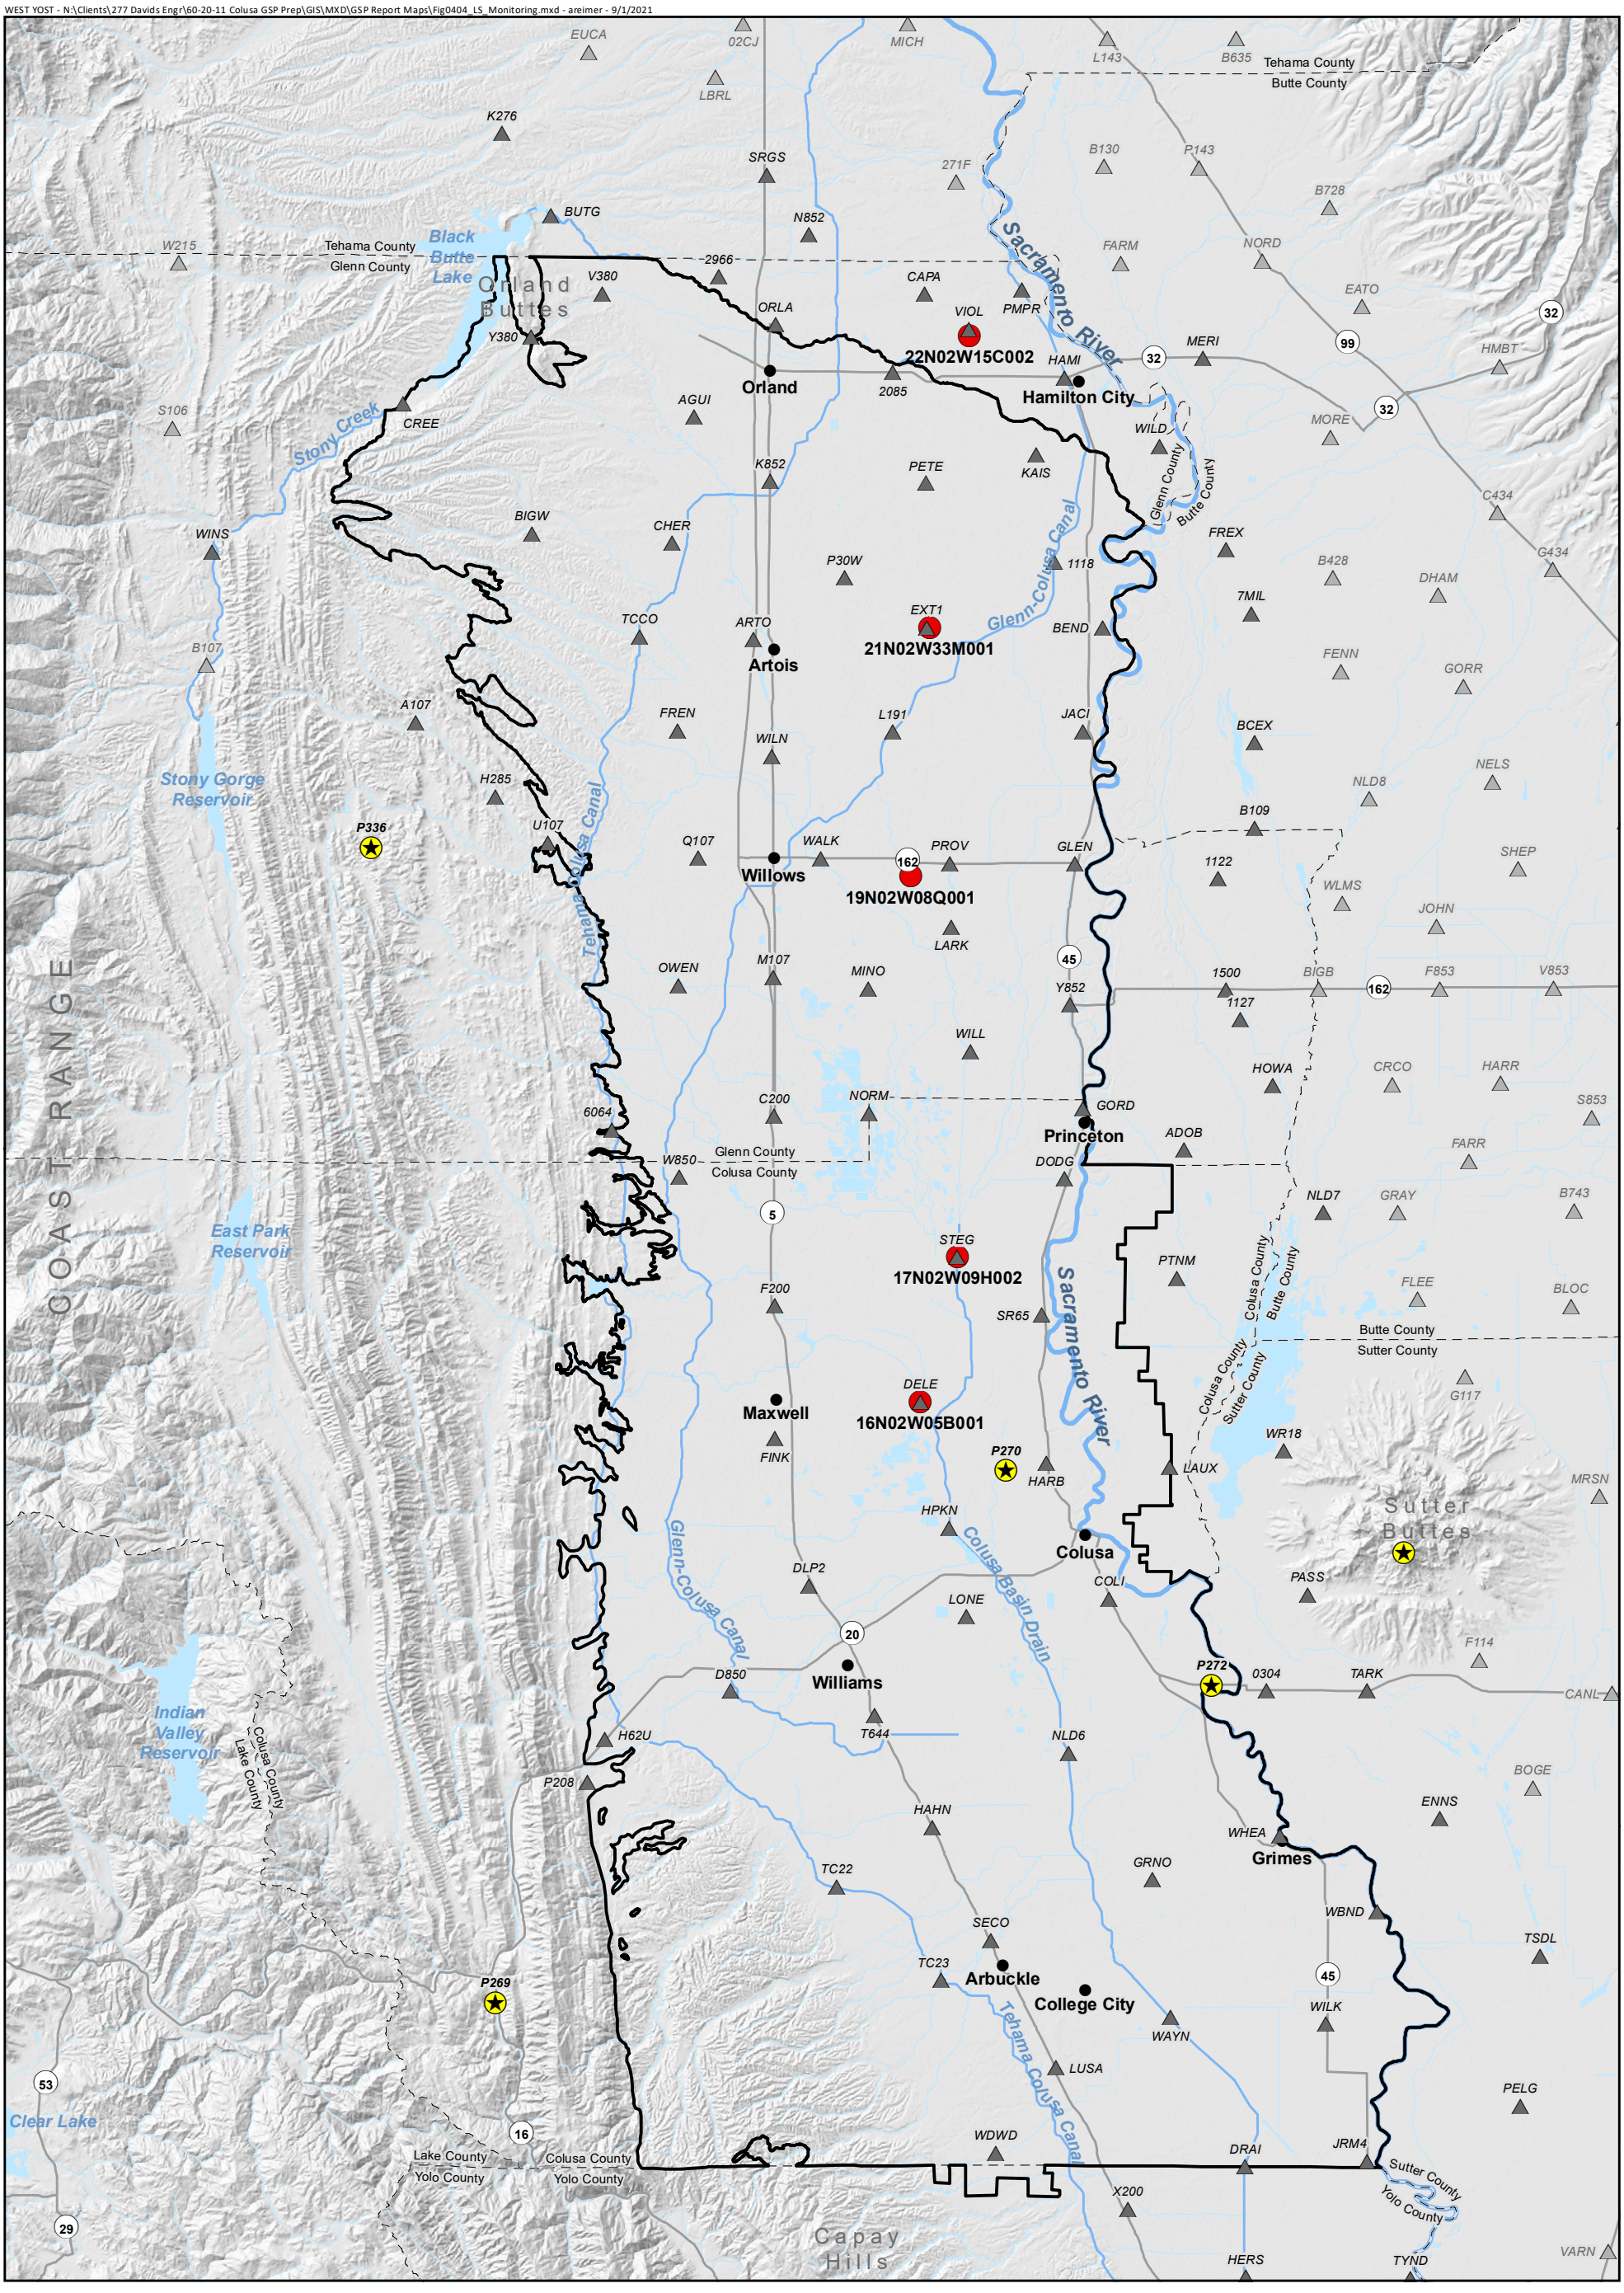
DWR monitors eleven extensometers within the Sacramento Valley, four of which are installed in wells within the Subbasin. One extensometer is within the Glenn County portion of the Corning Subbasin, just north of Stony Creek. All five of the extensometers within Glenn and Colusa Counties are included in the Subbasin land subsidence monitoring network.

UNAVCO Plate Boundary Observatory GPS/GNSS Network

The University of California Agriculture and Natural Resources (UNAVCO) Plate Boundary Observatory (PBO) network of continuously operating global positioning system (CGPS) stations was developed for measuring vertical and horizontal deformation of the North American and Pacific tectonic plates in the western United States. The data collected with the CPGS stations, however, can be used for near-real-time measurements of land subsidence.

There are two CPGS stations within the Subbasin, both in Colusa County west of the Sutter Buttes. Two additional stations are located out of the Subbasin in the Coast Range foothills west of Willows and west of Arbuckle. One station is located in the Sutter Buttes. The stations are measured on 15-second intervals and data is evaluated to provide a daily displacement record.

Sacramento Valley Height Modernization Project



The Sacramento Valley benchmark network is managed by DWR in cooperation with USBR and local agencies to both monitor land subsidence and extend the high-accuracy geodetic control of USBR facilities. As of 2017, the network contained 305 benchmarks within the Sacramento Valley, of which 63 benchmarks are located within the Subbasin and 76 benchmarks are included in the Subbasin land subsidence monitoring network. The benchmarks are surveyed by field crews on an as-needed or as-requested basis.

Table 4-5. Land Subsidence Monitoring Network Extensometers and Benchmarks

(a) Latitude and longitude values are in North American Datum of 1983 (NAD 83), decimal degrees.
(b) Extensometers are maintained and managed by California DWR under their Ground Surface Displacement-Land Subsidence Monitoring program.
(c) Extensometers include those that are within or near the Colusa Subbasin. Extensometers are installed at depths of approximately 700-800 ft.
(d) Continuous global positioning system (GPS) benchmark data is received, cleaned, and managed by UNAVO's Geodetic Facility for the advancement of Geoscience (GAGE) Facility with support from the National Science Foundation and NASA.
(e) Continuous global positioning system (GPS) benchmark.
(f) Bolded benchmarks are included in the representative land subsidence monitoring network and were used to determine the sustainability thresholds discussed in Chapter 5.
(g) Frequency to be determined (TBD). Benchmarks have historically been re-surveyed irregularly, on an as-needed/as-requested basis, by DWR staff in coordination with local agencies.
(h) Benchmarks are those listed for the Sacramento Valley Height Modernization Project within 5 miles of the Colusa Subbasin.

Land Subsidence Monitoring Network

Colusa Groundwater Authority and Glenn Groundwater Authority

Colusa Subbasin

Groundwater Sustainability Plan

InSAR Remote Sensing

The land subsidence monitoring network is mostly comprised of discrete monitoring point locations. The exception to this are remote sensing datasets. Interferometric Synthetic Aperture Radar (InSAR) is a remote sensing technique that uses satellites to scan the earth's surface and measure displacement. The technology is used for studies regarding land subsidence, tectonic movement, earthquake and volcano activity, and public safety due to earth hazards.

As part of DWR's effort to provide relevant and up-to-date data to assist with SGMA-related projects and compliance, InSAR data was collected and analyzed for vertical land displacement across the State's groundwater basins (TRE ALTAMiRA, 2020). This data was used to assess existing land subsidence conditions within the Subbasin in Chapter 3. Future InSAR surveys and other remote sensing datasets contracted for local, state, or federal agency projects will be used to monitor land subsidence within the Subbasin as they become available, and so are included in the Subbasin land subsidence monitoring network.

4.2.3.3 Monitoring Protocols

Data will either be obtained from the agencies that are responsible for managing the monitoring sites within the land subsidence monitoring network or downloaded from dataset host websites. If necessary, the Colusa Subbasin GSAs will request resurvey of the Sacramento Valley benchmarks. The relevant websites are:

- California DWR Ground Surface Displacement – Land Subsidence Monitoring:
  - CNRA website: https://data.cnra.ca.gov/dataset/wdl-ground-surface-displacement
  - UNAVCO Plate Boundary Observatory GPS/GNSS Network:
  - UNAVCO website: https://www.unavco.org/data/data.html
- Sacramento Valley Height Modernization Project:
  - California DWR Northern Region Office: No website available
- InSAR remote sensing:
  - CNRA database: https://data.cnra.ca.gov/dataset/tre-altamira-insar-subsidence
  - UNAVCO website: https://www.unavco.org/data/data.html

Since all of the land subsidence monitoring locations identified as part of the Subbasin land subsidence monitoring network are included in existing state or federal monitoring programs, collection of displacement data complies with existing regulatory monitoring protocols.

The following land subsidence monitoring protocols have been established by DWR (DWR, 2016c):

- Levelling surveys should follow standards defined in the California Department of Transportation's (Caltrans) Surveys Manual (Caltrans, assorted dates).
- Continuous GPS surveys should follow standards defined in the Caltrans Surveys Manual.
- Extensometer instruments should be installed, calibrated, and maintained per the manufacturer's instructions.
- InSAR surveys should be obtained via interpretative reports for specific regions. Raw data files may be obtained and processed instead, if needed.

4.2.3.4 Data Gaps in Land Subsidence Monitoring Network

Land subsidence has been measured in the greater Arbuckle and southern Colusa County area (Section 3.2.6). The benchmarks must be manually surveyed in order to determine the magnitude of displacement. This is currently done on an irregular frequency and does not provide short-term insight regarding ongoing land subsidence. The installation of a CGPS station or extensometer would allow near real-time monitoring of subsidence in the Arbuckle area without relying on the irregular re-survey frequency of the Sacramento Valley benchmarks.

4.2.3.5 Proposed Actions to Address Data Gaps

No additional benchmarks are recommended at this time. However, a new CGPS station or extensometer near Arbuckle, where subsidence has been occurring, is recommended. A new near real-time monitoring site located in a location with known of subsidence would provide a better understanding of the rate and magnitude of subsidence.

Additionally, all future Sacramento Valley benchmark survey reports and results will be evaluated as they are made available. The Sacramento Valley benchmarks provide a good spatial distribution of vertical displacement measurements over time. Ongoing studies using InSAR data to determine vertical displacement should also be evaluated as they are published and data is made available.

Annual reports and future revisions to the GSP will provide updates on actions taken to address data gaps over the reporting period.

4.2.4 Surface Water Monitoring

Surface water monitoring is conducive for evaluating stream-aquifer relations. Comparing stream flows and stages with groundwater levels from specific monitoring wells can provide insight into how the surface waters are interconnected with the groundwater system. The surface water monitoring network includes stream gages placed on rivers, streams, and canals. All of the stream gages included in the surface water monitoring network are managed and monitored via existing federal and state programs. The representative surface water depletion monitoring network includes shallow groundwater level monitoring wells from which water levels will be used as a proxy for evaluating surface water depletions. The representative surface water depletion monitoring network is discussed in Section 4.2.5.3.

4.2.4.1 Requirements

In accordance with the Monitoring Network BMP (DWR, 2016b), the surface water monitoring network should be designed such that the sustainability indicators are adequately covered not just over the entire subbasin, but also within any specific GSP-defined Management Areas, of which there are none defined within the Subbasin. The surface water monitoring network shall be designed to characterize spatial and temporal changes between interconnected waters such that depletions from surface waters caused by groundwater extraction can be calculated (23 CCR §354.34(c)(6); DWR, 2016b).

Data collected from the surface water monitoring network shall be sufficient to:

- Characterize flow conditions including surface water discharge, stage, and baseflows.
- Identify locations and flow periods of ephemeral and intermittent stream channels, if any. The Monitoring Network BMPs state that monitoring of ephemeral or intermittent streams should be conducted annually or as appropriate to characterize flow changes (DWR, 2016b).
- Identify temporal trends due to localized, regional, and seasonal surface water discharge and groundwater extraction impacts.
- Identify and collect information necessary to evaluate adverse effects to the beneficial use of surface water.
- Support evaluation of stream-aquifer interactions, including impacts to surface water supplies due to changes in groundwater levels and impacts to native riparian land or GDEs.

Stream gages should be located along stream reaches with known groundwater connection, per the Monitoring Network BMP (DWR, 2016b). Locations should account for surface water diversions and return flows, if necessary. Per the Monitoring Network BMP (DWR, 2016b), surface water discharge monitoring should be accompanied by groundwater level monitoring within shallow wells.

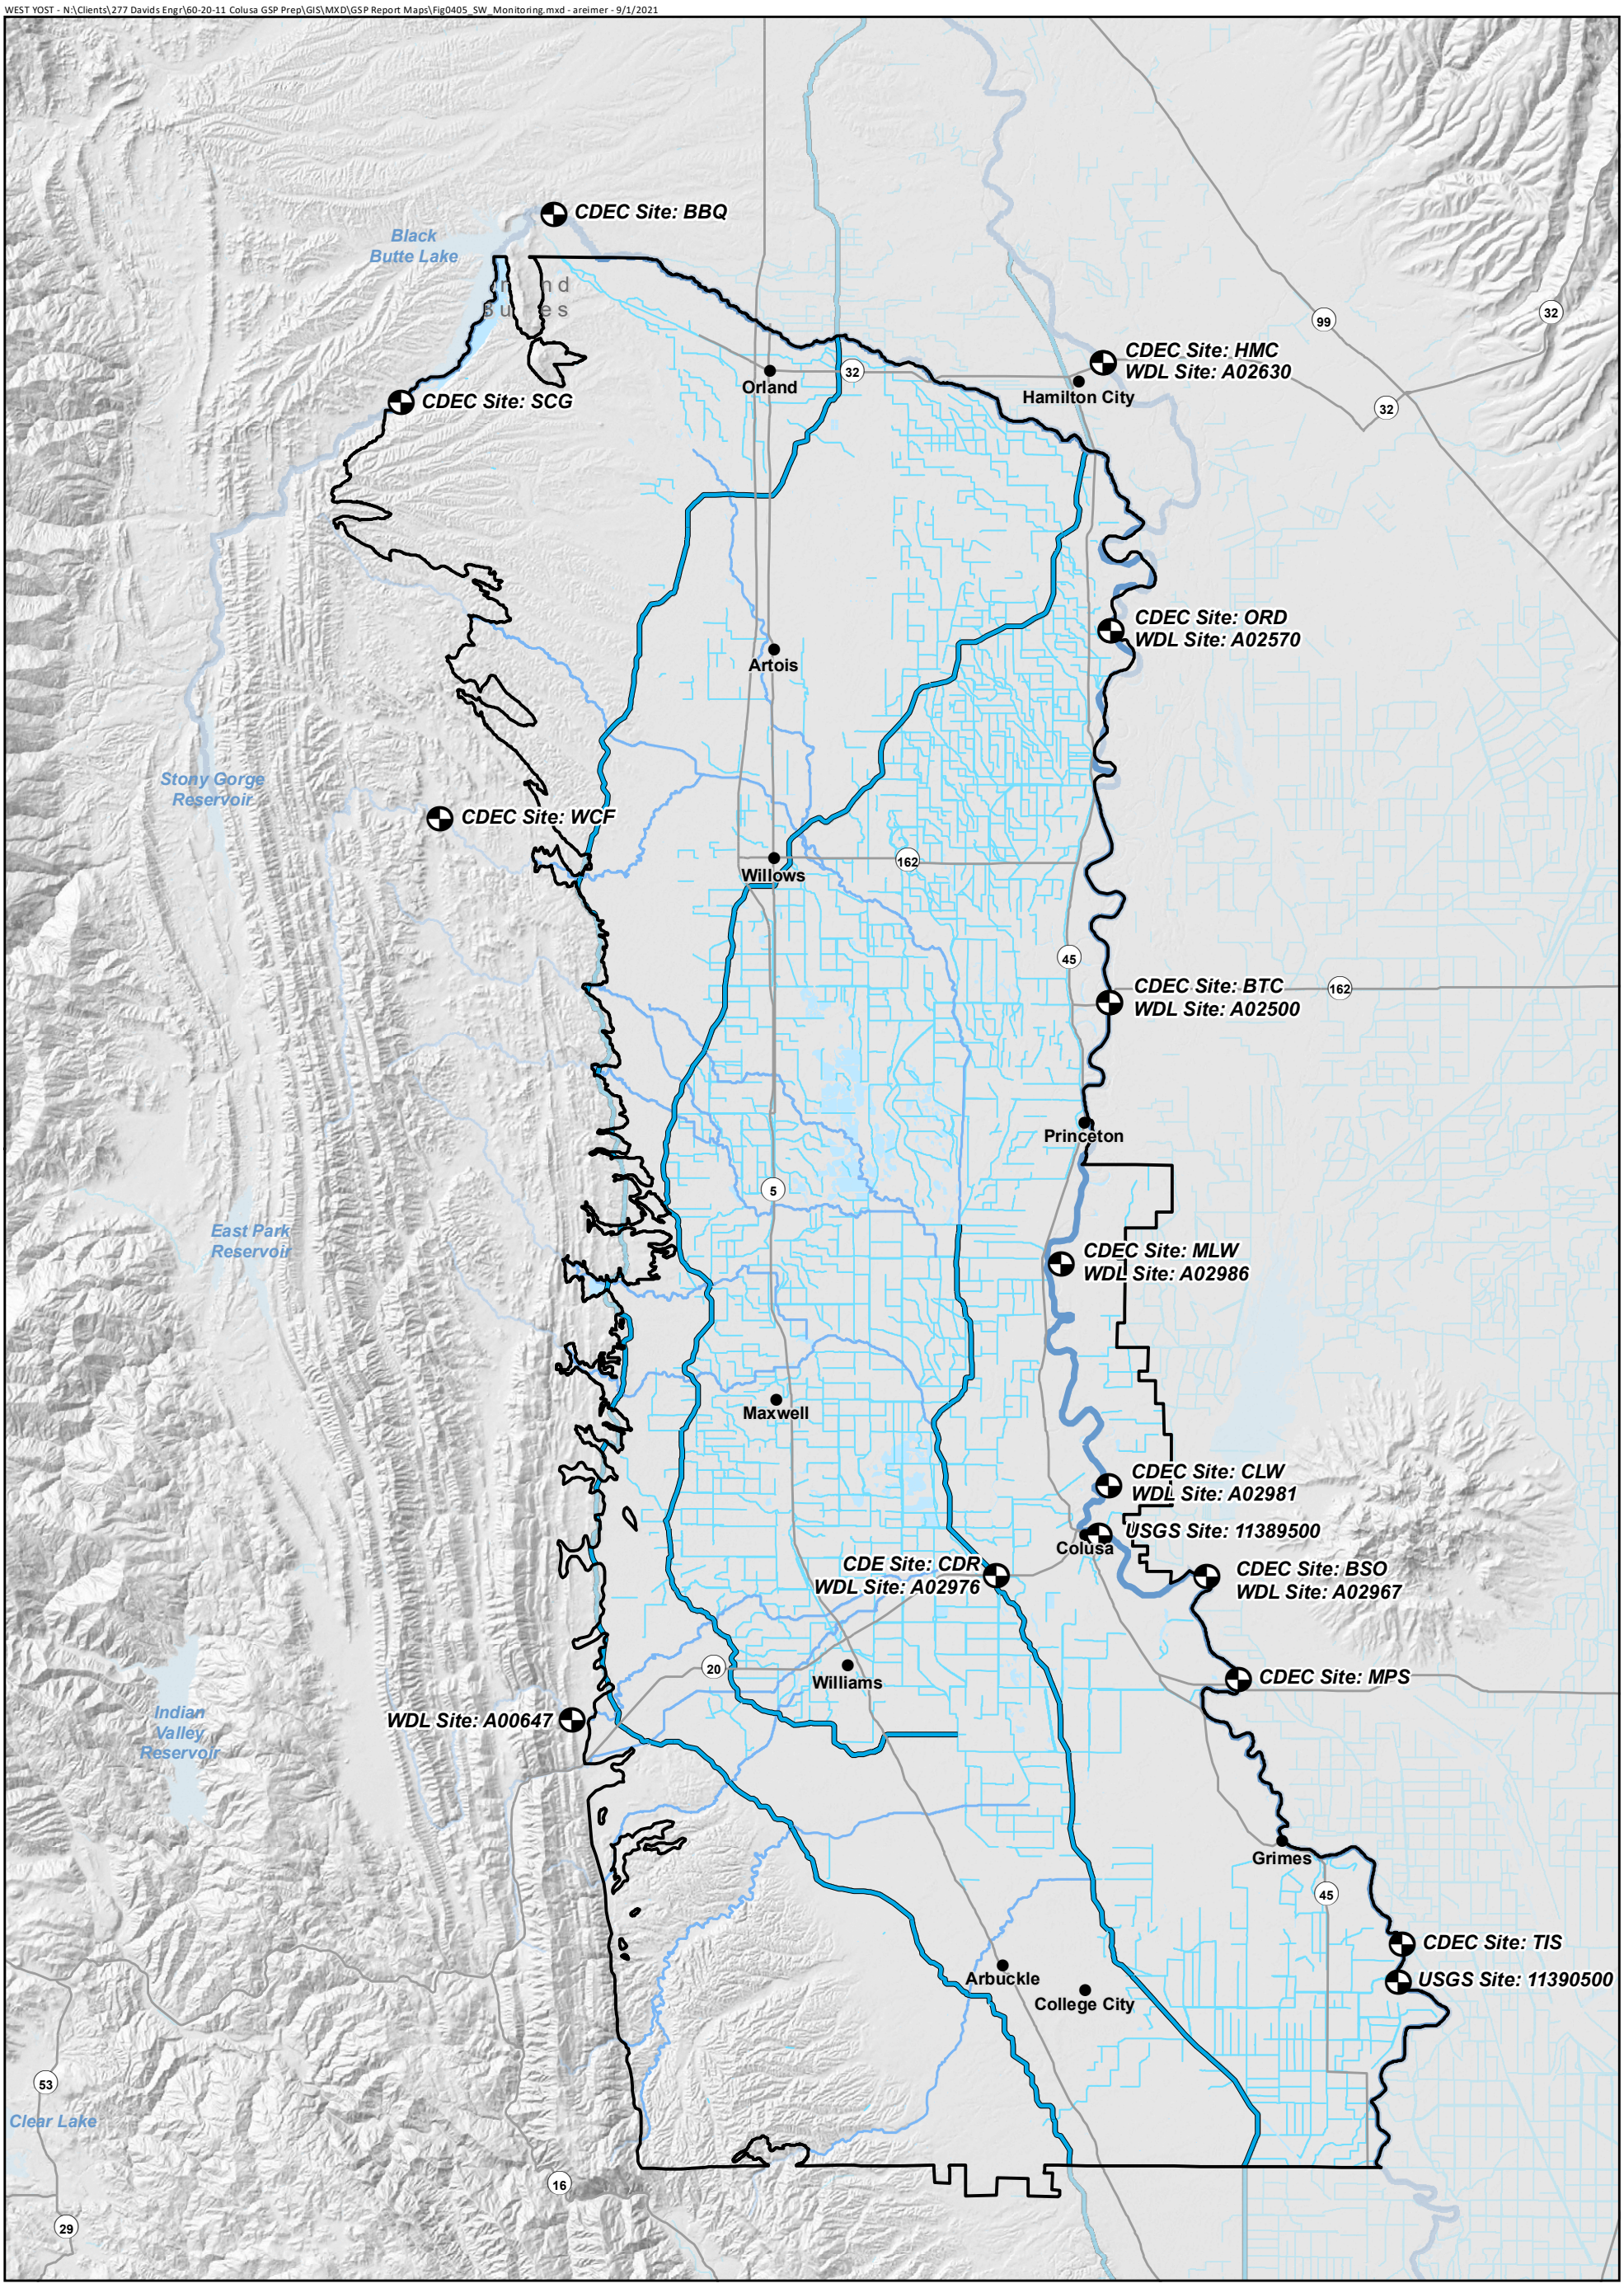
The Subbasin surface water monitoring network has been established using the best available data and science to identify, assess, and select existing monitor wells and stream gages meeting these requirements. However, significant data gaps exist, which need to be addressed during implementation of this GSP. Data gaps in the network are discussed in Section 4.2.4.4.

4.2.4.2 Surface Water Monitoring Network

Table 4-6 lists the surface water monitoring network, their locations, and monitoring frequency. These station locations are shown on Figure 4-5 and include all of the active stream gages and monitoring sites managed state and federal agencies both within and upstream of the Subbasin. The surface water monitoring sites are managed and maintained by WDL, California Data Exchange Center (CDEC), and USGS NWIS.

There are 15 active stream gages within the Subbasin surface water monitoring network.

Table 4-6. Surface Water Monitoring Network Stream Gages



County	Station ID	Station Name	Latitude[a]	Longitude	Site Type	Frequency	Source

Data will either be obtained from the agencies that are responsible for managing the monitoring stream gages within the surface water monitoring network or downloaded from dataset host websites.

- California DWR WDL: https://wdlbeta.water.ca.gov/Map.aspx
- CDEC: https://cdec.water.ca.gov/
- USGS NWIS: https://waterdata.usgs.gov/nwis

Since all of the stream gages identified as part of the Subbasin surface water monitoring network are included in existing state or federal monitoring programs, collection of discharge and river stage measurements comply with existing regulatory monitoring protocols.

Per the Monitoring Protocols BMP (DWR, 2016c), streamflow measurements should be collected, analyzed, and reported in accordance with procedures defined in the USGS Water Supply Paper 2175, volumes 1 and 2 (Rantz, 1982). This methodology is currently being used for both DWR and USGS surface water monitoring networks within the Subbasin.

4.2.4.4 Data Gaps in Surface Water Monitoring Network

Data gaps in the surface water monitoring network include the following:

- The temporal changes in ephemeral and intermittent stream stage and flow within the subbasin may not be sufficiently addressed by the existing surface water monitoring network to the extent required by 23 CCR §354.34(c).
- Colusa Basin Drainage Canal System (Colusa Drain) outflows from the Subbasin are not currently monitored, and historical monitoring records for Colusa Drain outflows from the Subbasin are not available within the CDEC, NWIS, and WDL databases.
- With the exception of the Black Butte Lake stream gages, there is currently no active stream gage on Stony Creek. A stream gage on Stony Creek that measured both discharge and river stage would benefit evaluating potential surface water depletions and help characterize the stream-aquifer relationship.

4.2.4.5 Proposed Actions to Address Data Gaps

The perennial streams (Stony Creek and the Sacramento River) that bound or intersect the Subbasin and adjacent subbasins are shown on Figure 4-4. Surface water monitoring, particularly as related to streamflow depletion, should be coordinated across subbasins. The Colusa Subbasin GSAs are participating in a surface water monitoring network data gap assessment and fulfillment in cooperation with neighboring GSAs.

Additionally, existing stream and drainage reports will be evaluated for additional information on the timing, stage, and magnitude of flows in ephemeral and intermittent streams in the subbasin, if necessary, to fill data gaps or support projects and management actions during GSP implementation. Willow or Walker Creek, two of the more prominent and long-ranging creeks in the Subbasin, could provide data representative of the subbasin's other ephemeral or intermittent creeks. If necessary, site-specific studies will be conducted to fill data gaps or address requirements for monitoring of ephemeral and intermittent streams, per 23 CCR §354.34(c)(6).

DWR is reportedly in the process of evaluating the adequacy of existing stream gages to support SGMA implementation. As a result of this effort, it is anticipated that DWR will identify data gaps and develop recommendations regarding the existing stream gage networks. There is one inactive USGS stream gage on Stony Creek (Station 11388500) near Hamilton City that may be identified as adequate to re-equip. Some of the ephemeral or intermittent streams within Subbasin have inactive stream gages that could also provide important information if re-equipped. Actions proposed by DWR, if any, will be taken into consideration by the Colusa Subbasin GSAs.

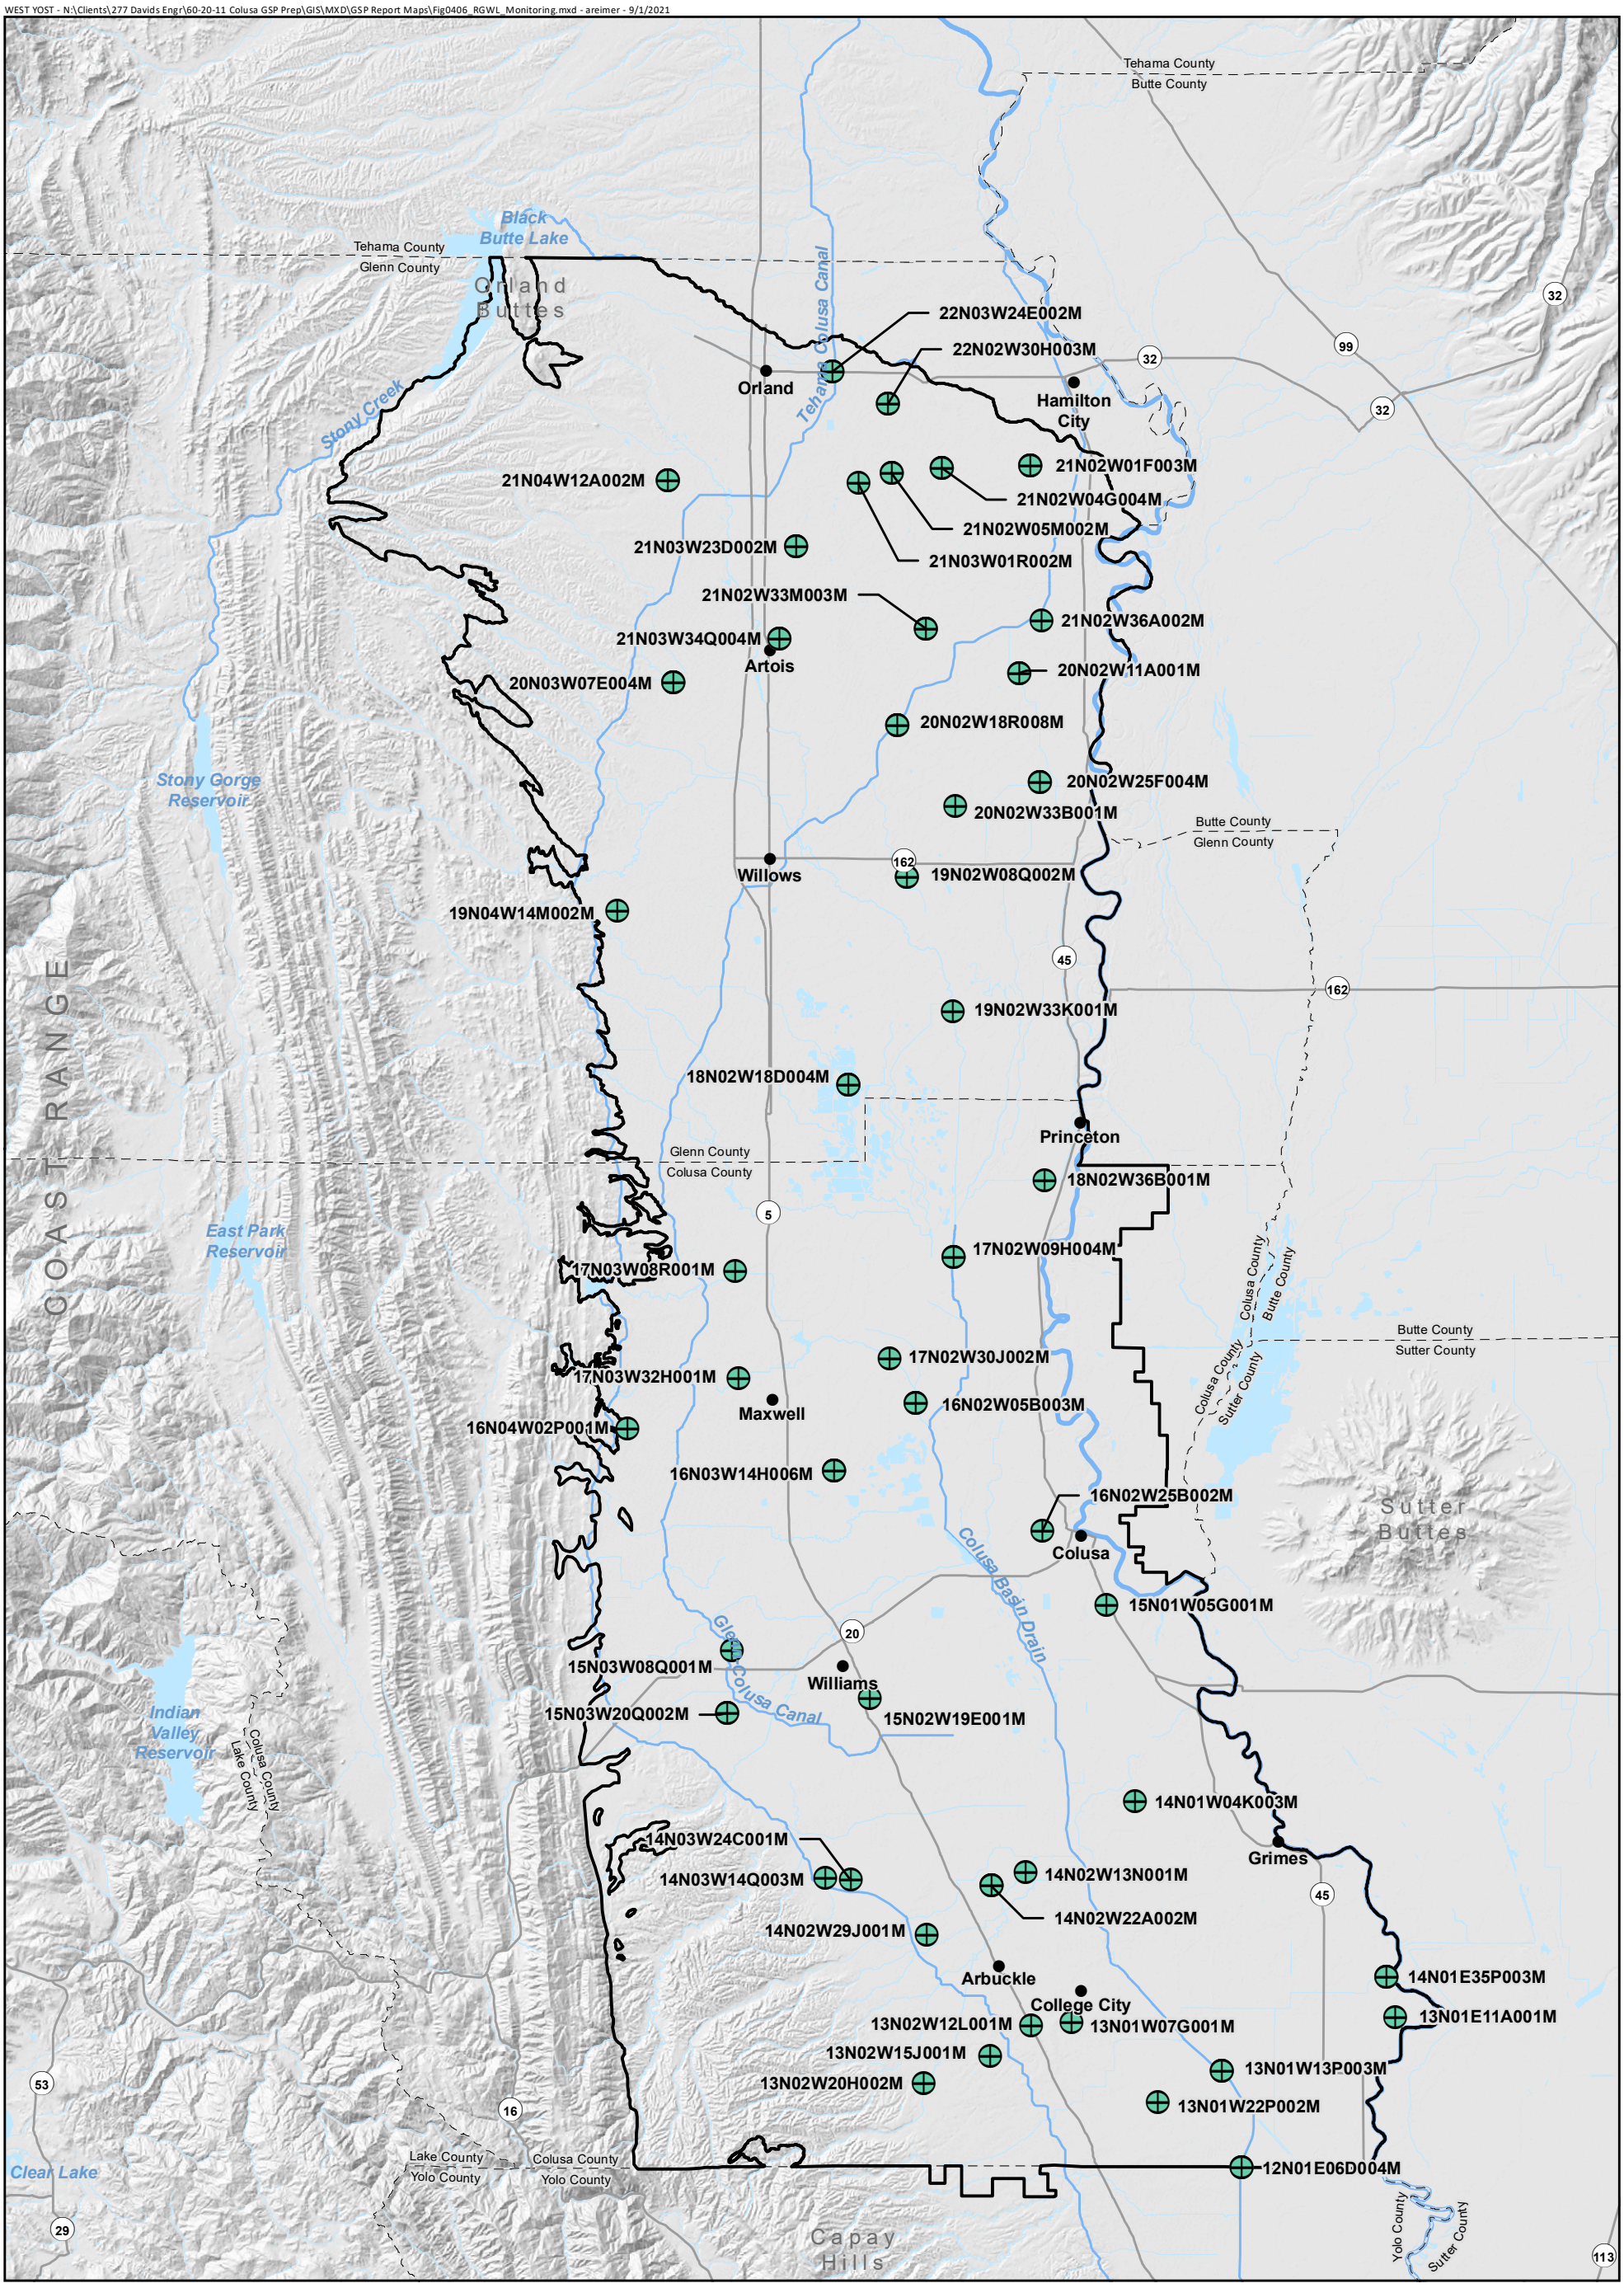
The need for additional monitoring wells to assist in the monitoring of stream-aquifer interactions will be assessed during implementation of this GSP. Evaluation of the new groundwater level data from the representative monitoring network described in the following section will be an important first step in determining the need for additional monitoring wells.

Annual reports and future revisions to the GSP will provide updates on actions taken to address data gaps over the reporting period.

4.2.5 Representative Monitoring Sites

Per 23 CCR §354.36, "*Each Agency may designate a subset of monitoring sites as representative of conditions in the basin or an area of the basin…*" to evaluate or monitor for sustainability indicators. Representative monitoring locations were designated to evaluate undesirable results due to lowering of groundwater levels, reduction of groundwater storage, groundwater quality degradation, inelastic land subsidence, and surface water depletions. The purpose and composition of the representative monitoring networks are discussed below. Undesirable results and sustainability thresholds determined by the representative monitoring networks are discussed in Chapter 5 (Sustainable Management Criteria).

4.2.5.1 Representative Groundwater Level Monitoring Network



The representative groundwater level monitoring network includes one completion from each of the 48 wells in the groundwater monitoring network. The representative groundwater level monitoring sites are indicated in Table 4-2 and shown on Figure 4-6. Each single completion well is a representative groundwater level monitoring site. For multiple completion wells in the representative monitoring network, the completion depth was selected based on the median depth of domestic wells within the Thiessen polygon bounding each multiple completion monitoring well.

Additional information regarding the selection of these representative groundwater level monitoring sites and how they were used to determine sustainability thresholds can be found in Chapter 5 and Appendix 5B.

4.2.5.2 Representative Groundwater Quality Monitoring Network

The Subbasin representative groundwater quality monitoring network includes 25 monitoring sites to monitor for groundwater quality degradation due to increasing salinity concentrations, either via migration of deep brackish to saline waters into the freshwater aquifer system or recharge from agricultural runoff. The representative groundwater quality monitoring sites are indicated in Appendix 4B and shown on Figure 4-7.

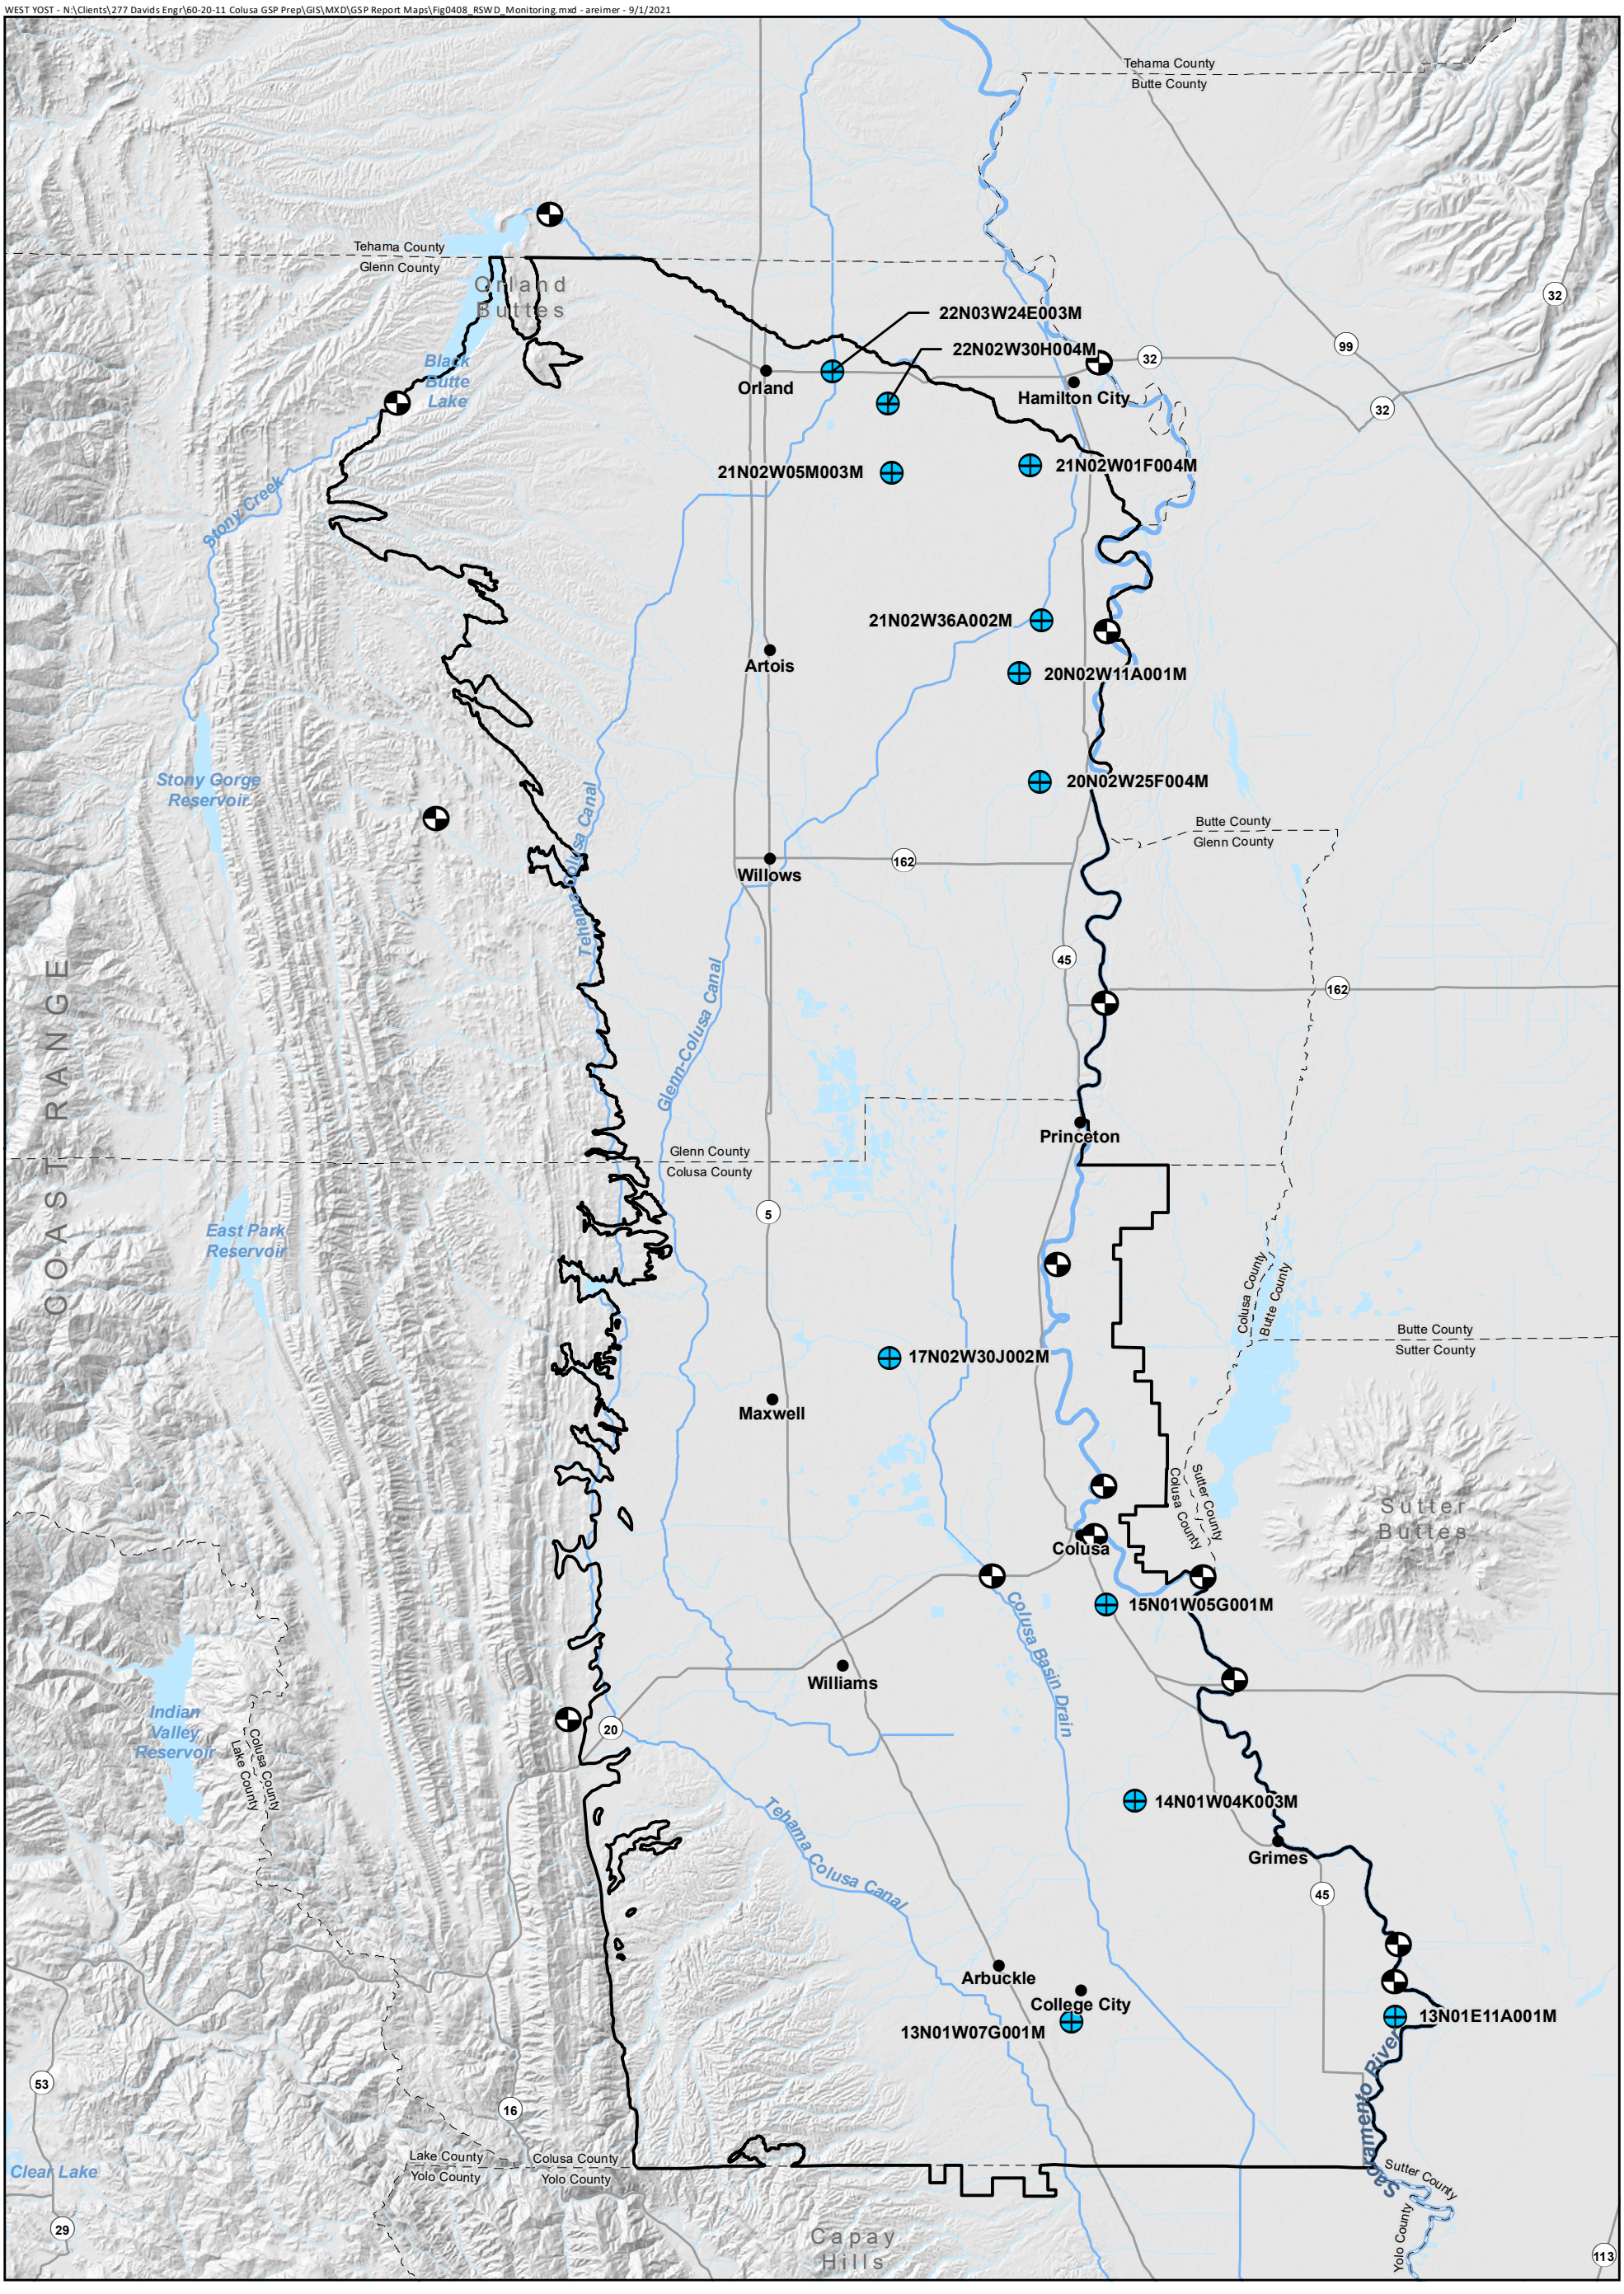
Ten California Rice Commission wells were selected as representative monitoring sites due to their shallow construction (less than 30 feet deep) to monitor recharge waters, proximity to irrigated agricultural lands, proximity to areas with known salinity concerns, inclusion in an existing groundwater quality monitoring program with a focus on salinity, and dedicated observation well status. Four Sacramento Valley Water Quality Coalition wells were selected as representative groundwater quality monitoring sites due to their locations near irrigated agricultural lands and surface waters, proximity to areas with high domestic and agricultural wells, relatively deeper constructed depth than the California Rice Commission wells, and inclusion in an existing groundwater quality monitoring program with a focus on salinity. One well from each community-level public water system was selected as a representative groundwater quality monitoring site based on their proximity to urban areas, status, level of use, and conversations with water agency operational staff. The groundwater quality monitoring network includes 11 public drinking water wells.

Additional information regarding the selection of these representative groundwater quality monitoring sites and how they were used to determine sustainability thresholds can be found in Chapter 5.

4.2.5.3 Representative Land Subsidence Monitoring Network

Sixty-three (63) benchmarks within the Subbasin are included in the representative land subsidence monitoring network to determine sustainability thresholds and evaluate the occurrence of undesirable results. The benchmarks are shown on Figure 4-4 and bolded in Table 4-5. None of the CGPS stations, extensometers, or benchmarks outside of the Subbasin are included in the representative monitoring network. The benchmarks are evenly distributed throughout the Subbasin, including through the areas with current land subsidence occurrence, and are easily re-surveyed to measure for vertical displacement.



Additional information regarding the representative land subsidence monitoring sites and how they were used to determine sustainability thresholds can be found in Chapter 5.

4.2.5.4 Representative Surface Water Depletion Monitoring Network

Groundwater levels in shallow wells are being used as a proxy to monitor for surface water depletions and interconnected surface waters. The rationale and methodology for this is explained in Chapter 5 and Appendix 5B. The criteria for inclusion in the representative surface water depletion monitoring network was that the site must be:

- Less than 200 feet deep, and
- More than 2,000 feet and less than 5 miles from the surface water feature of concern.

Twelve (12) shallow wells from the groundwater level monitoring network qualified as representative monitoring sites. These wells may also be useful as monitoring sites for GDEs, although a dedicated network of shallow monitoring wells will be developed specifically for GDE monitoring during implementation of the GSP. The representative surface water depletion monitoring sites are indicated in Table 4-2 and shown on Figure 4-8. Additional information regarding the selection of these representative surface water depletion monitoring sites and how they were used to determine sustainability thresholds can be found in Chapter 5 and Appendix 5B.

CHAPTER 5
Sustainable Management Criteria

This chapter describes the sustainable management criteria (SMC) for each applicable sustainability indicator for the Subbasin (Subbasin). These sustainable management criteria are used by the CGA and GGA to gauge progress towards achieving the Sustainability Goal during GSP implementation. This chapter also describes undesirable results for each applicable sustainability indicator and how undesirable results are detected.

5.1 SUSTAINABILITY TERMINOLOGY

This section defines key terminology used is discussing groundwater sustainability in the Subbasin.

- **Sustainability goal**: The sustainability goal qualitatively describes the overall objectives of the GSP and desired conditions for the Subbasin.
- **Undesirable results**: Undesirable results statements describe the Subbasin conditions at which each applicable sustainability indicator would have significant and unreasonable effects on the beneficial uses and users of groundwater in the Subbasin.
- **Minimum thresholds**: Minimum thresholds are quantitative values established for each applicable sustainability indicator that, when exceeded, indicate that undesirable results could occur.
- **Measurable objectives**: Measurable objectives are quantitative goals for the maintenance or improvement of specified groundwater conditions, reflecting desired Subbasin conditions and providing a benchmark to achieve and maintain the Subbasin sustainability goal.
- **Interim milestones**: Interim milestones are target values representing measurable groundwater conditions, in increments of five years, set by the GSAs to provide a glidepath toward sustainability over the GSP implementation horizon, ultimately leading to the measurable objectives and achievement and maintenance of the Subbasin sustainability goal.
- **Sustainable management criteria**: Sustainable management criteria refer to the criteria by which the GSAs define conditions in the GSP that constitute sustainable groundwater management for the Subbasin. The sustainable management criteria include the processes by which undesirable results are characterized, and by which minimum thresholds and measurable objectives are established for each applicable sustainability indicator.

5.1.1 Sustainability Indicators

A sustainability indicator is defined in SGMA as one of six effects caused by groundwater conditions that, when significant and unreasonable, cause undesirable results. The six sustainability indicators are described by the DWR in the document *Sustainable Management Criteria, Best Management Practices for the Sustainable Management of Groundwater* (DWR, 2017) as follows:

Indicator Symbol	Explanation
	Chronic lowering of groundwater levels indicating a significant and unreasonable depletion of supply if continued over the planning and implementation horizon. Overdraft during a period of drought is not sufficient to establish a chronic lowering of groundwater levels if extractions and groundwater recharge are managed as necessary to ensure that reductions in groundwater levels or storage during a period of drought are offset by increases in groundwater levels or storage during other periods.
	Significant and unreasonable reduction of groundwater storage.
	Significant and unreasonable seawater intrusion.
	Significant and unreasonable degraded water quality, including the migration of contaminant plumes that impair water supplies.
	Significant and unreasonable land subsidence that substantially interferes with land uses.
	Depletions of interconnected surface water that have significant and unreasonable adverse impacts on beneficial uses of the surface water.

SGMA allows several pathways to meet the distinct local needs of each subbasin, including:

- Development of sustainable management criteria for each sustainability indicator.
- Use of groundwater elevation as a proxy metric for other sustainability indicators
- Exclusion of specific indicators that are not applicable to the subbasin

Five sustainability indicators are applicable to the Subbasin:

- Chronic lowering of groundwater levels

- Reduction of groundwater storage

- Degraded water quality

- Inelastic land subsidence

- Depletions of interconnected surface water

Sustainable management criteria have been established herein for the chronic lowering of groundwater levels, degraded water quality, and inelastic land subsidence. For sustainability indicators that have a significant, demonstrated correlation to groundwater levels, the sustainable management criteria for groundwater levels may be used as a proxy metric. Both depletions of interconnected surface water and reduction of groundwater storage are significantly correlated to groundwater levels (as described below), and thus utilize groundwater levels as a proxy. Seawater intrusion is not applicable to the Subbasin due to the distances between the Subbasin and the Pacific Ocean, bays, deltas, or inlets ranging from about 30 to

60 miles. Because seawater intrusion is neither occurring nor anticipated to occur in the subbasin over the planning horizon, only the five applicable sustainability indicators are addressed hereinafter.

Continued data collection and an improved understanding of Subbasin conditions in the future may lead to changes in the sustainable management criteria discussed herein. Section 7.8 describes the 5-year GSP update process. Including an evaluation of the progress towards meeting interim goals and a reassessment of sustainable management criteria in light of new data.

5.2 SUSTAINABILITY GOAL

23 CCR §354.24 requires establishment of a sustainability goal for the subbasin that culminates in the absence of undesirable results by 2042. The sustainability goal provides a qualitative description of the Subbasin's objectives relative to sustainable management and desired groundwater conditions in the Subbasin. Information from Chapter 3, Basin Setting, including information on historical, current, and future water budgets, have informed understanding of the status of the Subbasin and, subsequently, development of the sustainability goal for the Subbasin. The sustainability goal is consistent with avoidance of locally-defined undesirable results and is supported by the quantitative minimum thresholds, measurable objectives, and interim milestones identified in this chapter. Demonstration of the absence of undesirable results supports a determination that a Subbasin is operating sustainably and thus the sustainability goal has been achieved.

The sustainability goal for the Subbasin is:

> *… to maintain, through a cooperative and partnered approach, locally managed sustainable groundwater resources to preserve and enhance the economic viability, social well-being and culture of all Beneficial Uses and Users, without experiencing undesirable results.*

5.2.1 Sustainable Operation of the Subbasin

Projects and management actions that the GSAs and other partners could implement to ensure that the Subbasin is operated sustainably (i.e., to avoid undesirable results) are described in Chapter 6. The Introduction to Chapter 6 describes an adaptive management approach for implementing projects and management actions that will be informed by monitoring of groundwater conditions and will lead to implementation of additional projects if Measurable Objectives (MOs) are not being maintained and Minimum Thresholds (MTs) are being approached.

An adaptive management approach recognizes that undesirable results do not currently exist in the Subbasin, and it is uncertain that undesirable results will develop in the future. The uncertainty is primarily related to the relatively small groundwater storage imbalances estimated to occur under future conditions (see Chapter 3, Section 3.3, Water Budget Information), the uncertainty associated with those estimates, and uncertainty associated with when and how potential future climate change actually affects the Subbasin. Monitoring of actual groundwater conditions over time will determine whether, when, and where implementation of projects and management actions may be needed to avoid undesirable results.

Despite the long-term adaptive implementation approach described above, certain Subbasin projects are currently moving toward implementation to address localized declining groundwater levels that are

believed to be primarily drought-induced[2]. These planned projects are described in Chapter 6 and are regarded as projects that will contribute to long-term sustainable groundwater management in addition to alleviating temporary drought-induced effects in the near term.

5.2.2 Achieving Sustainability within 20 Years

As discussed above, the Subbasin does not currently have undesirable results, which shows that the Subbasin is being managed sustainably. Additionally, it is uncertain that undesirable results will occur in the future. If monitoring detects that Measurable Objectives are not being maintained and Minimum Thresholds are being approached, the GSAs and other project proponents are committed to implementing projects and management actions to avoid undesirable results, as described in Chapters 6 and 7.

5.3 UNDESIRABLE RESULTS

As described in 23 CCR §354.26, undesirable results occur when one or more significant and unreasonable effects are caused by groundwater conditions occuring throughout the Subbasin, as assessed using the five applicable sustainability indicators described earlier: chronic lowering of groundwater levels, reduction of groundwater storage, degraded water quality, inelastic land subsidence, and/or depletions of interconnected surface water. The DWR's *Sustainable Management Criteria Best Management Practices* was developed to help GSAs establish their sustainability criteria by first identifying the significant and unreasonable effects caused by groundwater conditions in the Subbasin that constitute undesirable results, and then identifying quantitative criteria to define when and where the effects of groundwater conditions cause undesirable results for each applicable sustainability indicator. These quantitative criteria define the number and location of monitoring points that may be below a specific minimum threshold prior to a GSA identifying conditions as an undesirable result. The *Sustainable Management Criteria* Best Management Practice (BMP) states that "undesirable results will be defined by minimum threshold exceedances" (DWR, 2017).

This section presents the undesirable results statements for the Subbasin, which were developed through a process that characterizes specific groundwater conditions that lead to undesirable results in the Subbasin and identifies minimum thresholds that, when exceeded, may indicate that undesirable results could occur. Input from Subbasin stakeholders, the public, and GSA members was used in conjunction with data collected and evaluated for preparation of the Plan Area and Groundwater Conditions chapters of this GSP (Chapter 2 and Chapter 3, respectively) to guide development of the undesirable results statements. These statements utilize quantitative thresholds (as described later in this section) to indicate where and when undesirable results might occur in the representative monitoring network, and therefore the Subbasin. Appendix 5A documents the decision-making process and adoption of the Subbasin sustainable management criteria by the CGA and GGA. The sustainable management criteria decision records identify these quantitative thresholds selected by the GSAs, and the process and considerations leading to these decisions.

Chapter 4 describes the Subbasin's monitoring networks and representative monitoring networks for each applicable sustainability indicator.

[2] A series of mostly dry years beginning in about 2007 has resulted in increased irrigation demands within the Subbasin and curtailments of Central Valley Project surface water supplies, and consequently increase in groundwater pumping. In some locations these effects of drought are compounded by expansion of irrigation lands served solely by groundwater.

The five applicable sustainability indicators are addressed to determine whether and when significant and unreasonable impacts are occurring on beneficial uses and/or users in the Subbasin. For each indicator, the potential for undesirable results is described. Causes of groundwater conditions leading to significant and unreasonable effects are identified, and undesirable results defined based on current Subbasin conditions, the California Water Code, SGMA regulations, BMPs, and stakeholder input. For each sustainability indicator, the following have been developed:

- Description of undesirable results – describes groundwater conditions causing the specific significant and unreasonable effects that constitute undesirable results.
- Identification of undesirable results – describes the criteria used to define when and where groundwater conditions cause undesirable results, defined and detected by minimum threshold exceedances.
- Potential causes of undesirable results – describes groundwater conditions that could lead to undesirable results.
- Potential effects of undesirable results – describes what could happen to beneficial uses and users of groundwater if undesirable results were to occur.
- Evaluation of the presence of undesirable results – describes whether undesirable conditions are present in the Subbasin and/or are detected through monitoring.

As previously noted, undesirable results related to seawater intrusion are neither occurring nor anticipated to occur in the subbasin over the planning horizon. Thus, criteria for undesirable results related to this sustainability indicator are not applicable to this GSP.

5.3.1 Chronic Lowering of Groundwater Levels

5.3.1.1 Description of Undesirable Results for Chronic Lowering of Groundwater Levels

The undesirable result for the chronic lowering of groundwater levels is a result that would cause significant and unreasonable reduction in the long-term viability of beneficial uses and users over the planning and implementation horizon of this GSP.

An undesirable result for chronic lowering of groundwater levels in the Subbasin is experienced if sustained groundwater levels are too low to reasonably satisfy beneficial uses and users within the Subbasin over the planning and implementation horizon of this GSP. Undesirable results for the chronic lowering of groundwater levels have not occurred historically and are not currently occurring. Per the projected water budget (Chapter 3), these effects are not likely to occur in the projected water budget analysis period (2016-2065).

Potential impacts of chronic lowering of groundwater levels and the extent to which they are considered significant and unreasonable were determined by the GSA members with input from local stakeholders and members of the public, as described in Chapter 2. During development of the GSP, potential undesirable results identified by stakeholders included:

- A significant and unreasonable number of wells going dry
- A significant and unreasonable reduction in the pumping capacity of existing wells
- A significant and unreasonable increase in the need for deeper wells or lower pump settings
- Adverse impacts to environmental uses and users, including reductions in the flows of interconnected surface waters and reductions in groundwater available to the root zones of groundwater-dependent ecosystems (GDEs)

As described in Chapter 2, most of the Subbasin is classified as an Economically Disadvantaged Area and has a high proportion of Disadvantaged Communities (DACs) and Severely Disadvantaged Communities (SDACs). These beneficial users, along with members of California Native American Tribes (Tribes), including the federally recognized Cachil Dehe Band of Wintun Indians and the Cortina Indian Rancheria of Wintun Indians of California, typically rely on groundwater to meet their drinking water needs. As expressed in California Water Code Section 106.3, "every human being has the right to safe, clean, affordable, and accessible water adequate for human consumption, cooking, and sanitary purposes." The human right to water extends to all Californians, including disadvantaged individuals and groups and communities in rural and urban areas (SWRCB, 2021). Undesirable results caused by chronic lowering of groundwater levels could affect the Human Right to Water by limiting the ability of drinking water beneficial users, including DACs, SDACs and Tribes, to access safe, clean, and affordable water for human consumption, cooking, and sanitary purposes. These drinking water beneficial users could experience cumulative effects of undesirable results caused by chronic lowering of groundwater levels and degraded water quality.

5.3.1.2 Identification of Undesirable Results

An undesirable result is considered to occur for the chronic lowering of groundwater levels during GSP implementation when 25 percent or more of the representative monitoring wells (i.e., 12 of 48 wells) in the Subbasin fall below their minimum groundwater elevation threshold levels for 24 consecutive months. The 12 wells must be the same subset of wells, not any combination of 12 wells. The subset of wells is not predetermined; rather, it is delineated only as wells collectively fall below their minimum threshold levels. Minimum threshold levels for each well were determined using the best available data by the process described in Section 5.4. Additional justification and information supporting the process and criteria used to define when and where the effects of the groundwater conditions may cause undesirable results are provided in Appendices 5B and 5C.

These criteria were determined based on an evaluation of the best available data pertaining to the Subbasin's specific conditions and characteristics, as described in the Plan Area and Basin Setting sections of this GSP (Chapter 2 and Chapter 3, respectively), in conjunction with input and feedback from the public, stakeholders, and GSA members. The GSAs determined these criteria based on the justification that minimum threshold exceedances of 25 percent or more of representative monitoring wells represent a "significant" impact, and that exceedance of these levels for 24 consecutive months or longer (e.g., no recovery of groundwater levels through two consecutive seasonal high periods) constitutes a chronic impact that would potentially harm the "long-term viability" of affected beneficial uses and users in the Subbasin. The criterion of 25 percent or more of the representative monitoring wells dropping below their

minimum thresholds for 24 consecutive months was regarded as an indicator of a significant, widespread problem representing undesirable results.

5.3.1.3 Potential Causes of Undesirable Results

Potential causes of groundwater conditions that would lead to this undesirable result for the chronic lowering of groundwater levels are excessive groundwater pumping, reductions in recharge of precipitation and applied surface water, and other factors. Potential local impacts to groundwater levels could be caused by one or more of the following:

- Reduction in surface water supplies available to the Subbasin, particularly surface water diversions from the Sacramento River and Stony Creek
- Increases in groundwater pumping to meet increased crop consumptive use caused by climate change or shifts to higher water use crops

For example, if reductions in surface water supplies available under existing contracts are reduced due to changes in federal water allocation policy or other factors, such as State Board decisions or orders limiting diversions and transfers, then the Central Valley Project (CVP) Settlement Contractors and the contractors receiving water under Tehama Colusa Canal Authority contracts would have to increase groundwater pumping to meet any water supply shortages. If surface water supplies remained unchanged but crop consumptive use increased due to climate change, groundwater pumping would need to increase to meet higher irrigation requirements. Excessive groundwater pumping could cause lowering of groundwater levels leading to undesirable results.

5.3.1.4 Potential Effects of Undesirable Results

If groundwater levels were to reach levels indicating undesirable results have occurred, specific undesirable effects to beneficial uses and users of groundwater, land uses, property interests, and others could potentially include:

- De-watering of some existing groundwater production wells, starting with the shallowest wells (which are primarly domestic wells)
- Decreased access to safe, clean, and affordable drinking water
- Increased production well construction costs
- Increased groundwater pumping costs due to increased lifts
- Adverse effects on GDEs if the depth to groundwater falls below the root zones of GDEs
- Forced changes to lower water use, lower economic return crops, or to idling of agricultural lands
- Adverse effects on property values and the regional economy
- Permanent loss of crops due to lack of water
- Hauling of water to meet minimum household needs
- Stock water impacts (hauling water, selling livestock, etc.)

Implementation of the GSP is intended to avoid these effects by monitoring and implementing projects and management actions as needed to maintain groundwater levels above the minimum thresholds at representative monitoring network wells. An economic analysis of groundwater level minimum thresholds

is included in Appendix 5C. Chapter 6 describes projects and management actions. Chapter 7 describes GSP implementation efforts directed towards maintaining groundwater levels and mitigating drought impacts to drinking water beneficial users.

5.3.1.5 Evaluation of the Presence of Undesirable Results

Section 5.4 discusses how minimum thresholds were selected. More information on how the thresholds were established is also included in Appendix 5B, along with hydrographs of groundwater levels for each monitoring site through 2020 and the established depth of the minimum threshold. Of the 48 monitoring wells, none were below the minimum threshold in the latest measurement in 2020, indicating that the Subbasin does not currently exceed the requirements for an undesirable result for the chronic lowering of groundwater levels. The GSAs will continue to monitor groundwater levels to identify potential undesirable results as part of GSP annual reports and five-year updates, and adapt GSP implementation, as needed, to avoid undesirable results.

5.3.2 Reduction of Groundwater Storage

5.3.2.1 Description of Undesirable Results for the Reduction of Groundwater Storage

The undesirable result for the reduction of groundwater in storage is a result that would cause significant and unreasonable reduction in the long-term viability of beneficial uses and users over the planning and implementation horizon of this GSP.

An undesirable result for the reduction of groundwater storage is experienced if storage volumes are insufficient to reasonably satisfy beneficial uses and users within the Subbasin over the planning and implementation horizon of this GSP. Undesirable results related to groundwater storage have not occurred historically and are not currently occurring. Per the projected water budget (Chapter 3), these effects are not likely to occur in the projected water budget analysis period (2016-2065).

5.3.2.2 Justification of Groundwater Levels as a Proxy

This GSP uses groundwater level minimum thresholds as a proxy for the reduction of groundwater storage sustainability indicator. GSP regulations allow GSAs to use groundwater level minimum thresholds as a proxy metric for any sustainability indicator provided the GSP demonstrates that there is a significant correlation between groundwater levels and the other metrics. In order to rely on groundwater levels as a proxy, one approach suggested by DWR is to:

> *Demonstrate that the minimum thresholds and measurable objectives for chronic declines of groundwater levels are sufficiently protective to ensure significant and unreasonable occurrences of other sustainability indicators will be prevented. In other words, demonstrate that setting a groundwater level minimum threshold satisfies the minimum threshold requirements for not only chronic lowering of groundwater levels but other sustainability indicators at a given site (DWR, 2017).*

Minimum thresholds for groundwater levels will effectively avoid undesirable results for reduction of groundwater storage if it is demonstrated that adequate storage remains in the Subbasin even if chronic lowering of groundwater levels occurs. Based on the estimated range of current storage volume in the Subbasin (Chapter 3) and the small percentage changes in storage estimated to occur over groundwater

levels ranging from current levels to the groundwater levels minimum thresholds, it is anticipated that an undesirable result related to the chronic lowering of groundwater levels would occur before the Subbasin would experience significant and unreasonable effects related to reduction of groundwater storage. This is because the base of fresh groundwater is generally far below the groundwater level minimum thresholds that have been adopted, and large volumes of groundwater would remain in storage even if minimum thresholds were reached.

As discussed in Chapter 3, the current groundwater storage volume within the Subbasin, above the crystalline basement rocks and base of freshwater, is estimated to be between about 26 million acre-feet (maf) and 140 maf. The estimated reduction of groundwater storage over the Subbasin brought about by the average decline from the lowest historical groundwater levels measured at each of the 48 wells in the representative monitoring network prior to January 1, 2015 to the groundwater level minimum threshold for each of the 48 wells ranges from 1.4 to 7.7 maf, using the range of specific yield documented in Chapter 3. This represents a change of approximately five percent across the range of total estimated current groundwater storage volumes. This small percentage change is unlikely to trigger undesirable results based on storage impacts alone. Also, this range of estimated reduction in storage would not be likely to occur, because undesirable results would be triggered and addressed when groundwater levels in the first 12 of the 48 representative wells dropped to their minimum thresholds for 24 consecutive months.

Therefore, by setting minimum thresholds for groundwater levels as they have been, groundwater storage is effectively protected. The use of groundwater levels as a proxy metric for the groundwater storage sustainability indicator is effective and appropriate.

As discussed in Section 5.2.1, implementation of the GSP will be based on adaptive management, as required to adapt to changing climatic conditions. The SMCs for groundwater levels and storage will continue to be evaluated and updated as new information about groundwater conditions is acquired and data gaps are filled.

5.3.2.3 Identification of Undesirable Results

The undesirable result for the reduction of groundwater storage is monitored by proxy using groundwater levels and is considered to occur during GSP implementation when 25 percent or more of representative monitoring wells (i.e., 12 of 48 wells) fall below their minimum groundwater elevation thresholds for 24 consecutive months. The 12 wells must be the same subset of wells, not any combination of 12 wells. The subset of wells is not predetermined; rather, it is delineated only as wells collectively fall below their minimum threshold levels. Minimum threshold levels for each well were determined using best available data by the process described in Section 5.4. Additional justification and information supporting the criteria used to define when and where the effects of the groundwater conditions cause undesirable results is provided in Appendix 5B.

These criteria were determined based on the evaluation of best available data pertaining to the Subbasin's specific conditions and characteristics, as described in the Plan Area and Basin Setting sections of this GSP (Chapter 2 and Chapter 3, respectively), in conjunction with input and feedback from the public, local stakeholders, and GSA members. The GSAs selected these criteria based on the justification that minimum threshold exceedances of 25 percent or more of representative monitoring wells represent a "significant" impact, and that exceedance of these levels for 24 consecutive months or longer (indicating a significant lack of groundwater recharge through two consecutive periods of seasonal groundwater fluctuation) constitutes a chronic impact that would potentially harm the long-term viability of affected beneficial uses and users in the Subbasin. The criterion of 25 percent or more of the representative monitoring wells

dropping below their minimum thresholds for 24 consecutive months was regarded as an indicator of a significant, widespread problem representing undesirable results.

5.3.2.4 Potential Causes of Undesirable Results

Potential causes of undesirable results for the reduction of groundwater storage are excessive groundwater pumping and decreases in recharge due to reductions in the availability of surface water or reductions in precipitation. Increases in groundwater pumping could be caused by increases in consumptive use of water due to increased agricultural productivity, and changes in land and water use. Increases in overall demand, especially for groundwater, and decreases in recharge of surface water and precipitation may cause groundwater conditions that lead to undesirable results if the reduction in groundwater storage is excessive (water budgets area described in Chapter 3).

Based on the estimated range of current storage volume in the Subbasin and the small percentage changes in storage estimated to occur over groundwater levels ranging from historical lows to the groundwater levels minimum thresholds, undesirable results due to decreases in groundwater levels would occur before undesirable results due to a significant reduction of groundwater storage. As such, the use of groundwater levels as a proxy for the establishment of thresholds for reductions in groundwater storage is protective of groundwater storage.

5.3.2.5 Potential Effects of Undesirable Results

Undesirable results for reductions in groundwater storage could potentially cause significant and unreasonable effects on beneficial uses and users of groundwater. These effects could be:

- De-watering of some existing groundwater production wells, starting with the shallowest wells (which are primarly domestic wells)
- Increased production well construction costs
- Increased groundwater pumping costs due to inreased lifts
- Adverse effects on GDEs if the depth to groundwater falls below the root zones of GDEs
- Forced changes to lower water use, lower economic return crops, or idling of agricultural lands
- Adverse effects on property values and the regional economy
- Stock water impacts (hauling water, selling livestock, etc.)

Implementation of the GSP is intended to avoid these effects by monitoring and implementing projects and management actions as needed to maintain groundwater levels above the minimum thresholds at representative monitoring wells.

5.3.2.6 Evaluation of the Presence of Undesirable Results

Section 5.4 discusses how minimum thresholds were selected; more information on the process used to establish minimum thresholds for groundwater levels (as a proxy for groundwater storage) is also included in Appendix 5B. Current groundwater level data show that none of the 48 monitored wells were below the minimum threshold in the latest measurement in 2020, indicating that the Subbasin does not currently exceed the requirements for an undesirable result for the reduction of groundwater storage. The GSAs will continue to monitor groundwater storage through groundwater levels to identify potential undesirable results as part of GSP annual reports and five-year updates, and adapt GSP implementation, as needed, to avoid these effects.

5.3.3 Seawater Intrusion

Seawater intrusion is not an applicable sustainability indicator because seawater intrusion is not present and is not likely to occur in the Subbasin due to the distances between the Subbasin and the Pacific Ocean, bays, deltas, or inlets ranging from about 30 to 60 miles.

5.3.4 Degraded Water Quality

5.3.4.1 Description of Undesirable Results for Degraded Water Quality

The undesirable result for degraded water quality is a result that would cause a significant and unreasonable reduction in the long-term viability of beneficial uses and users, including domestic, agricultural, municipal, environmental, or other beneficial uses and users over the planning and implementation horizon of this is GSP. An undesirable result for degraded water quality in the Subbasin is experienced if, as the result of projects and management actions implemented under the GSP or other groundwater development (such as groundwater extraction or groundwater recharge), groundwater quality for regulated constituents is degraded to levels exceeding historical levels existing prior to January 1, 2015, or applicable water quality objectives, including drinking water standards, whichever are greater over the planning and implementation horizon of this GSP.

Existing regulatory programs address most water quality concerns, and the CGA and GGA will coordinate with these programs, the lead regulatory agencies, and the regulated community within the Subbasin during implementation of this GSP, including during development and implementation of projects and management actions.

The State Water Resources Control Board (SWRCB) and the Central Valley Regional Water Quality Control Board (CVRWQCB) regulate point and nonpoint source discharges to land that have potential to impact groundwater quality under a range of policy and regulatory programs, including the Basin Plan Amendment for the Salt and Nitrate Control Program, and the Irrigated Lands Regulatory Program. The California Department of Toxic Substance Control regulates releases of toxic substances, including those that impact groundwater quality.

The California Safe Drinking Water Act addresses the regulation and control of public water systems in the State of California, including enforcing provisions of the federal Safe Drinking Water Act. The federal government first granted primary enforcement responsibility to the State in 1978. The SWRCB Division of Drinking Water is the agency responsible for enforcement in Colusa and Glenn Counties, including the entire Subbasin.

The CGA and GGA will rely on existing monitoring and reporting carried out by the regulated community within the Subbasin when and where possible to address water quality concerns. The CGA and GGA will conduct supplemental water quality monitoring using existing wells or new monitoring wells constructed for that purpose when and where necessary to fill data gaps and to develop and implement projects and management actions.

Groundwater quality in the Subbasin is generally good, with local exceedances of water quality objectives for some constituents. The sole groundwater quality concern not addressed by the existing groundwater quality regulatory programs is mobilization of saline water from deeper parts of the aquifer along faults, other geologic structures, or other naturally-occurring zones with high salinity as a result of GSP projects and management actions and other groundwater development. Sustainable management criteria for salinity have been established to supplement existing regulatory programs.

Potential impacts of degraded water quality caused by GSP projects and management actions and the extent to which they are considered significant and unreasonable were determined by the GSA members with input from local stakeholders and members of the public. During development of the GSP, potential undesirable results identified by stakeholders included:

- A significant and unreasonable number of additional public supply wells requiring treatment, blending, control or replacement to remain in service
- A significant and unreasonable reduction in pumping capacity in existing public supply due to water quality degradation
- A significant and unreasonable reduction in pumping capacity in existing irrigation or stock water supply wells due to water quality degradation
- A significant and unreasonable increase in the number of domestic supply wells exceeding water quality objectives
- Adverse impacts to environmental uses and users, including significant and unreasonable impairment to water quality of interconnected surface waters and groundwater available to the root zones of GDEs

Undesirable results caused by degraded water quality could affect the Human Right to Water by limiting the ability of drinking water beneficial users, including DACs, SDACs and Tribes, to access safe, clean, and affordable water for human consumption, cooking, and sanitary purposes. These drinking water beneficial users could experience cumulative effects of undesirable results caused by chronic lowering of groundwater levels and degraded water quality.

5.3.4.2 Identification of Undesirable Results

The undesirable result for degraded water quality is considered to occur during GSP implementation when 25 percent of representative monitoring sites (i.e., 6 of 25 wells) exceed their minimum thresholds for two consecutive years. The six sites must be the same subset of sites, not any combination of six sites. The subset of sites is not predetermined; rather, it is delineated only as sites collectively exceed their minimum threshold values. Minimum thresholds were selected for each site by the process described in Section 5.4.

These criteria were determined based on the evaluation of best available data pertaining to the Subbasin's specific conditions and characteristics, as described in the Plan Area and Basin Setting sections of this GSP (Chapter 2 and Chapter 3, respectively), in conjunction with input and feedback from the public, local stakeholders, and GSA members. The GSAs selected these criteria based on the justification that minimum threshold exceedances at 25 percent or more of representative monitoring sites represent a "significant" impact, and that exceedance of these levels for two years or longer (indicating a significant and prolonged degradation of groundwater quality through two consecutive periods of seasonal groundwater fluctuation) constitutes an impact that would potentially harm the long-term viability of affected beneficial uses and users. Exceedance of minimum thresholds for two consecutive years at twenty-five

percent of the representative network wells was estimated to be an indicator of a significant, widespread problem indicating undesirable results.

5.3.4.3 Potential Causes of Undesirable Results

Potential causes of undesirable results for degraded water quality may be caused by:

- Mobilization of saline water from deeper parts of the aquifer along faults, other geologic structures, or other naturally-occurring zones with high salinity as a result of GSP projects and management actions and other groundwater development
- Mobilization of poor quality water, including contaminant plumes, monitored under existing regulatory programs as the result of GSP projects and management actions and other groundwater development
- Mobilization of naturally-occurring constituents in soils, the unsaturated zone, or the aquifer matrix as the results of projects involving direct groundwater recharge
- Direct groundwater recharge using water with constituent concentrations exceeding applicable water quality objectives or historical concentrations for the same constituents in groundwater

5.3.4.4 Potential Effects of Undesirable Results

If groundwater quality were degraded such that undesirable results occurred, the effects could potentially cause a shortage in supply to groundwater users without additional treatment, with domestic wells being most vulnerable as treatment costs or access to alternate supplies can be high for small users. This could limit access to safe, clean, and affordable drinking water for drinking water beneficial users, including DACs, SDACs and Tribes.

High salinity can impact both drinking water uses and agricultural uses, as there are maximum values associated with aesthetics (taste, color, and odor) for drinking water and crop health and yield for agriculture. Water quality degradation could potentially impact GDEs, surface water quality and the health of aquatic species, cause changes in crops grown and irrigation practices, and cause adverse effects to property values.

5.3.4.5 Evaluation of the Presence of Undesirable Results

Section 5.4 discusses how minimum thresholds were selected. Appendix 5D presents the historical salinity results expressed as electrical conductivity (EC) and the established minimum threshold for each representative monitoring site. Of the 25 monitoring sites, four wells exceeded their respective minimum thresholds in the most recent monitoring event after January 1, 2015. Although the Subbasin does not currently exceed the requirements for an undesirable result for degraded water quality, the CGA and GGA will coordinate with the entities responsible for monitoring, reporting, and compliance with applicable regulations to assess whether actions are required and being taken to achieve compliance for the wells.

The GSAs will continue to coordinate with the regulated community to identify potential undesirable results as part of GSP annual reports and five-year updates, and adapt GSP implementation, as needed, to avoid undesirable results. Chapter 7 describes GSP implementation efforts directed towards coordinating with drinking water providers and regulatory agencies to support drinking water beneficial uses and users.

5.3.5 Inelastic Land Subsidence

5.3.5.1 Description of Undesirable Results for Inelastic Land Subsidence

The undesirable result for inelastic land subsidence due to groundwater withdrawal is a result that would cause significant and unreasonable impacts to critical infrastructure over the planning and implementation horizon of this GSP.

An undesirable result is experienced if groundwater withdrawal causes inelastic land subsidence that substantially interferes with the condition or functionality of critical infrastructure within the Subbasin over the planning and implementation horizon of this GSP.

Potential impacts of inelastic land subsidence and the extent to which they are considered significant and unreasonable were determined by the GSA members with input from local stakeholders and members of the public. During development of the GSP, potential undesirable results identified by stakeholders included:

- Significant and unreasonable impacts to critical infrastructure in the Subbasin, including canals, pipelines, roadways, bridges, and groundwater wells.

5.3.5.2 Identification of Undesirable Results

Inelastic land subsidence within the Subbasin is monitored at 63 sites in DWR's Sacramento Valley Subsidence Monitoring Benchmark Network. An undesirable result is considered to occur during GSP implementation when 20 percent or more of representative monitoring locations (i.e., 13 of 63 locations) measure a subsidence rate greater than the specified minimum threshold of 0.5 feet per five years. The 13 locations must be the same subset of locations, not any combination of 13 locations. The subset of locations is not predetermined; rather, it is delineated only as sites collectively exceed their minimum threshold values. Minimum threshold levels were selected for each monitoring point by the process described in Section 5.4.

These criteria were determined based on the evaluation of best available data pertaining to the Subbasin's specific conditions and characteristics, as described in the Plan Area and Basin Setting sections of this GSP (Chapter 2 and Chapter 3, respectively), in conjunction with input and feedback from the public, local stakeholders, and GSA members. The GSAs selected these criteria based on the justification that minimum threshold exceedances at 20 percent or more of representative monitoring sites represent a significant impact, and that exceedance of these levels for 24 consecutive months or longer (indicating significant inelastic land subsidence through two consecutive periods of seasonal groundwater fluctuation) would substantially interfere with the condition or functionality of critical infrastructure within the Subbasin. Exceedance of the minimum thresholds for 24 consecutive months at 20 percent of monitoring sites was estimated to be an indicator of a significant, widespread problem indicating undesirable results.

5.3.5.3 Potential Causes of Undesirable Results

Inelastic land subsidence due to groundwater withdrawal is caused by a reduction in pore pressure brought about by pumping. The reduction in pore pressure increases the effective stress borne by the aquifer skeleton. The increase in the effective stress causes compaction of compressible clays.

The potential causes of undesirable results for inelastic land subsidence are:

- Increasing pumping or decreasing recharge in subsidence-prone areas
- Initiating pumping in areas or at depths with no or minimal historical groundwater pumping

5.3.5.4 Potential Effects of Undesirable Results

If inelastic land subsidence reaches levels indicating that undesirable results have occurred, the effects could potentially cause damage to local infrastructure such as canals, pipelines, roadways, bridges, and groundwater wells. Excessive subsidence may also lead to decreased groundwater storage and decreased hydraulic conductivity, with a resultant increase in well operations and maintenance costs.

5.3.5.5 Evaluation of the Presence of Undesirable Results

Section 5.4 discusses how the minimum thresholds were selected. Chapter 3 presents maps showing the extent and rate of historical subsidence. Of the 63 monitoring sites, none were below the minimum threshold in the latest measurement from 2017 indicating that the Subbasin does not currently exceed the requirements for an undesirable result for inelastic land subsidence. However, recognizing that there is uncertainty in Subbasin conditions and that data gaps exist, the GSAs will continue to monitor inelastic land subsidence to identify potential undesirable results as part of GSP annual reports and five-year updates, and adapt GSP implementation, as needed, to avoid undesirable results.

Ongoing monitoring of Subbasin conditions and data collection will inform potential updates to the SMC in the periodic updates. Chapter 7 documents plans to coordinate and fund additional surveys of the subsidence benchmarks.

5.3.6 Depletions of Interconnected Surface Water

5.3.6.1 Description of Undesirable Results for Depletions of Interconnected Surface Water

The undesirable result for depletions of interconnected surface water is a result that causes significant and unreasonable adverse effects on beneficial uses and users of interconnected surface waters within the Subbasin over the planning and implementation horizon of this GSP. During development of the GSP, potential undesirable results identified by stakeholders included:

- Significant and unreasonable impacts to stream flows
- Significant and unreasonable impact to riparian and riverine habitat
- Significant and unreasonable impacts to GDEs
- Significant and unreasonable impacts to springs

5.3.6.2 Justification of Groundwater Elevations as a Proxy

The use of groundwater elevation as a proxy metric for this sustainability indicator is necessary because the network of existing stream gages is not adequate to measure changes in stream accretions and depletions as related to the Subbasin. The network is inadequate because gages are not located such that changes in streamflow can be correlated directly and solely to Subbasin groundwater conditions. Additionally, it is unlikely that the relatively small, expected changes in streamflow associated with changes in groundwater

conditions can be accurately quantified given the measurement error associated with the gages. In contrast, changes in streamflow volume and rates can be estimated by modeling of groundwater levels and stream stages together with characterization of soil and aquifer properties. However, the levels of uncertainty in the available Subbasin groundwater model are currently too great to allow sufficiently reliable quantification of the rates and volume of stream depletions during GSP implementation.

Depletions of interconnected surface water are driven by the gradient between water surface elevation in the surface water body and groundwater elevations in the connected, shallow groundwater system. By setting minimum thresholds in representative monitoring wells near interconnected surface water, the GGA and CGA can monitor and manage this gradient, and in turn, manage potential changes in depletions of interconnected surface water. Monitoring for impacts to interconnected surface waters will occur utilizing a subset of wells in the Subbasin's groundwater elevation monitoring network selected for this purpose (see Chapter 4).

5.3.6.3 Identification of Undesirable Results

The undesirable result for depletions of interconnected surface water is considered to occur during GSP implementation when 25 percent of representative monitoring wells (i.e., 3 of 12 wells) fall below their minimum groundwater elevation thresholds for 24 consecutive months. The three wells must be the same subset of wells, not any combination of three wells. The subset of wells is not predetermined; rather, it is delineated only as wells collectively fall below their minimum threshold levels. Minimum thresholds were selected for each site by the process described in Section 5.4. Additional justification and information supporting the criteria used to define when and where the effects of the groundwater conditions cause undesirable results is provided in Appendix 5B.

These criteria were determined based on the evaluation of best available data pertaining to the Subbasin's specific conditions and characteristics, as described in the Plan Area and Groundwater Conditions sections of this GSP (Chapter 2 and Chapter 3, respectively), in conjunction with input and feedback from the public, local stakeholders and GSA members. The representative monitoring network was selected based on identification of existing monitoring wells with locations and depths considered appropriate for monitoring groundwater with potential to influence interconnected streams in the Subbasin. These interconnected streams are the Sacramento River, the Colusa Drain and portions of Stony Creek below Black Butte Dam. Monitoring wells with screened intervals less than 200 feet deep located within 2,000 feet to five miles of the interconnected streams were selected.[4] These wells are expected to provide the best available monitoring of groundwater levels that have an influence on the volume and rates of stream depletion. Wells closer than 2,000 feet were excluded based on the assumption that wells in too close a proximity to an interconnected stream may be directly influenced by stream stage. Wells deeper than 200 feet and farther than five miles from interconnected streams were excluded because pumping at greater depths or distances was assumed to cause capture from multiple sources (e.g., recharge zones, springs, ponded water, and other wells), which cannot be resolved with existing data and models. The GSAs selected these criteria based on the justification that minimum threshold exceedances at 25 percent or more of representative monitoring sites represent a significant impact, and that exceedance of these levels for 24 consecutive months or longer (indicating significant depletions of interconnected surface water through two consecutive periods of seasonal groundwater fluctuation) constitutes an impact that would potentially harm the long-term viability of affected beneficial uses and users. The criterion of 25

[4] For wells within a few thousand feet of a waterway, groundwater levels are expected to be controlled by the elevation of the connected surface water. For wells in intermediate locations between waterways and groundwater pumping centers, declines in water levels could also indicate current and future streamflow depletion (EDF, 2018).

percent or more of the representative monitoring wells dropping below their minimum thresholds for 24 consecutive months was regarded as an indicator of a significant, widespread problem representing undesirable results.

5.3.6.4 Potential Causes of Undesirable Results

Potential causes of undesirable results for depletions of interconnected surface water are likely tied to groundwater production, which could result in lowering of groundwater elevations in shallow aquifers near the connected streams. Increased groundwater production near interconnected streams may cause groundwater conditions that lead to undesirable results if this production changes the hydraulic gradient between the stream stage and the groundwater level. For the connected streams, an increase in the hydraulic gradient between the shallow groundwater and the stream bed may result in increases in the rate and volume of stream depletions.

5.3.6.5 Potential Effects of Undesirable Results

If depletions of interconnected surface waters reach levels indicating that undesirable results have occurred, the effects could potentially reduce the availability or change the timing of streamflow available for beneficial uses and users of surface water. Additionally, reduced streamflow could potentially reduce the availability of water to GDEs and riparian habitats. In addition, reduced stream flows can lead to increased water temperatures which can also potentially negatively impact certain species.

5.3.6.6 Evaluation of the Presence of Undesirable Results

Section 5.4 discusses how minimum thresholds were selected; more information on how the thresholds were established is also included in Appendix 5B, along with hydrographs of groundwater levels through 2020 for the depletions of interconnected surface waters monitoring points and the established depth of the minimum threshold for each monitoring site. Of the 12 monitoring sites, none were below the minimum threshold in the latest measurement in 2020, indicating that the Subbasin does not currently exceed the requirements for an undesirable result for depletions of interconnected surface water.

5.4 SUSTAINABILITY THRESHOLDS

Sustainability thresholds include minimum thresholds, measurable objectives, and interim milestones. Sustainability thresholds are described below by sustainability indicator. No management areas are identified for the Subbasin (see Chapter 3), and the same methodology for establishing sustainability thresholds was applied subbasin-wide for each applicable sustainability indicator. Potential effects of the selected sustainability thresholds on other neighboring subbasins are summarized at the end of this section.

Table 5-1 summarizes the sustainability thresholds for all applicable sustainability indicators in the Subbasin. Additional information and considerations are provided in the sections that follow.

Table 5-1. Summary of Sustainability Thresholds for All Sustainability Indicators Applicable to the Subbasin

Sustainability Indicator	Monitoring Network	Undesirable Result	Minimum Threshold (MT)	Measurable Objective (MO)
Chronic Lowering of Groundwater Levels	48 Representative Monitoring Network (RMN) wells monitored at least 2 to 3 times annually by DWR	25% (12 of 48) RMN wells fall continuously below their MT for 24 consecutive months	The lower of 50% of measured historical groundwater elevation range below the historical measured low elevation and the elevation corresponding to the 20th percentile of domestic well depths in the RMN well's Thiessen polygon, subject to interbasin coordination and consistency to ensure operational compatibility	Mean of the most recent 5 years of available groundwater elevation measurements up to 2020 subject to interbasin coordination and consistency to ensure operational compatibility; A fixed value, not a rolling average
Reduction in Groundwater Storage	48 RMN wells monitored at least 2 to 3 times annually by DWR (same as Groundwater Level monitoring network)	Use groundwater levels as proxy	Use groundwater levels as proxy	Use groundwater levels as proxy
Seawater Intrusion	Not applicable	Not applicable	Not applicable	Not applicable
Degraded Groundwater Quality	25 RMN wells monitored by others at variable intervals under existing State of California regulatory programs	Electrical conductivity (EC) in 25% (6 of 23) of the RMN wells exceeds the MT for two (2) consecutive years	The higher of EC of 900 microSiemens per centimeter (µS/cm) (the recommended California Secondary Maximum Contaminant Level) OR the pre-2015 historical maximum measured EC	EC of 700 µS/cm (corresponding to an agricultural water quality objective providing for no yield reduction for crops commonly grown in the Subbasin)
Land Subsidence	Existing Sacramento Valley Height Modernization Project (SVHMP) benchmarks (63 sites)	20% or more (13 of 63) monitoring sites (benchmarks) experience subsidence rates above the MT	0.5 feet per five years	0.25 feet per five years
Depletions of Interconnected Surface Waters	12 RMN wells less than 200 feet deep and between 2,000 feet and five miles of interconnected stream (Sacramento River, Colusa Drain, Stony Creek)	25% (3 of 12) RMN wells fall below their MT for 24 consecutive months	Ten (10) feet below the observed fall 2015 groundwater level (Fall 2015 level is the measured elevation recorded on the date closest to Oct 15)	Mean of last 5 years available groundwater elevation measurements subject to interbasin coordination and consistency to ensure operational compatibility; A fixed value, not a rolling average

5.4.1 Chronic Lowering of Groundwater Levels

As described in Section 5.3.1, chronic lowering of groundwater levels is considered to be significant and unreasonable when:

> *… it causes a significant and unreasonable reduction in the long-term viability of beneficial uses and users over the planning and implementation horizon of this GSP.*

Chronic lowering of groundwater levels may cause undesirable results when 25 percent of monitoring wells fall below the minimum threshold for 24 consecutive months. The following subsections describe the sustainability thresholds used to monitor and track the chronic lowering of groundwater levels. Appendix 5B provides additional information describing how the minimum thresholds and measurable objectives were established. Appendix 5C documents an economic analysis of the groundwater level minimum thresholds. That analysis generally supports setting minimum thresholds at the specified levels.

As described in Chapter 3, Basin Setting, the Subbasin has one principal aquifer, and therefore one groundwater level monitoring network. Thresholds have been established for all 48 groundwater level representative monitoring wells, as presented in Chapter 4, Monitoring Networks.

5.4.1.1 Minimum Thresholds

Minimum thresholds for the chronic lowering of groundwater levels were developed primarily by considering historical and current groundwater conditions, with lesser emphasis on projected future groundwater conditions. In general, groundwater levels during the 26-year historical period from 1990 through 2015 were used as the primary reference. This period includes relatively wet and dry periods including the back-to-back critically dry years of 2014 and 2015. Evaluation of historical and projected groundwater use in the Subbasin is further discussed in the Plan Area and Basin Setting chapters of this GSP (Chapter 2 and Chapter 3, respectively). Minimum threshold values were defined for individual representative monitoring wells as the groundwater level below which conditions may lead to undesirable results for beneficial uses and users in the vicinity of each well. The minimum threshold for each groundwater level representative monitoring well was calculated by utilizing a simple stepwise function. The minimum threshold is calculated by finding the deeper value of:

1. **20th percentile of shallowest domestic well depths in the monitoring well's Thiessen polygon**: Based on stakeholder input, it was determined that dewatering of domestic wells may be a potential undesirable result that could potentially be used to confirm the adequacy of the minimum threshold methodology. Domestic wells are generally shallower than agricultural and municipal wells and thus more sensitive to undesirable effects from decreases in groundwater elevations, such as well stranding. Additionally, the loss of a domestic well usually results in a loss of water for consumption, cooking, and sanitation purposes, which can often have substantial impacts on the users of the water and can be financially difficult for the well owner to mitigate. These potential adverse effects are addressed in the State's commitment to the Human Right to Water as codified in California Water Code Section 106.3. To protect the beneficial uses and users of groundwater from domestic wells, including supporting the Human Right to Water, groundwater levels need to remain higher than the bottom depth of domestic wells. Analysis of the DWR Well Completion Report (WCR) Database by the GSAs suggests that not all wells provided in the database are still active. Some of the wells included in the database are old enough that the usable lifespan of the well has been exceeded, some wells may not be constructed to meet current health standards (e.g., sanitary seals or other aspects of the well construction or

condition may be deficient), and some well depths and screen intervals would suggest that some wells have been dewatered prior to the implementation of SGMA (i.e., prior to January 1, 2015). The GSAs therefore determined, based on the analysis and feedback from the public and stakeholders, that protection of 100 percent of domestic wells in the WCR database was not reasonable or warranted, and that protection of 80 percent of wells in the WCR database was reasonable and acceptable. Consequently, it was determined that minimum threshold exceedances at more than 20 percent of domestic wells in the current version of the WCR database may constitute an undesirable result. This results in a minimum threshold that would protect 80 percent of domestic wells contained in the current version of the WCR database.

2. **50 percent of range below the historical low groundwater elevation**: To protect the conjunctive use of groundwater for agricultural production, groundwater levels must be able to fluctuate, lowering during droughts when groundwater pumping increases to augment reduced surface water availability, and increasing during years when surface water is available for recharge. For agricultural conjunctive use, the effects of declining groundwater levels are expected to be significant and unreasonable when groundwater levels drop below the lowest historical groundwater elevation by more than 50 percent of the historical range. After an analysis of available historical data, and with considerations of groundwater conditions, the GSAs determined that 50 percent of the historical range below the historical low groundwater level provided adequate operational flexibility at each representative monitoring well site. Consequently, minimum threshold exceedances of this level may constitute an undesirable result.

Appendices 5B and 5C provide additional information on the setting and evaluation of the minimum thresholds. As documented in Appendices 5B and 5C, for the Subbasin as a whole, approximately 46 percent of the domestic wells in the WCR database are shallower than the pre-2015 historical groundwater levels as defined by the groundwater level representative monitoring network. Many of these shallow wells may no longer be used, or they may have been deepened because they would have otherwise been dry at times prior to 2015. Nevertheless, all wells in the WCR database were considered in the calculation of the groundwater level minimum thresholds. Including these shallow, potentially unused or deepened wells in the analysis of well completions depths resulted in groundwater level minimum thresholds that are shallower than they would have been if the wells had been excluded.

Setting minimum thresholds using this methodology is protective of beneficial users and uses of groundwater, including agricultural, municipal, environmental and domestic uses in the Subbasin. The minimum thresholds align with the State's Human Right to Water policy by supporting the ability of drinking water beneficial users, including DACs, SDACs and Tribes, to access safe, clean, and affordable water for human consumption, cooking, and sanitary purposes. The GSAs chose this methodology for calculating the minimum threshold to balance the needs of multiple beneficial uses and users of the groundwater by allowing for adequate flexibility to compensate for drought periods while potentially protecting approximately 80 percent of nearby domestic wells, therefore avoiding undesirable results. Additionally, anecdotal evidence provided by the GSA member stakeholders suggests that groundwater levels seen in recent drought periods did not result in significant and unreasonable Subbasin-wide impacts to beneficial uses and users. The GSAs therefore consider the 2015 historical low groundwater elevation to be protective of current and future beneficial uses and users. In addition, this methodology includes consideration of the spatial location of each monitoring site and variable conditions (such as hydrogeological conditions or nearby infrastructure) across the Subbasin.

Figure 5-1 is a sample hydrograph with the calculated thresholds plotted, including the minimum threshold, in relation to historical groundwater levels. Similar hydrographs for all wells in the representative monitoring networks are included in Appendix 5B.

Table 5-2 presents the minimum thresholds for representative monitoring wells in the chronic lowering of groundwater levels monitoring network in the Subbasin. Additional information on the calculation of minimum thresholds is provided in Appendix 5B.

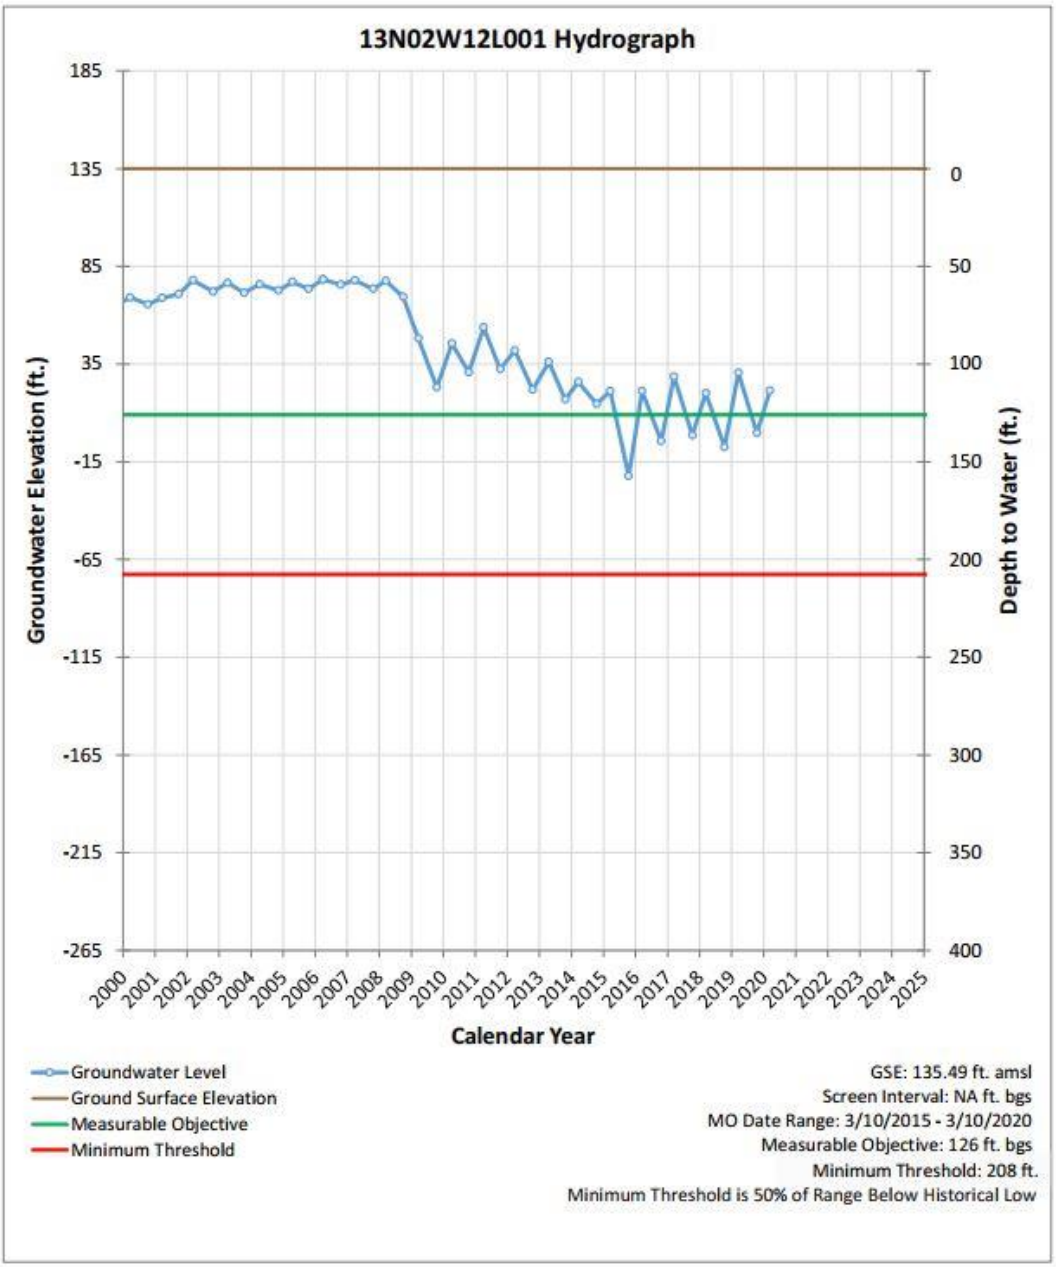

Figure 5-1. Hydrograph, Measurable Objective and Minimum Threshold for Groundwater Monitoring Well 13N02W12L001

5.4.1.1.1 Potential Effects on Other Sustainability Indicators

Groundwater levels have the potential to impact all other sustainability indicators applicable to the Subbasin. These potential effects are described below by sustainability indicator.

- **Reduction of Groundwater Storage:** Chronic lowering of groundwater levels is directly related to reduction of groundwater storage, as changes in groundwater levels are indicative of changes in groundwater storage in the Subbasin. As described in Section 5.4.2.1, the minimum thresholds for groundwater levels will effectively avoid undesirable results for reduction of groundwater storage since undesirable results related to chronic lowering of groundwater levels are expected to occur before the Subbasin would experience significant and unreasonable impacts related to groundwater storage, predominantly as a result of the large volume of groundwater in storage in the Subbasin.
- **Degraded Water Quality:** Chronic lowering of groundwater levels can impact groundwater quality by affecting the direction and rate of groundwater flows, potentially mobilizing saline water, and by affecting the location and characteristics of groundwater recharge or discharge, impacting the concentration of water quality parameters. The minimum thresholds determined for groundwater levels are not expected to contribute to undesirable results for degraded water quality, as they are protective of existing domestic well depths and historical groundwater elevations. Evaluation of 25 groundwater quality representative monitoring sites indicates that the Subbasins does not currently have undesirable results for degraded water quality. Implementation of the GSP is expected to maintain groundwater levels at the average of the last five years of measured groundwater level data (see Section 5.4.1.2). Given the similar trends in historical, current, and projected future groundwater levels, groundwater level sustainable management criteria are expected to support the maintenance of the generally good groundwater quality of the Subbasin.
- **Inelastic Land Subsidence:** Chronic lowering of groundwater levels can potentially cause inelastic land subsidence if it results in compaction of compressible clays in the subsurface. The minimum thresholds for groundwater levels are not expected to contribute to undesirable results for inelastic land subsidence, as they are protective of a range around historical groundwater elevations. Minimum thresholds for land subsidence have also been determined based on consideration of historical subsidence data between 2006-2017, providing flexibility around that range. Evaluation of 63 subsidence monitoring sites indicate that none were below the minimum threshold in the latest measurement from 2017, indicating that historical groundwater levels have not contributed to undesirable results for inelastic land subsidence.
- **Depletions of Interconnected Surface Water:** Reductions in groundwater levels can impact the rate and volume of stream depletions in interconnected streams and reduce the amount of groundwater available for GDEs. The representative groundwater level monitoring network used for monitoring the potential for depletions in interconnected streams is comprised of a selected, collocated subset of the representative monitoring network used for monitoring reductions in groundwater levels. For these selected wells, the interconnected stream depletions sustainable management criteria are more restrictive than the groundwater levels sustainable management criteria and take precedence over them. Therefore, coordinated implementation of the groundwater levels and the depletions of interconnected surface water sustainable management criteria are expected to be protective of interconnected surface waters and GDEs.

5.4.1.2 Measurable Objectives

Measurable objectives are quantitative goals that reflect desired Subbasin conditions and allow the Subbasin to achieve and maintain its sustainability goal. The measurable objectives for chronic lowering of groundwater levels in the Subbasin are shown in Table 5-2. The methodology for establishing these measurable objectives was determined by the Subbasin GSAs, including their respective Technical Advisory Committees, and bases the measurable objectives on the average of the last five years of measured groundwater level data. This method is generally representative of drought and recovery conditions within the Subbasin, as most wells utilize data collected between 2015 and 2020. These measurable objectives are expected to support achievement of the GSP sustainability goal and maintenance of groundwater sustainability over the planning and implementation horizon.

5.4.1.3 Margin of Operational Flexibility

The margin of operational flexibility is the difference between the measurable objective and the minimum threshold for each well. The margin of operational flexibility is intended to provide adequate flexibility to allow for increased groundwater production during drought years with recovery during normal or wet years, accounting for uncertainty in each. This ensures undesirable results are not triggered due to drought conditions that the GSAs cannot control, while allowing for adequate local recovery of groundwater levels after those drought periods, therefore maintaining sustainability in the long term. Because the measurable objective and minimum threshold at each well take into consideration the historical water budgets, seasonal and long-term trends, and periods of drought, the margin of operational flexibility also accounts for these factors.

The margins of operational flexibility for chronic lowering of groundwater levels are shown in Table 5-2.

5.4.1.4 Interim Milestones

Interim milestones are intended to provide a glidepath towards sustainability over the implementation horizon by providing progressive targets for groundwater levels every five years after GSP submittal. After sustainability is reached, interim milestones are not required and subbasins are managed according to the measurable objective (defined in the GSP Emergency Regulations as "…specific, quantifiable goals for the maintenance or improvement of specified groundwater conditions…to achieve the sustainability goal for the basin"). For subbasins that are already sustainable (such as the Subbasin), interim milestones are intended to provide numerical metrics for GSAs to track progress toward meeting the subbasin's sustainability goal and ensuring that the subbasin remains sustainable. Because the minimum thresholds and measurable objectives for chronic lowering of groundwater levels were established to support Subbasin sustainability, the interim milestones were established to maintain water levels in the Subbasin's margin of operational flexibility as established by the minimum thresholds and measurable objectives. The interim milestones for chronic lowering of groundwater levels are consistent with the measurable objectives, as shown in Table 5-2.

SWN = State Well Number
CASGEM ID = California Statewide Groundwater Elevation Monitoring Identification Code
GWE = groundwater elevation
DTW = depth to water
ft = feet
amsl = above mean sea level
bgs = below ground surface
Minimum Thresholds were calculated as either (a) the 20th percentile of domestic well depth near the monitoring well, or (b) 50 percent of the measured water level range below the historical low within the monitoring well.

5.4.2 Reduction of Groundwater Storage

The undesirable result for the reduction of groundwater storage is:

> *…a result that would cause significant and unreasonable reduction in the long-term viability of beneficial uses and users over the planning and implementation horizon of this GSP.*

The undesirable result for the reduction of groundwater storage is monitored by proxy using groundwater levels. The thresholds set for the reduction of groundwater storage have been established so that when 25 percent of monitoring wells fall below the minimum threshold for 24 consecutive months, an undesirable result is detected. The following subsections describe the sustainability thresholds used for the reduction of groundwater storage.

5.4.2.1 Proxy Monitoring

Monitoring for a reduction of groundwater storage in the Subbasin uses groundwater levels as a proxy for determining sustainability, as permitted by 23 CCR §354.28(d). As described above, any benefits to groundwater storage are expected to coincide with groundwater level management.

The limiting factor to storage use is existing well infrastructure (depth of wells) and near surface conditions, not the volume of groundwater in storage (see Section 5.3.2.2). Therefore, the established groundwater levels minimum thresholds are protective against significant and unreasonable changes in groundwater storage. Minimum thresholds for groundwater levels will effectively avoid undesirable results for reduction of groundwater storage since undesirable results related to chronic lowering of groundwater levels would occur before the Subbasin would experience significant and unreasonable impacts related to groundwater storage, predominantly as a result of the large volume of groundwater in storage in the Subbasin (see Section 5.3.2.2). Therefore, by setting minimum thresholds for groundwater levels, storage is also effectively managed and the use of groundwater levels as a proxy metric for the groundwater storage sustainability indicator is appropriate. Minimum thresholds for groundwater levels, and thus for groundwater storage, are calculated with consideration of historical trends, water year type, and historical and projected groundwater use within the Subbasin, and support sustainable operation, as described in Section 5.2.

5.4.3 Seawater Intrusion

Seawater intrusion is not an applicable sustainability indicator because seawater intrusion is not present and is not likely to occur in the Subbasin due to the distance between the Subbasin and the Pacific Ocean, bays, deltas, or inlets.

5.4.4 Degraded Water Quality

The undesirable result for degraded water quality is described as:

> *Significant and unreasonable degradation of water quality that occurs when GSP projects or management actions cause an increase in the concentration of applicable constituents of concern in groundwater supply wells that lead to adverse impacts on beneficial uses or users of groundwater.*

The thresholds set for degraded water quality have been established so that when 25 percent of representative monitoring sites exceed the minimum threshold for two consecutive years, an undesirable result is detected. The following subsections describe the sustainability thresholds used for degraded water quality. The foregoing sustainability thresholds were established with the GSAs' understanding that additional new or existing wells will need to be added to the monitoring network over time. Additionally, the GSAs acknowledge that the sustainability thresholds will need to be reviewed and evaluated, and potentially refined, as additional wells are added, and additional data is collected and analyzed.

Thresholds have been established for all 25 groundwater quality representative wells, as presented in Appendix 5D. Management areas were not used in the calculations of any thresholds.

5.4.4.1 Minimum Thresholds

The minimum threshold for degraded water quality has been established as the higher of either 900 microSiemens per centimeter (μS/cm) EC, which is consistent with the recommended California Secondary Maximum Contaminant Level (SMCL), or the pre-2015 historical maximum recorded EC value.[5] In developing the minimum thresholds for groundwater quality, beneficial uses of groundwater as a drinking water supply and as an agricultural supply were considered. The potential adverse effects to drinking water addressed in the State's commitment to Human Right to Water as codified in California Water Code Section 106.3 were considered. Setting minimum thresholds using this methodology is protective of beneficial uses and users of groundwater, including agricultural, municipal, and domestic uses in the Subbasin.

The minimum threshold for degraded water quality is calculated to be at an EC level that allows for adequate flexibility within the pre-2015 historical maximum EC level, to compensate for changing groundwater conditions during drought periods, while protecting SMCLs established for aesthetic reasons, such as taste, odor, and color. It is important to note that SMCLs are not based on public health concerns and established to address other non-health related concerns. Exceedance of these minimum threshold values may therefore cause undesirable results for domestic well users related to non-health related concerns at wells where the pre-2015 historical maximum EC level did not exceed the SMCL. At wells where the pre-2015 historical maximum EC level exceeded the recommended California SMCL, groundwater management through coordination with existing regulatory and monitoring programs with respect to this minimum threshold will ensure that degradation of groundwater quality does not exceed historical levels as a result of Subbasin groundwater management activities pursuant to the GSP.

5.4.4.2 Measurable Objectives

The measurable objective for degraded water quality is 700 μS/cm EC, which is consistent with the agricultural water quality objective providing for no yield reduction for crops commonly grown in the Subbasin. The measurable objective for degraded water quality therefore supports ongoing sustainability by protecting water quality within levels that are suitable for drinking water use and agricultural water use, among other beneficial uses. Measurable objectives have not been determined for other water quality constituents.

[5] Consistent with SGMA, the GSP "is not required to address undesirable results that occurred before, and have not been corrected by, January 1, 2015" (Water Code Section 10727.2 (b) (4)).

5.4.4.3 Margin of Operational Flexibility

The margin of operational flexibility for degraded water quality is 200 μS/cm EC (the difference between the measurable objective and minimum threshold). The margin of operational flexibility is intended to provide adequate flexibility to allow for changes in groundwater quality constituent concentrations during various subbasin conditions, such as drought years. This ensures undesirable results are not triggered due to temporary fluctuations in conditions that are anticipated to occur during the implementation horizon, accounting for uncertainty in future conditions. Because the measurable objective and minimum threshold at each site take into consideration historical water quality characteristics, the margin of operational flexibility also accounts for these factors.

5.4.4.4 Interim Milestones

Interim milestones are intended to provide a glidepath towards sustainability over the implementation horizon by providing progressive targets for groundwater quality every five years after GSP submittal. After sustainability is reached, interim milestones are not required and basins are managed according to the measurable objectives (defined in the GSP Emergency Regulations as "…specific, quantifiable goals for the maintenance or improvement of specified groundwater conditions…to achieve the sustainability goal for the basin"). For basins that are already sustainable (such as the Subbasin), interim milestones are intended to provide numerical metrics for GSAs to track progress toward meeting the Subbasin's sustainability goal and ensuring that the Subbasin remains sustainable. Because the minimum thresholds and measurable objectives for degraded water quality were established to support Subbasin sustainability, the interim milestones were established to maintain water quality constituent levels in the Subbasin's margin of operational flexibility as established by the minimum thresholds and measurable objectives. The interim milestone for degraded water quality is consistent with the measurable objective, and is set at 700 μS/cm. This interim milestone is also consistent with the GSAs' role in working with the State of California to guarantee the Human Right to Water to the residents of the Subbasin. Additional discussion of the Human Right to Water and its relationship to the GSAs and the GSP is provided in Chapter 2.

5.4.5 Inelastic Land Subsidence

The undesirable result for inelastic land subsidence is:

> *…a result due to groundwater extraction that would cause significant and unreasonable impacts to critical infrastructure over the planning and implementation horizon of this GSP.*

The undesirable result for inelastic land subsidence is monitored by DWR extensometers, continuously operating global positioning system (CGPS) benchmarks, and traditional benchmarks. The thresholds set for inelastic land subsidence have been established so that when 20 percent of representative monitoring locations (i.e., 13 of 63 locations) exceed their minimum thresholds, an undesirable result is detected. The 13 locations must be the same subset of locations, not any combination of 13 locations. Management areas were not used in establishing or calculating thresholds.

5.4.5.1 Minimum Thresholds

Minimum thresholds for inelastic land subsidence were determined based on consideration of historical subsidence using data available from the Sacramento Valley Height Modernization Project. Minimum thresholds were calculated as the maximum rate of subsidence, described below, above which conditions could collectively generate undesirable results in the Subbasin. While the sensitivity of local infrastructure to land subsidence is not well understood at this time, the Subbasin has extensive networks of pipelines and

open canals and drains owned by various surface water suppliers that are used to convey irrigation and drain water. These networks are likely the existing infrastructure most sensitive to land subsidence. A study is proposed in Chapter 7 that would evaluate the sensitivity of local infrastructure to potential subsidence in the Subbasin. Should additional information be developed on the vulnerability of this infrastructure to subsidence, these minimum thresholds may be refined. The GSAs will continue monitoring to continue to improve subbasin understanding during GSP implementation. Refinement of minimum thresholds and any improved understanding of subsidence in the subbasin will be reported in annual reports.

The minimum threshold for this sustainability indicator has been set at 0.5 feet per five years (6 inches).

The sustainable management criteria will be reviewed and adjusted to account for potential changes in subsidence rates brought about by implementation of projects and management actions and future groundwater resource development. The extent of subsidence-prone areas, which may be underlain by sediments that have greater susceptibility to subsidence due to groundwater withdrawal, will continue to be delineated as data gaps are filled through the ongoing subsidence monitoring programs (using data from benchmarks, extensometers and InSAR surveys) and subsidence-prone sediments are characterized during drilling for well construction, extensometer installation or other subsurface investigations needed for the development of specific projects and management actions.

Managing groundwater conditions in the Subbasin to avoid exceedance of the rate of inelastic subsidence established by the minimum threshold is considered unlikely to cause a significant and unreasonable reduction in the viability of the use of critical infrastructure over the planning and implementation horizon of this GSP.

5.4.5.2 Measurable Objectives

The measurable objective for inelastic land subsidence is set at 0.25 feet (3 inches) of subsidence per five years at each site. This rate, in conjunction with sustainable extractions of groundwater over the implementation horizon, is believed to provide enough operational flexibility during drought periods while protecting infrastructure and beneficial users and uses in the Subbasin.

The selected minimum threshold rate of 0.5 feet per five years allows for possible future acceleration of land subsidence. However, because the measurable objective is set at 0.25 feet per five years, projects and management actions will be implemented before the minimum threshold rates are reached.

DWR reports that the probable error in the subsidence values reported for the monitoring benchmarks is ±0.17 feet, meaning that for any reported value, the actual subsidence value is likely to fall in a range between plus or minus 0.17 feet of the reported value. The selected measurable objective subsidence rate of 0.25 feet per five years is deliberately greater than the reported probable error of ±0.17 feet as a means of avoiding false exceedance of the measurable objective.

5.4.5.3 Margin of Operational Flexibility

The land subsidence margin of operational flexibility is 0.25 feet per five years. This value is more than the potential error (±0.17 feet) in the benchmark measurements, allowing for a range of allowable subsidence between the minimum thresholds and a measurable objective that is set within the measurable range (outside the typical range of measurement error and uncertainty) to allow for management if the measurable objective were to be exceeded. Because the measurable objective and minimum threshold at each site take into consideration historical data from the Sacramento Valley Height Modernization Project, the margin of operational flexibility also accounts for these data.

5.4.5.4 Interim Milestones

Interim milestones are intended to provide a glidepath towards sustainability over the implementation horizon by providing progressive targets for subsidence rates every five years after GSP submittal. After sustainability is reached, interim milestones are not required and basins are managed according to the measurable objectives (defined in the GSP Emergency Regulations as "…specific, quantifiable goals for the maintenance or improvement of specified groundwater conditions…to achieve the sustainability goal for the basin"). For subbasins that are already sustainable (such as the Subbasin), interim milestones are intended to provide numerical metrics for GSAs to track progress toward meeting the subbasin's sustainability goal and ensuring that the subbasin remains sustainable. Because the minimum thresholds and measurable objectives for inelastic land subsidence were established to support Subbasin sustainability, the interim milestones are to ensure subsidence rates remain in the Subbasin's margin of operational flexibility as established by the minimum thresholds and measurable objectives. The interim milestones for land subsidence are consistent with the measurable objectives and are set at 0.25 feet (3 inches) of subsidence per five years at each site.

5.4.6 Depletions of Interconnected Surface Water

The undesirable result for depletions of interconnected surface water is:

> *…a result that causes significant and unreasonable adverse effects on beneficial uses and users of interconnected surface water within the Subbasin over the planning and implementation horizon of this GSP.*

The undesirable result for depletions of interconnected surface water is monitored by proxy using groundwater levels. The thresholds set for depletions of interconnected surface water have been established so that when 25 percent of monitoring wells (i.e., 3 of 12 wells) fall below the minimum threshold for 24 consecutive months, an undesirable result is detected. The following subsections describe the sustainability thresholds used for depletions of interconnected surface water. Additional information describing how the minimum thresholds and measurable objectives were established is also included in Appendix 5B.

The foregoing sustainable management criteria were established with the GSAs' understanding that additional new or existing wells will need to be added to the monitoring network over time. Additionally, the GSAs acknowledge that the sustainability thresholds will need to be reviewed and evaluated, and potentially refined, as additional wells are added, and additional data is collected and analyzed.

5.4.6.1 Minimum Thresholds

Minimum thresholds for depletions of interconnected surface waters were determined based on evaluation of historical data from the monitoring network for interconnected surface water, which is composed of 12 shallow groundwater wells located proximate to interconnected streams in the Subbasin. The minimum thresholds set at these sites for assessing impacts to interconnected surface waters were calculated by finding the groundwater elevations in Fall of 2015 and adding 10 feet to that depth. Measurements selected for Fall 2015 were found by selecting measurements closest to October 15, 2015, considered to the be period of lowest groundwater elevations during the last drought based on review of historical groundwater levels and hydrologic data. All wells recorded measurements within three days of this date, providing a relative "snapshot" of groundwater conditions during this time. Management areas were not used in calculating the minimum threshold, or any other threshold for depletions of interconnected surface waters. Figure 5-2 provides an example hydrograph with all depletions of interconnected surface water thresholds plotted. Minimum thresholds for interconnected surface water are provided in Table 5-3. Additional

information on the calculation of minimum thresholds is provided in Appendix 5B along with hydrographs for all representative monitoring wells in the interconnected surface water monitoring network showing the site-specific minimum thresholds. The minimum threshold was selected such that groundwater levels near interconnected surface water courses would be protective of the beneficial use and users of shallower groundwater near streams and rivers, including those of shallower domestic users and potential groundwater dependent ecosystems. Levels from Fall 2015 represent conditions during a drought period but are generally believed to have still protected beneficial users at that time and therefore avoid undesirable results. The addition of 10 feet to the Fall 2015 groundwater depth to water is intended to provide an appropriate margin of operational flexibility in the future during GSP implementation based on recommendations made through discussion with the GSAs and stakeholders.

Consideration for the location, quantity, and timing of depletions of interconnected surface water along the primary waterways in the Subbasin is described in Chapter 3 and Appendix 3D. Volumes of projected (future) streamflow depletion during the GSP implementation period and sustainability monitoring horizon were assessed using the C2VSimFG-Colusa model, the best available information to support quantification of streamflow depletion. Documentation of this model is provided in Appendix 3D. Results of these analyses indicate that streamflow gain and loss do not appear to be strongly affected by increases in groundwater pumping needed to satisfy increased irrigation requirements resulting from potential future climate change, or by recharge projects than could be implemented in the Subbasin. Therefore, it is concluded, on a provisional basis, that the effects of groundwater management in the Subbasin will not have significant and unreasonable effects on beneficial uses and users of surface water.

While information and understanding of interconnected surface waters is limited, groundwater levels that exceed the minimum threshold in the future for an extended period of time could impact the beneficial uses and users of shallow groundwater by dewatering domestic wells and limiting resources for groundwater dependent ecosystems. However, as additional data are collected during GSP implementation, the understanding of interconnected surface waters may change and the threshold calculations revised to reflect a better understanding of this complex interaction and the Subbasin's unique conditions.

Special considerations were made in establishing the minimum threshold for monitoring well 21N02W36A002, which experienced drawdowns over an approximately eight-month period in 2015 and 2016. A deeper measurement recorded on October 20, 2015 was selected for the minimum threshold calculation for this well to better represent local conditions at that time, rather than adding an additional 10 feet (in order to be more protective). Figure 5-3 provides the depletions of interconnected surface water hydrograph with applicable thresholds plotted for well 21N02W36A002.

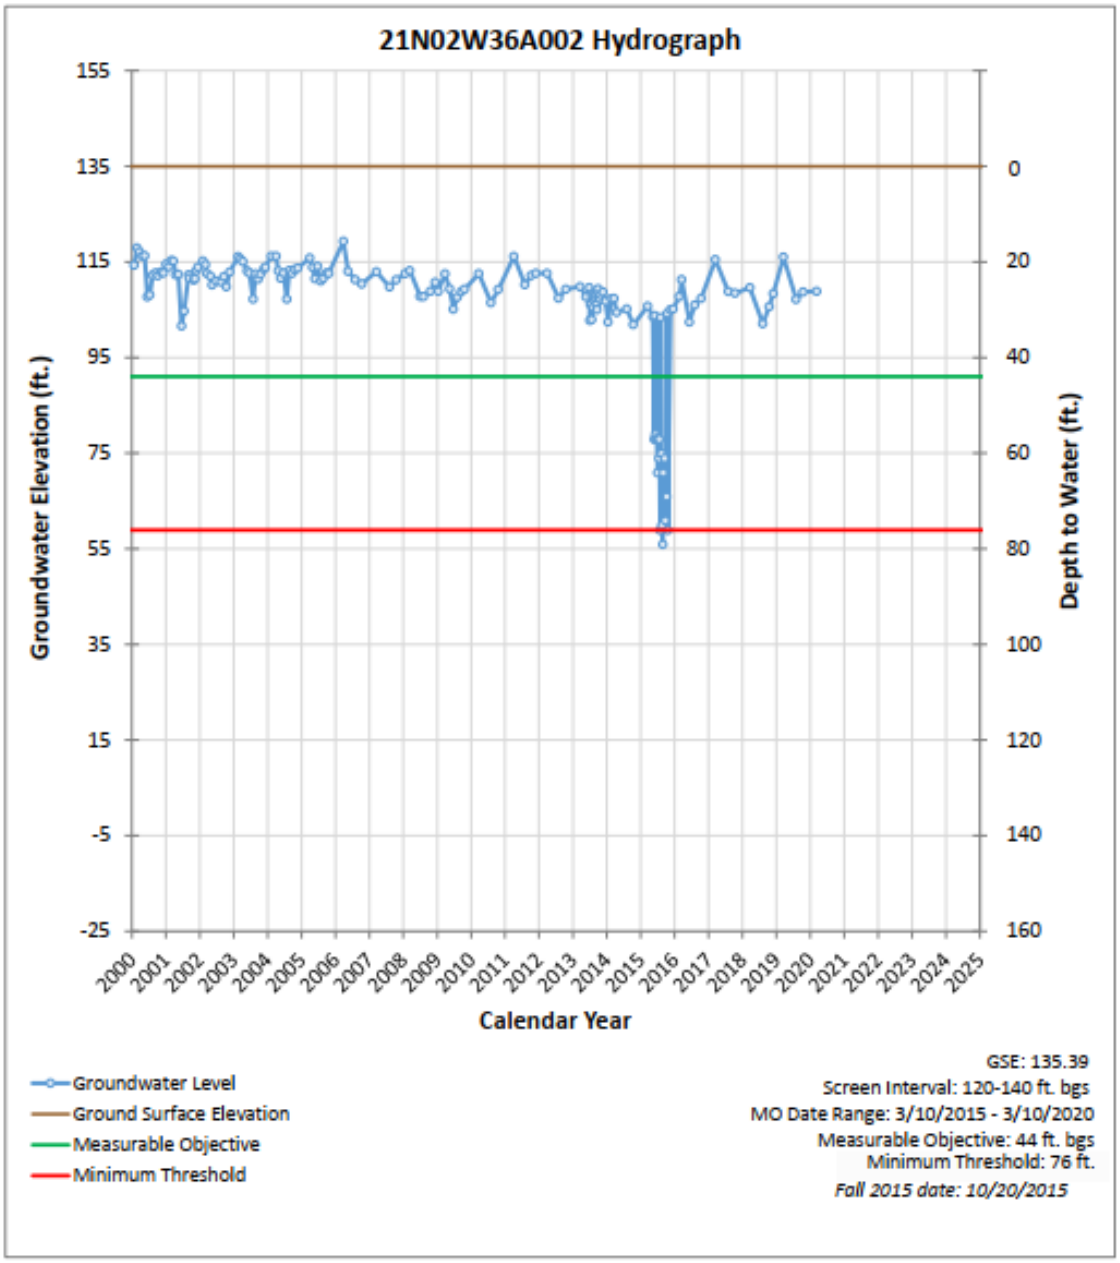

Figure 5-3. Hydrograph, Measurable Objective and Minimum Threshold for Interconnected Surface Water Monitoring Well 21N02W36A002

5.4.6.2 Measurable Objectives

Measurable objectives for depletions of interconnected surface water at representative monitoring locations are shown in Table 5-3. The measurable objective was calculated for each well using the average of the most recent five years of available groundwater level measurements. This methodology is consistent with that used in setting the measurable objectives for the chronic lowering of groundwater levels measurable objectives. This method is generally representative of drought and recovery conditions within the Subbasin as most wells utilize data recorded between 2015 and 2020. It is also consistent with the measurable objective calculation method for groundwater levels sustainability indicator.

5.4.6.3 Margin of Operational Flexibility

The margin of operational flexibility is the difference between the measurable objective and the minimum threshold for each well. The margin of operational flexibility is intended to provide adequate flexibility to allow for increased groundwater production during drought years with recovery during normal or wet years, accounting for uncertainty in each. This ensures undesirable results are not triggered due to drought conditions that the GSAs cannot control while allowing for adequate local recovery of groundwater levels after those drought periods, thereby maintaining sustainability in the long term. The margins of operational flexibility for depletions of interconnected surface water are shown in Table 5-3. The methodology used to set these margins of operational flexibility is consistent with that used for setting the margins of operational flexibility for the chronic lowering of groundwater levels. Because the measurable objective and minimum threshold at each well take into consideration the historical water budgets, seasonal and long-term trends, and periods of drought, the margin of operational flexibility also accounts for these factors.

5.4.6.4 Interim Milestones

Interim milestones are intended to provide a glidepath towards sustainability over the implementation horizon by providing progressive targets for groundwater levels every five years after GSP submittal. After sustainability is reached, interim milestones are not required and subbasins are managed according to the measurable objectives (defined in the GSP Emergency Regulations as "…specific, quantifiable goals for the maintenance or improvement of specified groundwater conditions…to achieve the sustainability goal for the basin"). For subbasins that are already sustainable (such as the Subbasin), interim milestones are intended to provide numerical metrics for GSAs to track progress toward meeting the subbasin's sustainability goal and ensuring that the subbasin remains sustainable. Because the minimum thresholds and measurable objectives for the depletions of interconnected surface waters were developed to support Subbasin sustainability, the interim milestones were established to maintain water levels within the Subbasin's margin of operational flexibility as set by the minimum thresholds and measurable objectives. The interim milestones for depletions of interconnected surface water are shown in Table 5-3. The methodology used to set these interim milestones is consistent with that used for setting the interim milestones for the chronic lowering of groundwater levels.

5.4.7 Effects of Minimum Thresholds on Adjacent Subbasins

The minimum thresholds described in the preceding sections have been selected and evaluated to ascertain that they do not cause undesirable results in adjacent subbasins, and that they do not affect the ability of adjacent subbasins to achieve their groundwater sustainability goals.

Based on groundwater model results, sustainable management of the Subbasin under SGMA is not expected to significantly affect the net groundwater exchange with surrounding subbasins. Table 3-9 in Chapter 3, *Basin Setting*, summarizes the average annual groundwater system inflows and outflows over the historical, current, and projected (future) water budget periods. Over all scenarios, subsurface inflows and subsurface outflows to and from the Subbasin generally remain unchanged. Total subsurface inflows are approximately 200 to 209 thousand acre-feet per year (taf/yr), on average, while total subsurface outflows are approximately 146 to 149 taf/yr, on average. The variations between scenarios are considered to be within the uncertainty of the model, indicating no significant change in the net groundwater exchange with surrounding subbasins.

Likewise, groundwater model results do not suggest that sustainable management of the Subbasin will significantly affect the net depletions of interconnected surface water along waterways that flow through the Subbasin. As summarized in Appendix 3D, streamflow gain and loss along the Sacramento River, Stony Creek, and the Colusa Drain do not appear to be strongly affected by increases in groundwater pumping needed to satisfy increased irrigation requirements resulting from potential future climate change, or by recharge projects than could be implemented in the Subbasin. Therefore, it is concluded, on a provisional basis, that the effects of groundwater management in the Subbasin will not have significant and unreasonable effects on beneficial uses and users of interconnected surface water.

The Subbasin GSAs and the GSAs in the adjacent subbasins coordinated their approach to developing sustainable management criteria during development of their respective GSPs and will continue to coordinate their efforts during plan implementation. The Subbasin GSAs and the GSAs in the adjacent subbasins developed similar sustainable management criteria for degraded water quality and inelastic land subsidence. Because of the similarity in these sustainable management criteria across the subbasins, and the ongoing interbasin coordination efforts, it is anticipated that the minimum thresholds established in the Subbasin for degraded water quality and inelastic land subsidence will help avoid undesirable results for the Subbasin and the adjacent subbasins. Section 7.1.2 describes implementation activities focused on interbasin coordination for the degraded water quality, inelastic land subsidence, and other sustainability indicators.

The GSAs will continue to monitor the effects of groundwater management according to the sustainability thresholds described in this chapter throughout GSP implementation, including those effects on adjacent Subbasins. The CGA, GGA, and neighboring GSAs have coordinated throughout GSP development and will continue to coordinate and share technical data during GSP implementation. Ongoing and planned coordination activities are described further in Chapter 7 of the GSP.

CHAPTER 6
Projects and Management Actions

This chapter describes the projects and management actions (PMAs) that are ongoing or planned for implementation by agencies in the Subbasin, and potential PMAs in various stages of development. In accordance with 23 CCR §354.44, PMAs were developed to achieve the Subbasin sustainability goal by 2042 and avoid undesirable results over the GSP planning and implementation horizon. Projects generally refer to structural features whereas management actions are typically non-structural programs or policies designed to support sustainable groundwater management.

6.1 PROJECTS AND MANAGEMENT ACTIONS DEVELOPMENT APPROACH

6.1.1 Overview

PMAs developed for the Subbasin are described in this chapter in accordance with 23 CCR §354.44. PMAs were formulated primarily to address possible future changes in Subbasin conditions that could cause undesirable results over the long term, and in the near term, to address effects of recent historical (2014-2015) and current (2020-2021) drought conditions that pose challenges to groundwater management in the northwest and southwest portions of the Subbasin respectively.

PMA development and implementation in the Subbasin applies an adaptive management approach informed by continued monitoring of groundwater conditions using the monitoring network and methods described in Chapter 4. The adaptive management approach is consistent with SGMA (CWC §10728.2, §10733.8) and with DWR recommendations.

Recognizing the GSP data gaps and uncertainties in the basin setting (per 23 CCR §354.44(d)), and recognizing known areas with declining groundwater levels, the adaptive management approach in the Subbasin includes:

- Planned PMAs that are expected to be implemented primarily to address current, localized declining groundwater levels in the Orland and Arbuckle areas. This includes five groundwater recharge projects that are currently moving toward implementation, including three substantial in-lieu recharge projects, one multi-benefit managed aquifer recharge project, and another direct recharge pilot project. At full implementation, planned PMAs are expected to provide more than 80 thousand acre-feet per year (taf/yr) in combined gross average annual benefits that will offset groundwater pumping and support groundwater sustainability in the Subbasin.
- A portfolio of other ongoing and potential PMAs to achieve and maintain long-term sustainable groundwater management across the Subbasin. Potential PMAs will be further evaluated and implemented if established measurable objectives (MOs) cannot be maintained and minimum thresholds (MTs) are being approached.

In the adaptive management approach, GSAs will continue monitoring sustainability indicators throughout the GSP planning and implementation horizon and will address any challenges related to maintaining groundwater sustainability by scaling and implementing PMAs in a targeted and proportional manner in accordance with the needs of the Subbasin. Ongoing management of the Subbasin under this GSP is planned to achieve and maintain sustainability and respond to unforeseen future conditions that may impact sustainable operation of the Subbasin. If the planned and ongoing PMAs are insufficient to

achieve and maintain sustainable groundwater conditions, additional PMAs will be considered and implemented. Any changes to the PMAs will be described in GSP annual reports and periodic evaluations.

Per 23 CCR § 354.44(b)(9), PMAs described in this GSP are expected to manage the balance of groundwater extractions and recharge to ensure that lowering of groundwater levels or depletion of supply during periods of drought is offset by increases in groundwater levels or storage in other years. In particular, PMAs that provide in-lieu and direct recharge benefits in the Arbuckle areas are planned to increase the use and recharge of available surface water supplies during wetter years, offsetting any potential increases in groundwater pumping during drought when curtailments of surface water supplies may occur. The expected recharge benefits of these PMAs are described in Section 6.3. The GSAs' extensive portfolio of additional PMAs will be informed by continued monitoring of groundwater conditions and implemented, as needed, to achieve and maintain long-term sustainable groundwater management.

6.1.2 Evaluation of Projected Future Conditions to Develop Projects and Management Actions

The possible future changes in Subbasin conditions without PMAs were assessed through comparison of the projected future water budget conditions without climate change and projected future water budget conditions adjusted by 2070 central tendency (CT) climate change factors (see Chapter 3 for additional water budget information).

Table 6-1 provides a comparison of key water budget parameters considered in formulation of PMAs. All water budget quantities are expressed in average annual volumes of taf/yr over the 50-year model simulation periods. An effect of climate change on Subbasin hydrology is a nearly 7 percent increase in agricultural evapotranspiration (ET), from 1,494 taf/yr to 1,596 taf/yr. A portion of this increased agricultural ET will be met by an approximate 6 percent increase in precipitation expected to result from 2070 CT climate change. The remaining increase in agricultural ET is expected to be met by increased groundwater pumping since projected future surface water diversions into the Subbasin from the Sacramento River and Stony Creek are not expected to be affected by climate change[1]. Pumping is projected to increase by 58 taf/yr, a nearly 13 percent increase from the projected future conditions without climate change.

Under projected future conditions without climate change, groundwater storage is forecast to increase modestly, at an average rate of 0.6 taf/yr. With 2070 CT climate change and the associated increase in groundwater pumping to meet increased irrigation demands, groundwater storage is projected to decrease at a rate of 7.3 taf/yr. This net change of -7.9 taf/yr is 0.8 percent of the approximately one million acre-feet (maf) that flow into and out of the Subbasin groundwater system annually.

[1] Average streamflow volumes in the Sacramento River and its tributaries are generally expected to increase slightly under 2070 Central Tendency climate change due to slightly increased precipitation. However, because Sacramento River and Stony Creek diversions are generally regulated in storage reservoirs, and because Central Valley Project water supplies from the Sacramento River are limited by contracts, it was assumed that future surface water supplies would be the same with and without climate change.

Table 6-1. Summary of Key Subbasin Water Budget Parameters Influencing Formulation of Projects and Management Actions (average annual volumes, taf/yr)

Water Budget Parameter[a]	Projected Future Conditions without Climate Change	Projected Future Conditions with 2070 Central Tendency Climate Change	Difference (Projected future with 2070 Central Tendency climate change minus without climate change)	Percent Difference[b]
Avg. Agricultural Evapotranspiration	1,494	1,596	102.0	6.8%
Precipitation	1,183	1,258	75.0	6.3%
Agricultural Pumping	458	516	58.0	12.7%
Avg. Rate of Change in Groundwater Storage, af/yr	0.6	-7.3	-7.9	-0.8%
Sacramento River and Stony Creek Diversions to Subbasin	1,287.0	1,287.0	0.0	0.0%
Net Steam Accretion	125	77	-48.0	-38.3%

(a) Water budget parameter values may differ from other summary tables due to rounding or slight changes in how parameters are aggregated from the C2VSimFG-Colusa model results.

(b) Calculated as the difference in the fourth column divided by the Projected Future Condition without Climate Change quantity in the second column, except for Avg. Rate of Change in Groundwater Storage, for which the percent difference is based on the approximately 1 million acre-feet that flow into and out of the Subbasin on an average annual basis. Water budget uncertainty is discussed in Chapter 3, Basin Setting, and model uncertainty is discussed in Appendix 3D. The average change in groundwater storage is considered to be within standard modeling error for this type of groundwater model analysis.

Under projected future conditions without climate change, net stream accretion (stream accretion minus stream depletion) is projected to be 125 taf/yr on average. This aggregate net stream accretion is for the Sacramento River, Stony Creek, and the Colusa Drain combined[2]. With 2070 CT climate change, net stream accretion is projected to remain positive but to decrease by about 48 taf/yr, or by 38 percent, with respect to the without climate change condition. Viewed in relation to the average Sacramento River flow above the Feather River confluence of approximately 11.7 million acre-feet per year (maf/yr) the projected change is roughly one half of one percent. The aggregate changes in groundwater storage, 0.8 percent, and net stream accretion, 0.5 percent of the average Sacramento River Flow, are considered to be within standard modeling error for this type of analysis.

Nevertheless, the GSAs have identified several planned PMAs (Section 6.3) that are expected to provide more than 80 taf/yr in combined gross average annual benefits that will offset groundwater pumping and support groundwater sustainability in the Subbasin. The GSAs will also continue to evaluate and review all Subbasin water budget parameters, including net stream accretion, as part of continued work to address data gaps and as part of ongoing monitoring to be reported in GSP annual reports. Chapter 4, Monitoring

[2] A more detailed assessment of projected streamflow accretion-depletion is presented in Appendix 3G. The analysis considers the Sacramento River, Stony Creek, and the Colusa Drain individually and collectively, and evaluates temporal accretion-depletion patterns over the 50-year simulation period.

Networks, and Chapter 3, Basin Setting, identify data gaps that will be addressed as part of GSP implementation (Chapter 7), which will improve the modeled outputs, water budget parameters, and understanding of the Subbasin groundwater conditions.

Despite these findings in the Subbasin boundary water budget, there are localized declining groundwater levels that have occurred over the past 15 to 20 years in the northwest and southwest portions of the Subbasin near the cities of Orland and Arbuckle, respectively (Figure 6-1). Water budget analyses suggest that groundwater level decline in these areas is due primarily to drought. A series of mostly dry years beginning in about 2007 has resulted in increased irrigation demands, curtailments of Central Valley Project surface water supplies, and consequent increases in groundwater pumping in these areas. Similar dynamics exist in the Orland area, compounded by recent expansion of irrigated agriculture into previously undeveloped lands that rely on groundwater supplies only. Localized declines in groundwater levels have also coincided with shifts in irrigation practices away from flood irrigation, which supplies substantial groundwater recharge, and toward pressurized drip and microirrigation methods. Localized effects of declining groundwater levels include stranding of shallow domestic and irrigation wells and increased rates of land subsidence, raising concerns both locally and more broadly within the Subbasin that mitigation actions should be taken as soon as possible. The planned PMAs are expected to address these localized declining groundwater levels in the Orland and Arbuckle areas by providing direct groundwater recharge or in lieu groundwater recharge in those areas of the Subbasin.

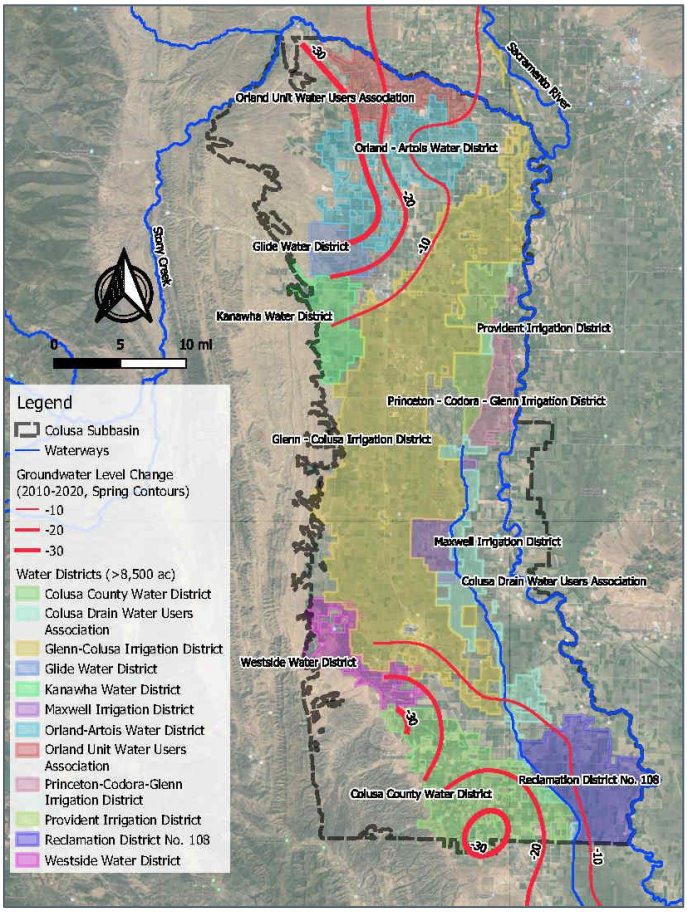

Figure 6-1. Localized Groundwater Level Declines in the Subbasin near Orland (Northwest) and near Williams and Arbuckle (Southwest)

6.1.3 Identification and Categorization of Projects and Management Actions

The PMAs included in this chapter have been planned or proposed by stakeholders, agencies, and interested parties in the Subbasin. During GSP development, the GSAs publicly requested that stakeholders and interested parties in the Subbasin submit plans and ideas for PMAs. The GSAs created a form to collect standard information about PMAs and hosted a webpage where PMA plans and ideas could be submitted by stakeholders and interested parties.[3] The GSAs and technical consultants reviewed the PMA plans and ideas, contacted project sponsors for clarifications and to gather additional PMA details, as needed, and proceeded through a screening process to categorize PMAs as "planned", "ongoing", or "potential." During GSP implementation, the GSAs plan to continue receiving PMA plans and ideas through this process, reviewing PMA submittals periodically and adding to the list of GSP PMAs if deemed appropriate.

PMAs are categorized and presented in this chapter according to the current status of implementation and development, as identified through the GSAs' screening process. However, the PMAs are not ranked. This categorization approach is consistent with the adaptive approach to PMA implementation and with development of PMAs based on the best available data and science (per 23 CCR §354.44(c)). This chapter also acknowledges ongoing investments made by agencies in the Subbasin (including prior to the passage of SGMA), such as projects that were identified and moved forward under regional water management planning efforts, including the Glenn and Colusa County Groundwater Management Plans and the Westside and Northern Sacramento Valley Integrated Regional Water Management Plans.

The PMA categories described in this chapter include:

- ***Planned*** **Projects and Management Actions** are PMAs that the GSA or other project proponents are working to implement that will support sustainable groundwater management in the Subbasin and mitigate historical and current drought effects. Detailed descriptions of these PMAs are presented in the GSP, reflecting available information including preliminary design and associated cost estimates. In accordance with 23 CCR §354.44(a) these are PMAs that would allow GSAs to achieve the sustainability goal for the Subbasin and avoid reaching the minimum thresholds defined in this GSP under future, changing conditions.
- ***Ongoing*** **Projects and Management Actions** are PMAs that are ongoing and will support sustainable groundwater management in the Subbasin. In accordance with 23 CCR §354.44(a) these are PMAs that would allow GSAs to achieve the sustainability goal for the Subbasin and avoid reaching the minimum thresholds defined in this GSP under future, changing conditions.
- ***Potential*** **Projects and Management Actions** are PMAs that may be implemented if necessitated by groundwater conditions in the Subbasin. These may have been studied by the project proponent, or in earlier regional water planning documents, but most project design, costs, and planning work has yet to be completed, and would only be initiated if the project is eventually triggered for implementation as a result of continued monitoring of groundwater conditions.

[3] https://colusagroundwater.org/projects-and-management-actions-submittals/

The rest of this chapter is structured as follows. Section 6.2 provides a summary of all (ongoing, planned, and potential) PMAs. The three subsequent sections – Sections 6.3 through 6.5 – describe the PMAs in each of the three categories. Within each category, PMAs are further classified by type (project or management action), which are described in corresponding subsections. Appendix 6A provides additional analysis of water available for recharge and other projects, as well as an assessment of incentives to encourage utilization of surface water supplies. Appendix 6B describes potential demand management action costs and Subbasin agricultural economic conditions. Appendix 6C provides a matrix summary of all planned, ongoing, and potential PMAs. Lastly, Appendix 6D describes modeling of selected PMAs to estimate the effects of those PMAs on groundwater conditions in the Subbasin.

6.2 PROJECT AND MANAGEMENT ACTIONS SUMMARY

6.2.1 Overview of All Proposed Projects and Management Actions

Table 6-2 summarizes all PMAs identified in the Subbasin. Summary information includes the PMA name, type, proponent, and a brief description. PMA types include:

- **Direct groundwater recharge:** PMAs that recharge groundwater using available surface water, flood water, stormflows, or other surface water supplies.
- **In-lieu groundwater recharge:** PMAs that offset groundwater pumping by supplying or otherwise incentivizing use of surface water or other surface water supplies "in lieu" of groundwater.
- **Management action:** Non-structural programs or policies designed to support sustainable groundwater management.
- **Reduce groundwater demand:** PMAs that reduce or remove sources of groundwater demand and extraction, such as invasive and non-native plant species along riparian corridors.

PMAs are grouped into subsections in the table according to their status (planned, ongoing, or potential). As described under Section 6.1 above, ongoing projects are currently being implemented in the Subbasin. Planned PMAs are currently being developed to achieve sustainable management conditions in the Subbasin. Potential PMAs will be implemented in the future, if or as required by changing conditions in the Subbasin.

All PMAs are described according to the requirements of 23 CCR §354.44(b). Planned projects are described in detail. Ongoing and potential PMAs are described concisely, reflecting the current operational status and "as-needed" basis of these projects. It is anticipated that additional information will be prepared in annual reports and five-year GSP updates, as needed.

Not all PMAs are the responsibility of the GSAs: some PMAs will be completed through a partnership with other agencies and proponents, while other PMAs will be completed by the agency or other proponents with support from the GSAs. The GSAs and/or other project proponents will notify the public and other agencies of the planned or ongoing implementation of PMAs through the communication channels identified in Sections 6.3 through 6.5 (23 CCR §354.44(b)(1)(B)). Noticing will occur as potential projects are being considered for implementation, and as ongoing and planned projects are implemented. Noticing will inform the public and other agencies that the GSA and/or other project proponents are considering or will be implementing the PMA, and will provide a description of the actions that will be taken.

The following subsections describe the planned, ongoing, and potential PMAs in accordance with the requirements of 23 CCR §354.44(b). The information presented in this chapter is based on the best available data and science. The estimated groundwater recharge benefit and capital, operating, and maintenance costs of developing and operating each project are shown. To the extent possible, project costs are adjusted and reported on a consistent basis. All costs are indexed using an appropriate index[4] and reported in current (2021) dollars. GSAs, districts, and other partners in the Subbasin will further develop projects during the GSP implementation period and refine estimated costs in GSP annual reports and five-year updates. Additional information about all PMAs is provided in a matrix format in Appendix 6C.

Table 6-2. Summary of All Projects and Management Actions

Project/ Management Action Name	Project/ Management Action Type	Proponent	Brief Description
Planned			
Projects			
Colusa County Water District (CCWD) In-Lieu Groundwater Recharge	In-lieu Groundwater Recharge	CCWD	CCWD will utilize 30 taf of additional surface water for irrigation in all years but Shasta Critical years for in-lieu recharge. The additional surface water will be made available through full use of the district's existing Central Valley Project (CVP) contract and annual and multi-year water purchase and transfer agreements. Additional surface water deliveries are estimated to be 27 taf/yr, enabling reduction of groundwater pumping by a like amount.
Colusa Drain MWC (CDMWC) In-Lieu Groundwater Recharge	In-lieu Groundwater Recharge	CDMWC	CDMWC diverters use both ground and surface water because Colusa Drain supplies are insufficient to satisfy all irrigation requirements. This project would provide additional surface supplies averaging approximately 28 taf/yr in the Drain allowing CDMWC diverters to increase their diversions of surface water to provide in-lieu groundwater recharge of a like amount.
Subbasin Multi-Benefit Groundwater Recharge	Direct Groundwater Recharge	CGA, GGA and TNC	The Nature Conservancy (TNC) is partnering with entities for an on-farm, multi-benefit groundwater recharge incentive program. The pilot program was initiated in Colusa County in 2018 and concluded in the spring of 2021, with plans to expand and continue into the future. DWR is a partner in the Subbasin Multi-Benefit Groundwater Recharge project as it moves into the expanded program.

[4] Either the Implicit Price Deflator or the Engineering News Report Construction Cost Index.

Table 6-2. Summary of All Projects and Management Actions

Project/ Management Action Name	Project/ Management Action Type	Proponent	Brief Description
Orland-Artois Water District (OAWD) Land Annexation and Groundwater Recharge	Direct and In-lieu Groundwater Recharge	OAWD	OAWD is planning to annex approximately 12,000 acres of groundwater-dependent agricultural lands. Additional direct recharge may be considered on suitable annexed lands. The project is an area where groundwater levels have been in decline in recent years. It is estimated that a long-term average of approximately 23 taf/yr of surface water would be available, reducing groundwater pumping by approximately 23 taf/yr.
Sycamore Slough Groundwater Recharge Pilot Project	Direct Groundwater Recharge	Landowner	Proctor and Gamble (P&G) and Davis Ranches have entered into an agreement to implement a 10-year groundwater recharge pilot project. A 66-acre field on Davis Ranches will receive surface water for groundwater recharge and provide habitat for migrating shorebirds. Water would be diverted from the Sacramento River during fall/winter months using existing riparian rights or would be available from settlement contract supplies (should the project begin before November 1). An expansion of the project is planned for recharge and revegetation in the neighboring Sycamore and Dry Sloughs.
Ongoing			
Projects			
Reclamation District 108 (RD108) and Colusa County Water District (CCWD) Agreement for Five-Year In-Lieu Groundwater Recharge Project	In-lieu Groundwater Recharge	RD108 and CCWD	CCWD (and Dunnigan Water District [DWD]) purchases surface water from RD108 for distribution within its service area. The agreement expires in 2022. This project supplies additional surface water to CCWD (and DWD) that provides in-lieu recharge.
Glenn-Colusa Irrigation District (GCID) Strategic Winter Water Use for Groundwater Recharge and Multiple Benefits	Direct and In-lieu Groundwater Recharge	GCID	GCID holds a water right for winter water. This project will increase the groundwater recharge and habitat enhancement benefits of winter water use by increasing use for rice straw decomposition, irrigation, and frost control provided that certain constraints can be alleviated.
Sycamore Marsh Farm Direct Recharge Project	Direct Groundwater Recharge	Landowner	Sycamore Marsh Farm is developing a groundwater recharge plan to store groundwater. The plan provides for 205 acres of year-round recharge basins and 163 additional acres of winter recharge areas.

Table 6-2. Summary of All Projects and Management Actions

Project/ Management Action Name	Project/ Management Action Type	Proponent	Brief Description
Glenn-Colusa Irrigation District Expansion of In-Basin Program for In-lieu Groundwater Recharge	In-lieu Groundwater Recharge	GCID	GCID has developed arrangements to supply district surface water to neighboring non-district agricultural lands that primarily use groundwater. These temporary arrangements expired in 2020. There is interest in continuing and expanding this in-basin surface water use for in-lieu groundwater recharge. Supplies would potentially be available only in Shasta Non-Critical years.
Orland Unit Water Users Association (OUWUA) Irrigation Modernization for Increased Surface Water Delivery and Reduced Groundwater Pumping	In-lieu Groundwater Recharge	OUWUA	Modernization of OUWUA southside system for more reliable and flexible farm deliveries that will provide incentive for growers to use more surface water and less groundwater.
Management Actions			
Urban Water Conservation in Willows	Management Action	California Water Service – Willows District	This project includes urban water conservation measures through water waste prevention ordinances, metering, conservation pricing, public education, and outreach programs to assess and manage distribution system real loss, water conservation program coordination and staffing support, and other demand management measures.
Potential			
Projects			
Glenn-Colusa Irrigation District In-lieu Groundwater Recharge	In-lieu Groundwater Recharge	GCID	GCID will investigate, develop, and implement measures to incentivize additional use of surface water supplied by GCID, which will provide in-lieu recharge through reduced groundwater pumping.
Westside Streams Diversion for Direct or In-lieu Groundwater Recharge	Direct and In-lieu Groundwater Recharge	CGA and GGA	A portion of western ephemeral stream flows could be diverted for in-lieu or direct groundwater recharge.
Sites Reservoir	Direct and In-lieu Groundwater Recharge	Sites Project Authority	The Sites Project is a new off-stream storage facility that is currently in development. Depending on project operation and yield, there is potential for groundwater benefits to accrue to the Subbasin from Sites Reservoir.

Table 6-2. Summary of All Projects and Management Actions

Project/ Management Action Name	Project/ Management Action Type	Proponent	Brief Description
Delevan Pipeline Colusa Basin Drainage Canal System (Colusa Drain) Intertie	Direct and In-lieu Groundwater Recharge	Interested Stakeholder	Intertie between proposed Delevan Pipeline component of the Sites Reservoir Project and the Colusa Drain, providing a connection to downstream water users, and providing protection for the ecosystems, and earthquake resilience.
Orland Unit Water Users Association (OUWUA) Flood Water Conveyance	Direct Groundwater Recharge	OUWUA	Divert Stony Creek water at OUWUA's south diversion and convey it to various locations for direct recharge within the OUWUA service area.
Orland-Artois Water District (OAWD) Direct Groundwater Recharge	Direct Groundwater Recharge	OAWD	OAWD would directly recharge groundwater. A pilot project was conducted in 2017.
Sycamore Slough Colusa Drain Multi-Benefit Recharge Project	Direct Groundwater Recharge	Landowner	Restoration of portions of Sycamore Slough would support diversion of winter flows from the Colusa Drain for recharge and restoration.
Tehama-Colusa Canal Trickle Flow to Ephemeral Streams	Direct Groundwater Recharge	RD108	Operate Tehama-Colusa Canal (TCC) existing gates for discharge into ephemeral streams at a rate where they do not flow out of the Subbasin but recharge the groundwater system.
Enhanced Infiltration of Precipitation on Agricultural Lands	Direct Groundwater Recharge	CGA and GGA	Develop and adoption of on-farm cultural practices to reduce precipitation runoff and increase infiltration, which would result in increased storage of precipitation in the crop root zone, thereby reducing irrigation water requirements and achieving some direct groundwater recharge.
Subbasin Flood-MAR	Direct Groundwater Recharge	CGA and GGA	The CGA and GGA would investigate, develop, and implement a program to divert flood waters within the Subbasin, when available, for spreading across agricultural lands for direct groundwater recharge.
Reclamation District 108 “Boards In” Program	Direct Groundwater Recharge	RD108	RD108 would institute a voluntary or financially incentivized program in which landowners leave spill boards in place during the winter to capture rainfall and hold it on the fields for recharge.
Colusa County Public Water System Water Treatment Plant	In-lieu Groundwater Recharge	Interested Stakeholder	Construct a water treatment plant on the Sacramento River between Colusa and Grimes to provide treated surface water to public water supply systems in Colusa and possibly Sutter and Yolo Counties.

Table 6-2. Summary of All Projects and Management Actions

Project/ Management Action Name	Project/ Management Action Type	Proponent	Brief Description
Glenn-Colusa Irrigation District Water Transfers to Tehama-Colusa Canal Authority (TCCA) CVP Contractors	In-lieu Groundwater Recharge	GCID	Evaluate potential for transferring water to CVP contractors served by the TCC for in-lieu groundwater recharge.
Subbasin In-lieu Recharge & Banking Program	In-lieu Groundwater Recharge	South Valley Water Resources Authority	Incentivize taking available contract surface water in-lieu of pumping groundwater, providing dedicated contribution to local groundwater sustainability, with a portion available to San Joaquin Valley partners.
Sycamore Marsh Farm In-lieu Recharge Project	In-lieu Groundwater Recharge	Landowner	Sycamore Marsh Farm is developing an in-lieu groundwater recharge plan, and could partner with additional lands in the CDMWC, allowing for diversion of surface water from CDMWC.
Westside Off-stream Reservoir and In-Lieu Groundwater Recharge	In-lieu Groundwater Recharge	TCCA Contractors	Construct off-stream surface reservoirs along the western edge of the Subbasin and up-slope from the TCC to divert surplus Sacramento River flows (e.g., Section 215 water) into these storage reservoirs. Release stored water on demand to serve lands otherwise served by groundwater.
Management Actions			
Domestic Well Mitigation Program	Management Action	CGA and GGA	To mitigate the effects of domestic well stranding due to groundwater level decline, the CGA and GGA will investigate implementing domestic well mitigation programs in their respective portions of the Subbasin.
Drought Contingency Planning for Urban Areas	Management Action	CGA, GGA, and cities (GSA member agencies)	The CGA and GGA will coordinate with M&I water suppliers dependent on groundwater to encourage drought planning consistent with the GSP.
Long-Term Demand Management Action	Management Action	CGA and GGA	Demand management broadly refers to any water management activity that reduces the consumptive use of irrigation water. A demand management action is one that incentivizes, enables, or possibly requires water users to reduce their consumptive use.
Strategic Short-Term Demand Management	Management Action	CGA and GGA	Develop a voluntary, flexible, short-run financial incentive program to alleviate impacts of drought in target areas through idling lands in drought-affected areas or in participating surface water-using portions of the Subbasin and conveying the saved surface water to the drought-affected areas.

Table 6-2. Summary of All Projects and Management Actions

Project/ Management Action Name	Project/ Management Action Type	Proponent	Brief Description
Well Abandonment Outreach and Funding Program	Management Action	CGA and GGA	Create a program providing outreach and education to landowners regarding the proper procedures for well decommissioning and abandonment, as well as funding sources. This effort would be accomplished by working with well permitting agencies.
Preservation of Lands Favorable for Recharge	Management Action	CGA and GGA	Working cooperatively with the counties, investigate, design, and implement a program providing incentives to landowners with lands favorable to groundwater recharge to preserve them as agricultural or undeveloped lands on which groundwater recharge.
Review of County Well Permitting Ordinances	Management Action	CGA and GGA	Review and revise the county well permitting processes in the Subbasin to ensure that future well permitting aligns with the Subbasin sustainability goal and that future changes to well permitting are reviewed by the GSAs. The GSAs would work with the counties to review and suggest revisions to ordinances (these are outside of the jurisdiction of the GSAs).
Reduce Non-beneficial Evapotranspiration/ Invasive Species Eradication	Reduce Groundwater Demand	CGA and GGA	Removal of invasive, non-native plant species from riparian corridors and other areas to reduce evapotranspiration from shallow groundwater and support native ecosystem restoration.
Development of a Dedicated Network of Shallow Monitoring Wells for GDE Monitoring	Management Action, Closing Data Gaps	CGA and GGA	Evaluate and develop a dedicated network of shallow monitoring wells specifically planned and sited for monitoring conditions in areas of the Subbasin where GDEs are most likely to be found. This action is also expected to incorporate biological monitoring to inform the location of new shallow monitoring wells and monitor whether GDEs are being impacted by changing groundwater conditions.

6.2.2 Benefits of Projects and Management Actions to Sustainability Indicators and Communities in the Subbasin

Volumetric benefits of all planned PMAs are identified in Table 6-2 and in Section 6.3. In total, the planned PMAs are expected to provide more than 80 taf/yr in gross average annual benefits at full implementation by offsetting groundwater pumping, providing direct recharge, and otherwise supporting groundwater sustainability. These benefits are expected to address potential sustainability concerns in the projected future conditions water budgets, even under the effects of 2070 CT climate change (Table 6-1). Planned PMAs are expected to help the GSAs achieve the sustainability goal for the Subbasin and avoid reaching the minimum thresholds defined in this GSP under future, changing conditions.

Table 6-3 summarizes how each type of PMA would benefit sustainability indicators in the Subbasin. All proposed PMAs are expected to benefit groundwater levels and groundwater storage, whether through direct or in-lieu groundwater recharge, management of water supplies, or demand reduction. Projects that incentivize additional use of available surface water in lieu of groundwater are also expected to reduce depletions of interconnected surface water. Planned PMAs will provide direct and in-lieu groundwater recharge benefits to the Subbasin, which the GSAs do not expect will significantly affect water quality conditions, including those experienced by domestic well users and DACs. However, the GSAs are planning to monitor groundwater quality during GSP implementation (Section 4.2.2), and will investigate additional PMAs and studies to improve water quality if they find that groundwater quality conditions are approaching MTs.

Many of the communities within the Subbasin are considered either a Disadvantaged Community (DAC) or a Severely Disadvantaged Community (SDAC)[5]. Additionally, nearly all of the Subbasin is considered an Economically Distressed Area (EDA).[6] The only area within the Subbasin that is not considered an EDA is the small portion of the Subbasin that exists within Yolo County (approximately 2.4 square miles, or 1,500 acres). Additional information about DACs, SDACs, and EDAs in the Subbasin is provided in Chapter 2, Plan Area. To the extent that PMAs are implemented directly in areas where these communities reside – the majority of areas across the Subbasin – and to the extent that PMAs benefit groundwater conditions throughout the Subbasin, PMAs are expected to benefit DACs, SDACs, and EDAs and prevent undesirable results for these communities. Ongoing outreach and implementation of the GSP and PMAs will directly benefit these communities and ensure that their concerns and feedback continue to be incorporated into PMA development and implementation.

Table 6-3. Sustainability Indicators Expected to Benefit from Projects and Management Action Types Proposed in the Subbasin

Project/ Management Action Type	Project/Management Action Names	Sustainability Indicators Expected to Directly Benefit				
		GW Levels	GW Storage	SW Depletion	Land Subsidence	Water Quality

6.3 PLANNED PROJECTS AND MANAGEMENT ACTIONS

The GGA and CGA have included five groundwater recharge projects that are planned for implementation. All five projects involve the use of surface water for direct or in-lieu recharge. Three of the five projects are substantial in-lieu recharge projects, meaning that they will require regulated surface water sources available on an irrigation demand schedule. These three projects are planning to acquire all or most of the required surface water through transfers of CVP water supplies that are available from other CVP water supply or Settlement Contractors.

Figure 6-2 illustrates the location and name of the five planned PMAs in the Subbasin. Planned projects are targeted to areas where groundwater levels have been declining in the Subbasin due primarily to historical and current drought conditions. In addition, recharge opportunities are targeted near the Sacramento River to provide multiple benefits including potential habitat and streamflow benefits.

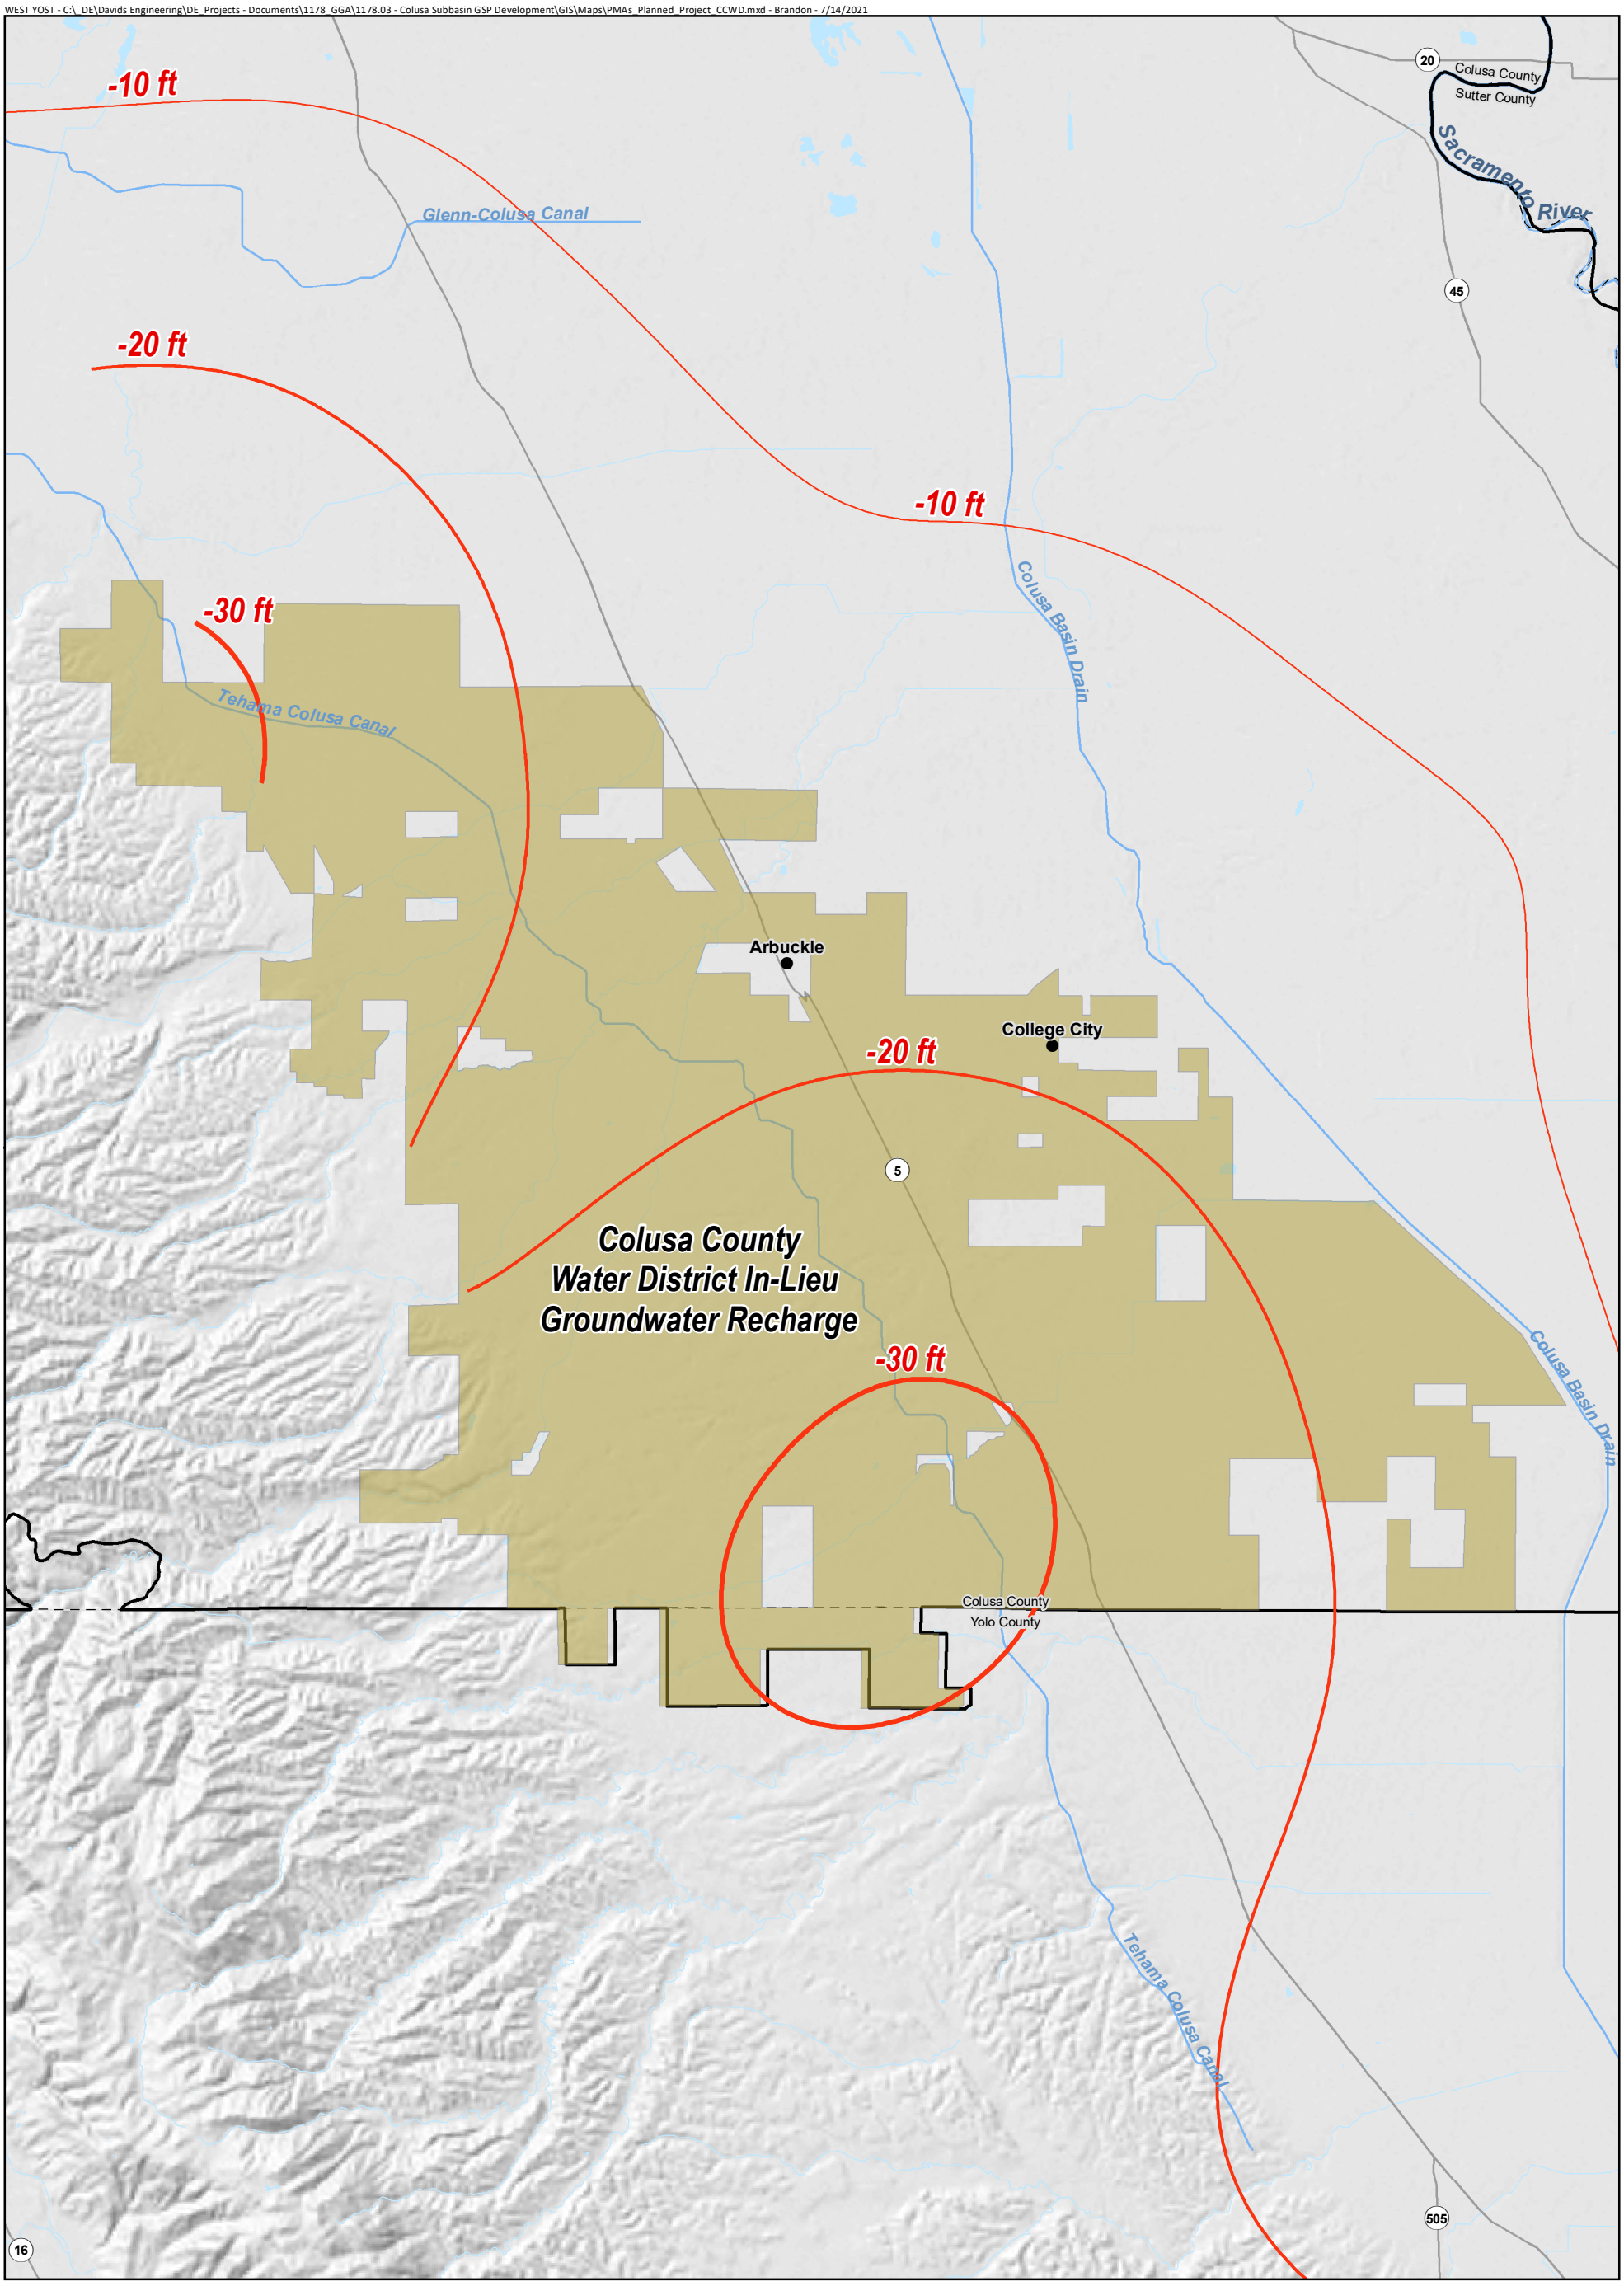
Table 6-4 lists the planned PMAs, project type, proponent, expected first year of implementation, estimated capital cost, and estimated gross annual benefit (taf/yr).

Table 6-4. Summary of Planned Projects



Project	Project Type	Proponent	Year Implemented	Estimated Capital / Establishment Cost, $ (thousands)[a]	Gross Average Annual Benefit, taf/yr
Colusa County Water District In-Lieu Groundwater Recharge	In-Lieu GW[b] Recharge	CCWD	2021	$100	27
Colusa Drain MWC In-Lieu Groundwater Recharge	In-Lieu GW Recharge	CDMWC	2021	$100	28
Colusa Subbasin Multi-Benefit Recharge	Direct GW Recharge	CGA, GGA, and TNC[c]	2021	$4 per site	5.2
Orland-Artois Water District Land Annexation and In-Lieu Groundwater Recharge	Direct and In-Lieu GW Recharge	OAWD	2020	$20,000	23
Sycamore Slough Groundwater Recharge Pilot Project	Direct GW Recharge	Landowner	2021	$28	0.5[d]

(a) Annual costs are summarized in the "Project Costs" sections of the project descriptions, below.
(b) GW = Groundwater
(c) TNC = The Nature Conservancy
(d) Project goal is to recharge 5 taf over 10 years.

6.3.1 Colusa County Water District In-Lieu Groundwater Recharge

6.3.1.1 Project Overview

Colusa County Water District (CCWD) includes over 45,000 acres within its service area, of which roughly 35,000 acres are irrigated. In this project, CCWD will utilize up to an additional 30 taf of surface water for irrigation in all years but Shasta Critical years, resulting in a long-term average annual additional surface water supply of 27 taf/yr. Shasta Critical conditions are declared when the forecast inflow to Lake Shasta for a particular water year is equal to or less than 3.2 maf. The additional surface water will be made available through full use of the district's existing CVP contract and annual and multi-year water purchase and transfer agreements. The additional water will be conveyed through the existing Tehama-Colusa Canal (TCC) and CCWD facilities and will be used primarily on existing district lands, resulting in in-lieu groundwater recharge through reduction of groundwater pumping. As an optional component of this project, CCWD is considering relatively small annexations of lands adjoining the district and supplying surface water to these lands in-lieu of groundwater pumping. If these annexations proceed, the additional water may also be used on the newly annexed lands that are currently dependent on groundwater and require construction of additional infrastructure for surface water delivery. Figure 6-3 illustrates the general location in CCWD where in-lieu recharge could occur, along with the groundwater elevation change between spring 2010 and spring 2020.

Spring 2010 to Spring 2020 Groundwater Elevation Change

Colusa Subbasin

Groundwater Sustainability Plan

Use of additional surface water within CCWD will require a combination of incentivizing additional use of CCWD existing CVP supplies and transfer arrangements with other districts. Transfers already occur in many years and would continue to be negotiated between parties as part of GSP implementation. Incentivizing use of existing CVP supplies would require making the cost comparable to the cost of pumping groundwater. Historically, according to federal law under the CVP improvement Act of 1992, CVP irrigation water supply contracts required payments of tiered water rates for contractual water entitlements. The lowest, Tier 1, rate applied to 80 percent of the contractual water entitlement. The highest, Tier 3, rate reflected the full cost rate and applied to the last 10 percent of the contractual water entitlement. The Tier 2 rate, applied to the middle 10 percent, is an average of the Tier 1 and 3 rates.

Even when blended with Tier 1 water, using Tier 2 and Tier 3 water resulted in excessive water cost, and so some or all of the Tier 2 and Tier 3 water went unused. CCWD, along with other CVP contractors in the Subbasin, has recently converted its water service contract to a repayment contract, thus paying off and removing the capital component from CVP rates. However, repayment of CVP capital required borrowing money that the district will pay off over the next 15 years or more, which is reflected in water rates to growers.

Depending on the relative costs of district supply versus groundwater, under the repayment contracts, CCWD rates may be low enough already to encourage full use of CVP supply. However, if groundwater pumping remains a lower cost alternative to CVP water for some growers, incentivizing their use of CVP water in lieu of pumping would require an incentive that is at least equal to the difference between district surface supply and the variable cost of pumping groundwater.

Appendix 6A provides a summary of CVP rates, repayment contracts, and incentives to encourage additional use of district surface water supplies.

6.3.1.2 Implementation

Planning is currently underway for utilization of this additional surface water through CCWD's existing CVP contract and annual and multi-year water purchase and transfer agreements, as shown in Table 6-5 below. Utilization of additional surface water is anticipated to begin in 2022 (subject to the availability of water).

Table 6-5. CCWD In-Lieu Groundwater Recharge Implementation Timeline

Phase	Description	Start	End
Program Structure and Planning	Specify program goals, structure, and targets for implementation	2020	2022
Evaluate Incentives, Partners, and Develop Strategy	Evaluate grower incentives and on-farm costs for surface and groundwater irrigation, quantify willingness to pay for each system, and define program incentives. Work with partner districts to identify transfers	2020	2022
Initial/Pilot Program Implementation	Develop and implement a pilot program to evaluate participation, incentives, and assess landowner feedback	2022	2023

Table 6-5. CCWD In-Lieu Groundwater Recharge Implementation Timeline			
Phase	Description	Start	End
Program Implementation	Implement full program and scale up over time to achieve specified program goals for in-lieu recharge	2023	Ongoing
Monitoring	Monitor and report on the status of program development for GSP implementation (annual reports and five-year updates)	2021	Ongoing

6.3.1.3 Notice to Public and Other Agencies

Public noticing for this project will be done in accordance with noticing requirements in National Environmental Policy Act (NEPA) and CEQA (as needed), as well as noticing for public meetings held by the CGA, GGA, CCWD, Tehama-Colusa Canal Authority (TCCA), and Colusa Local Agency Formation Commission (LAFCO).

6.3.1.4 Construction Activities and Requirements

The project plans to utilize existing water conveyance facilities, including the TCC and the CCWD's piped distribution system. Under this project configuration, no additional construction activities would be required.

As an optional component of this project, CCWD is considering relatively small annexations of lands adjoining the district and supplying surface water to these lands in-lieu of groundwater pumping. However, the operation, benefits, and expected costs of the project does not depend on these annexations. Annexing lands would require construction of new water conveyance facilities for delivery and measurement of surface water to these newly annexed lands. These costs would be assessed as part of program development, if CCWD decides to annex lands.

6.3.1.5 Water Source

The surface water source for the project will come from CCWD's existing CVP contract and from multiple Sacramento Valley entities with existing surface water entitlements that are regularly available in below-normal to wet year types. These entities include CVP water supply and Settlement Contractors and, potentially, Sacramento River water rights holders.

The intent is to first utilize existing CCWD CVP supplies by making the cost of that supply comparable, or less, than the cost to pump groundwater. Additional water supply would be acquired through annual and multi-year, renewable water purchase or transfer agreements, building on similar existing agreements that CCWD has with certain Sacramento Valley entities. New surface supplies would be diverted from the Sacramento River at the Red Bluff Pumping Plant and Fish Screen facility and conveyed through the Tehama-Colusa Canal, which is operated and maintained by the Tehama-Colusa Canal Authority.

Appendix 6A summarizes an assessment of the volumes of water potentially available for in-lieu recharge. The CCWD project would acquire surface water primarily via water transfers from other entities with available CVP contract supplies and CVP Settlement Contract project water under the provisions of Central Valley Project Improvement Act (CVPIA) Section 3405(a). Transfer of project supplies under Settlement

Contracts alone would meet most of the needs of in-lieu recharge, with full use of existing contract supplies in CCWD and potential transfers of additional available CVP contract supplies adding to that amount.

6.3.1.6 Circumstances and Criteria for Implementation

This project is planned for immediate implementation. As described above, CCWD has already converted its water service contract to a repayment contract and is evaluating potential transfer opportunities with partner districts in the region. This process in 2021 was hampered by historically dry conditions across the state and the resulting lack of surface water. Beginning later in 2021, and into 2022 as water conditions hopefully improve, CCWD will begin evaluating incentives to encourage additional use of CVP supplies. It is anticipated that the utilization of additional surface water will begin in 2022.

Implementation of the in-lieu recharge program in CCWD does not depend on the implementation or performance of other PMAs or district activities. While operation of this project is not expected to terminate, any future changes will be made to align with CCWD goals and the overall Subbasin sustainability goal.

6.3.1.7 Legal Authority, Permitting Processes, and Regulatory Control

CCWD has the legal authority as a water district to provide for the acquisition and conveyance of supplemental surface water to its lands and pursue expansion of its service area. The planning and implementation of this project will be done in accordance with the required permitting processes and regulatory control. Required permitting and regulatory review is being initiated through consultation with applicable governing agencies.

Because the additional surface water supplies will be conveyed through the existing TCC and CCWD facilities and used primarily on existing district lands, there are no anticipated permitting requirements for this project. However, if additional land is annexed and new facilities are required to serve those lands, then permits will be required. In that case, governing agencies with which consultation may need to be initiated include, but are not limited to: DWR, the California State Water Resources Control Board (SWRCB), the California Department of Fish and Wildlife (CDFW), the Central Valley Flood Protection Board (Flood Board), Regional Water Boards, the United States Bureau of Reclamation (Reclamation or USBR), the United States Army Corps of Engineers (USACE), the United States Fish and Wildlife Service (USFWS), the National Marine Fisheries Service (NMFS), LAFCOs, the Counties of Colusa and/or Glenn, and the California Air Resources Board (CARB). Specific permitting and regulatory processes that may affect the construction of additional infrastructure include, but are not limited to:

- USACE Section 404 Permits (potential exemption under Section 404(f)(1)(C) of Clean Water Act)
- Regional Water Quality Control Board Section 401 Water Quality Certification (not required if exempt from USACE Section 404)
- SWRCB Construction General Permit and Storm Water Pollution Prevention Plan (SWPPP)
- State Historic Preservation Office (SHPO) and National Historic Preservation Act (NHPA) Section 106 Coordination
- California Endangered Species Act (CESA) Consultation
- Endangered Species Act (ESA) Compliance
- National Environmental Policy Act (NEPA) Compliance
- California Environmental Quality Act (CEQA) Compliance

6.3.1.8 Project Operations and Monitoring

CCWD will operate and maintain its existing district facilities and conduct project monitoring. If CCWD annexes additional lands into the district, the district would operate and maintain facilities developed for these lands, and conduct project monitoring.

Project monitoring will include a range of activities to evaluate the benefits described in the next section. This will include local monitoring to track the additional volumes of water made available through transfers and estimates of the reduction in pumping relative to pre-project baselines. Additionally, the district may monitor grower adoption through delivery records and periodic grower surveys during project design and implementation. Information gathered from these surveys would be used to refine the initial program design and encourage additional adoption.

The benefit of in-lieu recharge on sustainability indicators in the Subbasin (groundwater levels and groundwater storage) will be monitored using the monitoring network sites and monitoring practices described in the GSP (Chapter 4).

6.3.1.9 Project Benefits

The primary benefit of the project is reduction of groundwater pumping resulting from in-lieu groundwater recharge with benefits to the sustainability indicators previously shown in Table 6-3. It is estimated that approximately 30 taf of surface water would be delivered to annexed lands in all years but Shasta Critical years, resulting in an average annual reduction of groundwater pumping of approximately 27 taf/yr over the long term. Transfer volumes would vary in Shasta Non-Critical years based on the terms of the transfer agreements, and broader water market conditions, but the average annual quantity in all Shasta Non-Critical years is estimated to be 27 taf/yr. These benefits are expected to begin to be realized in 2022. Table 6-6 summarizes the expected annual volume. These project benefits have been assessed, and may continue to be assessed, using the C2VSimFG-Colusa model developed for GSP development by simulating groundwater conditions with and without the project. Additional information on the project modeling is described in Appendix 6D.

Table 6-6. CCWD In-Lieu Groundwater Recharge Estimated Average Recharge Volume by Year Type, in af/yr (2016-2065)

Year Type	Total Annual Volume	% of Years	Weighted Avg.
Shasta Non-Critical	Up to 30,000	90%	27,000
Shasta Critical	0	10%	0
Average Annual			**27,000**

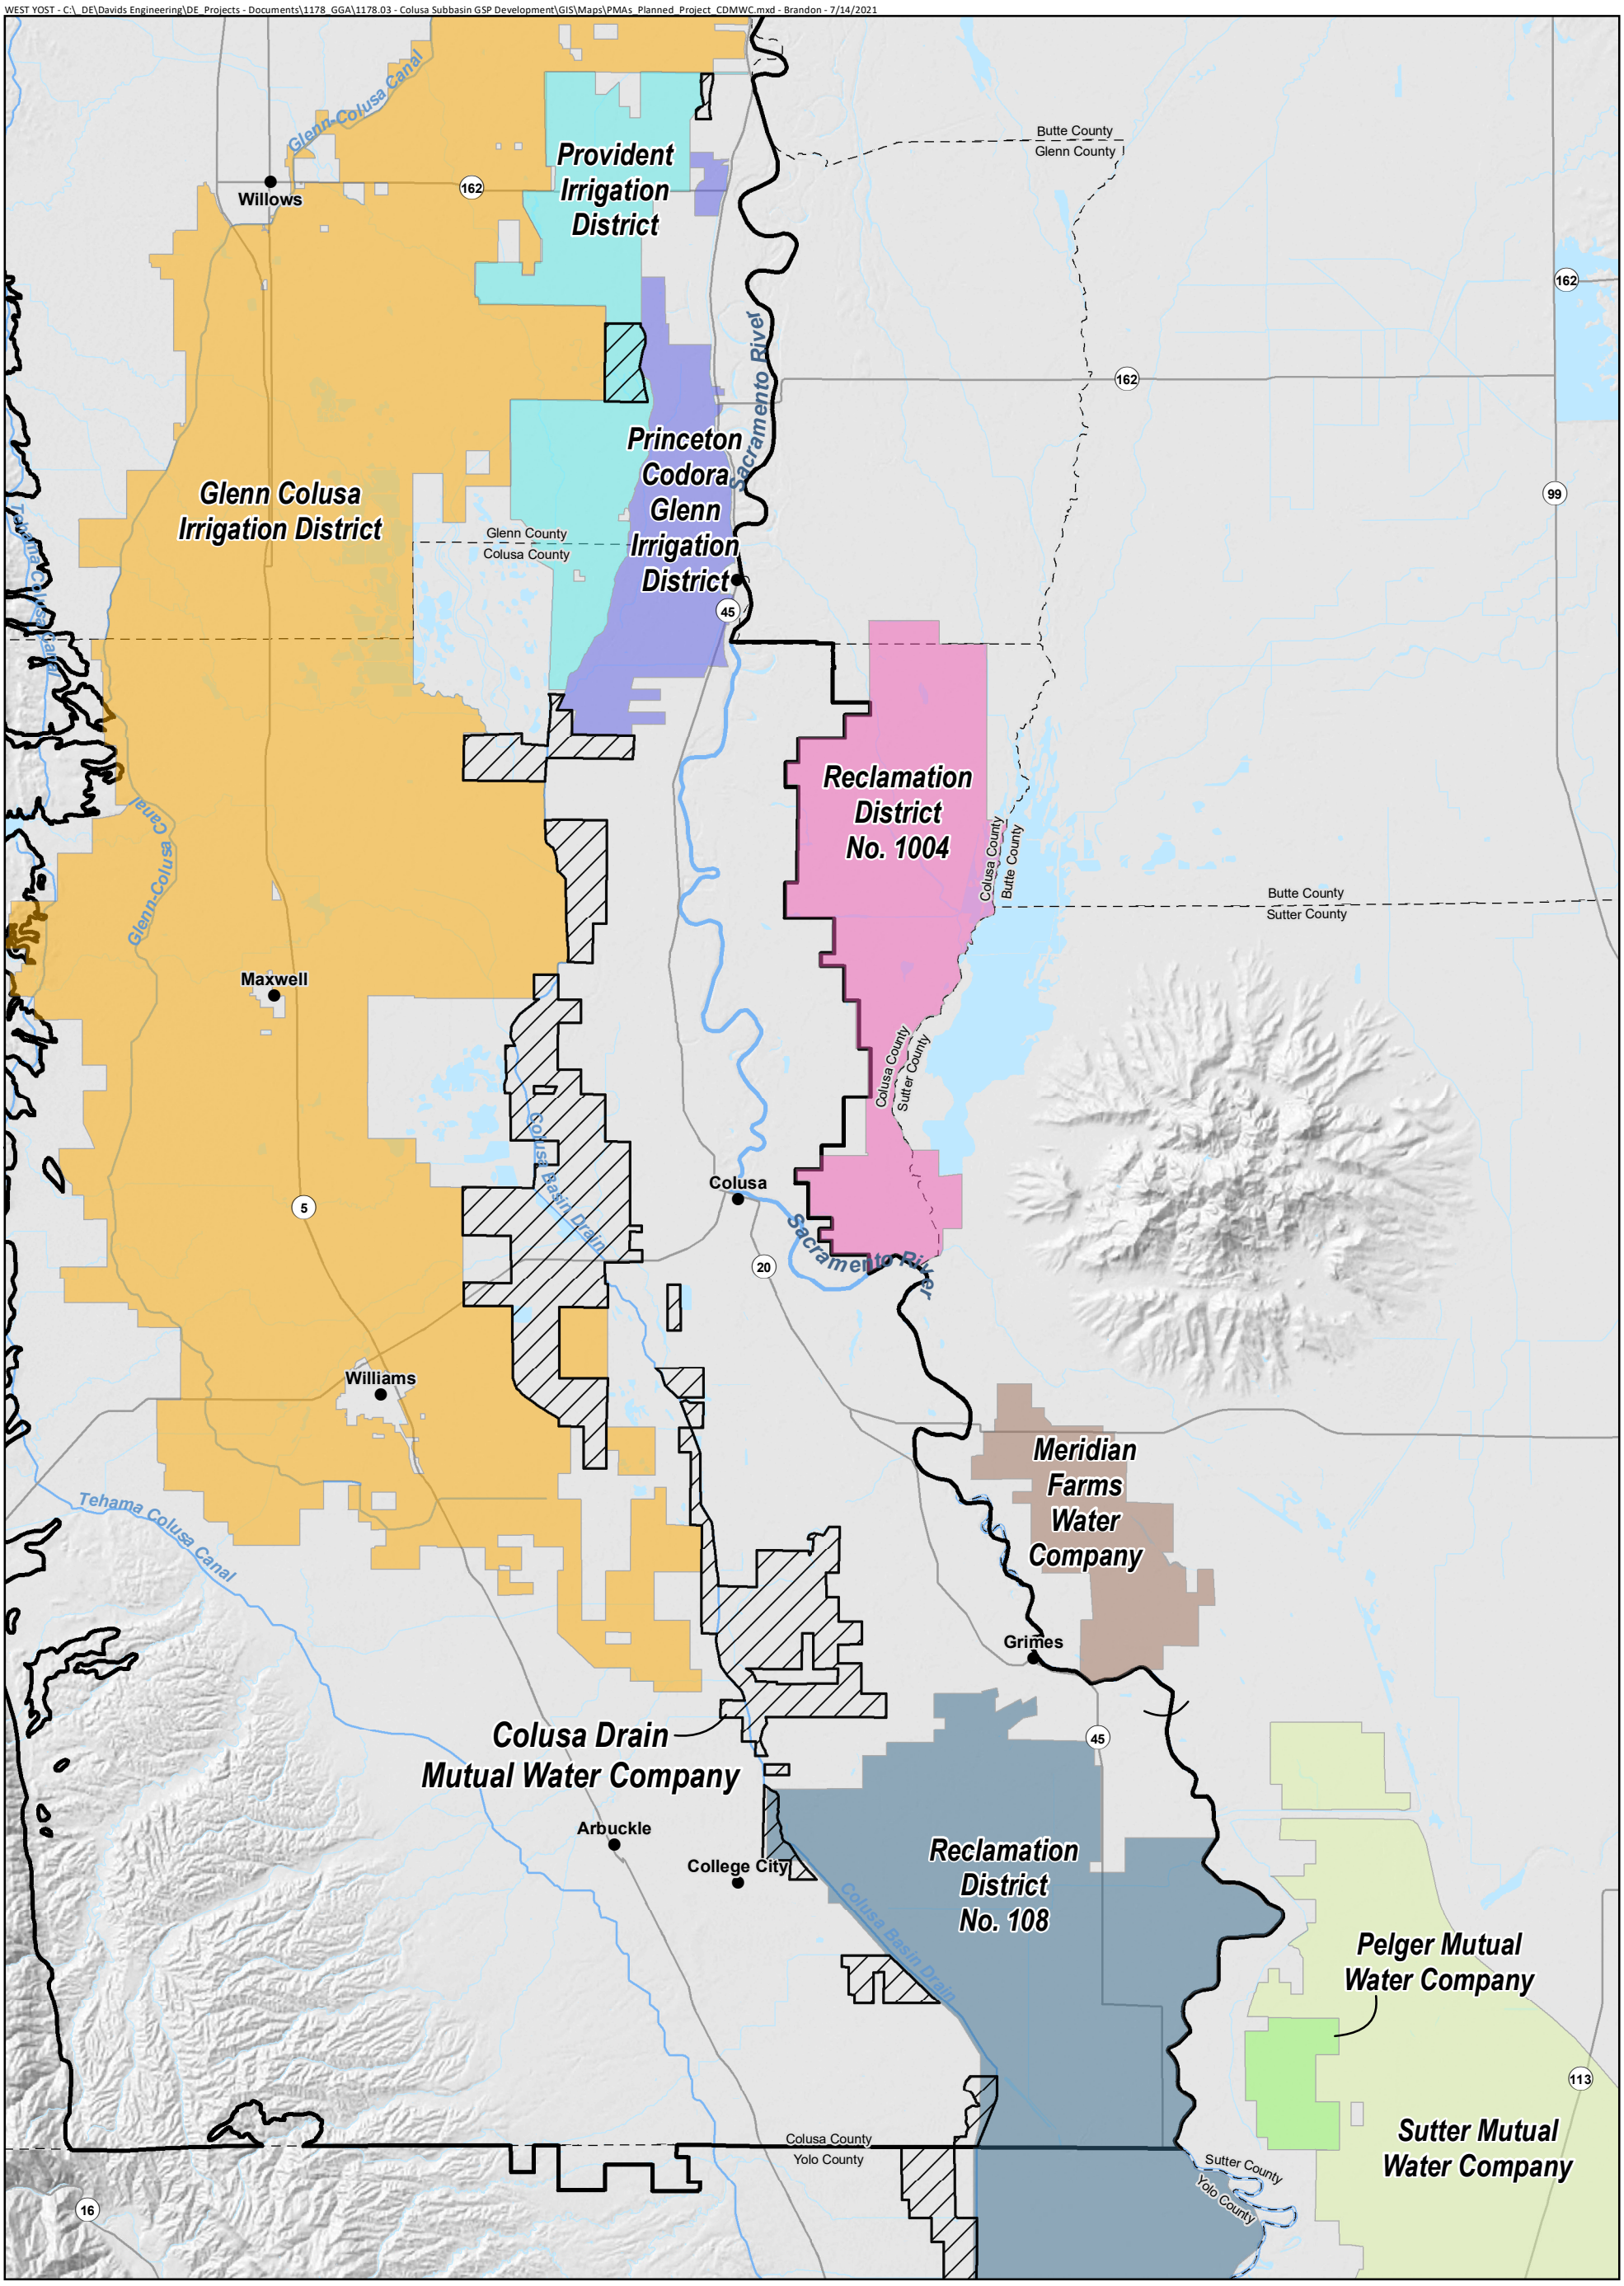
6.3.1.10 Project Costs

Project costs include the cost of purchased water, applicable CVP costs associated with the use of the TCC, and CCWD operation and maintenance costs. If some additional lands are annexed into the district, costs will also include capital costs associated with construction of new facilities, but none are included in preliminary planning costs. Other fixed costs include $100,000 for CCWD effort to develop a preliminary project plan, and establish potential incentives based on an assessment of grower willingness to pay.

An initial estimate of $75 per af corresponding to estimated CCWD fully-loaded water rates (see Appendix 6A) is applied for the initial planning-level annual operating cost assessment. As described in Appendix 6A, this is CCWD staff's rough estimate of CCWD's 2021 water rate if it had received full CVP supply. It includes its repayment rate for CVP water, other CVP charges, Tehama-Colusa Canal Authority charges, and District charges. Using this rate, the total water supply cost would be approximately $2.0 million per year. Efforts are currently underway by CCWD to estimate and refine these project costs, and to identify funding sources and establish repayment terms. Table 6-7 summarizes project costs.

Table 6-7. CCWD In-Lieu Groundwater Recharge Estimated Project Costs

Item	Total Cost	Year Incurred	Notes
Capital Costs			
Project planning and development	$100,000	2021-2022	Project studies and planning; does not include any capital costs
O&M Costs			
Fully-loaded water supply cost	$2.0 million	All	Assumed water supply cost equal to CCWD fully-loaded rate in full water supply years



23 CCR §354.44(b)(8) requires a summary of how the district plans to pay these costs. It is anticipated that the cost of incentivizing additional use of CVP supplies, and transfer purchases would primarily be recovered through district assessments. This may include more land-based assessments to reduce the variable cost of water rates, thereby making district water comparatively less expensive than groundwater. Other potential funding sources include grants, loans, and bonds for capital financing, if new facilities are needed to serve any annexed lands. Debt service and operations would be funded through assessments and charges. Potentially, a type of cost-share program could be developed where other groundwater-dependent water users in the Subbasin share a portion of the costs since they will also realize regional benefits through this in-lieu recharge project. Appendix 7A in Chapter 7 describes different funding mechanisms, and the conceptual approach for allocating project costs across multiple potential project beneficiaries.

6.3.2 Colusa Drain Mutual Water Company (CDMWC) In-Lieu Groundwater Recharge

6.3.2.1 Project Overview

The CDMWC encompasses approximately 46,000 acres of agricultural land and environmental habitat adjacent to the Colusa Drain. Shareholders in CDMWC divert water for summer irrigation from the drain under a combination of appropriative water rights held individually by the shareholders, a long-term service supply agreement with the United States Bureau of Reclamation (Reclamation or USBR), and annual and multi-year transfer agreements with neighboring Settlement Contractors. Figure 6-4 illustrates the general locations of CDMWC, neighboring Settlement Contractors, and other entities in the surrounding area. Historically, many CDMWC diverters use both groundwater and surface water for summer irrigation because physical supplies of surface water in the Colusa Drain are often unreliable and insufficient to satisfy all irrigation requirements.

Note:
1. Sacramento River Settlement Contractors (SRSC) in the vicinity of the Colusa Drain MWC within the Colusa Subbasin are included in this map, although there are other SRSCs that exist and could potentially provide a water source for this project.

N

0 2.5 5

Scale in Miles

Figure 6-4

Colusa Drain MWC In-Lieu Groundwater Recharge

Colusa Groundwater Authority and Glenn Groundwater Authority
Colusa Subbasin
Groundwater Sustainability Plan

The purpose of this project is to provide a reliable and sufficient supply of surface water in the Drain allowing CDMWC diverters to increase their diversions of surface water and decrease groundwater pumping by an equal amount. It is estimated that an average annual yield of up to 28 taf of in-lieu groundwater recharge could be realized through this project.

6.3.2.2 Implementation

The project is currently being planned for implementation. The planned implementation timeline is shown in Table 6-8. CDMWC has existing transfer agreements with Settlement Contractors upon which the transfer terms under this project would be based. In addition, CDMWC has existing water rights, permitting, and infrastructure in place to operate the program. Initial program implementation will require a planning study of water transfer, prices, full-cost of transferred water delivered to CDMWC diverters, and a comparison to the cost to continue utilizing groundwater. This would establish program feasibility and potential program scale. Preliminary program design is already under way and will continue through 2022.

Benefits could begin to accrue as early as during the 2022 irrigation season, depending on availability of surface water via transfers. 2021 is a Shasta Critical year, with dry conditions across the state. Several criteria necessary for implementation are already in place:

- Most CDMWC shareholders have necessary infrastructure required to divert water from the drain and deliver it to their agricultural lands, and several Settlement Contractors have the infrastructure in place to introduce surface water supplies into the Colusa Drain for CDMWC diversion and use (pursuant to transfer agreements).
- CDMWC shareholders have the necessary licenses and permits in place with DWR and SWRCB to allow diversions from the drain.
- CDMWC has a long-term supply agreement with Reclamation to supply water into the Sacramento River to offset shareholders diversions from the drain that would otherwise infringe the rights of senior water right holders in the Sacramento River.
- CDMWC and Glenn-Colusa Irrigation District (GCID, a Settlement Contractor) currently have a transfer agreement in place that includes the necessary environmental permitting with Reclamation and DWR.

Following the model of the transfer agreement with GCID, CDMWC would establish transfer agreements with other Settlement Contractors or other entities to provide surface water to the Colusa Drain for CDMWC diversion and use.

These transfer agreements would need to be designed to provide settlement contractors with sufficient economic incentive to deliver water to the Colusa Drain and, at the same time, provide CDMWC diverters with a sufficient incentive to access and utilize this surface water supply in-lieu of using groundwater. Coordination and planning for these transfer agreements is currently underway.

Table 6-8. CDMWC In-Lieu Groundwater Recharge Implementation Timeline			
Phase	Description	Start	End
Project Planning and Concept Development	Evaluate lands, existing infrastructure, permitting, and potential partners	2020	2021
Program Development and Incentives Analysis	Develop program costs and financial parameters; assess groundwater costs to CDMWC irrigators and willingness to accept payment for transfer from partners; establish program costs and structure	2021	2022
Transfer Agreements	Model and pursue transfer agreements based on the existing agreement with GCID	2019	Ongoing
Program Operation	Program implementation, monitoring, updates, and ongoing agreements	2022	Ongoing

6.3.2.3 Notice to Public and Other Agencies

Public noticing for this project will be done in accordance with noticing requirements and in public meetings held by CDMWC and others. This would include CGA public meetings.

6.3.2.4 Construction Activities and Requirements

There are no infrastructure construction activities and requirements, as the project will use existing infrastructure and facilities.

6.3.2.5 Water Source

The surface water source for the project will come from multiple Sacramento Valley entities with existing surface water entitlements that result in water available for transfer in some normal to wet year types. These entities include Settlement Contractors, Sacramento River water rights holders, and potentially others. The intent is to acquire the water through annual and multi-year, renewable water transfer agreements. A framework for this has already been established based on the existing agreement between CDMWC and GCID. New surface supplies would be provided to the Colusa Drain for diversion and use by CDMWC shareholders.

Appendix 6A summarizes an assessment of the volumes of water available for transfer in the Subbasin. The water availability assessment finds there is sufficient water available for transfer for the CDMWC project, in addition to the other four planned GSP recharge projects.

6.3.2.6 Circumstances and Criteria for Implementation

This project is planned for immediate implementation. Coordination and planning are currently underway, and depending on outcomes, implementation and project benefits could potentially begin in 2022.

Implementation of the CDMWC program does not depend on the implementation or performance of other PMAs or district activities. While operation of this project is not expected to terminate, any future changes will be made to align with CDMWC goals and the overall Subbasin sustainability goal.

6.3.2.7 Legal Authority, Permitting Processes, and Regulatory Control

As a mutual water company, CDMWC has the legal authority to plan for and pursue the acquisition and conveyance of supplemental surface water to its shareholders' lands. The planning and implementation of this project will be done in accordance with the required permitting processes and regulatory control. CDMWC already has water rights, permitting, and infrastructure in place to operate the program. CDMWC shareholders have the necessary licenses and permits in place with DWR and SWRCB to allow diversions from the drain, and CDMWC and GCID currently have a transfer agreement in place that includes the necessary environmental permitting with Reclamation and DWR. No additional permitting requirements are anticipated, though CDMWC will consult with governing agencies, as needed.

6.3.2.8 Project Operations and Monitoring

CDMWC will operate, maintain, and monitor its existing facilities that would be utilized for the project during implementation and operation. No new additional facilities are planned for development.

Ongoing project monitoring will include a range of activities to evaluate the benefits described in the next section. This will include local monitoring to track the use of additional volumes of surface water made available through the project and estimates of the reduction in groundwater use relative to pre-project baselines. Assessments of economic incentives will also be conducted to evaluate their utility in encouraging surface water usage. Monitoring may include additional outreach to shareholders, which would be used to refine the program design and encourage additional adoption. It is further anticipated that annual and multi-year transfer agreements would be continually reviewed, negotiated, and executed to ensure sufficient supplies to achieve the desired program scale.

The benefit of utilizing additional surface water for in-lieu recharge on sustainability indicators in the Subbasin (groundwater levels and groundwater storage) will be monitored using the monitoring network sites and monitoring practices described in the GSP (Chapter 4).

6.3.2.9 Project Benefits

CDMWC anticipates that the project would scale up over time, based on water transfer availability and the economics of utilizing those available supplies. A detailed assessment of project benefits will be completed during GSP implementation, as additional information is available from potential water transfer partners. A preliminary project benefits assessment was developed for the GSP.

The primary benefit of the project is reduction of groundwater pumping resulting from in-lieu groundwater recharge with benefits to the sustainability indicators previously shown in Table 6-3. A preliminary analysis estimates this project has the potential to provide 28 taf/yr of additional surface water for in-lieu recharge to CDMWC. The quantities transferred in each year would depend on water supply conditions in the Sacramento and San Joaquin Valleys. In Shasta Critical years, such as 2021, it is estimated that no water would be available for transfer for the project. Under recent historical conditions, this occurs approximately 1 in 10 years. In other, Shasta Non-Critical years it is estimated that an average of approximately 31 taf/yr would be transferred under agreements entered for this project.

Transfer volumes would vary in Shasta Non-Critical years based on the terms of the transfer agreements, and broader water market conditions. Prices for water transfers to the San Joaquin Valley have increased in recent years, affecting volumes available for transfer, particularly in drier years. Delta capacity constraints limit transfer potential south of the Delta in wet years. It is anticipated that CDMWC transfer volumes would vary with availability of CVP supplies in Shasta Non-Critical years. Table 6-9 summarizes

the historical CVP final allocation for North of Delta agricultural water service contracts. Average CVP contract deliveries were 75 percent between 1990 and 2021, over the more recent 15 years, average deliveries were 67 percent of contracts.

Table 6-9. North of Delta CVP Water Service Contract Allocations Summary

CVP Water Service Contract Allocation (%)	Historical Period	
	1990 - 2021	2007 - 2021
>90%	63%	53%
50%-90%	13%	13%
25% - 50%	16%	13%
<25%	9%	20%
Average	**75%**	**67%**

Table 6-10 summarizes estimated project benefits. Project benefits would also be assessed using the C2VSimFG-Colusa model developed for GSP development by simulating groundwater conditions with and without the project. Benefits assume 31 taf/yr of transfers in Shasta Non-Critical years. As described above, the specific volume in each year type would be specified in transfer agreements. It is estimated that groundwater pumping within the CDMWC area is approximately 40 taf/yr. This project has the potential to provide an average of 28 taf/yr of additional surface water for in-lieu recharge. Therefore, assuming there is no development of groundwater on previously unirrigated lands, the project potential benefit would be 28 taf of in-lieu recharge, reducing the 40 taf annual pumping in CDMWC by 70 percent.

Table 6-10. CDMWC In-Lieu Groundwater Recharge Estimated Average Recharge Volume by Year Type, in af/yr (2016-2065)

Year Type	Total Annual Volume	% of Years	Weighted Avg.
Shasta Non-Critical	Up to 31,000	90%	28,000
Shasta Critical	0	10%	0
Average Annual			**28,000**

6.3.2.10 Project Costs

The primary project cost is the cost of purchased and transferred water. Water transfer prices will be defined in the water transfer agreements. A detailed assessment of the water transfer market in the Subbasin and greater Sacramento Valley is beyond the scope of this initial project investigation for the GSP. Water transfer prices have increased substantially over the last decade. This is due to a combination of more limited supply due to drought, GSP implementation in the San Joaquin Valley, and the biological opinion regarding operation of the CVP system, as well as demand driven by plantings of permanent crops and strong nut prices. Historical (1993 – 2020) data for water transfers (price and volume) for agricultural water within the Sacramento Valley were reviewed.

Table 6-11 summarizes that average and range of within-Sacramento Valley transfer prices. The range highlights the variability in observed prices. Water conditions are classified according to the Sacramento River Index (Sacramento 40-30-30 index), which is formally defined in the State Water Board's Decision 1641. Year types are classified as follows: Wet (Wet), Average (Above Normal, Below Normal, Dry), and Dry (Critical). Prices are typically lower in longer-term agreements, which would be included under this project. As such, the lower end of the range is applied for planning cost estimates in this GSP.

Table 6-11. North of Delta Water Transfer Price Summary

Sacramento Valley WY Index	Average, $/af	Range, $/af	
		Low	High
Wet	$140	$50	$225
Average	$210	$75	$415
Dry	$265	$95	$430
Weighted-Average	$192	$83	$347

Table 6-12 summarizes the estimated project costs. An initial estimate of the anticipated cost of the project is approximately $1.7 million per year. This assumes a water transfer cost of $62 per af for an average annual transfer volume of 28,000 af. This is within the range of prices observed in wetter conditions. It is anticipated that water transfer prices will depend on the length of the transfer, terms, and hydrologic conditions. The price of $62 per af is used for initial planning purposes and does not include any additional conveyance or delivery costs.

Table 6-12. CDMWC In-Lieu Groundwater Recharge Estimated Project Costs

Item	Total Cost	Year Incurred	Notes
Capital Costs			
Project planning and development	$100,000	Start of project	Initial project design, planning, and implementation
O&M Costs			
Water supply cost	$1.7 million	Annual average	Average annual water purchase cost that does not include any additional O&M or overhead costs.

23 CCR §354.44(b)(8) requires a summary of how CDMWC plans to pay the costs of the project. It is anticipated that the cost of transfer purchases would primarily be recovered through CDMWC assessments. Other potential funding sources include grants, loans, and potentially, a type of cost-share program where other groundwater-dependent water users in the Subbasin share a portion of the costs since they will also realize regional benefits through this project. Appendix 7A describes different funding mechanisms, and the conceptual approach for allocating project costs across multiple potential project beneficiaries.

6.3.3 Colusa Subbasin Multi-Benefit Groundwater Recharge

6.3.3.1 Project Overview

The Nature Conservancy (TNC) is partnering with private landowners and the Colusa and Glenn Groundwater Authorities for an on-farm, multi-benefit groundwater recharge incentive program. Program objectives are to benefit:

- Disadvantaged communities and other communities by replenishing critical domestic and agricultural water supplies,
- Private landowners economically through incentive payments,
- Migratory shorebirds through the creation of critical winter habitat on farms, and
- Groundwater conditions (via groundwater recharge).

Surface water from the Sacramento River, subject to availability, is conveyed and applied to participating fields using existing diversion, conveyance, and on-farm infrastructure, flooding and maintaining ponded conditions during the program's annual implementation period.

The pilot program was initiated on Davis Ranches in Colusa County and in other locations within the Subbasin in 2018 and concluded in the spring of 2021. The pilot program evaluated different durations and locations of flooding that would provide multiple benefits for migratory shorebird habitat and groundwater recharge. The habitat and recharge benefits are equal goals of the project.

The program is planned to expand into the future. DWR will be participating in the Multi-Benefit Groundwater Recharge Project as it is expanded into a larger program. Program expansion would include:

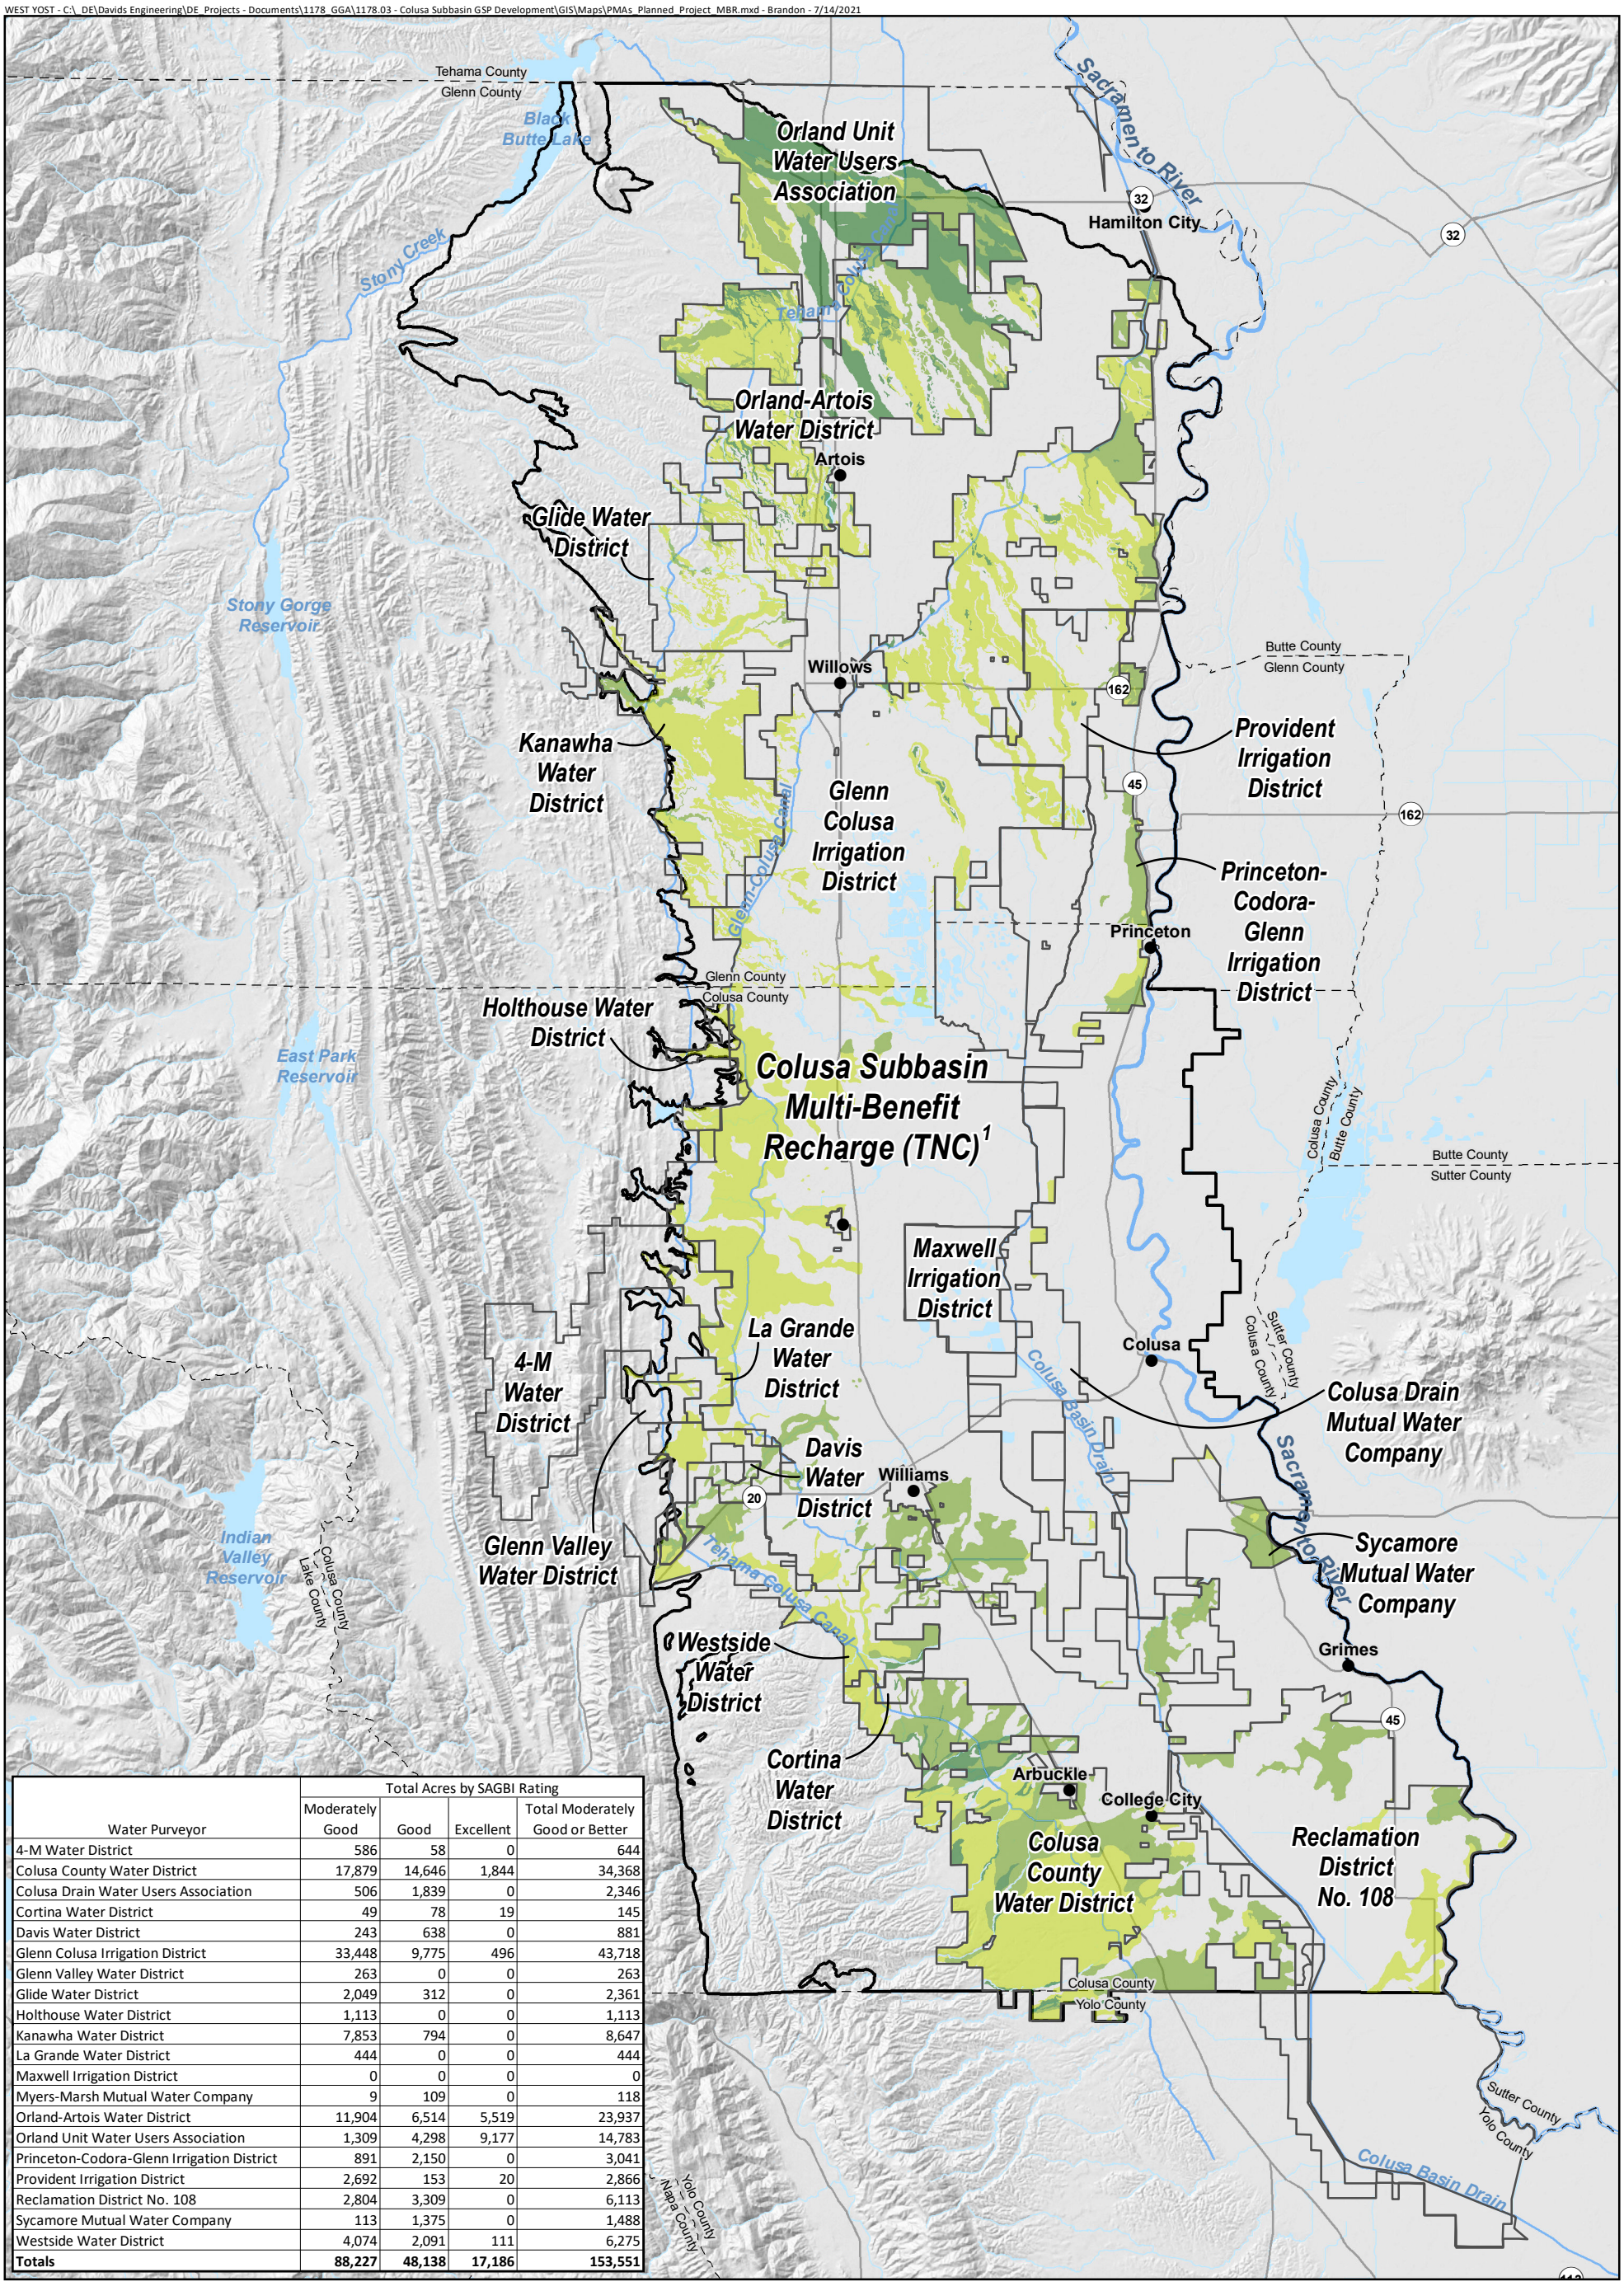
- Identifying willing landowner participants to participate in the program. Preliminary mapping based on migratory bird habitat and recharge suitability using the Soil Agricultural Groundwater Banking Index (SAGBI[7]) has been developed to identify potential areas of interest.
- Review and analyze pilot program data to quantify potential multi-benefits and evaluate economic incentives that would be required to support additional program enrollment.
- Evaluate options for funding sources to support program implementation. This may include State funding earmarked for the Department of Conversation to support multi-benefit agricultural land repurposing, or additional funding that may be allocated under potential bill AB-252 or similar initiatives.
- Develop program incentives and funding opportunities to encourage enrollment. Monitor and revise the program annually in response to landowner participant feedback and changing incentive conditions in the Subbasin (e.g., changes in the returns to farming that would affect willingness to accept payment to participate in the program). Continue to refine program to achieve desired multi-benefit outcomes.

[7] SAGBI is a suitability index indicating the potential for groundwater recharge on agricultural land, determined according to five main factors: deep percolation, root zone residence time, topography, chemical limitations, and soil surface condition. SAGBI ratings for lands in California are developed by the California Soil Resource Lab at University of California, Davis and University of California Agriculture and Natural Resources (UC-ANR) and are available online at: https://casoilresource.lawr.ucdavis.edu/sagbi/ .

With an incentive structure developed, the project would provide financial compensation for recharging groundwater through normal farming operations while also providing critical wetland habitat for shorebirds migrating along the Pacific Flyway, and potential ancillary benefits for water levels near disadvantaged communities or other communities in the Subbasin, depending on where the multi-benefit recharge projects are implemented.

Figure 6-5 below illustrates the location of lands that are potentially suitable for participation in the program near the Sacramento River, identified according to elements in the C2VSimFG-Colusa model domain. The areas indicated in Figure 6-5 were selected for modeling the potential project effects near the Sacramento River[8], though in general fields can be selected throughout the Subbasin by evaluating the SAGBI index to identify areas suitable for recharge and by evaluating land characteristics that benefit migratory shorebird habitat. In practice, the location and scale of the project will depend on the effectiveness of incentives to attract willing landowners, which might or might not be located near the river. Locations will depend on grower enrollment and could be anywhere within the Subbasin where surface water supplies are available and recharge conditions are favorable. Landowner participation would be voluntary, and subject to incentives that would be developed as part of ongoing program implementation.

6.3.3.2 Implementation



Following successful completion of a pilot program from 2018 to 2021, continuation and expansion of the project is currently being planned within the Subbasin. DWR will be participating in the Multi-Benefit Groundwater Recharge project as it is expanded into a larger program. Table 6-13 summarizes the expected implementation timeline for the expanded program.

Table 6-13. Colusa Subbasin Multi-Benefit Groundwater Recharge Implementation Timeline

Phase	Description	Start	End
Pilot Program	Completion of a pilot project for multi-benefit recharge on Davis Ranches	2018	2021
Planning for Expansion of Multi-Benefit Groundwater Recharge	Planning and coordination for expansion and continuation of multi-benefit recharge projects within the Subbasin	2018	2022
Implementation of Multi-Benefit Recharge	Implementation of multi-benefit recharge projects within the Subbasin	2022/2023	Ongoing, if deemed appropriate

[8] Project modeling is described in Appendix 6D. For modeling, proximity of lands to the Sacramento River was considered when selecting potential recharge areas because these lands are expected to have the greatest positive impact on streamflows.

Multi-Benefit Recharge Project

Colusa Groundwater Authority and Glenn Groundwater Authority
Colusa Subbasin
Groundwater Sustainability Plan

6.3.3.3 Notice to Public and Other Agencies

Public noticing for this project will be done in accordance with noticing requirements in coordination with the CGA and GGA.

6.3.3.4 Construction Activities and Requirements

There are no infrastructure construction activities and requirements, as the project will use existing infrastructure and facilities.

This project may be configured and operated to utilize existing diversion and conveyance infrastructure and facilities. If existing infrastructure and facilities are available and used for this project, there would be no anticipated infrastructure construction activities and requirements upstream of participating fields.

The program would involve some on-farm activities for participating landowners to develop "pop up" recharge sites on existing fields. The program is designed to work within existing field infrastructure and irrigation systems. Any on-farm water management modifications are expected to be modest to increase standing water on fields in specific months to support both habitat and recharge.

Depending on the existing infrastructure available in participating fields, the project may also require some on-farm activities to support project monitoring. Required project monitoring equipment may include flow meters and groundwater level monitoring devices. Prior to field flooding, the project proponents could facilitate a survey of the fields and install pressure transducers and/or flow meters at inlets and outlets and in adjacent wells to facilitate measurement of applied water and changes in groundwater depth.

6.3.3.5 Water Source

The surface water source for the project will be Sacramento River water available under existing rights, subject to availability and agreements established between TNC, CGA, GGA, and private landowners that choose to participate in this voluntary program. The water supply would need to be available during prime flooding windows that support migratory bird habitat and recharge, which are generally in the late summer and early fall (July 15 through October 15) and/or spring (March 15 through April 15). It is anticipated that water will generally be available for this project in all years except Shasta Critical years.

6.3.3.6 Circumstances and Criteria for Implementation

This pilot program was completed in spring 2021. The expanded project is currently planned for implementation, and TNC is working with potential partners. However, due to dry conditions in 2021, the project implementation was delayed. Depending on the outcome of current implementation, and landowner interest, implementation and project benefits could potentially begin in 2022/2023.

Implementation will proceed in several phases. The first phase will be selection of sites suitable for multi-benefit recharge (see above). This would concurrently include initiation of any required environmental documentation. Site selection will be based on:

- Lands that would provide multiple benefits for bird habitat and local communities.
- Soil characteristics that are suitable for recharge, using the SAGBI index in addition to local data developed for the GSP or in coordination with landowner partners.

- Identification of crop types that are suitable for recharge and could accept flooding in late summer and early fall (July 15 through October 15) and/or spring (March 15 through April 15), with minimal impacts (costs) to crops and farming operations.
- Availability of surface water rights and infrastructure to support implementation of the program.
- Availability of existing measurement and monitoring infrastructure.

The second phase of implementation will include developing incentives to encourage landowner participation. This would concurrently include identification of potential funding sources to support the program. Incentives would consider:

- Landowner costs to participate in the program (e.g., on-farm costs, potential crop damage, other direct costs to implement recharge).
- Benefits that would accrue to the local region, the Subbasin, and general public from implementation of the program. These may include improved groundwater levels, other groundwater sustainability indicators, and regional benefits of improved habitat for migratory birds.
- Funding sources would be identified to develop financial incentives. In addition, some program costs could be covered with GGA and CGA participation, where costs would be allocated in proportion to benefits received.

The final phase of program implementation would include ongoing monitoring to measure groundwater (and habitat) benefits for the Subbasin. It is expected that this would result in adjustment to program parameters to support continued expansion and adoption of the program.

Implementation of the multi-benefit program does not depend on the implementation or performance of other PMAs or district activities. Operation of this pilot project could be continued if deemed appropriate. Any future changes will be made to align with landowner participant goals and the overall Subbasin sustainability goal.

6.3.3.7 Legal Authority, Permitting Processes, and Regulatory Control

The multi-benefit recharge project will be implemented as a collaborative effort between private landowners that have the legal authority to implement this project and facilitate multi-benefit recharge on their lands. Implementation will be done in accordance with the required permitting processes and regulatory control.

The following agencies have potential permitting roles for the multi-benefit groundwater recharge project: the Counties of Colusa and/or Glenn, the CGA and GGA, SWRCB, and Reclamation. The project may also require applications for permits required from the SWRCB for diversion of surface water to the extent that diversion is not already permitted under existing water rights and contracts. Recharge projects may also require an environmental 1199 process under CEQA. If required, this project would need either an Environmental Impact Report and Negative Declaration or Mitigated Negative Declaration.

6.3.3.8 Project Operations and Monitoring

Operations and monitoring will be completed by the various project proponents to evaluate the benefits described in the next section. It is anticipated that the total amount of surface water applied to the field will be measured, other flow paths will be measured or estimated, and the amount of recharge achieved will be determined using a mass balance approach. This is consistent with the approach used in the pilot program.

During the implementation period, participants will spread water on their fields and maintain a shallow depth (4 inches maximum) for four to six weeks. Landowner participants will record any changes in water flow in an irrigation log, or other field measurement as appropriate. TNC would coordinate monitoring of field depth, bird presence, water delivery, and changes in groundwater depth.

Project performance would be summarized as part of GSP annual reports and five-year updates.

6.3.3.9 Project Benefits

The primary benefits of the project are direct groundwater recharge and temporary habitat creation for migrating shorebirds, with benefits to the sustainability indicators previously shown in Table 6-3. The potential project groundwater recharge benefits were evaluated in the C2VSimFG-Colusa model, assuming that approximately 4,100 acres participate in the program each year that water is available (anticipated in all but Shasta Critical years). The model was used to simulate field flooding on participating land within the elements identified in Figure 6-5 during the annual project implementation period.[9] From this analysis, it is estimated that an average of 11.5 taf/yr of surface water could be delivered to those participating lands over all year types for multi-benefit recharge, or approximately 2.8 feet per acre of participating land. Over all years simulated, this results in an average annual net groundwater recharge benefit of approximately 5.2 taf/yr, or approximately 1.3 feet per acre of participating land. Additionally, environmental benefits will occur through habitat for migrating shorebirds. All benefits will ultimately depend on grower participation in the program, as it affects the scale of recharge areas and the location where recharge occurs.

During project implementation, actual benefits each year will be evaluated as described in Section 0. Potential project benefits have been assessed, and may continue to be assessed, using the C2VSimFG-Colusa model developed for GSP development by simulating groundwater conditions with and without the project. Additional information on the project modeling is described in Appendix 6D.

Program participation will vary from year to year, depending on landowner interest, financial incentives, water availability, changes in crop market conditions, and sustainability indicators. The program is anticipated to continue every year, providing both groundwater recharge and migratory bird habitat along the Pacific Flyway.

6.3.3.10 Project Costs

Project costs include costs of incentive payments to landowners, land preparation, water conveyance and application, and operations and monitoring.

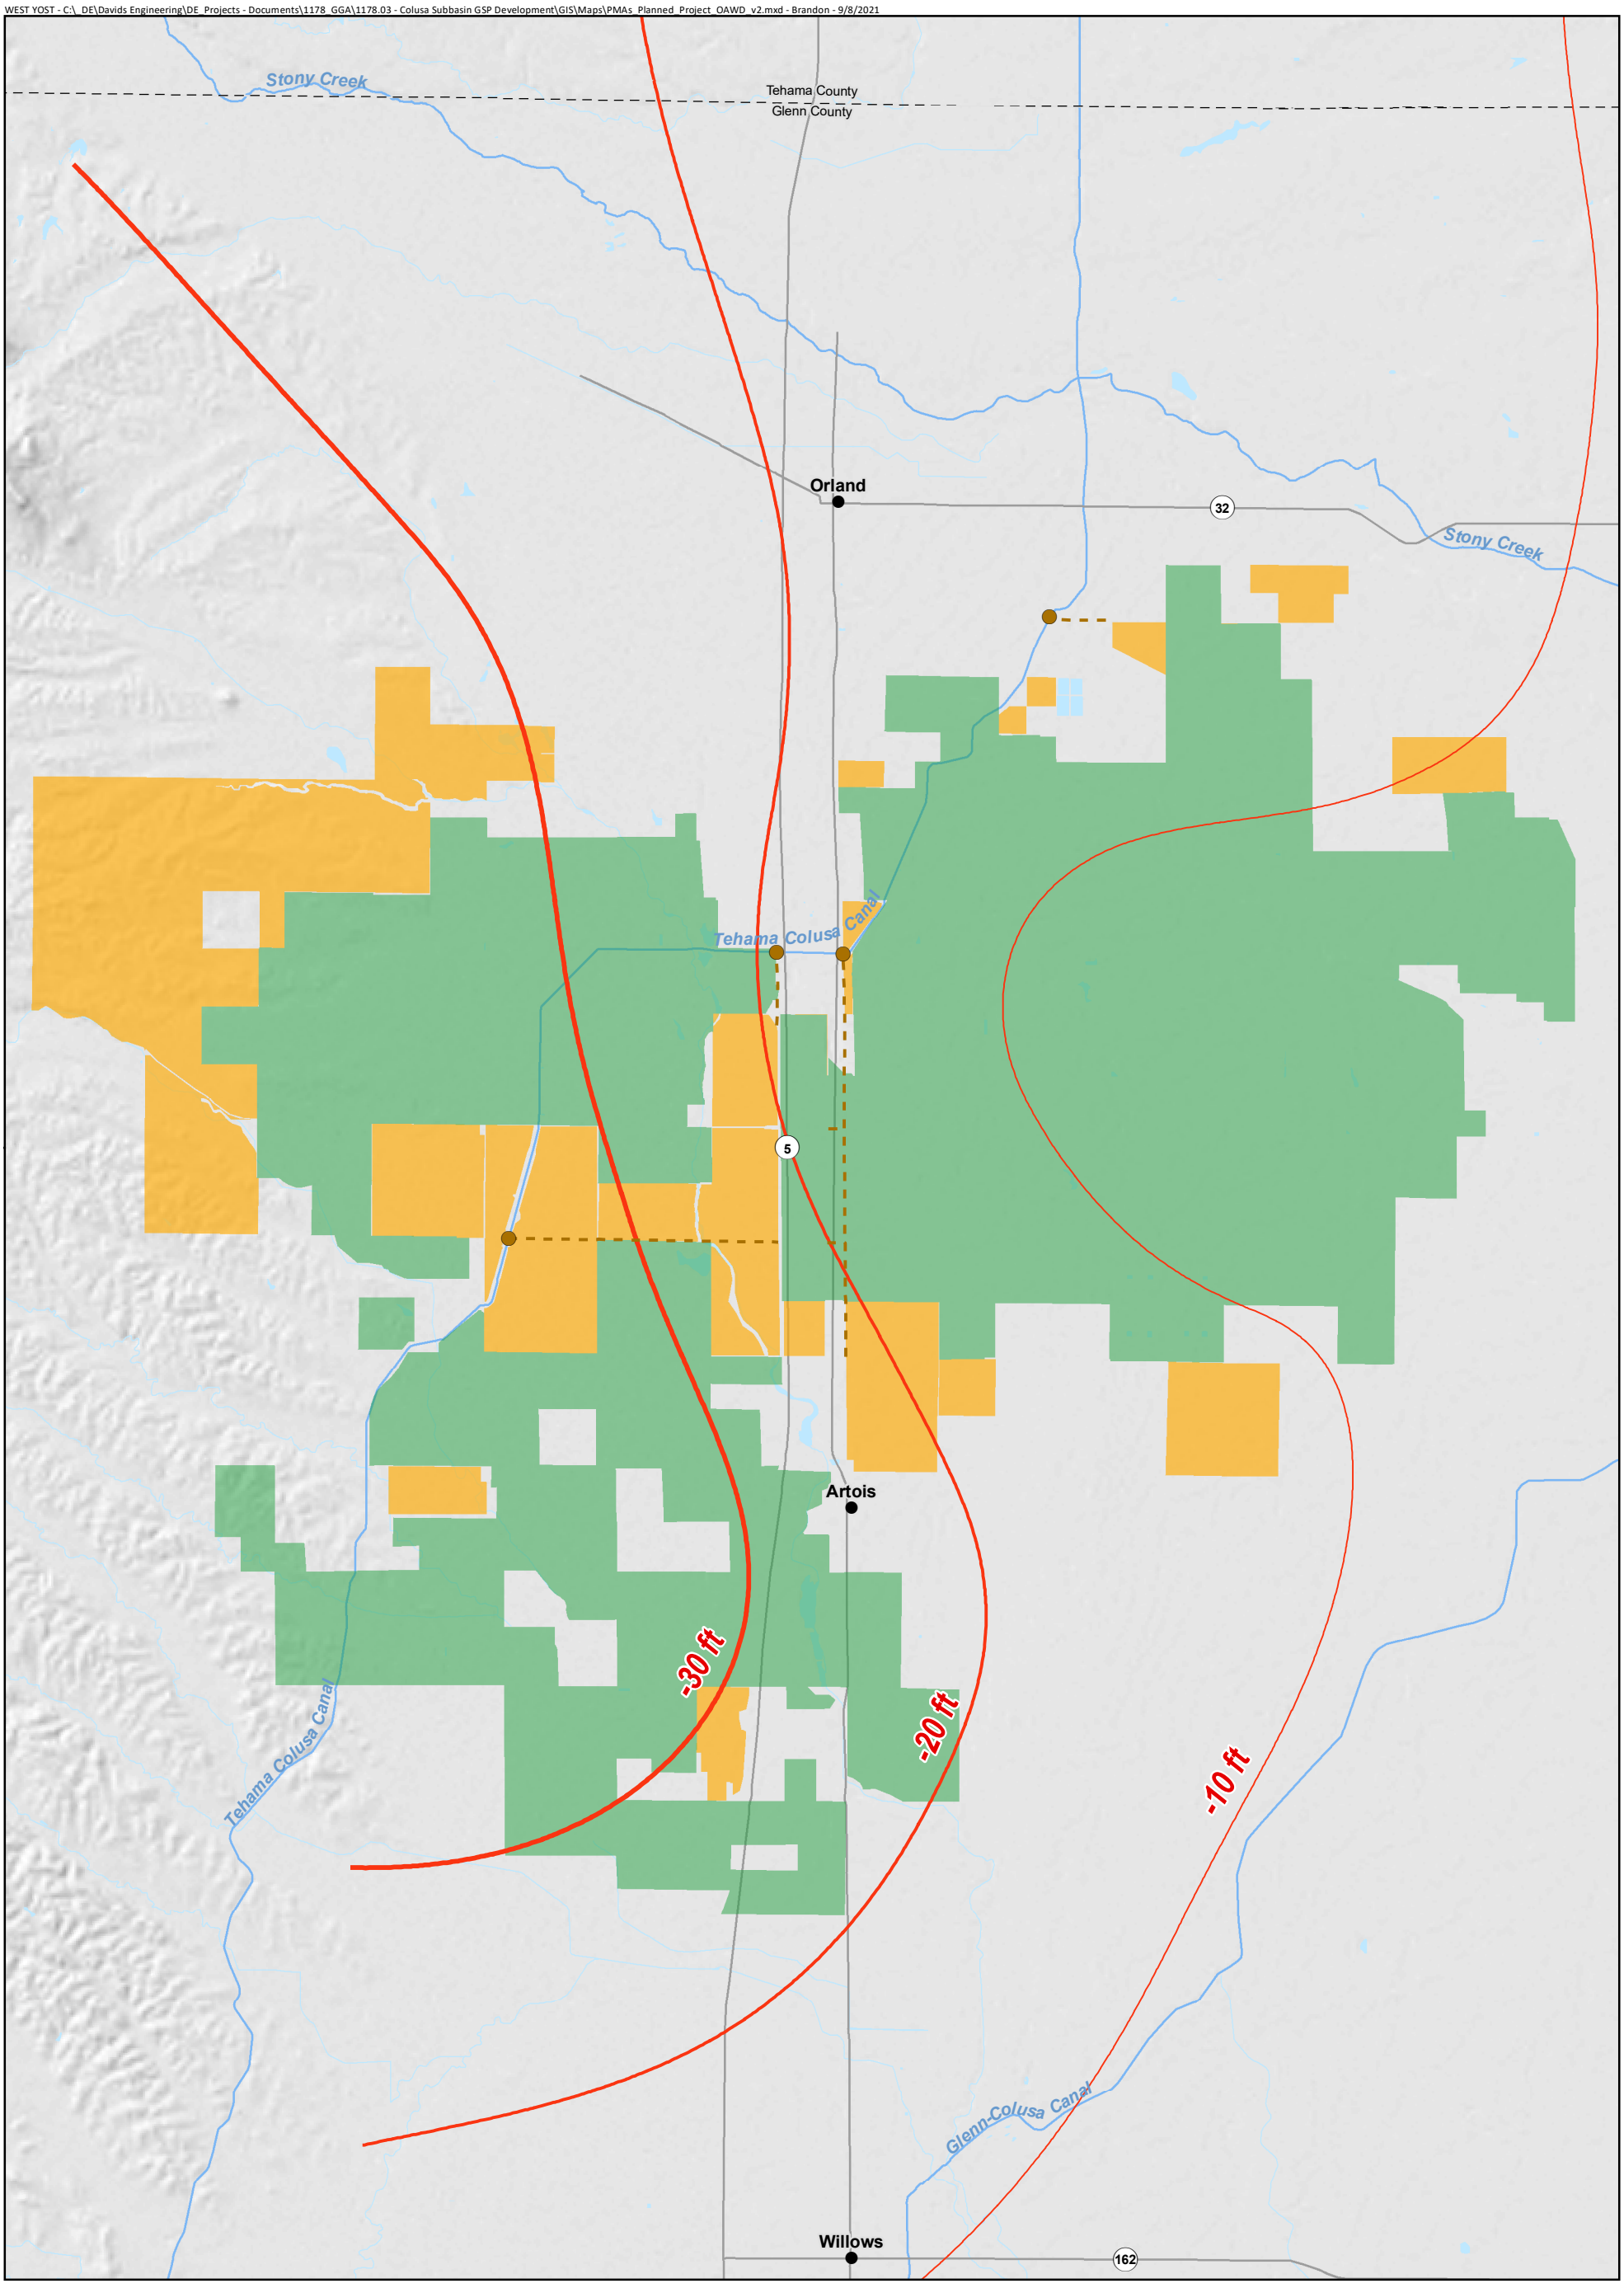
[9] Multi-benefit recharge was modeled by applying water during a 30-day flooding window (September) to designated irrigated lands (approximately 4,100 acres total) within the selected model elements. Soil characteristics were set to simulate flooding by setting the target soil moisture equal the total porosity of the soil.

Table 6-14 summarizes typical program costs based on the results of the pilot project. Costs are greatest in the initial year of the program due to coordination and site preparation but would be expected to fall over time. Site-specific costs will vary based on field conditions and changes to the program over time. As such, the total costs of the program will vary over time, depending on the number of participating landowners.

Table 6-14. Colusa Subbasin Multi-Benefit Groundwater Recharge Estimated Project Costs

Item	Total Cost	Year Incurred	Notes
Capital Costs			
Site preparation	$4,000	First project year	Per site cost
O&M Costs			
Site management	$3,000	All years	Per site cost. Includes on-farm equipment, labor, and administration costs.
Other O&M cost	TBD	All years	Additional water costs, conveyance, and other site-specific costs would be assessed as part of entering into an agreement with willing landowners

23 CCR §354.44(b)(8) requires a summary of how the project proponent plans to pay these costs. It is anticipated that the cost of incentivizing multi-benefit on-farm recharge would primarily be recovered through funding sources including grants, loans, and potentially, a type of cost-share program where other groundwater-dependent water users in the Subbasin share a portion of the costs since they will also realize regional benefits through this multi-benefit recharge project. Appendix 7A describes different funding mechanisms, and the conceptual approach for allocating project costs across multiple potential project beneficiaries.



6.3.4 Orland-Artois Water District Land Annexation and In-Lieu Groundwater Recharge

6.3.4.1 Project Overview

Orland-Artois WD (OAWD), a Central Valley Project (CVP) water contractor, is working with a group of neighboring non-district landowners to annex approximately 12,000 acres into the district. Figure 6-6 illustrates the location of lands that would be annexed into the district. These lands are already developed agricultural lands that currently rely solely on groundwater for irrigation water supplies. Supplemental surface water for the annexed lands would be secured through annual and multi-year purchase or transfer agreements with willing sellers, conveyed through the existing TCC, and distributed to the annexed lands through new distribution facilities. New facilities include turnouts off the TCC, pipelines, pumping plants, and metered farm deliveries.

It is estimated that approximately 25 taf of surface water would be delivered to annexed lands in all years but Shasta Critical years, resulting in a reduction of groundwater pumping of 23 taf/yr on average across all years. Additionally, certain annexed lands with high infiltration characteristics would be configured for direct recharge by surface spreading. Direct recharge would be done primarily with Section 215 water. Preliminary project design shows seven proposed recharge areas totaling 371 acres in the project. OAWD is evaluating recharge potential and will refine these estimates.

Figure 6-6

Orland-Artois WD Land Annexation and Groundwater Recharge Overview

Colusa Groundwater Authority and Glenn Groundwater Authority
Colusa Subbasin
Groundwater Sustainability Plan

This project would address an area within the Subbasin where groundwater levels have been in decline in recent years due to increasing irrigation demands being met through groundwater pumping, compounded in recent years by drought and related curtailments of surface water supplies to OAWD and other neighboring CVP contractors. The sustainability indicators expected to benefit from the project are groundwater levels, groundwater storage, and depletion of interconnected surface water.

6.3.4.2 Implementation

Planning is currently underway for annexation of these lands into OAWD and extension and expansion of the OAWD distribution system. Table 6-15 summarizes the current and planned implementation of the project. It is anticipated that annexed lands would receive surface water deliveries starting in 2025.

Table 6-15. OAWD Land Annexation and In-Lieu Groundwater Recharge Implementation Timeline

Phase	Description	Start	End
Annexation of Additional Lands	Determination of terms and conditions of annexation; development of agreements between OAWD and landowners; requires approval by OAWD, Reclamation, and Glenn LAFCO	2020	2022
Negotiation of Annual and Multi-year Water Purchase or Transfer Contracts	Including engineering and environmental review; requires approval by TCCA, Reclamation and OAWD	2021	2022
Design of New Facilities	Including engineering and environmental review; requires approval by TCCA, Reclamation, and OAWD	2021	2022
Construction of New Facilities	Construction of new turnouts off Tehama-Colusa Canal, pumping plants, pipelines, and metered farm deliveries	2023	2025
Delivery of Surface Water to Annexed Lands	Delivery of purchased or transferred surface water under multi-year agreements	2025	Annually, in perpetuity, except for Shasta-Critical years

6.3.4.3 Notice to Public and Other Agencies

Public noticing for this project will be done in accordance with noticing requirements in NEPA and CEQA, as well as noticing for public meetings held by OAWD, TCCA, and Glenn LAFCO.

6.3.4.4 Construction Activities and Requirements

Construction of new water conveyance facilities will be required for distribution of surface water from the existing TCC to the newly annexed lands. The new facilities include the following:

- Approximately four new turnouts on the TCC to regulate releases from the canal into newly constructed distribution facilities
- Pumping plants on the TCC to lift water to annexed lands that are up-gradient from the TCC

- Distribution pipelines ranging in size from approximately 12 to 36 inches in diameter
- Farm deliveries with instantaneous and totalizing flow measurement devices
- Recharge basins for surface spreading in certain locations with high infiltration rate (gravelly) soils

6.3.4.5 Water Source

The surface water source for the project will come from multiple Sacramento Valley entities with existing surface water entitlements that are willing to transfer water in normal to wet year types. These entities include CVP water supply and settlement contractors and, potentially, Sacramento River water rights holders. The intent is to acquire the water through annual and multi-year, renewable water purchase or transfer agreements, building on similar existing agreements that OAWD has with certain Sacramento Valley entities. Surface water supplies would be diverted from the Sacramento River at the Red Bluff Pumping Plant and Fish Screen facility and conveyed through the Tehama-Colusa Canal, which is operated and maintained by the Tehama-Colusa Canal Authority.

Appendix 6A summarizes an assessment of the volumes of water available for transfer in the Subbasin. The water availability assessment finds there is sufficient water available for transfer for the OAWD project, in addition to the other four planned GSP recharge projects.

6.3.4.6 Circumstances and Criteria for Implementation

This project is planned for implementation as soon as possible, with planning for annexation and new facilities design already underway. In the latter half of 2020 and in 2021, the planning effort has included multiple discussions with OAWD, TCCA and Glenn LAFCO. A formal letter has also been submitted by OAWD to the USBR notifying them of the proposed project. The initial feedback from all agencies has been positive to date.

6.3.4.7 Legal Authority, Permitting Processes, and Regulatory Control

As a Water District, OAWD has the legal authority to pursue expansion of their service area and provide for the acquisition and conveyance of supplemental surface water to these additional lands. The planning and implementation of this project will be done in accordance with the required permitting processes and regulatory control.

Governing agencies with which consultation may need to be initiated include, but are not limited to: DWR, SWRCB, CDFW, the Flood Board, Regional Water Boards, Reclamation, USACE, USFWS, NMFS, LAFCO, the County of Colusa and/or Glenn, and CARB.

Specific permitting and regulatory processes that may affect the construction of new infrastructure include, but are not limited to:

- USACE Section 404 Permits (potential exemption under Section 404(f)(1)(C) of Clean Water Act)
- Regional Water Quality Control Board Section 401 Water Quality Certification (not required if exempt from USACE Section 404)
- SWRCB Construction General Permit and SWPPP
- SHPO and NHPA Section 106 Coordination

- California Endangered Species Act (CESA) Consultation
- ESA Compliance
- NEPA Compliance
- CEQA Compliance

6.3.4.8 Project Operations and Monitoring

OAWD plans to operate and maintain its existing district facilities, new facilities for annexed lands, and conduct project monitoring.

Project monitoring will include a range of activities to evaluate the benefits described in the next section. This will include local monitoring to track the additional volumes of water made available through transfers and estimates of the reduction in pumping relative to pre-project baselines. The district plans to monitor deliveries of surface water to newly annexed lands in-lieu of groundwater pumping. The benefit of in-lieu recharge on sustainability indicators in the Subbasin (groundwater levels and groundwater storage) will be monitored using the monitoring network sites and monitoring practices described in the GSP (Chapter 4).

6.3.4.9 Project Benefits

The primary benefit of the project is reduction of groundwater pumping resulting from in-lieu groundwater recharge with benefits to the sustainability indicators previously shown in Table 6-3. It is estimated that approximately 25 taf of surface water would be delivered to annexed lands in all years but Shasta Critical years, resulting in an average reduction of groundwater pumping of 23 taf/yr across all years.

Certain annexed lands with high infiltration characteristics would be configured for direct recharge by surface spreading. Direct recharge would be done primarily with Section 215 water. The direct recharge capacity has not yet been estimated. These benefits would be realized after construction of the water delivery infrastructure is complete and delivery of surface water to these newly annexed lands begins.

Table 6-16 summarizes the expected annual volume of in-lieu recharge under the OAWD program. Project benefits have been assessed, and may continue to be assessed, using the C2VSimFG-Colusa model developed for GSP development by simulating groundwater conditions with and without the project. Additional information on the project modeling is described in Appendix 6D. Transfer volumes would vary in Shasta Non-Critical years based on the terms of the transfer agreements, and broader water market conditions. It is anticipated that OAWD transfer volumes would vary with availability of CVP supplies in Shasta Non-Critical years. Average CVP contract deliveries were 75 percent between 1990 and 2021, over the more recent 15 years, average deliveries were 67 percent of contracts. At full implementation (in 2025) the expected average annual volume equals 25 taf in Shasta Non-Critical years, with total average annual volume of 23 taf.

Table 6-16. OAWD Land Annexation and In-Lieu Groundwater Recharge Estimated Average Recharge Volume by Year Type, in af/yr (2016-2065)

Year Type	Total Annual Volume	% of Years	Weighted Avg.
Shasta Non-Critical	Up to 25,000	90%	22,500
Shasta Critical	0	10%	0
Average Annual	-	-	**22,500**

6.3.4.10 Project Costs

Project costs include the cost of purchased water, applicable costs associated with the use of the TCC, capital costs associated with construction of new facilities, and OAWD operation and maintenance costs for the facilities serving the annexed lands. Efforts are currently underway by OAWD and owners of proposed annexed lands to estimate these project costs, and to identify funding sources and establish repayment terms. Table 6-17 summarizes estimated project costs.

Table 6-17. OAWD Land Annexation and In-Lieu Groundwater Recharge Estimated Project Costs

Item	Total Cost	Year Incurred	Notes
Capital Costs			
Distribution system and LAFCO costs	$20 million	Start of project	Preliminary cost estimate; OAWD is currently refining the cost of expanding its distribution to serve the annexed lands. Annexed lands would be responsible for additional costs.
O&M Costs			
Water supply cost	$1.9 million	Annual average	Average annual water purchase cost to acquire water in W, AN, and BN years; costs are incurred in years when water is available.
Other O&M cost	$0.73 million	Annual average	Estimated O&M costs, not including volumetric charge.

The cost of purchased and transferred water will be defined in the water transfer agreements. A detailed assessment of the water transfer market in the Subbasin and greater Sacramento Valley is beyond the scope of this initial project investigation for the GSP. Water transfer prices have increased substantially over the last decade. This is due to a combination of more limited supply due to drought, GSP implementation in the San Joaquin Valley, and the biological opinion regarding operation of the CVP system, as well as demand driven by plantings of permanent crops and strong nut prices.

As shown in Table 6-11 in Section 6.3.2, the weighted-average cost for the lower range of within-Sacramento Valley transfer prices is $83 per af. With approximately 23 taf average annual supply, the expected annual water supply cost (excluding any additional O&M or overhead charges) is $1.9 million. Other operating and maintenance (O&M) costs for the annexed lands are estimated based on current OAWD charges, which include an operations charge of $38.11 per acre and CVP Construction charge of $23.00 per acre. This does not include any additional district O&M costs recovered through volumetric charges.

Potential funding sources include grants, loans, and potentially, a type of cost-share program where other groundwater-dependent water users in the Subbasin share a portion of the costs since they will also realize regional benefits through this in-lieu recharge project.

23 CCR §354.44(b)(8) requires a summary of how OAWD plans to cover the costs of the project. It is anticipated that the cost of transfer purchases would primarily be recovered through OAWD assessments. Landowners in annexed lands would pay for additional distribution system costs. Other potential funding sources include grants, loans, and potentially, a type of cost-share program where other groundwater-dependent water users in the Subbasin share a portion of the costs since they will

also realize regional benefits through this project. Appendix 7A describes different funding mechanisms, and the conceptual approach for allocating project costs across multiple potential project beneficiaries.

6.3.5 Sycamore Slough Groundwater Recharge Pilot Project

6.3.5.1 Project Overview

Proctor and Gamble (P&G) and Davis Ranches recently entered into a cooperative agreement to implement a 10-year groundwater recharge pilot project. The project will apply surface water diverted from the Sacramento River to a 66-acre field on Davis Ranches for groundwater recharge and to provide habitat for migrating waterfowl for 30 to 45 days during the fall or winter each year. The timing of the project may be targeted to provide fall and winter habitat for migratory shorebirds, in addition to groundwater recharge benefits. However, the precise timing of the project is flexible to accommodate changes in water availability and other factors between years.

Sacramento River water is available to Davis Ranches under riparian rights and a Sacramento River settlement contract with Reclamation. If the project starts before November 1, settlement contract water would be used. Otherwise, riparian water rights would be exercised for beneficial use (habitat). The objective is to recharge 5,000 acre-feet over the 10-year study period and to revegetate a portion of Sycamore Slough. Monitoring of groundwater conditions will be done in eight existing groundwater wells, including dedicated monitoring wells and agricultural production wells. If the project is successful and cost effective it could be continued in perpetuity to sustain long-term groundwater recharge and environmental benefits. Subject to acquisition of funding, an expansion of the project is planned for recharge and revegetation in the neighboring Sycamore and Dry Sloughs. The general project location is shown in Figure 6-7.

6.3.5.2 Implementation

The project implementation timeline is shown in Table 6-18. The pilot project is scheduled to begin in the early fall of 2021 and will proceed for ten consecutive years. Subject to acquisition of funding, an expansion of the project is planned for neighboring Sycamore and Dry Sloughs in future years.

Table 6-18. Sycamore Slough Groundwater Recharge Pilot Project Implementation Timeline

Phase	Description	Start	End
Pilot Project	Develop and implement pilot project program	2021	2030
Evaluation and Project Updates	Perform periodic project assessments and update project accordingly	2021	2030
Project Expansion	Evaluate opportunities to expand the project to additional lands in Dry and Sycamore Sloughs	2025	2030
Full Program Implementation	Adjust program based on pilot project performance, and scale program based on interest and funding availability; implement full program	2031	Annually, in perpetuity

0 0.5 1
Scale in Miles

6.3.5.3 Notice to Public and other Agencies

Public noticing for this project will be done in accordance with all legal noticing requirements. The project is funded through a private grant, and there is no requirement for public notice at initiation. However, the project proponents plan to host public outreach events and field days to communicate and illustrate project goals, challenges, and successes.

6.3.5.4 Construction Activities and Requirements

There are no infrastructure construction activities and requirements, as the project will use existing infrastructure and facilities. Minor earthwork would be required on the pilot project field to support increased recharge and bird habitat.

Future expansion of the program to other participating lands may require a similar level of earthwork to increase recharge and habitat benefits. No major construction activities are anticipated at this time.

6.3.5.5 Water Source

The surface water source for the project will be Sacramento River water available to Davis Ranches under existing riparian rights and an existing Sacramento River settlement contract with Reclamation (before November 1). The water would be diverted and conveyed through existing facilities.

6.3.5.6 Circumstances and Criteria For Implementation

The pilot project is scheduled to begin in the early fall of 2021 and will proceed for ten consecutive years through 2030.

Subject to acquisition of funding, an expansion of the project is planned for neighboring Sycamore and Dry Sloughs in future years. If the project is successful and cost effective it could be continued in perpetuity to sustain long-term groundwater recharge and environmental benefits.

6.3.5.7 Legal Authority, Permitting Processes, and Regulatory Control

As a private landowner, Davis Ranches has the legal authority to implement this project. Implementation will be done in accordance with the required permitting processes and regulatory control.

The following agencies have potential permitting roles for the Sycamore Slough groundwater recharge pilot project: the County of Colusa, SWRCB, and Bureau of Reclamation. Davis Ranches has access to water through existing riparian rights and a Sacramento River settlement contract with Reclamation.

Recharge projects may also require an environmental 1199 process under CEQA. If required, this project would need either an Environmental Impact Report and Negative Declaration or Mitigated Negative Declaration.

6.3.5.8 Project Operations and Monitoring

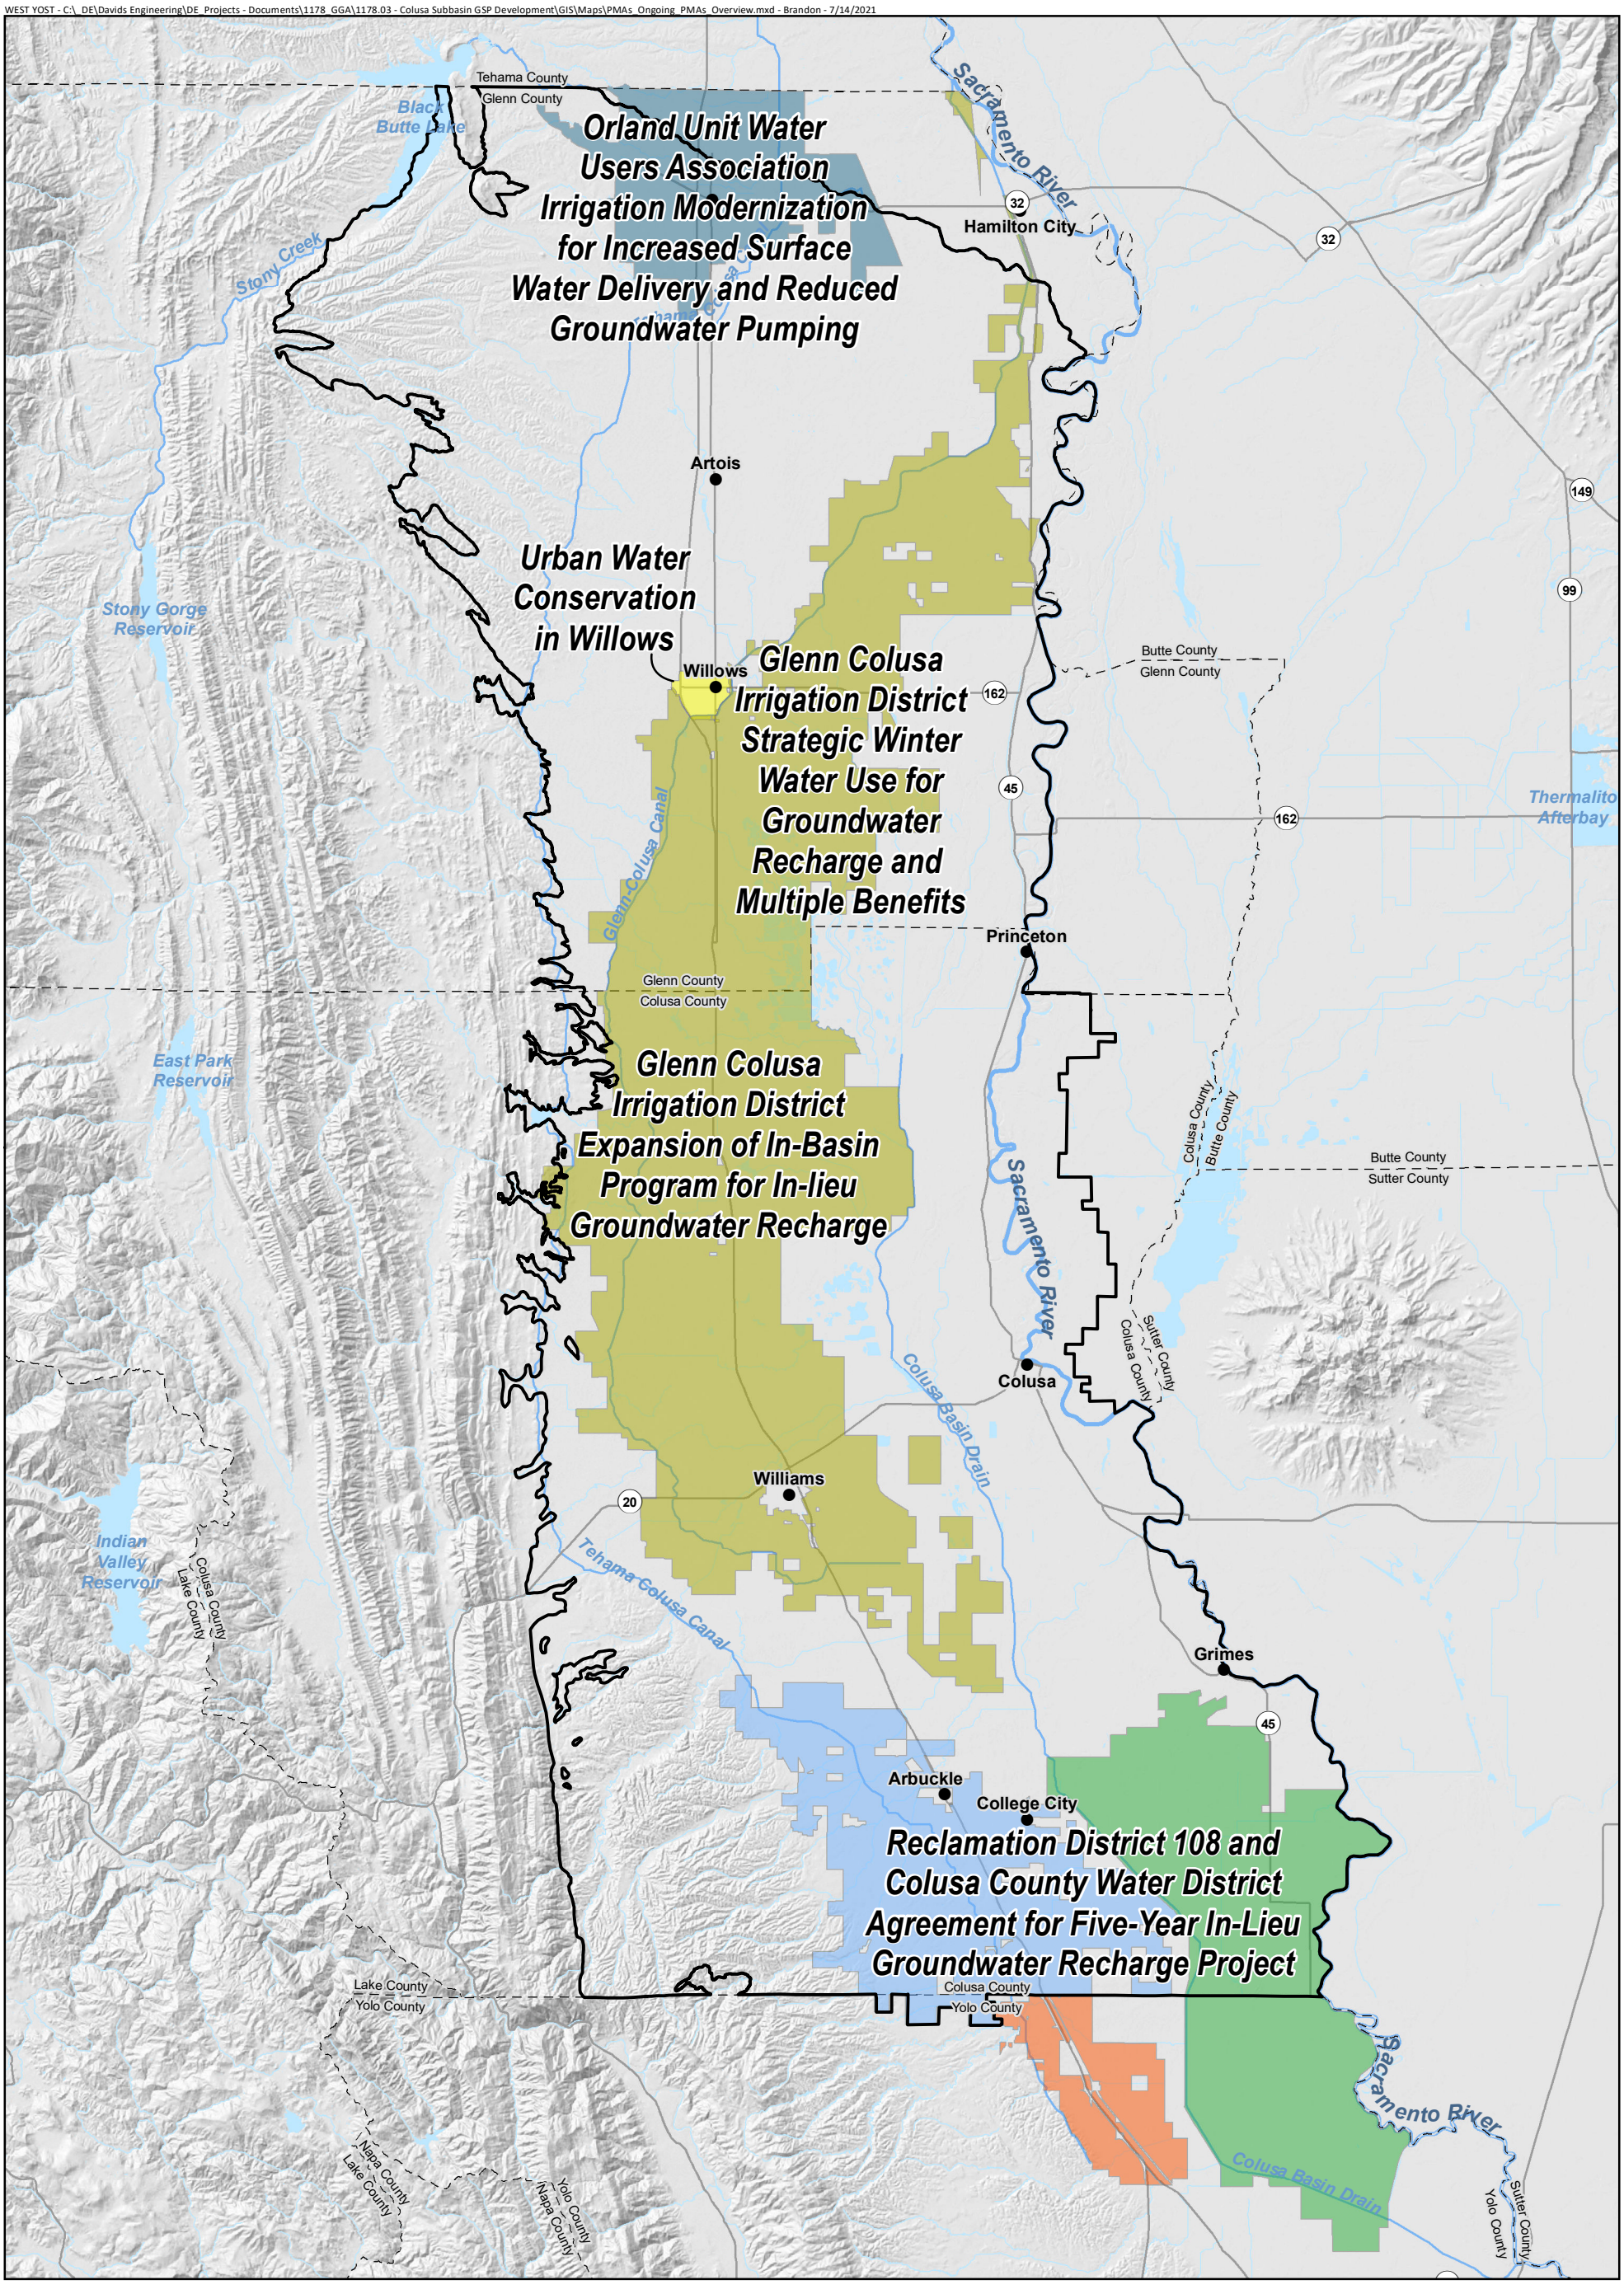
Davis Ranches will operate and maintain project facilities and monitoring equipment. Monitoring will be completed to evaluate the benefits described in the next section. The total amount of surface water applied to the field will be measured, other flow paths will be measured or estimated, and the amount of recharge achieved will be determined using a mass balance approach. Groundwater levels in eight groundwater wells in the project vicinity will be monitored and analyzed to determine the extent and magnitude of benefits to groundwater conditions.

6.3.5.9 Project Benefits

The primary benefits of the project are direct groundwater recharge and temporary bird habitat formation, with benefits to the sustainability indicators previously shown in Table 6-3. The objective of the pilot project is to recharge 5,000 acre-feet of water over ten years, with the potential to increase this volume if the project is expanded for neighboring Sycamore and Dry Sloughs in future years. Groundwater recharge benefits could also be assessed using the C2VSimFG-Colusa model developed for GSP development by simulating groundwater conditions with and without the project. Additionally, environmental benefits will occur through habitat for migrating waterfowl and revegetation of a portion of Sycamore Slough.

6.3.5.10 Project Costs

Project costs include costs of land preparation, water application, operations and monitoring, and revegetation costs. The estimated capital cost for monitoring equipment is approximately $28,000, and the estimated annual costs for project implementation total approximately $26,000 per year. The pilot project has secured funding through P&G for ten years, and Davis Ranches is currently working with the Freshwater Trust to identify other potential funders for expansion of the recharge program or longer-term funding beyond the 10-year pilot project.



23 CCR §354.44(b)(8) requires a summary of how P&G and Davis Ranches would cover the costs of the project. Initial program costs are covered under a grant. Potential future funding sources include grants, loans, and potentially, a type of cost-share program where other groundwater-dependent water users in the Subbasin share a portion of the costs since they will also realize regional benefits through this project. Appendix 7A describes different funding mechanisms, and the conceptual approach for allocating project costs across multiple potential project beneficiaries.

6.4 ONGOING PROJECTS AND MANAGEMENT ACTIONS

Several agencies and other proponents have ongoing projects and actions which could provide benefits with respect to one or more of the sustainability indicators. In accordance with 23 CCR §354.44(a) these are PMAs that would allow GSAs to achieve the sustainability goal for the Subbasin and avoid minimum thresholds defined in this GSP under future, changing conditions.

Data for these PMAs will be developed under future monitoring, and as the GSAs continue to identify and fill data gaps and reported in annual reports. Ongoing PMAs are classified by projects and management actions, which are described in the following subsections. Projects are generally structural activities that include direct recharge and in-lieu recharge. Management actions are activities to improve water management or reduce groundwater pumping. There is one ongoing management action, which is an urban water conservation project in the Willows area. Figure 6-8 illustrates the location of ongoing PMAs in the Subbasin.

WEST YOST - C:_DE\Davids Engineering\DE_Projects - Documents\1178_GGA\1178.03 - Colusa Subbasin GSP Development\GIS\Maps\PMAs_Ongoing_PMAs_Overview.mxd - Brandon - 7/14/2021

Scale in Miles

Figure 6-8

Ongoing Projects and Management Actions Overview

Colusa Groundwater Authority and Glenn Groundwater Authority
Colusa Subbasin
Groundwater Sustainability Plan

Ongoing PMAs are described at a reconnaissance-level of detail relative to the planned projects described under Section 6.3, above. However, project information is still reported in accordance with 23 CCR §354.44(b). The required information is summarized in a table following the general description for each ongoing PMA. The information provided with each ongoing project table maps to the GSP regulation requirements as follows:

- Implementation (§354.44(b)(1)(A))
- Timeline (§354.44(b)(4))
- Notice to public and other agencies (§354.44(b)(1)(B))
- Water source and reliability (§354.44(b)(6))
- Legal authority, permitting processes, and regulatory control (§354.44(b)(3), (§354.44(b)(7))
- Benefits and benefit evaluation methodology (§354.44(b)(5), (§354.44(b)(9))
- Costs (§354.44(b)(8))

6.4.1 Ongoing Projects

This section describes ongoing projects. Ongoing projects include direct and in-lieu recharge opportunities being implemented across the Subbasin. Table 6-19 summarizes the ongoing projects included in the GSP. The following subsections provide project descriptions for each project.

Table 6-19. Summary of Ongoing Projects

Project	Project Type	Proponent	Year Implemented	Estimated Capital / Establishment Cost, $M	Gross Average Annual Benefit, af/yr
Reclamation District 108 and Colusa County Water District Agreement for Five Year In-Lieu Groundwater Recharge Project	In-lieu Groundwater Recharge	RD108 and CCWD	Pending Extension	Under Development	8,000
Glenn-Colusa Irrigation District Strategic Winter Water Use for Groundwater Recharge and Multiple Benefits	Direct and In-lieu Groundwater Recharge	GCID	2021	Under Development	TBD
Sycamore Marsh Farm Direct Recharge Project[(a)]	Direct Groundwater Recharge	Landowner	2020	Under Development	TBD
Glenn-Colusa Irrigation District Expansion of In-Basin Program for In-lieu Groundwater Recharge	In-lieu Groundwater Recharge	GCID	2021	Under Development	TBD
Orland Unit Water Users Association Irrigation Modernization for Increased Surface Water Delivery and Reduced Groundwater Pumping	In-lieu Groundwater Recharge	OUWUA	2021	Under Development	TBD

(a) Project is not depicted on the map in Figure 6-8.

6.4.1.1 Reclamation District 108 and Colusa County Water District Agreement for Five-Year In-Lieu Groundwater Recharge Project

RD108 and CCWD (and Dunnigan Water District [DWD] located in the neighboring Yolo Groundwater Subbasin) are entering the final year (2022) of a five-year agreement that provides for the purchase of water by CCWD (and DWD) from RD108. The purchased water is available to RD108 through contractual rights under Sacramento River Settlement Contract 14-06-200-876A between RD108 and the Bureau of Reclamation. Under the five-year agreement, 10,000 acre-feet is purchased by and transferred to CCWD and DWD, with 80 percent of the 10,000 acre-feet going to CCWD and 20 percent to DWD. Water purchased under the agreement is diverted at the Red Bluff Pumping Plant and Fish Screen facility and conveyed via the Tehama-Colusa Canal for distribution within CCWD and DWD. The price schedule for the water is tied to Reclamation's annual water rates with an additional charge per acre-foot that depends on CCWD's annual allocation under its CVP contract. The additional charge varies from $0 per acre-foot to $50 per acre-foot. However, in years when RD108's water supply under its settlement contract is cut by 75 percent, the price schedule does not govern and instead the price is $275 per acre-foot. It is expected that the five-year agreement will be extended with the price schedule potentially renegotiated.

This project supplies additional surface water to CCWD (and DWD) that provides in-lieu recharge to meet water demands that otherwise would be met through groundwater pumping.

A summary of the project is provided in Table 6-20.

Table 6-20. Reclamation District 108 and Colusa County Water District Agreement for Five-Year In-Lieu Groundwater Recharge Project Summary

Item	Description
Implementation	RD108 and CCWD proposed this project, if extended, for GSP implementation in the CCWD service area. The project provides in-lieu groundwater recharge through utilization of surface water supplies available to RD108. This is an ongoing project, which will be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	The current project is ending, and extension is still pending. Thus, the start and completion dates for this project have yet to be determined and will be provided in GSP annual reports and five-year updates when known.
Notice to public and other agencies	Public and/or Inter-Agency Noticing is being facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	The source is Sacramento River water available to RD108 through contractual rights under existing Sacramento River Settlement Contract 14-06-200-876A between RD108 and the Bureau of Reclamation.

Table 6-20. Reclamation District 108 and Colusa County Water District Agreement for Five-Year In-Lieu Groundwater Recharge Project Summary

Item	Description
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement projects. Required permitting and regulatory review is project specific and being initiated through consultation with applicable governing agencies. Governing agencies for which consultation is being initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The sustainability indicators expected to benefit are groundwater levels, groundwater storage, land subsidence, and depletion of interconnected surface water. The expected yield of the project is 8,000 af/yr in Shasta Non-Critical years, and about 7,000 af/yr on average across all years. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and land subsidence. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.
Costs	The current project is ending, and extension is still pending. Thus, the anticipated costs of this project have yet to be determined and will be reported in GSP annual reports and five-year updates when known. The project proponent is identifying funding sources to cover project costs as part of project development. These may include grants, fees, loans, and other assessments.

6.4.1.2 Glenn-Colusa Irrigation District Strategic Winter Water Use for Groundwater Recharge and Multiple Benefits

In addition to the water supply available to Glenn-Colusa Irrigation District under its settlement contract with the Bureau of Reclamation, GCID holds a 1999 water right permit[10] to divert Sacramento River water for irrigation and rice straw decomposition annually between November 1 and March 31. Water used under the permit is referred to as "winter water." Use under the permit began in 2000 and on average between 2000 and 2019, about 43 percent of the district land planted to rice each year has used winter water. Additionally, use for winter irrigation of a variety of permanent and annual crops has gradually expanded, particularly to meet late fall irrigation demands of almonds. Finally, winter water is occasionally used for frost control purposes, particularly on almonds. Water applied for rice straw decomposition creates multiple benefits, including habitat enhancement for Pacific Flyway migrating waterfowl and groundwater recharge in the Subbasin. Water used for winter irrigation and frost control of non-rice crops contributes to in-lieu recharge to the extent that groundwater would have been used absent the availability of winter water.

The potential exists to increase the groundwater recharge and habitat enhancement benefits of winter water use by increasing winter use for rice straw decomposition, winter irrigation, and frost control provided that certain constraints can be alleviated. The main constraints include: the current cost of winter water; the labor cost and management effort involved with applying winter water; GCID's inability to provide of winter water during its annual system construction and maintenance period traditionally

[10] GCID is currently preparing to petition the State Water Resources Control Board (SWRCB) to convert its winter water permit to a water right license.

from early January through late February each winter; and, water supply constraints posed by water right Term 91, which limits Sacramento River diversions during dry periods.

Under this project, working in collaboration with partners within the Subbasin and with environmental advocacy groups, GCID will investigate opportunities to increase winter water use by alleviating the constraints mentioned above. The objectives will be to incentivize growers to: 1) maximize winter water use on rice land including targeting rice lands with highest recharge potential, 2) expand use of winter water for irrigation and frost control where groundwater would otherwise be used, and 3) encourage temporary flooding of permanent and annual crop lands including targeting lands with the highest recharge potential. Critical elements of this investigation include demonstration on-farm economic and agronomic feasibility.

A summary of the project is provided in Table 6-21.

Table 6-21. Glenn-Colusa Irrigation District Strategic Winter Water Use for Groundwater Recharge and Multiple Benefits Summary

Item	Description
Implementation	GCID proposed this ongoing project for GSP implementation in the GCID service area. The project would provide direct and in-lieu groundwater recharge through increased winter water utilization. This is an ongoing project, which will be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This project is beginning in 2021 and will be ongoing.
Notice to public and other agencies	Public and/or Inter-Agency Noticing is being facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	The source is an existing appropriative water right for diversion and use of "winter water" from November 1 through March 31 each year. Appropriative winter water supplies are subject to availability and curtailments according to water right Term 91.
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement projects. Required permitting and regulatory review is being initiated through consultation with applicable governing agencies. Governing agencies for which consultation is being initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.

Table 6-21. Glenn-Colusa Irrigation District Strategic Winter Water Use for Groundwater Recharge and Multiple Benefits Summary

Item	Description
Benefits and benefit evaluation methodology	The sustainability indicators expected to benefit are groundwater levels, groundwater storage, and depletion of interconnected surface water. Potential expansion of this project to increase recharge is currently in the early conceptual stage. Thus, the expected yield of this project has yet to be determined and will be reported in GSP annual reports and five-year updates when known. Other benefits are increased ponded habitat for migrating waterfowl and improved air quality through reduced rice straw burning. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.
Costs	Project costs are primarily related to the cost of diverting and distributing winter water through the GCID canal network, with costs paid by participating growers. Current rates for winter water service vary between approximately $9 and $27 per acre depending on the level of service (duration of flooding), on top of a fixed assessment of about $42 per acre.

This project will be implemented by GCID working together with project collaborators by continuing use of winter water and investigating alternatives for alleviating constraints and developing incentives for expanding use of winter water. This will include the following actions, among others:

- Petitioning the SWRCB to license GCID's current water right permit, including investigation of provisions for relieving water supply limitations posed by Term 91.
- Characterizing baseline winter water use to better understand the destination of winter water to consumptive use, deep percolation (groundwater recharge), and surface return flows.
- Quantifying the groundwater recharge and habitat enhancement benefits derived from winter water use under baseline and potential future conditions with increased winter water use.
- Identifying beneficiaries of baseline and increased winter water use.
- Identifying and addressing data gaps associated characterizing winter water use and identifying beneficiaries.
- Exploring potential financial, operational, and other types of partnerships with beneficiaries and collaborators.
- Conducting temporary pilot programs to test operational and financial collaborations, potentially leading to implementation of permanent or long-term arrangements.
- Assessing environmental impacts and preparing environmental documents, as necessary.

Winter water would be diverted from the Sacramento River and delivered using GCID's existing distribution system, so no additional conveyance infrastructure is expected to be required. Minor facilities to connect the GCID system to lands currently served by groundwater only might be required.

6.4.1.3 Sycamore Marsh Farm Direct Recharge Project

Sycamore Marsh Farm has been in process of developing a groundwater recharge plan to store water in the aquifer by several different methods. The plan provides for 205 acres of year-round recharge basins and 163 additional acres of winter recharge areas. A summary of the project is provided in Table 6-22.

Table 6-22. Sycamore Marsh Farm Direct Recharge Project Summary

Item	Description
Implementation	The landowner proposed this ongoing project for GSP implementation which would be located on their property. The project provides direct groundwater recharge through several methods. This is an ongoing project, which will be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	The project began in 2020 and will be ongoing.
Notice to public and other agencies	Public and/or Inter-Agency Noticing is being facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	The source for this project is the Colusa Drain. The reliability is to be determined. However, no new water rights are expected to be necessary.
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement projects. Required permitting and regulatory review is being initiated through consultation with applicable governing agencies. Governing agencies for which consultation is being initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The sustainability indicators expected to benefit are groundwater levels, groundwater storage, depletion of interconnected surface water, land subsidence, and potentially groundwater quality. This project is still developing. Thus, the expected yield of this project has yet to be determined and will be reported in GSP annual reports and five-year updates when known. Other benefits include ponded habitat for migratory waterfowl. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.
Costs	This project is still developing. Thus, the anticipated costs of this project have yet to be determined and will be reported in GSP annual reports and five-year updates when known. The project proponent is identifying funding sources to cover project costs as part of project development. These may include grants, fees, loans, and other assessments.

6.4.1.4 Glenn-Colusa Irrigation District Expansion of In-Basin Program for In-lieu Groundwater Recharge

In cooperation with the Bureau of Reclamation (Reclamation), GCID has developed temporary arrangements to supply district surface water to neighboring non-district agricultural lands that primarily use groundwater. These temporary arrangements were implemented under agreements that recently expired in 2020. There is continued interest from participating landowners, and interest from landowners in additional closely neighboring areas, in continuing and expanding this in-basin surface water use. GCID is currently working in cooperation with Reclamation to renew these agreements and expand this program for the purpose of reducing groundwater pumping and increasing in-lieu groundwater recharge. Construction of new water delivery infrastructure may be required to deliver surface water to some neighboring lands. GCID is also evaluating the possibility of annexing some or all of these lands into its service area. Supplies would potentially be available for this project only in Shasta Non-Critical years. A summary of the project is provided in Table 6-23.

Table 6-23. Glenn-Colusa Irrigation District Expansion of In-Basin Program for In-lieu Groundwater Recharge Summary

Item	Description
Implementation	GCID proposed this recently expired project to become an ongoing project for GSP implementation in GCID and neighboring areas. The project would provide in-lieu groundwater recharge through increased surface water utilization. This is an ongoing project, which will be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This project would resume in 2021 and be ongoing.
Notice to public and other agencies	Public and/or Inter-Agency Noticing is being facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	The source is the Sacramento River under GCID's existing contractual and appropriative rights. Supplies would potentially be available in Shasta Non-Critical years. This is expected to be a reliable source during those years.
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement projects. Required permitting and regulatory review is being initiated through consultation with applicable governing agencies. Governing agencies for which consultation is being initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.

Table 6-23. Glenn-Colusa Irrigation District Expansion of In-Basin Program for In-lieu Groundwater Recharge Summary	
Item	Description
Benefits and benefit evaluation methodology	The sustainability indicators expected to benefit are groundwater levels, groundwater storage, and depletion of interconnected surface water. Potential expansion of this project is currently in the early conceptual stage. Thus, the expected yield of this project has yet to be determined and will be reported in GSP annual reports and five-year updates when known. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.
Costs	Potential expansion of this project is currently in the early conceptual stage. Thus, the anticipated costs of this project have yet to be determined and will be reported in GSP annual reports and five-year updates when known. The project proponent is identifying funding sources to cover project costs as part of project development. These may include grants, fees, loans, and other assessments.

6.4.1.5 Orland Unit Water Users Association Irrigation Modernization for Increased Surface Water Delivery and Reduced Groundwater Pumping

This project continues the modernization of the OUWUA's southside irrigation conveyance and distribution system involving the following features: regulating reservoirs, expanded and improved flow measurement and water level control, system interties, and expansion and upgrading of the existing supervisory control and data acquisition (SCADA) system. These improvements are expected to result in more reliable and flexible farm deliveries that will provide incentives for growers to use more surface water and pump less groundwater. In-lieu recharge is expected to increase groundwater levels within and neighboring the OUWUA service area. A summary of the project is provided in Table 6-24.

Table 6-24. Orland Unit Water Users Association Irrigation Modernization for Increased Surface Water Delivery and Reduced Groundwater Pumping Summary	
Item	Description
Implementation	OUWUA proposed this ongoing project for GSP implementation in the OUWUA service area and neighboring areas. The project provides in-lieu groundwater recharge through more efficient utilization of existing surface water. This is an ongoing project, which will be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This project is still developing. Thus, the start and completion dates for this project have yet to be determined and will be provided in GSP annual reports and five-year updates when known.

Table 6-24. Orland Unit Water Users Association Irrigation Modernization for Increased Surface Water Delivery and Reduced Groundwater Pumping Summary	
Item	Description
Notice to public and other agencies	Public and/or Inter-Agency Noticing is being facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	The source is Stony Creek water available to the OUWUA under the Angle Decree. This is highly reliable with significant shortages historically occurring once every 10 to 20 years on average.
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement projects. Required permitting and regulatory review is project specific and being initiated through consultation with applicable governing agencies. Governing agencies for which consultation is being initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The sustainability indicators expected to benefit are groundwater levels, groundwater storage, and depletion of interconnected surface water. This project is still developing. Thus, the expected yield of this project has yet to be determined and will be reported in GSP annual reports and five-year updates when known. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.
Costs	This project is still developing. Thus, the anticipated costs of this project have yet to be determined and will be reported in GSP annual reports and 5-year updates when known. The project proponent is identifying funding sources to cover project costs as part of project development. These may include grants, fees, loans, and other assessments.

6.4.2 Ongoing Management Actions

This section described ongoing management actions. There is one ongoing management action, summarized in Table 6-25. It incentivizes urban water conservation in the Willows area, providing an important benefit in reducing groundwater pumping in the area.

Table 6-25. Summary of Ongoing Management Actions					
Management Action	Management Action Type	Proponent	Year Implemented	Estimated Capital Cost	Gross Average Annual Benefit, af/yr
Urban Water Conservation in Willows	Management Action	RD108 and CCWD	2016	TBD	2

6.4.2.1 Urban Water Conservation in Willows

The California Water Service - Willows District is implementing urban water conservation measures through water waste prevention ordinances, metering, conservation pricing, public education and outreach, programs to assess and manage distribution system real loss, water conservation program coordination and staffing support, and other demand management measures. These are described in greater detail in Chapter 9 of the 2020 Urban Water Management Plant (UWMP) for the California Water Service - Willows District. A summary of the management action is provided in Table 6-26.

Table 6-26. Urban Water Conservation in Willows Summary

Item	Description
Implementation	California Water Service - Willows District proposed this ongoing management action for GSP implementation which would occur in the City of Willows. The action would reduce demand for groundwater. This is an ongoing management action, which will be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This management action began in 2016 and is ongoing.
Notice to public and other agencies	Public and/or Inter-Agency Noticing is being facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	Not applicable for this demand management action.
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual proponents have the authority to plan and implement management actions. Required permitting and regulatory review is being initiated through consultation with applicable governing agencies. Governing agencies for which consultation is being initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The sustainability indicators expected to benefit are groundwater levels, groundwater storage, and depletion of interconnected surface water. The expected yield of this management action is 2 af/yr. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.
Costs	The cost is being covered by rate structure of Cal Water - Willows Division.

6.5 POTENTIAL PROJECTS AND MANAGEMENT ACTIONS

In addition to the planned and ongoing projects and management actions identified above, the GSAs and other project proponents are considering a number of other potential PMAs that could provide benefits with respect to one or more of the sustainability indicators. These PMAs are still under development and require additional information that would be developed under future monitoring, and as the GSAs continue to identify and fill data gaps and reported in annual reports. This section provides descriptions for these identified potential PMAs.

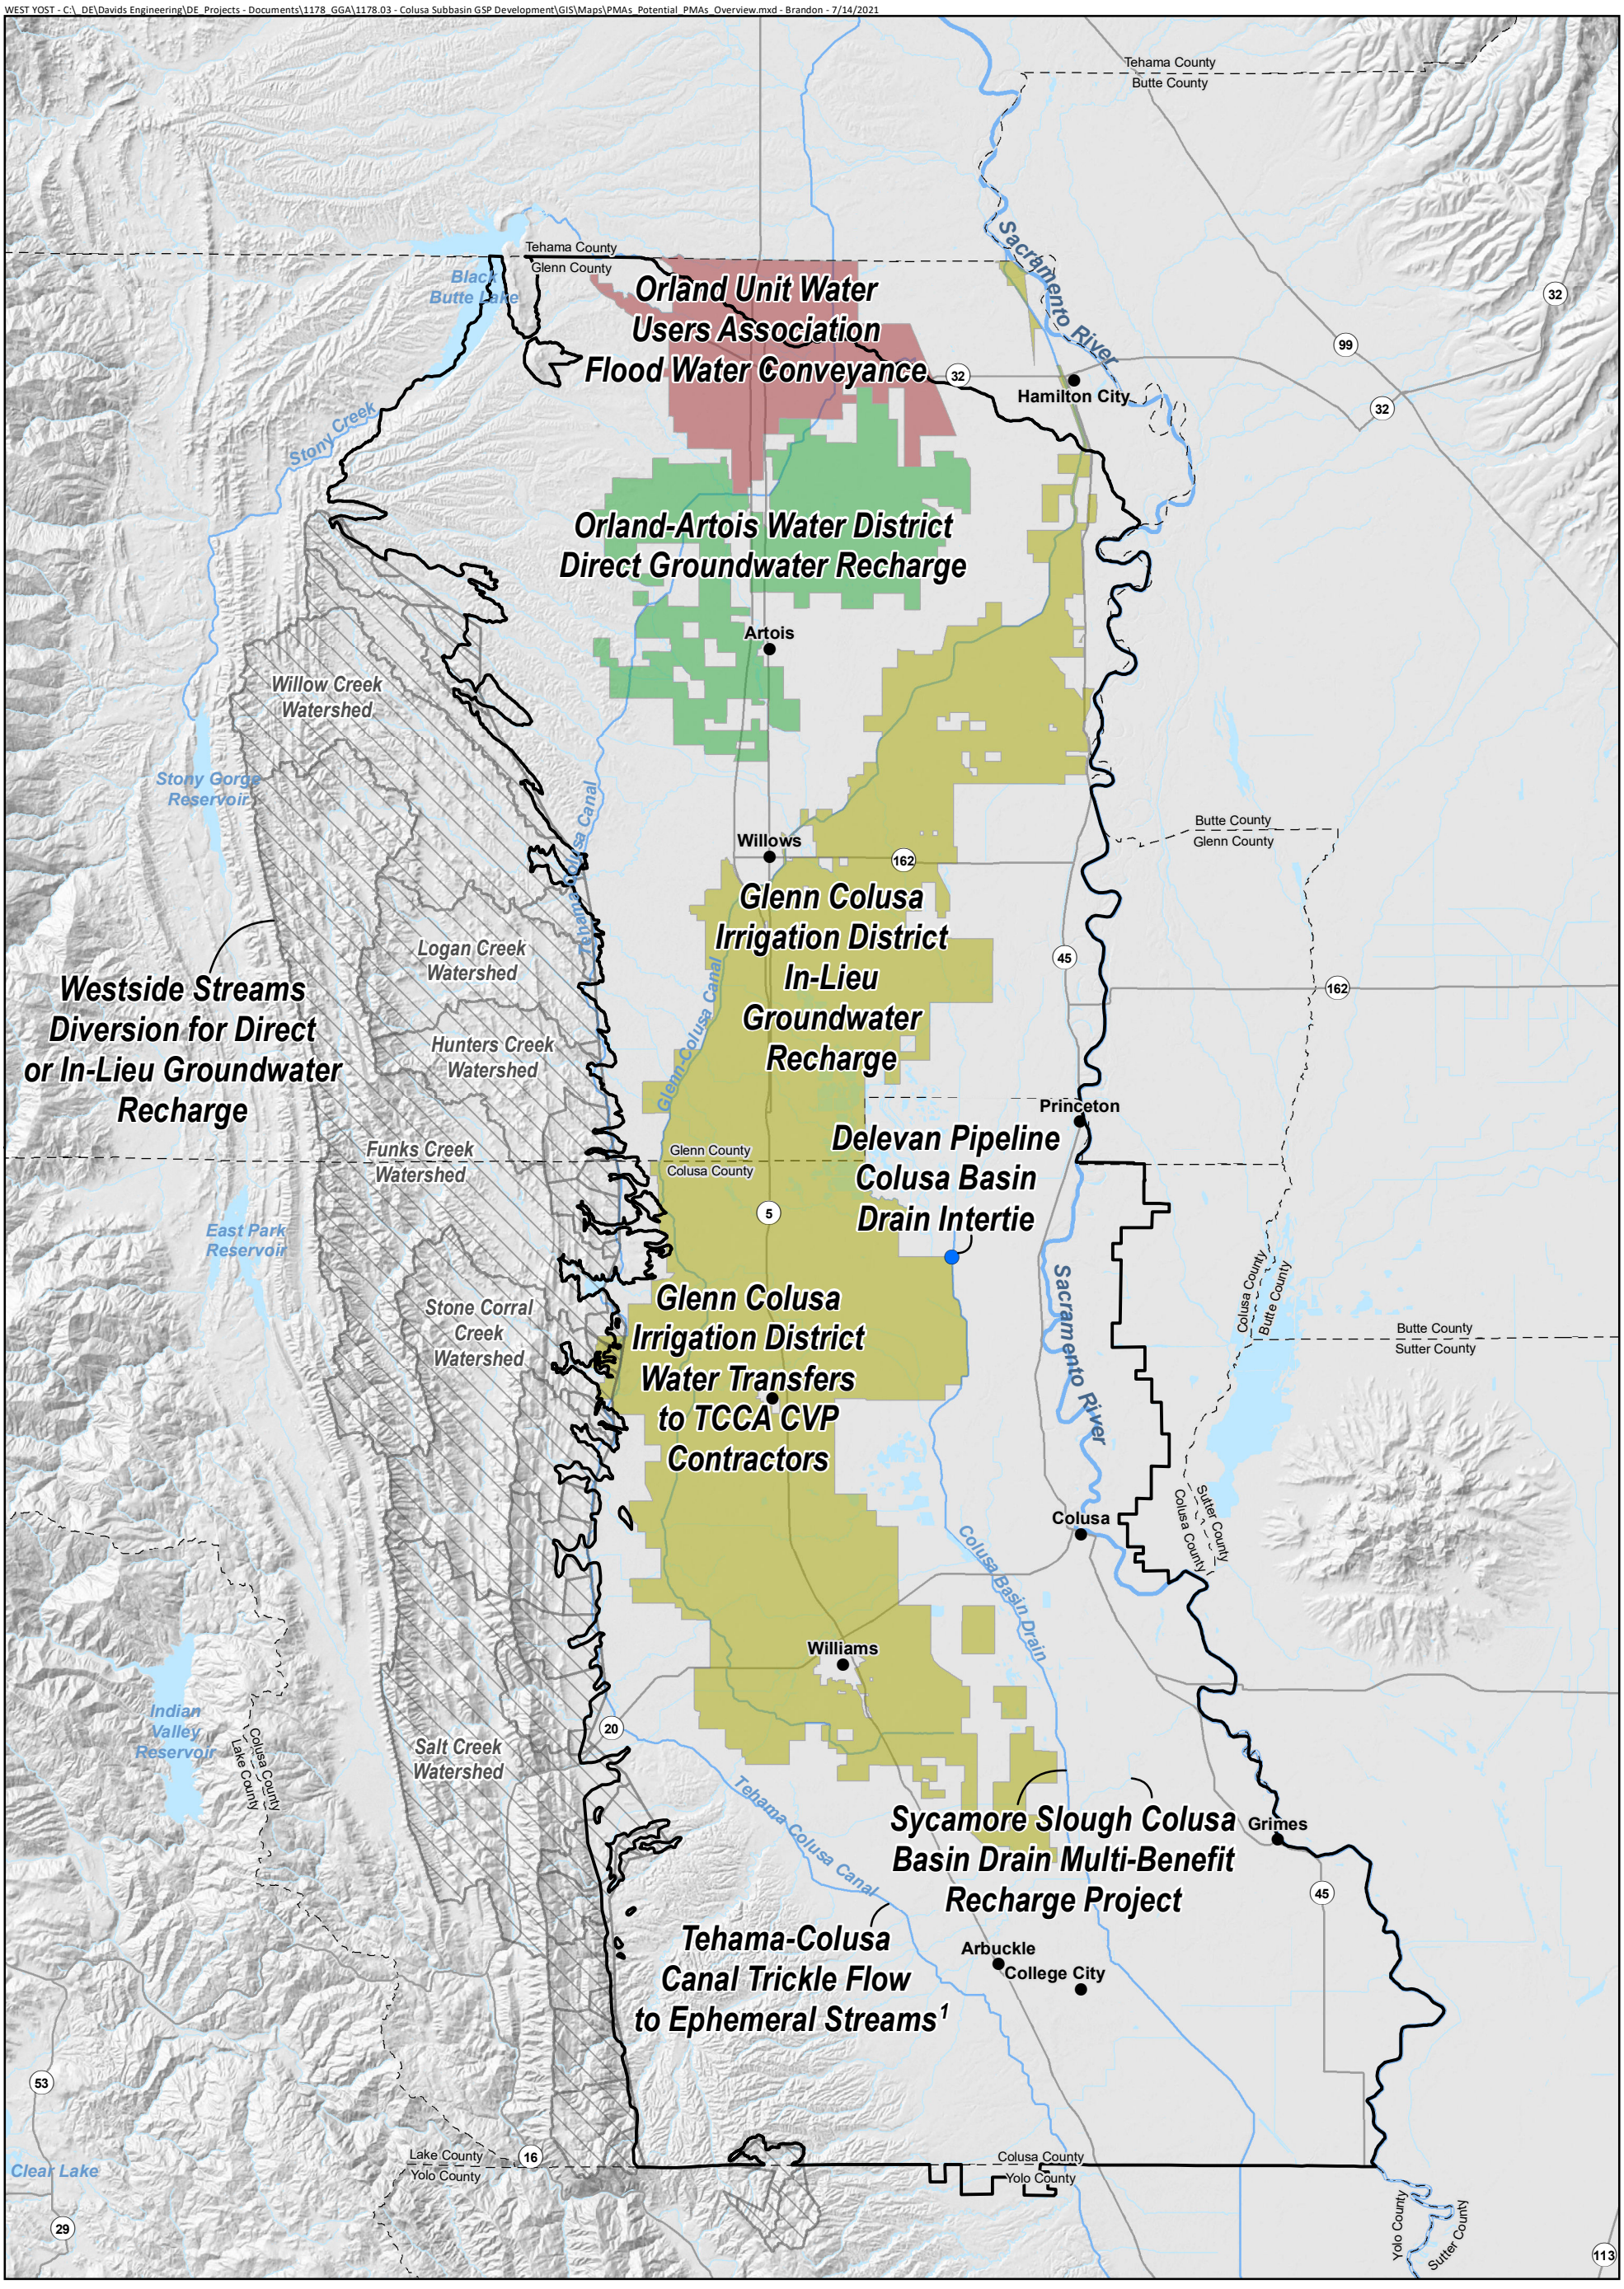

Figure 6-9 illustrates the location of potential PMAs in the Subbasin.

Potential PMAs are classified by projects and management actions, which are described in the following subsections. Projects are generally structural activities that include direct recharge, in-lieu recharge, and utilization of additional surface water supplies. Management actions are activities to improve water management or reduce groundwater pumping. Potential management actions include two demand management programs, which per 23 CCR §354.44(b)(2), could be rapidly implemented if the Subbasin is approaching minimum thresholds specified in the GSP.

Potential PMAs are described at a reconnaissance-level of detail relative to the planned projects described under Section 6.3, above. However, PMA information is still reported in accordance with 23 CCR §354.44(b). The required information is summarized in a table following the general description for each potential PMA. The information provided with each potential project table maps to the GSP regulation requirements as follows:

- Implementation (§354.44(b)(1)(A))
- Timeline (§354.44(b)(4))
- Notice to public and other agencies (§354.44(b)(1)(B))
- Water source and reliability (§354.44(b)(6))
- Legal authority, permitting processes, and regulatory control (§354.44(b)(3), (§354.44(b)(7))
- Benefits and benefit evaluation methodology (§354.44(b)(5), (§354.44(b)(9))
- Costs (§354.44(b)(8))

Groundwater Sustainability Plan

6.5.1 Potential Projects

This section describes potential projects that would be implemented if determined to be necessary or desirable under future monitoring of the Subbasin. Potential projects include direct and in-lieu recharge opportunities that could be implemented across the Subbasin, as well as local and regional (e.g., Sites) storage projects. Table 6-27 summarizes the potential projects included in the GSP. The following subsections provide project descriptions for each project.

Table 6-27. Summary of Potential Projects

Project[(a)]	Project Type	Proponent
Glenn-Colusa Irrigation District In-lieu Groundwater Recharge	In-lieu Groundwater Recharge	GCID
Westside Streams Diversion for Direct or In-lieu Groundwater Recharge	Direct and In-lieu Groundwater Recharge	CGA and GGA
Sites Reservoir	Direct and In-lieu Groundwater Recharge	Sites Project Authority
Delevan Pipeline Colusa Drain Intertie	Direct and In-lieu Groundwater Recharge	Landowner
Orland Unit Water Users Association Flood Water Conveyance	Direct Groundwater Recharge	OUWUA
Orland-Artois Water District Direct Groundwater Recharge	Direct Groundwater Recharge	OAWD
Sycamore Slough Colusa Basin Drain Multi-Benefit Recharge Project	Direct Groundwater Recharge	Landowner
Tehama-Colusa Canal Trickle Flow to Ephemeral Streams	Direct Groundwater Recharge	RD108
Enhanced Infiltration of Precipitation on Agricultural Lands	Direct Groundwater Recharge	CGA and GGA
Colusa Subbasin Flood-MAR	Direct Groundwater Recharge	CGA and GGA
Reclamation District 108 “Boards In” Program	Direct Groundwater Recharge	RD108
Colusa County Public Water System Water Treatment Plant	In-lieu Groundwater Recharge	Landowner
Glenn-Colusa Irrigation District Water Transfers to TCCA CVP Contractors	In-lieu Groundwater Recharge	GCID
Colusa Subbasin In-lieu Recharge & Banking Program	In-lieu Groundwater Recharge	South Valley Water Resources Authority
Sycamore Marsh Farm In-lieu Recharge Project	In-lieu Groundwater Recharge	Landowner
Westside Off-stream Reservoir and In-Lieu Groundwater Recharge	In-lieu Groundwater Recharge	TCCA Contractors

(a) Fourteen projects and management actions are not depicted on the map in Figure 6-9. These projects and management actions are excluded either because they will be implemented subbasin-wide or because the planning process is not far enough along to locate these projects at this time.

6.5.1.1 Glenn-Colusa Irrigation District In-lieu Groundwater Recharge

Despite GCID having highly reliable surface water supplies, a small percentage of district lands rely primarily on groundwater for irrigation supply. GCID will investigate, develop, and implement measures to incentivize associated growers to utilize surface water supplied by GCID, which will provide in-lieu recharge through reduced groundwater pumping. A summary of the project is provided in Table 6-28.

Table 6-28. Glenn-Colusa Irrigation District In-lieu Groundwater Recharge Summary

Item	Description
Implementation	GCID proposed this planned project for GSP implementation in the GCID service area. The project will provide in-lieu groundwater recharge through increased surface water utilization. This project may be implemented and would be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This project is currently in the early planning stage. Thus, the start and completion dates for this project have yet to be determined and will be provided in GSP annual reports and five-year updates when known.
Notice to public and other agencies	Public and/or Inter-Agency Noticing will be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	The source is the Sacramento River under GCID's contractual rights according to its Sacramento River Water Right Settlement contract and under an appropriative water right for diversion and use of "winter water" from November 1 through March 31 each year. Settlement contract water supplies are subject to 25% reductions in Shasta Critical years; appropriative winter water subject to availability and curtailments according to water right Term 91.
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement projects. Required permitting and regulatory review will be project specific and initiated through consultation with applicable governing agencies. Governing agencies for which consultation will be initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The sustainability indicators expected to benefit are groundwater levels, groundwater storage, and depletion of interconnected surface water. This project is currently in the early planning stage. Thus, the expected yield of this project has yet to be determined and will be reported in GSP annual reports and five-year updates when known. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.

Table 6-28. Glenn-Colusa Irrigation District In-lieu Groundwater Recharge Summary	
Item	Description
Costs	This project is currently in the early planning stage. Thus, the anticipated costs of this project have yet to be determined and will be reported in GSP annual reports and five-year updates when known. The project proponent would identify funding sources to cover project costs as part of project development. These may include grants, fees, loans, and other assessments.

6.5.1.2 Westside Streams Diversion for Direct or In-lieu Groundwater Recharge

There are numerous ephemeral streams that originate in the Coastal Range to the west of the Subbasin and flow eastward into the Subbasin. A portion of the winter and spring flows along these many streams could be diverted for a variety of in-lieu and direct groundwater recharge efforts in the Subbasin.

An analysis was completed to evaluate the potential recharge of diversions from the six largest streams along the western side of the Subbasin: Willow Creek, Logan Creek, Hunters Creek, Funks Creek, Stone Corral Creek, and Salt Creek[11]. A map of these watersheds and streams is shown on Figure 6-10. It is noted that other streams and creeks, such as Walker Creek and Hambright Creek, also provide significant recharge benefits and offer potential recharge opportunities. However, for the purposes of this preliminary analysis, only the six streams listed above were considered based on their size and available monthly flow estimates.

All of the westside streams considered in this preliminary analysis are tributary to the Colusa Drain, which flows southward out of the Subbasin at the Colusa-Yolo County boundary. The Colusa Drain is tributary to the Sacramento River near Knights Landing in Yolo County and has an average annual discharge of 358,000 acre-feet[12], including irrigation return flows as well as westside natural streamflow.

During periods of flow in the winter and spring, some portion of these flows could be diverted for either 1) off-stream storage and subsequent use for irrigation, or 2) direct groundwater recharge through Flood-MAR[13], dedicated recharge basins, or modified stream beds. A summary of the project is provided in Table 6-29.

[11] The location for Sites Reservoir is within the Funks and Stone Corral Creek watersheds. After construction of Sites Reservoir, flow through these creeks would primarily be inflow to Sites Reservoir and would no longer be available for downstream diversion and use within the Subbasin unless water were released into these creeks from Sites Reservoir in a pattern that matched historical flows.

[12] Average annual discharge of Colusa Drain at Knights Landing, 1986 through 2011.

[13] Flood-MAR stands for Flood-Managed Aquifer Recharge. It is a groundwater recharge strategy that takes advantage of periods of high flow to divert flood waters for aquifer recharge on agricultural lands or other working landscapes (i.e., wildlife refuges or flood bypasses).

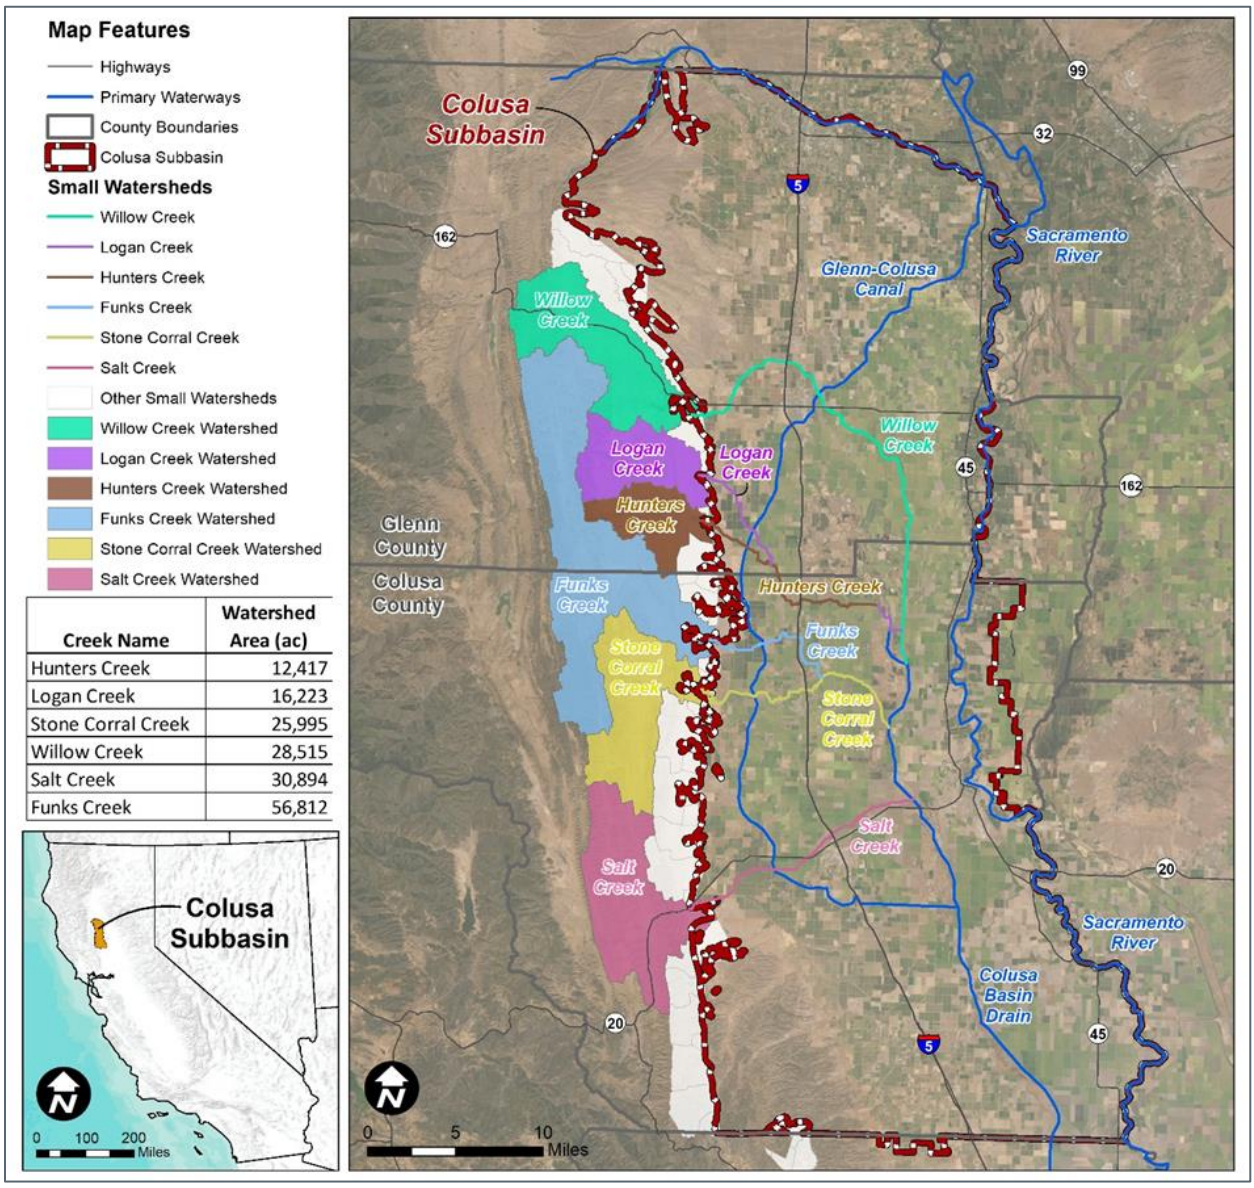

Figure 6-10. Watershed Area and Stream Path through Colusa Subbasin for the Six Largest Westside Streams

Table 6-29. Westside Streams Diversion for Direct or In-lieu Groundwater Recharge Summary

Item	Description
Implementation	This potential project is proposed by CGA and GGA and would be implemented in Colusa and Glenn Counties. The additional water diverted could be used as supplemental irrigation water to provide in-lieu recharge or be diverted to provide direct recharge through Flood-MAR, dedicated recharge basins, or modified stream beds. This project may be implemented and would be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This project is currently in the early conceptual stage. Thus, the start and completion dates for this project have yet to be determined and will be provided in GSP annual reports and five-year updates when known.
Notice to public and other agencies	Public and/or Inter-Agency Noticing would be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	The water source would be the Westside Streams, which includes Willow Creek, Logan Creek, Hunters Creek, Funks Creek, Stone Corral Creek, Salt Creek, and potentially smaller streams. Water will only be available during periods of runoff occurring during heavy precipitation events or wet years.
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement projects. Required permitting and regulatory review would be project specific and initiated through consultation with applicable governing agencies. Governing agencies for which consultation would be initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The sustainability indicators expected to benefit are groundwater levels, groundwater storage, and depletion of interconnected surface water. This project is currently in the early conceptual stage. Thus, the expected yield of this project has yet to be determined and will be reported in GSP annual reports and five-year updates when known. Multi-benefits would include reduced flood impacts to the extent that diversions reduce the severity of downstream flooding. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.
Costs	This project is currently in the early conceptual stage. Thus, the anticipated costs of this project have yet to be determined and would be reported in GSP annual reports and five-year updates when known. The project proponent would identify funding sources to cover project costs as part of project development. These may include grants, fees, loans, and other assessments.

1

2

A new water right (or rights) through the State Water Resources Control Board (SWRCB) would have to be obtained for this water use. While it is recognized that water rights permitting can take significant time to complete, this potential project is not intended to be implemented quickly. Thus, there is considered to be sufficient time to complete water rights permitting for this project.

New diversion, conveyance, and recharge infrastructure would also have to be constructed. This infrastructure would likely be located on private property through collaborative arrangements with landowners. Depending on the scale of implementation, this project would be expected to result in an average annual benefit ranging from roughly 1,000 af to 16,000 af for the Subbasin. The estimated costs of the project will vary depending on the scale of implementation.

This project concept has already been explored by two private landowners in the Subbasin and implemented on a small scale. One project captures storm water runoff on private lands for groundwater recharge through an underground recharge structure designed to mimic a residential septic leach field, and the other considers diversion of flood flows off of Sand Creek into an existing gravel pit (former excavation site) adjacent to the creek to facilitate direct groundwater recharge.

As described below, evaluation of this project by the CGA and/or the GGA and interested parties within the Subbasin will be done in conjunction with evaluation of the full suite of potential PMAs under consideration by the GSAs. A series of increasingly detailed studies, culminating in a feasibility study, would be required to evaluate project costs and benefits to determine whether or not to proceed with implementation. Because the outcomes of these studies are uncertain, the project implementation schedule cannot be determined at this time. Public noticing for this project as it progresses will be done in accordance with the general plan outlined in the Notice/Communication section of the GSP.

The water source would be natural flow from these six ephemeral streams (and potentially other, smaller westside streams) that flow into the Subbasin from the Coastal Range. To provide preliminary estimates, the timing and volume of these flows, expressed as an average monthly flow, were estimated using C2VSim model rainfall-runoff algorithms. The original C2VSim small watershed rootzone parameters were used in the analysis, and flows runoff from these small Coastal range watersheds into the Subbasin were extracted from the C2VSim small watershed output file. Substantial flow does not occur through these creeks in every year and depends on the seasonal timing and volume of precipitation. Based on simulated rainfall-runoff, this water source is highly variable from year to year, including years of essentially zero runoff, and from month to month within years. When flow does occur, it is typically between the months of December and June and largely occurs between January and April.

A pre-requisite for studying this project concept would be to install stream gages and conduct monitoring to gather multiple years of streamflow records, including stream discharge, water quality measurements, and sediment loads at different flows and for the rising and falling legs of runoff hydrographs. A design objective would be to divert low sediment load flows, probably on the falling leg of runoff events, to minimize the potential for clogging of recharge facilities. Water quality monitoring would also be required to evaluate flow through these streams and determine whether or not poor water quality exists and may impact beneficial uses provided through diversion for direct or in-lieu recharge.

This project would require the design and construction of new diversion and conveyance facilities, as well as either off-stream storage facilities or recharge facilities (i.e., spreading basins)[14]. Further study would

[14] In some cases, these facilities may already be in place and would only need to be repurposed to facilitate this new water use.

need to be conducted to identify estimated volumes of water available for diversion and suitable locations for diversion and recharge facilities; these analyses would result in more detailed information about size and capacity of required infrastructure improvements, construction requirements. and estimated costs.

Further investigation into this project will provide more detailed information of project costs and benefits, which, in comparison with the current and projected conditions of the Subbasin, will allow for determination of whether or not the project should be implemented, and at what scale, to contribute to sustainable operation of the Subbasin. The results of any further analysis will be reported in the annual reports. If implemented, monitoring and quantification of benefits would be accomplished by the GSAs in coordination with other stakeholders and partners.

The timing and volume of flows into the Subbasin through these six creeks have been modeled and evaluated to estimate preliminary potential project benefits. Assuming a range of maximum flow thresholds that can be diverted from each of the six streams when they are flowing, the volumes available for diversion can be calculated. These numbers are long-term annual averages; in some years, no water would be available, while in other years volumes greater than those seen in Table 6-30 would be available. These numbers only represent an initial estimate of potential project benefit volumes and require more in-depth evaluation to verify their accuracy. As shown, initial estimated volumes range from roughly 1,000 af to 16,000 af at different levels of implementation.

Table 6-30. Timing and Volume (af) of Flows into the Subbasin

Maximum Flow Threshold	Dec.	Jan.	Feb.	March	April	May	June	**Total**
Flow = 10 cfs	170	240	204	186	157	165	30	**1,153**
Flow = 20 cfs	286	589	386	523	459	324	68	**2,635**
Flow = 40 cfs	406	1,266	979	1,575	1,281	507	68	**6,082**
Flow = 60 cfs	406	1,817	1,590	2,770	1,854	628	181	**9,246**
Flow = 80 cfs	499	2,571	1,970	3,699	2,432	708	181	**12,061**
Flow = 100 cfs	615	3,462	2,467	5,252	2,961	927	181	**15,865**

Project costs will depend on the scale of implementation and other factors and will need to be estimated through further study, including an economic analysis and finance strategy designed to outline alternatives for meeting the costs for project implementation.

6.5.1.3 Sites Reservoir

The Sites Project would utilize existing infrastructure to divert unregulated and unappropriated flow from the Sacramento River at Red Bluff and Hamilton City and convey water to a new off stream reservoir west of the town of Maxwell. New and existing facilities would move water into and out of the reservoir, with ultimate release back to the Sacramento River system via existing canals and a new pipeline located near Dunnigan. The reservoir capacity would be between 1.3 maf and 1.5 maf depending on the project alternative selected. The reservoir would be operated in coordination with the State Water Project and Central Valley Project, yielding approximately 250,000 to 300,000 af in dry and critical years, and more in other year types. The managing agency is the Sites Project Authority. A summary of the project is provided in Table 6-31.

Table 6-31. Sites Reservoir Summary	
Item	Description
Implementation	The Sites Project Authority proposed this project concept which would be located in the Antelope Valley west of the Subbasin. The project may provide direct and in-lieu groundwater recharge through utilization of surface water from this project, as available. This project may be implemented and would be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This project is currently in the early conceptual stage. Thus, the start and completion dates for this project have yet to be determined and would be provided in GSP annual reports and five-year updates when known.
Notice to public and other agencies	Public and/or Inter-Agency Noticing will be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	The source would be Sacramento River under new appropriative water rights. Settlement contract water supply is subject to 25% reductions in Shasta Critical years. New water rights would have junior priority and therefore would be subject to senior rights and water right Term 91
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement projects. Required permitting and regulatory review will be project specific and initiated through consultation with applicable governing agencies. Governing agencies for which consultation is being initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The sustainability indicators expected to benefit are groundwater levels, groundwater storage, and depletion of interconnected surface water (to the extent that project yield is dedicated to recharge projects). This project is currently in the early conceptual stage. Thus, the expected yield of this project for the Subbasin specifically has yet to be determined and will be reported in GSP annual reports and five-year updates when known. Evaluation of benefits is being quantified through post project monitoring. Additional benefits could include increased local, regional, and statewide water supply reliability, climate change resiliency, recreation, and increased cold water pool for endangered salmon. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.
Costs	The full cost of the project is $5.2 billion. The portion of this which would be covered by Subbasin water users specifically is uncertain at this time.

6.5.1.4 Delevan Pipeline Colusa Drain Intertie

This project would construct an intertie between the proposed Delevan Pipeline component of the Sites Reservoir Project and the Colusa Drain. Currently, the only proposed intertie is the Dunnigan intertie. This intertie would provide a connection to downstream water users to utilize surface water storage from Sites

Reservoir, improve conjunctive use, and potentially decrease groundwater pumping. This intertie would also provide protection for the ecosystems upstream of the proposed Dunnigan intertie and redundancy in case the TCC becomes inoperable due to subsidence or earthquake damage. A summary of the project is provided in Table 6-32.

Table 6-32. Delevan Pipeline Colusa Drain Intertie Summary

Item	Description
Implementation	A landowner proposed this project concept, which would be located at the intersection of Colusa Drain and the proposed Delevan Pipeline. The project would provide direct and in-lieu groundwater recharge through utilization of surface water. This project may be implemented and would be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This project is currently in the early conceptual stage. Thus, the start and completion dates for this project have yet to be determined and will be provided in GSP annual reports and five-year updates when known.
Notice to public and other agencies	Public and/or Inter-Agency Noticing would be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	The source would be Sacramento River under new appropriative water rights (conveyed to Sites Reservoir and through Delevan Pipeline). The reliability is uncertain at this time.
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement projects. Required permitting and regulatory review would be project specific and initiated through consultation with applicable governing agencies. Governing agencies for which consultation would be initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The sustainability indicators expected to benefit are groundwater levels, groundwater storage, and depletion of interconnected surface water. This project is currently in the early conceptual stage. Thus, the expected yield of this project has yet to be determined and will be reported in GSP annual reports and five-year updates when known. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.
Costs	This project is currently in the early conceptual stage. Thus, the anticipated costs of this project have yet to be determined and would be reported in GSP annual reports and five-year updates when known. The project proponent would identify funding sources to cover project costs as part of project development. These may include grants, fees, loans, and other assessments.

6.5.1.5 Orland Unit Water Users Association Flood Water Conveyance

During periods of high flow and reservoir release on Stony Creek, water would be diverted at OUWUA's south diversion and conveyed to various locations for direct recharge within the OUWUA service area. Direct groundwater recharge could be conducted by OUWUA or by participating landowners and growers who have the ability to assist with groundwater recharge. Types of recharge facilities that may be used include creek beds, existing irrigation canals and laterals, agricultural fields, new, dedicated recharge basins, and, potentially, dry groundwater production wells. For example, flood water may be conveyed through existing facilities from the South Canal into the "Low Line Ditch" and Hambright Creek, or flood water may be strategically delivered to provide recharge in fields where groundwater levels have declined. Existing water rights may be used for this project, or a new water right (or rights) through the SWRCB may need to be obtained. While it is recognized that water rights permitting can take significant time to complete, this potential project is not intended to be implemented quickly. Thus, there is considered to be sufficient time to complete any necessary water rights permitting for this project. A summary of the project is provided in Table 6-33.

Table 6-33. Orland Unit Water Users Association Flood Water Conveyance Summary

Item	Description
Implementation	OUWUA proposed this potential project for GSP implementation in the OUWUA service area. The project would provide direct groundwater recharge through utilization of high flow and reservoir release on Stony Creek. This project may be implemented and would be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This project is currently in the early conceptual stage. Thus, the start and completion dates for this project have yet to be determined and would be provided in GSP annual reports and five-year updates when known.
Notice to public and other agencies	Public and/or Inter-Agency Noticing would be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	The source would be Stony Creek flood releases that cannot be held in Stony Creek reservoirs. This would be highly variable year to year depending on hydrology.
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement projects. Required permitting and regulatory review would be project specific and initiated through consultation with applicable governing agencies. Governing agencies for which consultation would be initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.

Table 6-33. Orland Unit Water Users Association Flood Water Conveyance Summary	
Item	Description
Benefits and benefit evaluation methodology	OUWUA would be responsible for operating and monitoring the project. This project is currently in the early conceptual stage. Thus, the expected yield of this project has yet to be determined and would be reported in GSP annual reports and five-year updates when known. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.
Costs	This project is currently in the early conceptual stage. Thus, the anticipated costs of this project have yet to be determined and would be reported in GSP annual reports and five-year updates when known. The project proponent would identify funding sources to cover project costs as part of project development. These may include grants, fees, loans, and other assessments.

6.5.1.6 Orland-Artois Water District Direct Groundwater Recharge

OAWD is interested in recharging groundwater through Managed Aquifer Recharge (MAR) on agricultural land to improve aquifer conditions, especially in the groundwater cone of depression to the west of Artois. A pilot project for MAR was conducted in 2017 on the VanTol site using water from a Section 215 Temporary Water Contract from USBR. The 215 water is low-cost but is only available during high flow conditions in rivers and streams. A summary of the project is provided in Table 6-34.

Table 6-34. Orland-Artois Water District Direct Groundwater Recharge Summary	
Item	Description
Implementation	OAWD proposed this project concept for GSP implementation in the OAWD service area. The project would provide direct groundwater recharge through MAR. OAWD completed a pilot project for MAR in 2017. This project may be implemented and would be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This project is currently in the early conceptual stage. Thus, the start and completion dates for this project have yet to be determined and would be provided in GSP annual reports and five-year updates when known.
Notice to public and other agencies	Public and/or Inter-Agency Noticing would be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	The source would be Sacramento River Section 215 water. This would be highly variable, and available only during periods of high flow in Sacramento River and tributaries.

Table 6-34. Orland-Artois Water District Direct Groundwater Recharge Summary	
Item	Description
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement projects. Required permitting and regulatory review would be initiated through consultation with applicable governing agencies. Governing agencies for which consultation would be initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The sustainability indicators expected to benefit are groundwater levels, groundwater storage, and depletion of interconnected surface water. This project is currently in the early conceptual stage. Thus, the expected yield of this project has yet to be determined and would be reported in GSP annual reports and five-year updates when known. An additional benefit would be possible ponded habitat for migratory birds depending on timing of flooding. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.
Costs	This project is currently in the early conceptual stage. Thus, the anticipated costs of this project have yet to be determined and would be reported in GSP annual reports and five-year updates when known. The project proponent would identify funding sources to cover project costs as part of project development. These may include grants, fees, loans, and other assessments.

6.5.1.7 Sycamore Slough Colusa Basin Drain Multi-Benefit Recharge Project

This project would restore portions of the Sycamore Slough through voluntary landowner participation in a multi-benefit recharge project. The recharge site will be hosted by Davis Ranches, a participating landowner within the Sycamore Mutual Water Company service. Water would be sourced from the Sacramento River during high flows in the system. The Sycamore Mutual Water Company is a Sacramento River Settlement Contractor, and could use a portion of its existing settlement contract water supplies for recharge if the project is initiated prior to November 1. If the project is initiated after November 1, water could be accessed using existing riparian water rights exercised for beneficial use (habitat). Field flooding would provide recharge, restoration, and multi-benefits such as winter floodplain habitat for migrating shorebirds/waterfowl as the field is pulse flooded, or habitat for monarch butterflies and other pollinator species. A summary of the project is provided in Table 6-35.

Table 6-35. Sycamore Slough Colusa Basin Drain Multi-Benefit Recharge Project Summary	
Item	Description
Implementation	This project would conduct multi-benefit groundwater recharge on fields within the Sycamore Mutual Water Company service area, restoring portions of the Sycamore Slough. This project may be implemented and would be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This project is currently in the early conceptual stage. Thus, the start and completion dates for this project have yet to be determined and will be provided in GSP annual reports and five-year updates when known.
Notice to public and other agencies	Public and/or Inter-Agency Noticing would be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	The source would be the Sacramento River. Water could be accessed through existing riparian water rights or from existing settlement contract supplies (if the project is initiated before November 1). This source is expected to be reliable, but the precise volume of available water is unknown at this time.
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement projects. Required permitting and regulatory review would be project specific and initiated through consultation with applicable governing agencies. Governing agencies for which consultation would be initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The sustainability indicators expected to benefit are groundwater levels, groundwater storage, and depletion of interconnected surface water. This project is currently in the early conceptual stage. Thus, the expected yield of this project has yet to be determined and would be reported in GSP annual reports and five-year updates when known. Multi-benefits include ponded habitat for migratory birds, along with other environmental benefits. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.
Costs	This project is currently in the early conceptual stage. Thus, the anticipated costs of this project have yet to be determined and will be reported in GSP annual reports and five-year updates when known. The project proponent would identify funding sources to cover project costs as part of project development. These may include grants, fees, loans, and other assessments.

6.5.1.8 Tehama-Colusa Canal Trickle Flow to Ephemeral Streams

The TCC has existing gates that are used to dewater sections of the canal. The gates discharge into ephemeral streams that intersect the canal. Water could be discharged from the TCC into these streams at a rate where they do not flow out of the Subbasin but recharge the groundwater system. Flow measurement devices would need to be added to the gates. Surface water for recharge would be Sacramento River available water under existing Bureau of Reclamation water supply contracts held by Tehama-Colusa Canal contractors, existing water rights settlement contracts, and annual Section 215 contracts. A summary of the project is provided in Table 6-36.

Table 6-36. TCC Trickle Flow to Ephemeral Streams Summary

Implementation	RD108 proposed this project concept which would be located at TCC and ephemeral stream crossings. The project would provide direct groundwater recharge through utilization of surface water. While this project is proposed for areas along the TCC, this concept could be applied throughout the Subbasin. This project may be implemented and would be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This project is currently in the early conceptual stage. Thus, the start and completion dates for this project have yet to be determined and would be provided in GSP annual reports and five-year updates when known.
Notice to public and other agencies	Public and/or Inter-Agency Noticing would be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	The source would be the Sacramento River (conveyed through TCC). Water could be supplied under existing Reclamation water supply contracts held by Tehama- Colusa Canal contractors, existing water rights settlement contracts, and annual Section 215 contracts. The reliability is uncertain at this time.
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement projects. Required permitting and regulatory review would be project specific and initiated through consultation with applicable governing agencies. Governing agencies for which consultation would be initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The sustainability indicators expected to benefit are groundwater levels, groundwater storage, and depletion of interconnected surface water. This project is currently in the early conceptual stage. Thus, the expected yield of this project has yet to be determined and would be reported in GSP annual reports and five-year updates when known. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.

Table 6-36. TCC Trickle Flow to Ephemeral Streams Summary	
Item	Description
Costs	This project is currently in the early conceptual stage. Thus, the anticipated costs of this project have yet to be determined and would be reported in GSP annual reports and five-year updates when known. The project proponent would identify funding sources to cover project costs as part of project development. These may include grants, fees, loans, and other assessments.

6.5.1.9 Enhanced Infiltration of Precipitation on Agricultural Lands

Current cultural practices, particularly in almond orchards, tend to reduce infiltration and increase runoff of precipitation. Development and adoption of on-farm cultural practices to reduce precipitation runoff and increase infiltration would result in increased storage of precipitation in the crop root zone, thereby reducing irrigation water requirements and groundwater pumping. Additionally, to the extent that infiltrated precipitation percolates through the root zone, this would result in increased direct groundwater recharge. The resulting in-lieu and direct recharge would benefit groundwater levels and reducing runoff could reduce soil erosion and provide water quality benefits. This project is proposed as a potential research management action; for example, a collaborative initiative between the GSAs and University of California Cooperative Extension, the Natural Resources Conservation Service, local resource conservation district, California State University Chico, or other interested organizations. A summary of the project is provided in Table 6-37.

Table 6-37. Enhanced Infiltration of Precipitation on Agricultural Lands Summary	
Item	Description
Implementation	This potential project is proposed by CGA and GGA and would be implemented across the Subbasin through cooperating growers. The project would provide in-lieu groundwater recharge through storage of precipitation in the root zone, and direct groundwater recharge through increased percolation of precipitation. This project may be implemented and would be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This project is currently in the early conceptual stage. Thus, the start and completion dates for this project have yet to be determined and would be provided in GSP annual reports and five-year updates when known.
Notice to public and other agencies	Public and/or Inter-Agency Noticing would be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	The main source of water providing additional recharge is precipitation. The reliability would be variable.

Table 6-37. Enhanced Infiltration of Precipitation on Agricultural Lands Summary	
Item	Description
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement projects. Required permitting and regulatory review would be project specific and initiated through consultation with applicable governing agencies. Governing agencies for which consultation would be initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The sustainability indicators expected to benefit are groundwater levels, groundwater storage, and depletion of interconnected surface water. This project is currently in the early conceptual stage. Thus, the expected yield of this project has yet to be determined and would be reported in GSP annual reports and five-year updates when known. Other benefits would include reduction of soil erosion and water quality benefits.
Costs	This project is currently in the early conceptual stage. Thus, the anticipated costs of this project have yet to be determined and would be reported in GSP annual reports and five-year updates when known. The project proponent would identify funding sources to cover project costs as part of project development. These may include grants, fees, loans, and other assessments.

6.5.1.10 Colusa Subbasin Flood-MAR

The CGA and GGA, in coordination with landowners and other agencies, would investigate, develop, and implement a program to divert flood waters within the Subbasin, when available, for spreading across agricultural lands or other working landscapes for direct groundwater recharge. A summary of the project is provided in Table 6-38.

Table 6-38. Colusa Subbasin Flood-MAR Summary	
Item	Description
Implementation	CGA and GGA proposed this project concept which would be implemented across the Subbasin with cooperating growers. The project would provide direct groundwater recharge through cooperating grower properties using flood waters when available. This project may be implemented and would be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This project is currently in the early conceptual stage. Thus, the start and completion dates for this project have yet to be determined and would be provided in GSP annual reports and five-year updates when known.
Notice to public and other agencies	Public and/or Inter-Agency Noticing would be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	The source and reliability of flood water for recharge are to be determined.

Table 6-38. Colusa Subbasin Flood-MAR Summary	
Item	Description
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement projects. Required permitting and regulatory review would be project specific and initiated through consultation with applicable governing agencies. Governing agencies for which consultation would be initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The sustainability indicators expected to benefit are groundwater levels, groundwater storage, and depletion of interconnected surface water. This project is currently in the early conceptual stage. Thus, the expected yield of this project has yet to be determined and would be reported in GSP annual reports and five-year updates when known. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.
Costs	This project is currently in the early conceptual stage. Thus, the anticipated costs of this project have yet to be determined and would be reported in GSP annual reports and five-year updates when known. The project proponent would identify funding sources to cover project costs as part of project development. These may include grants, fees, loans, and other assessments.

6.5.1.11 Reclamation District 108 "Boards In" Program

RD108, in coordination with landowners, would institute a voluntary or financially incentivized program in which landowners leave their spill boards in place during the winter months to capture rainfall and hold it on their fields for recharge. The project would occur in any fields with spill boards throughout RD108, though the program concept could be expanded across the Subbasin. A summary of the project is provided in Table 6-39.

Table 6-39. Reclamation District 108 "Boards In" Program Summary	
Item	Description
Implementation	RD108 proposed this project, which would be implemented in coordination with landowners in fields with spill boards throughout RD108. The program concept could also be expanded Subbasin-wide. The project would institute a voluntary or financially incentivized program in which landowners leave their spill boards in place during the winter months to capture rainfall and hold it on their fields for recharge. This project is ready for implementation now, but may also be initiated, monitored, and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This project is currently in the conceptual stage, but could be implemented immediately. However, the precise start and completion dates for this project have yet to be determined and would be provided in GSP annual reports and five-year updates when known.

Table 6-39. Reclamation District 108 "Boards In" Program Summary	
Item	Description
Notice to public and other agencies	Public and/or Inter-Agency Noticing would be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings, and environmental/regulatory permitting notification.
Water source & reliability	This project relies on precipitation, not on water sources outside the Subbasin.
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement projects. Required permitting and regulatory review would be project specific and initiated through consultation with applicable governing agencies. Governing agencies for which consultation would be initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The sustainability indicators expected to benefit are groundwater levels, groundwater storage, and depletion of interconnected surface water. This project is currently in the conceptual stage. Assuming that approximately 20% of rice fields in RD108 participate each year, the estimated average annual recharge benefit of the project over the 2022 to 2065 period is approximately 1.8 taf/yr. The actual yield of this project would be reported in GSP annual reports and five-year updates when known. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.
Costs	This project is currently in the conceptual stage. Thus, the anticipated costs of this project, if any, have yet to be determined and would be reported in GSP annual reports and five-year updates when known. It is anticipated that the project will have no costs if implemented as a voluntary program. The project proponent would identify funding sources to cover project costs as part of project development. These may include grants, fees, loans, and other assessments.

6.5.1.12 Colusa County Public Water System Water Treatment Plant

This project would construct a water treatment plant on the Sacramento River between the Cities of Colusa and Grimes to provide treated surface water to public water supply systems in Colusa and possibly Sutter and Yolo Counties. A summary of the project is provided in Table 6-40.

Table 6-40. Colusa County Public Water System Water Treatment Plant Summary	
Item	Description
Implementation	A landowner proposed this potential project which would be implemented in Colusa County. By increasing the surface water available for drinking water supply this project would provide in-lieu groundwater recharge. This project may be implemented and would be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This project is currently in the early conceptual stage. Thus, the start and completion dates for this project have yet to be determined and will be provided in GSP annual reports and five-year updates when known.
Notice to public and other agencies	Public and/or Inter-Agency Noticing would be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	The water source would be the Sacramento River under new appropriative water rights. The reliability is uncertain at this time.
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement projects. Required permitting and regulatory review would be project specific and initiated through consultation with applicable governing agencies. Governing agencies for which consultation would be initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The sustainability indicators expected to benefit are groundwater levels, groundwater storage, and depletion of interconnected surface water. This project is currently in the early conceptual stage. Thus, the expected yield of this project has yet to be determined and would be reported in GSP annual reports and five-year updates when known. Other benefits would be improved drinking water quality, and less threat to 1) Arbuckle and Dunnigan facing loss of well supply, 2) Grimes and Princeton's drinking well arsenic contamination, and 3) Williams' elevated salinity (TDS) levels. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.
Costs	This project is currently in the early conceptual stage. Thus, the anticipated costs of this project have yet to be determined and will be reported in GSP annual reports and five-year updates when known. The project proponent would identify funding sources to cover project costs as part of project development. These may include grants, fees, loans, and other assessments.

6.5.1.13 Glenn-Colusa Irrigation District Water Transfers to TCCA CVP Contractors

GCID is exploring the possibility of transferring surface water to Central Valley Project (CVP) contractors served by the TCC to provide in-lieu groundwater recharge and reduce groundwater pumping. The water to be transferred would be Sacramento River water available to GCID under its water rights settlement contract that is temporarily surplus to GCID's needs under certain conditions. Transferred water would be diverted into the Tehama-Colusa Canal at the Red Bluff Pumping Plant and Fish Screen facility rather than at the GCID pumping plant and fish screen facility north of Hamilton City. Priority would be placed on transfers to CVP contractors in areas where groundwater levels have been declining over the past approximately 20 years, particularly in the areas around the cities of Orland and Arbuckle. A summary of the project is provided in Table 6-41.

Table 6-41. Glenn-Colusa Irrigation District Water Transfers to TCCA CVP Contractors Summary

Item	Description
Implementation	GCID proposed this potential project for GSP implementation with participating TCCA CVP contractors. The project would provide in-lieu groundwater recharge through increased CVP water utilization. This project may be implemented and would be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This project is currently in the early conceptual stage. Thus, the start and completion dates for this project have yet to be determined and would be provided in GSP annual reports and five-year updates when known.
Notice to public and other agencies	Public and/or Inter-Agency Noticing would be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	The source would be the Sacramento River under GCID's existing contractual rights according to its Sacramento River Water Right Settlement contract. Settlement contract water supplies are subject to 25 percent reductions in Shasta Critical years.
Legal authority, permitting processes, and regulatory control	GSAs, Districts and individual project proponents have the authority to plan and implement projects. Required permitting and regulatory review would be project specific and initiated through consultation with applicable governing agencies. Governing agencies for which consultation would be initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The sustainability indicators expected to benefit are groundwater levels, groundwater storage, and depletion of interconnected surface water. This project is currently in the early conceptual stage. Thus, the expected yield of this project has yet to be determined and would be reported in GSP annual reports and five-year updates when known. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. These analyses may include: flow measurement consistent with SBx7-7 (23 CCR §931-938), ET analysis, reductions in GW use, well monitoring, determination of infiltration rates, water balance analysis, as-built drawings and stream gaging. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.

Table 6-41. Glenn-Colusa Irrigation District Water Transfers to TCCA CVP Contractors Summary	
Item	Description
Costs	This project is currently in the early conceptual stage. Thus, the anticipated costs of this project have yet to be determined and would be reported in GSP annual reports and five-year updates when known. The project proponent would identify funding sources to cover project costs as part of project development. These may include grants, fees, loans, and other assessments.

6.5.1.14 Colusa Subbasin In-Lieu Recharge & Banking Program

The project would incentivize landowners to take surplus contract surface water in-lieu of pumping groundwater by providing financial incentives (subsidizing surface water costs) to make surface water less expensive than groundwater. If needed, South Valley would subsidize the cost of new distribution systems to facilitate the delivery of additional surface water or provide funds to districts to implement other programs. The magnitude of such payments would depend on the size of the banking project but could exceed $100,000 per year per district. A predetermined portion of the additional water brought into the districts would be dedicated to contributing to local groundwater sustainability and some portion of the remaining quantities would be available for delivery, directly or by exchange, to South Valley members in the San Joaquin Valley. Additional groundwater production wells may need to be constructed to enable recovery of banked water. Such facilities would be paid for by South Valley but located and constructed in coordination with local districts. A summary of the project is provided in Table 6-42.

Table 6-42. Colusa Subbasin In-Lieu Recharge & Banking Program Summary	
Item	Description
Implementation	The South Valley Water Resources Authority proposed this project concept which would be located within the districts who participate. The project would provide direct and in-lieu groundwater recharge through utilization of surface water from this project, as available. This project may be implemented and would be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This project is currently in the early conceptual stage. Thus, the start and completion dates for this project have yet to be determined and would be provided in GSP annual reports and five-year updates when known.
Notice to public and other agencies	Public and/or Inter-Agency Noticing would be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	To be determined.

Table 6-42. Colusa Subbasin In-Lieu Recharge & Banking Program Summary	
Item	Description
Legal authority, permitting processes, and regulatory control	GSAs, Districts and individual project proponents have the authority to plan and implement projects. Required permitting and regulatory review would be project specific and initiated through consultation with applicable governing agencies. Governing agencies for which consultation would be initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The sustainability indicators expected to benefit are groundwater levels, groundwater storage, depletion of interconnected surface water, land subsidence, and potentially groundwater quality. This project is currently in the early conceptual stage. Thus, the expected yield of this project has yet to be determined and would be reported in GSP annual reports and five-year updates when known. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.
Costs	This project is currently in the early conceptual stage. Thus, the anticipated costs of this project have yet to be determined and would be reported in GSP annual reports and five-year updates when known. The project proponent would identify funding sources to cover project costs as part of project development. These may include grants, fees, loans, and other assessments.

6.5.1.15 Sycamore Marsh Farm In-Lieu Recharge Project

Sycamore Marsh Farm is in the process of developing an in-lieu groundwater recharge plan. Sycamore Marsh Farm encompasses approximately 420 acres in the Colusa Drain Mutual Water Company (CDMWC) and has an additional 449 acres that could potentially be annexed into the CDMWC, allowing for diversion of surface water from CDMWC. A summary of the project is provided in Table 6-43.

Table 6-43. Sycamore Marsh Farm In-Lieu Recharge Project Summary	
Item	Description
Implementation	The landowner proposed this project concept for GSP implementation which would be located on their property. The project would provide in-lieu groundwater recharge through annexation into CDMWC. This project may be implemented and would be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This project is currently in the early conceptual stage. Thus, the start and completion dates for this project have yet to be determined and would be provided in GSP annual reports and five-year updates when known.

Table 6-43. Sycamore Marsh Farm In-Lieu Recharge Project Summary	
Item	Description
Notice to public and other agencies	Public and/or Inter-Agency Noticing would be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	The source for this project would be the Colusa Drain. The reliability is still to be determined.
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement projects. Required permitting and regulatory review would be initiated through consultation with applicable governing agencies. Governing agencies for which consultation would be initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The sustainability indicators expected to benefit are groundwater levels, groundwater storage, depletion of interconnected surface water, land subsidence, and potentially groundwater quality. This project is currently in the early conceptual stage. Thus, the expected yield of this project has yet to be determined and would be reported in GSP annual reports and five-year updates when known. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.
Costs	This project is currently in the early conceptual stage. Thus, the anticipated costs of this project have yet to be determined and would be reported in GSP annual reports and five-year updates when known. The project proponent would identify funding sources to cover project costs as part of project development. These may include grants, fees, loans, and other assessments.

6.5.1.16 Westside Off-stream Reservoir and In-Lieu Groundwater Recharge

TCCA Contractors would construct off-stream surface reservoirs along the western edge of the Subbasin and up-slope from the TCC. They would divert surplus Sacramento River flows (e.g., Section 215 water) at the Red Bluff Pumping Plant and Fish Screen, and convey water through the TCC and pump water up into storage reservoir(s). Stored water would be released into the TCC for irrigation supply to enable reduction of groundwater pumping (i.e., in-lieu groundwater recharge). New pumping plants on the TCC and new storage impoundments would need to be planned, designed, and constructed subject to a determination of economic and environmental feasibility. A summary of the project is provided in Table 6-44.

Table 6-44. Westside Off-stream Reservoir and In-Lieu Groundwater Recharge Summary	
Item	Description
Implementation	TCCA Contractors proposed this project concept for GSP implementation which would be located on the western edge of the Subbasin. The project would provide in-lieu groundwater recharge through increased storage of surface water. This project may be implemented and would be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This project is currently in the early conceptual stage. Thus, the start and completion dates for this project have yet to be determined and would be provided in GSP annual reports and five-year updates when known.
Notice to public and other agencies	Public and/or Inter-Agency Noticing would be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	The source for this project would be Sacramento River Section 215 water. The reliability is highly variable; available only during periods of high flow in the Sacramento River and tributaries.
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement projects. Required permitting and regulatory review would be initiated through consultation with applicable governing agencies. Governing agencies for which consultation would be initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The sustainability indicators expected to benefit are groundwater levels, groundwater storage, and depletion of interconnected surface water. This project is currently in the early conceptual stage. Thus, the expected yield of this project has yet to be determined and would be reported in GSP annual reports and five-year updates when known. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.
Costs	This project is currently in the early conceptual stage. Thus, the anticipated costs of this project have yet to be determined and would be reported in GSP annual reports and five-year updates when known. The project proponent would identify funding sources to cover project costs as part of project development. These may include grants, fees, loans, and other assessments.

6.5.2 Potential Management Actions

This section describes potential management actions that would be implemented if determined to be necessary under future monitoring of the Subbasin. Table 6-45 summarizes the potential management actions included in the GSP. The following subsections provide descriptions for each management action.

Table 6-45. Summary of Potential Management Actions

Management Action[(a)]	Management Action Type	Proponent
Domestic Well Mitigation Program	Management Action	CGA and GGA
Drought Contingency Planning for Urban Areas	Management Action	CGA, GGA, and cities (GSA member agencies)
Long-Term Demand Management Action	Management Action	CGA and GGA
Strategic Short-Term Demand Management	Management Action	CGA and GGA
Well Abandonment Outreach and Funding Program	Management Action	CGA and GGA
Preservation of Lands Favorable for Recharge	Management Action	CGA and GGA
Review of County Well Permitting Ordinances	Management Action	CGA and GGA
Reduce Non-beneficial Evapotranspiration/Invasive Species Eradication	Reduce Groundwater Demand	CGA and GGA
Development of a Dedicated Network of Shallow Monitoring Wells for GDE Monitoring	Management Action, Closing Data Gaps	CGA and GGA

(a) Fourteen projects and management actions are not depicted on the map in Figure 6-9. These projects and management actions are excluded either because they will be implemented subbasin-wide or because the planning process is not far enough along to locate these projects at this time.

6.5.2.1 Domestic Well Mitigation Program

Groundwater level measurable objectives (MOs) adopted for sustainable management of the Subbasin operation are based on the most recent five years of measured water levels in each representative monitoring well (generally 2015 through 2020 with some exceptions), and therefore should be highly protective of domestic water supply wells. However, it is possible that in certain portions of the Subbasin groundwater levels will fall below the adopted MOs and approach the adopted minimum thresholds (MTs) as projects and management actions are being implemented for recovery of groundwater levels. As a consequence, it is possible that that some domestic wells will go dry in the future.

To mitigate the effects of domestic well stranding due to groundwater level decline, the CGA and GGA will investigate implementing domestic well mitigation programs in their respective portions of the Subbasin. These programs may consider supporting consolidation of smaller public water systems and expansion of larger public water systems to cover domestic users that may see impacts to their existing wells. The exact details of the potential domestic well mitigation programs have yet to be determined, but will be reported in GSP annual reports and five-year updates when known. Outreach to domestic well users, including those in DACs, SDACs, and EDAs, will occur throughout program development and implementation using the communication pathways identified in Chapter 2 and in Table 6-46. Outreach will be conducted to ensure that the interests and feedback of domestic well users are known and considered throughout the development and implementation of these programs.

Program development would involve establishing a funding mechanism to accumulate mitigation funds, establishing a process and criteria for determining when dewatered wells are eligible for mitigation funding, and establishing criteria for scaling mitigation payments (for example, relatively new dewatered wells might qualify for more funding than old wells). Possible mechanisms that could be used to generate well mitigation funds include a groundwater extraction fee (which would require flow measurement at each well) and a per well assessment (which would not require measurement). A summary of the program is provided in Table 6-46.

Table 6-46. Domestic Well Mitigation Program Summary

Item	Description
Implementation	CGA and GGA proposed this potential management action for GSP implementation which would occur across the Subbasin. The action would respond to potentially changing conditions in the Subbasin and would be implemented as needed if groundwater levels fall. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This action is currently in the early conceptual stage. Thus, the start and completion dates have yet to be determined and would be provided in GSP annual reports and five-year updates when known.
Notice to public and other agencies	Public and/or Inter-Agency Noticing would be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	Not applicable for this demand management action.
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual proponents have the authority to plan and implement management actions. Required permitting and regulatory review would be initiated through consultation with applicable governing agencies. Governing agencies for which consultation would be initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The sustainability indicators expected to benefit is groundwater levels, as this management action would alleviate problems associated with potential changes in conditions. The expected yield of this management action is not quantified as it is proposed for responding to changing conditions. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.
Costs	This management action is currently in the early conceptual stage. Thus, the anticipated costs have yet to be determined and would be reported in GSP annual reports and five-year updates when known. The proponent would identify funding sources to cover costs as part of development of this management action. These may include grants, fees, loans, and other assessments.

6.5.2.2 Drought Contingency Planning for Urban Areas

The CGA and GGA will coordinate with cities, towns, and other municipal and industrial water suppliers, which are all fully dependent on groundwater in the Subbasin, to encourage drought contingency planning and drought preparedness in a manner consistent with sustainable groundwater management according the GSP. A summary of the management action is provided in Table 6-47.

Table 6-47. Drought Contingency Planning for Urban Areas Summary

Item	Description
Implementation	CGA, GGA, and cities (GSA member agencies) proposed this potential management action for GSP implementation which would occur across the Subbasin. The action would reduce the demand for groundwater pumping. This action may be implemented and would be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This action is currently in the early conceptual stage. Thus, the start and completion dates have yet to be determined and will be provided in GSP annual reports and five-year updates when known.
Notice to public and other agencies	Public and/or Inter-Agency Noticing would be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	Not applicable for this management action.
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement management actions. Required permitting and regulatory review would be initiated through consultation with applicable governing agencies. Governing agencies for which consultation would be initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The sustainability indicators expected to benefit are groundwater levels, groundwater storage, and depletions of interconnected surface water. This management action is currently in the early conceptual stage. Thus, the expected yield has yet to be determined and would be reported in GSP annual reports and five-year updates when known. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.
Costs	This management action is currently in the early conceptual stage. Thus, the anticipated costs have yet to be determined and would be reported in GSP annual reports and five-year updates when known. The proponent would identify funding sources to cover costs as part of development of this management action. These may include grants, fees, loans, and other assessments.

6.5.2.3 Long-Term Demand Management Action

The planned PMAs described in this chapter will be pursued by the Colusa Subbasin GSAs to achieve and maintain sustainable groundwater conditions. The GSAs have also included a potential demand management program as a "backstop" to other PMAs. Events that may trigger this management action include, but are not limited to: severe, prolonged drought conditions result in groundwater levels approaching MT in specific parts of the Subbasin; other PMAs are not achieving the expected level of benefits; or new information about projected future conditions show that sustainability objectives will not be met. This section describes the demand management action.

Demand management broadly refers to any water management activity that reduces the consumptive use of irrigation water. To be effective for purposes of sustainable groundwater management, demand management must result in a reduction in net groundwater pumping (pumping net of recharge). That is, it must reduce consumptive use or irrecoverable losses into a saline water body. Activities that, for example, reduce canal seepage or reduce deep percolation from irrigation will not be effective. They may decrease quantity of water diverted or applied but they also reduce recharge to usable groundwater, so do not improve the net pumping from the aquifer.

For purposes here, a demand management action is one that incentivizes, enables, or requires water users to reduce their consumptive use, but does not dictate exactly how users have to do it. Users can respond to demand management by changing to lower water-using crops, water-stressing crops (providing less water than the crop would normally consume for full yield), reducing evaporation losses, and reducing irrigated acreage.

The following types of demand management activities are included under this management action:

- **Allocation**. Under an allocation, the different sources of groundwater are quantified and allocated to individual parcels, wells, or entities (such as, for example, farming operations). Sources of groundwater that can be included in the allocation can include the sustainable yield, natural recharge, imported water recharge, new developed recharge sources, and, for a limited period of time, overdraft (sometimes called "transitional water"). By defining the quantities of groundwater available to individuals this can incentivize reductions in use and development of new recharge opportunities. Allocation design may include specific considerations for managed wetlands and other habitat uses of water.

  Implementing an allocation does not necessarily result in reducing groundwater use. For example, if the allocation is greater than historical use this would not be a constraint for groundwater users and would not result in less consumptive groundwater use. In the context of GSP implementation, the allocation is typically tied to the sustainable yield of the Subbasin. When the sustainable yield (including yield of other PMAs like recharge projects) is less than current pumping, the effect of an allocation is an overall reduction in net groundwater use.

  An allocation is a rigid method for implementing demand management. It effectively limits water use on a well, parcel, or operation basis. This could require idling land or switching crop on lands that have insufficient allocation to meet crop demand, which imposes costs on water users (e.g., growers). There are ways to increase the flexibility of allocations to reduce the costs of demand management. For example, the allocation could be defined as an average over a period of time rather than a fixed amount every year, or users could be allowed to carry over unused allocation into the next year.

- **Allocation + Water Market**. An allocation that is less than historical water use can be coupled with a water market. A groundwater market is another way to increase the flexibility of an allocation to reduce costs of demand management. A market is an institution that allows willing buyers and sellers to exchange groundwater allocation ("credits"). The market allows groundwater users to shift allocation to higher-valued uses. Defining an allocation across an entire farming operation establishes a kind of market in which the owner or manager moves water to produce the highest return (e.g., remove an older block of an orchard and use the allocation to meet crop demand on a more productive block). More broadly, a market allows a means to exchange allocation with another groundwater user, whether for a single season or using a multi-year trade. Willing sellers trade a part of their allocation to willing buyers in exchange for a payment that the seller expects will exceed the return he/she would have earned from using the water for irrigation. This additional flexibility reduces the cost to the GSA's users of achieving demand reduction under an allocation.

  Development of a water market institution is a complex process that encompasses more than defining the groundwater allocation. The water market requires an administrator (e.g., the GSA or a third party) and methods for monitoring, enforcement, and accounting of groundwater use. It also requires development of market rules that determine what sources of the allocation are tradeable, under what conditions, and over what periods of time. For example, market rules would consider, and possibly limit, the potential impacts of local concentrations of groundwater pumping if trades occur within specific areas. Other market rules might consider habitat and ecosystem service benefits. Finally, the water market requires a marketplace for buyers and sellers to post bids, review prices, and execute deals. The GSAs would consider these factors in the future if a groundwater market is considered.

- **Land Repurposing**. Land repurposing programs are more targeted than an allocation or market program but maintain flexibility for participants by its voluntary nature. Such a program would provide a financial incentive to willing participants for their currently irrigated lands to be repurposed into other, non-irrigated uses. Programs can focus on short-term drought conditions, or they can provide multi-year reductions in demand if that is needed under some conditions. For longer-term programs, lands can be repurposed to achieve other multi-benefit objectives - for example, to create habitat corridors or to support local endangered species[15].

  Land repurposing programs typically include incentives to stop irrigating. These incentives need, at minimum, to exceed the return to farming on a parcel. An additional incentive may be provided to convert land into an alternative use. For example, the United States Department of Food and Agriculture (USDA) Conservation Reserve Enhancement Program (CREP[16]) will pay lands to forgo irrigation and offer an additional per acre payment to convert lands into different types of habitats. Other land repurposing program considerations might consider strategic location of repurposed lands considering proximity to protected areas (e.g., National Wildlife Refuges).

[15] See, for example: Environmental Defense Fund, Strategic Land Repurposing. The Nature Conservancy, Rewilding Agricultural Lands.

[16] Note that CREP is state-specific and is not currently being implemented in California.

- **Other financial incentives**. Demand management can also be achieved through a range of other financial incentives. This could include positive financial incentives to reduce consumptive groundwater use. It could also include groundwater extraction fees that disincentivize groundwater use. Financial incentives could consider public benefits (e.g., habitat) separately from private benefits (e.g., irrigation) of water use.

  As described above, the demand management action could be triggered if required under future monitoring by the GSAs. The following principles would guide development of the demand management program; these are in no order of preference and the GSAs recognize that tradeoffs exist among these principles:

  - Minimize the economic impacts of any demand management
  - Maintain established water rights
  - Incentivize investment in water supply infrastructure
  - Incentivize economically efficient water use
  - Complement other PMAs such as direct and in-lieu recharge projects in aggregate, and in specific regions
  - Allow sufficient program flexibility for groundwater pumpers to adjust over time
  - Ensure access for domestic water users (de minimis domestic use as defined by SGMA is less than 2 af annually per user for domestic purposes only)

This potential management action will be evaluated further in GSP annual reports and five-year updates, as required by conditions in the Subbasin. Appendix 6B summarizes the economic value of irrigated agriculture to the Subbasin and quantifies the direct economic costs of demand management. Table 6-48 summarizes GSP regulation requirements and describes how the management action meets those requirements.

Table 6-48. Long-Term Demand Management Action Summary

Item	Description
Implementation	CGA and GGA proposed this management action for GSP implementation, but it would only be implemented if groundwater conditions in the Subbasin, or specific areas of the Subbasin, require it. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This action is currently in the early conceptual stage. Thus, the start and completion dates have yet to be determined and would be provided in GSP annual reports and five-year updates when known, and only if the management action is triggered for implementation.
Notice to public and other agencies	Public and/or Inter-Agency Noticing would be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	Not applicable for this demand management action.

Table 6-48. Long-Term Demand Management Action Summary	
Item	Description
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement management actions. Required permitting and regulatory review would be initiated through consultation with applicable governing agencies. This would likely include local county agencies, as appropriate.
Benefits and benefit evaluation methodology	The measurable objective expected to benefit is groundwater levels, as this management action would reduce net pumping to achieve sustainability conditions in specific areas. The expected yield of this management action is not quantified because: 1) it will only be triggered if necessary, and 2) the scale of the demand management program is flexible. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.
Costs	This management action is currently in the early conceptual stage. Thus, the anticipated costs have yet to be determined and would be reported in GSP annual reports and five-year updates when known, and only if the management action is triggered for implementation. The proponent would identify funding sources to cover costs as part of development of this management action. These may include grants, fees, loans, and other assessments.

6.5.2.4 Strategic Temporary Land Idling for Drought and Localized Short-Term Groundwater Management

The Colusa Subbasin GSP identified potential areas of concern in the Subbasin where groundwater levels have declined significantly over recent years due to disproportionate reliance on groundwater to meet crop irrigation demands. Planning and constructing projects (e.g., conveyance or recharge) to offset short-run impacts of drought and local groundwater level impacts would take time and require substantial capital costs. This program is a potential management action that would provide the GSAs with a voluntary, flexible, short-run response to alleviate impacts in local areas of concern.

The program would be focused on specific drought-affected areas with sustainability challenges. It would be voluntary and provide financial incentives (payments) to encourage participation. Payment terms and other conditions would be specified as part of program design. Two potential structures for the program are: 1) participating groundwater-using lands in drought-affected areas in the Subbasin would be idled and the quantified groundwater saved would be left in the ground to alleviate sustainability challenges, or 2) participating surface water-using lands anywhere in the Subbasin would be idled, and the saved surface water would be conveyed to replace groundwater pumping in other areas of the Subbasin with groundwater sustainability challenges.

Appendix 6B summarizes the economic value of irrigated agriculture to the Subbasin and quantifies the direct economic costs of demand management in the potential areas of concern. A summary of the management action is provided in Table 6-49.

Table 6-49. Strategic Temporary Land Idling for Drought and Localized Short-Term Groundwater Management Summary

Item	Description
Implementation	CGA and GGA proposed this management action concept for GSP implementation which would occur across the Subbasin. The action would reduce the demand for groundwater pumping. This action may be implemented and would be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This action is currently in the early conceptual stage. Thus, the start and completion dates have yet to be determined and would be provided in GSP annual reports and five-year updates when known.
Notice to public and other agencies	Public and/or Inter-Agency Noticing would be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	Not applicable for this demand management action.
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual proponents have the authority to plan and implement management actions. Required permitting and regulatory review would be initiated through consultation with applicable governing agencies. Governing agencies for which consultation would be initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The measurable objectives expected to benefit are groundwater levels, groundwater storage, and depletions of interconnected surface water in areas with potential sustainability challenges. The expected yield of this management action will depend on the level of participation and water needs. There is also potential for multi-benefits on temporarily idled lands, depending on program design.
Costs	This management action is currently in the early conceptual stage. Thus, the anticipated costs have yet to be determined and would be reported in GSP annual reports and five-year updates when known. The proponent would identify funding sources to cover costs as part of development of this management action. These may include grants, fees, loans, and other assessments.

6.5.2.5 Well Abandonment Outreach and Funding Program

The CGA and GGA will coordinate with Colusa and Glenn counties, respectively, to create a program providing outreach and education to landowners regarding the proper procedures for well decommissioning and abandonment, as well as a funding source to assist landowners with these procedures. This effort would be accomplished through coordination between the GSAs and well permitting agencies. This program is anticipated to improve the Subbasin well inventory and potentially have water quality benefits, as improperly abandoned wells are a potential point source for water quality contaminant transport from the ground surface to the underlying groundwater system. A summary of the management action is provided in Table 6-50.

Table 6-50. Well Abandonment Outreach and Funding Program Summary	
Item	Description
Implementation	CGA and GGA proposed this management action concept for GSP implementation which would occur across the Subbasin. The action would respond to potentially changing conditions in the Subbasin and would be implemented as needed based on the number of wells abandoned and water quality concerns. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This action is currently in the early conceptual stage. Thus, the start and completion dates have yet to be determined and would be provided in GSP annual reports and five-year updates when known.
Notice to public and other agencies	Public and/or Inter-Agency Noticing would be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	Not applicable for this management action.
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement management actions. Required permitting and regulatory review would be initiated through consultation with applicable governing agencies. Governing agencies for which consultation would be initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The measurable objective expected to benefit is water quality. The expected yield of this management action is not quantified as it is proposed for responding to changing conditions. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.
Costs	This management action is currently in the early conceptual stage. Thus, the anticipated costs have yet to be determined and would be reported in GSP annual reports and five-year updates when known. The proponent would identify funding sources to cover costs as part of development of this management action. These may include grants, fees, loans, and other assessments.

6.5.2.6 Preservation of Lands Favorable for Recharge

The CGA and GGA will coordinate with those agencies having authority over land use planning in Colusa and Glenn counties, respectively, to investigate, design, and implement a program providing incentives to landowners with lands favorable to groundwater recharge to preserve them as agricultural or undeveloped lands on which groundwater recharge will be possible in perpetuity. An update of ongoing coordination will appear in annual reports. A summary of the management action is provided in Table 6-51.

Table 6-51. Preservation of Lands Favorable for Recharge Summary	
Item	Description
Implementation	CGA and GGA proposed this management action concept for GSP implementation which would occur across the Subbasin. The action could help create additional direct groundwater recharge in the future. This action may be implemented and would be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This action is currently in the early conceptual stage. Thus, the start and completion dates have yet to be determined and would be provided in GSP annual reports and five-year updates when known.
Notice to public and other agencies	Public and/or Inter-Agency Noticing would be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	Not applicable for this management action.
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement management actions. Required permitting and regulatory review would be initiated through consultation with applicable governing agencies. Governing agencies for which consultation would be initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The measurable objectives expected to benefit are groundwater levels, groundwater storage, and depletions of interconnected surface water. This management action is currently in the early conceptual stage. Thus, the expected yield has yet to be determined and would be reported in GSP annual reports and five-year updates when known. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.
Costs	This management action is currently in the early conceptual stage. Thus, the anticipated costs have yet to be determined and would be reported in GSP annual reports and five-year updates when known. The proponent would identify funding sources to cover costs as part of development of this management action. These may include grants, fees, loans, and other assessments.

6.5.2.7 Review of County Well Permitting Ordinances

Modification to well regulations is one potential mechanism to ensure that groundwater sustainability is achieved and maintained in the Subbasin. Well permitting regulations can help avoid adverse impacts on groundwater beneficial users by reducing the potential for mutual well interference or streamflow depletion through limitations on well screen depths, well spacing, and/or setbacks.

This management action would review and suggest potential revisions to the county well permitting processes in the Subbasin to ensure that:

- Future well permitting aligns with the subbasin sustainability goal
- Future changes to well permitting are reviewed by the GSAs

Through this management action, the Counties and GSAs would coordinate to establish processes whereby the GSAs would review and agree upon future changes to well permitting requirements. This coordination could occur through the potential framework for coordination between the Counties and GSAs that is described in Chapter 7, Plan Implementation. The Counties would also review existing well permitting processes and assess whether additional well permitting requirements are warranted to maintain sustainable groundwater conditions in the Subbasin. Existing well regulations may be modified to help protect water quality, allow for appropriate screening, require depths be deeper than MTs, and avoid interference or impacts of pumping on neighboring wells. Efforts may also be designed to be protective of domestic wells.

A summary of the management action is provided in Table 6-52.

Table 6-52. Review of County Well Permitting Ordinances Summary

Item	Description
Implementation	This management action would review and suggest potential revisions to the county well permitting processes in the Subbasin to ensure that future well permitting aligns with the Subbasin sustainability goal and that future changes to well permitting are reviewed by the GSAs. This action may be implemented and would be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This action is currently in the early conceptual stage. Thus, the start and completion dates have yet to be determined and would be provided in GSP annual reports and five-year updates when known.
Notice to public and other agencies	Public and/or Inter-Agency Noticing would be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	Not applicable for this management action.
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement management actions, and Counties have the authority to review and modify county well permitting ordinances. Required permitting and regulatory review would be initiated through consultation with applicable governing agencies. Governing agencies for which consultation would be initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.

Table 6-52. Review of County Well Permitting Ordinances Summary	
Item	Description
Benefits and benefit evaluation methodology	All sustainability indicators may benefit from changes in groundwater pumping that result from revisions to county well permitting ordinances. This management action is currently in the early conceptual stage. Thus, the expected yield has yet to be determined and would be reported in GSP annual reports and five-year updates when known. Evaluation of benefits will be based on analysis of pre- and post-project measurements supported by modeling. Measured parameters will include surface water deliveries, groundwater levels, and others to be determined. Modeling will be done with the C2VSimFG-Colusa model used for GSP development.
Costs	This management action is currently in the early conceptual stage. Thus, the anticipated costs have yet to be determined and would be reported in GSP annual reports and five-year updates when known. The proponent would identify funding sources to cover costs as part of development of this management action. These may include grants, fees, loans, and other assessments.

6.5.2.8 Reduce Non-beneficial Evapotranspiration

This project would remove the invasive, non-native plant species (i.e., Arundo donax, eucalyptus, tamarisk, etc.) from riparian corridors and other areas they may be present. This would provide both a reduction in evapotranspiration from shallow groundwater and native ecosystem restoration. A summary of the management action is provided in Table 6-53.

Table 6-53. Reduce Non-beneficial Evapotranspiration Summary	
Item	Description
Implementation	This potential project is proposed by CGA and GGA and would be implemented across the Subbasin. This action could be done in coordination with neighboring GSAs, especially along Stony Creek. The project would reduce groundwater demand by reducing evapotranspiration. This action may be implemented and would be monitored and quantified with respect to groundwater conditions, as needed, if sustainable levels are not reached following implementation of other projects and management actions. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This project is currently in the early conceptual stage. Thus, the start and completion dates for this project have yet to be determined and would be provided in GSP annual reports and five-year updates when known.
Notice to public and other agencies	Public and/or Inter-Agency Noticing would be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	Not applicable.

Table 6-53. Reduce Non-beneficial Evapotranspiration Summary	
Item	Description
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement projects. Required permitting and regulatory review would be project specific and initiated through consultation with applicable governing agencies. Governing agencies for which consultation would be initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The measurable objectives expected to benefit are groundwater levels, groundwater storage, and depletion of interconnected surface water. This project is currently in the early conceptual stage. Thus, the expected yield of this project has yet to be determined and would be reported in GSP annual reports and five-year updates when known. Other benefits would include decreased ET, increased native vegetation and habitat, and decreased sediment trapping.
Costs	This project is currently in the early conceptual stage. Thus, the anticipated costs of this project have yet to be determined and would be reported in GSP annual reports and five-year updates when known. The proponent would identify funding sources to cover costs as part of development of this management action. These may include grants, fees, loans, and other assessments.

6.5.2.9 Development of a Dedicated Network of Shallow Monitoring Wells for GDE Monitoring

This action would evaluate and develop a dedicated network of shallow monitoring wells specifically planned and sited for monitoring conditions in areas of the Subbasin where GDEs are most likely to be found. Although the GSAs used the best available scientific data and information to assess potential GDEs within the Subbasin during GSP development, significant data gaps exist in the understanding of GDEs and associated species in those GDEs. This action would be developed to close those data gaps, prioritizing installation of new monitoring sites in locations where the GSAs determine that GDEs are most likely to be found. It is expected that this action would also incorporate biological monitoring to collect biological data (e.g., biological surveys, remote sensing indexes, and/or assessment of vegetation rooting depth information). This data would be used to inform the location of new shallow monitoring wells and monitor whether GDEs are being impacted by changing groundwater conditions. A summary of the management action is provided in Table 6-54.

Table 6-54. Development of a Dedicated Network of Shallow Monitoring Wells for GDE Monitoring Summary

Item	Description
Implementation	This potential action is proposed by CGA and GGA and would be implemented across the Subbasin, focusing on areas determined during GSP development as most likely to be a GDE, and areas where GDE-related data gaps exist. This action could be done in coordination with neighboring GSAs and agencies, especially along Stony Creek and the Sacramento River. The action would evaluate and develop a dedicated network of shallow monitoring wells specifically planned and sited for monitoring conditions in areas of the Subbasin where GDEs are most likely to be found. This action is expected to be implemented and would be monitored and quantified with respect to groundwater conditions, as needed, during GSP implementation in order to close data gaps related to GDEs. This will be done in the context of Sustainable Management Criteria defined in Chapter 5 to ensure sustainable operation of the Subbasin.
Timeline	This action is currently in the early conceptual stage. Thus, the start and completion dates for this action have yet to be determined and would be provided in GSP annual reports and five-year updates when known.
Notice to public and other agencies	Public and/or Inter-Agency Noticing would be facilitated through GSA board meetings, GSA and/or cooperating agency website(s), GSA newsletter, member agency newsletter, inter-basin coordination meetings, member agency governing body public meetings, GSP annual report(s), public scoping meetings and environmental/regulatory permitting notification.
Water source & reliability	Not applicable.
Legal authority, permitting processes, and regulatory control	GSAs, Districts, and individual project proponents have the authority to plan and implement projects. Required permitting and regulatory review would be project specific and initiated through consultation with applicable governing agencies. Governing agencies for which consultation would be initiated may include, but is not limited to: DWR, SWRCB, CDFW, Flood Board, Regional Water Boards, USFWS, NMFS, LAFCO, County of Colusa and/or Glenn and CARB.
Benefits and benefit evaluation methodology	The measurable objectives expected to benefit are groundwater levels, groundwater storage, and depletion of interconnected surface water. This action is currently in the early conceptual stage. Thus, the expected yield of this action has yet to be determined and would be reported in GSP annual reports and five-year updates when known.
Costs	This action is currently in the early conceptual stage. Thus, the anticipated costs of this action have yet to be determined and would be reported in GSP annual reports and five-year updates when known. The proponent would identify funding sources to cover costs as part of development of this action. These may include grants, fees, loans, and other assessments.

CHAPTER 7
Plan Implementation

This chapter outlines the schedule and costs to implement the GSP over the first five years (through 2026) and describes implementation activities in accordance with §354.8(f)(3). Implementation of the GSP in the Subbasin will include GSA administrative requirements, periodic reporting required under 23 CCR §356.2 and §356.4, and studies to address data gaps and support implementation. In addition, to address possible future changes in the Subbasin conditions that could cause undesirable results over the long term, and in the near term, to address effects of recent historical (2014 to 2015) and current (2020 to 2021) drought conditions, a range of planned projects and management actions (planned PMAs) has been developed and will be implemented by the GSAs, as described in Chapter 6.

In accordance with 23 CCR §354.6(e), GSP implementation costs are estimated and described. Estimated costs are shown for the first five years of GSP implementation and any resulting changes from that set-forth herein will be reported in annual reports. Costs are split into the following two aggregate categories (which are further disaggregated in the subsequent subsections):

- **GSA Costs**. GSA costs are for activities related to GSP implementation that are (generally) not specific to a specific area or water district in the Subbasin. For example, this includes GSA administration costs for coordination, meetings, outreach, legal, and other general administrative requirements to support GSP implementation.
- **PMA Costs**. PMA costs are specific to PMAs that were described in Chapter 6 of this GSP. These costs may be covered by individual project proponents, the GSA more broadly, or be split between multiple entities. As such, they are reported separately from GSA costs.

The following GSP elements are described in this chapter:

- Costs for GSAs to administer GSP activities as required by 23 CCR §354.6(e)
- PMA-specific costs are summarized to illustrate the total cost of GSP implementation; however, PMAs are described in more detail (e.g., benefit, capital, and operating costs) in Chapter 6: Projects and Management Actions
- Financing approaches / funding mechanisms
- Timeline and roadmap for implementing all GSA projects and management actions between 2022 and 2042
- Implementation of additional actions to achieve Subbasin sustainability goals (Data Management System [DMS], monitoring wells, water model updates, etc.)
- Monitoring and reporting, including the contents of annual reports and five-year periodic evaluations that must be provided to the Department of Water Resources (DWR) (23 CCR §356.2 and §356.4)
- The Colusa Subbasin DMS

This chapter is structured as follows. The following section describes the different activities and costs that GSAs are estimated to incur for GSP implementation. This is followed by a summary of those costs and approximate breakdown by the two GSAs in the Subbasin. Section 7.3 summarizes costs for PMAs using the information presented in Chapter 6. Only planned PMAs are included in the GSP implementation cost estimates because these are the PMAs (in accordance with 23 CCR §354.44(a)) that would allow the GSAs to achieve the sustainability goal for the Subbasin and avoid reaching the minimum thresholds defined in this GSP under future, changing conditions. Section 7.4 summarizes all GSA and PMA costs, expressed on

an annual basis, which represents the estimated total cost of GSP implementation. Section 7.5 describes the implementation schedule for GSP activities. Section 6 provides a concise overview of financing and funding mechanisms that provides the basis for how the GSAs plan to cover GSP implementation costs and Sections 7.7, 7.8, and 7.9 describe the required elements for the GSP annual reporting, periodic (five-year) evaluations, and features of the DMS.

7.1 GSA COSTS FOR GSP IMPLEMENTATION

Total GSP implementation costs include both PMA-specific costs and costs for the CGA and GGA to administer and support all other aspects of the GSP. GSP implementation costs will include costs for managing the GSP, planning and studies, monitoring, and providing general administration.

Estimated GSA costs for GSP implementation are split into the following four categories:

- **GSA Administration**. General costs for GSA operations including meetings, coordination, outreach, legal, accounting, and other services that are required to support GSP implementation and updates.
- **GSP Studies**. Technical evaluations that are required for GSP implementation. These include addressing data gaps, updating groundwater information to satisfy GSP Regulations, and studies that are required to evaluate and manage the Subbasin to achieve the sustainability goal.
- **GSP Updates**. GSP updates includes annual reports and five-year periodic evaluations. These are required under the GSP Regulations, as described in detail under Section 7.6 and 7.7.
- **GSA Contingency**. An additional contingency is included to cover unanticipated legal costs and other unanticipated cost associated with GSP implementation.

The following subsections describe the general types of required activities and costs for each of the GSA cost categories.

7.1.1 GSA Administration

Administrative costs generally include meetings, reporting, record keeping, bookkeeping, legal, continued outreach to stakeholders, and government relations. GSAs will also need to continue to monitor projects and management actions to assess their benefit, feasibility, and coordinate with stakeholders and water managers if modification of projects and management actions is necessary to ensure the Subbasin meets the sustainability objectives.

GSAs will implement programs to monitor groundwater, measure elevations, and track total water use to satisfy reporting requirements in the GSP Regulations. Monitoring activities may include data management, installing monitoring wells, maintaining existing wells, and initiating studies to support GSP implementation. Other activities may include data collection for both groundwater and water quality monitoring networks.

GSAs will oversee the groundwater monitoring programs outlined in Chapter 4. This will include tracking Subbasin conditions and sustainability indicators. Data from the monitoring programs will be routinely evaluated to ensure progress is being made toward sustainability or to identify whether undesirable results are occurring.

GGA and CGA administrative costs are based on the existing rate studies[1] adopted by each GSA in 2018 and a review of audited financial statements for fiscal year 2020 (year ended June 30, 2020). Audited financial statements for fiscal year 2021 are not currently available as of the publication date of this GSP (December 2021). The rate studies covered the five-year period spanning fiscal years 2019/20 through 2023/24 and were prepared as property-related fees for water service under Proposition 218. The estimated annual operations (administration) expenses are approximately $465,000 for the CGA and up to $550,000 in the GGA.

7.1.2 GSP Studies

During the GSP development process, various data gaps were identified, in addition to areas where additional studies will be needed to support refinements to the GSP. This includes planning and technical studies that will be required to meet the annual and five-year reporting requirements under 23 CCR §356.2 and §356.4. It is anticipated that many of the studies to support GSP implementation—particularly those that affect sustainable management criteria in future revisions to the GSP—would be conducted in the same public and transparent process with which the GSP was prepared. These studies are described below.

Table 7-1 summarizes the technical studies to support GSP implementation. A total of15 studies have been identified. Many of the studies listed focus on filling data gaps associated with monitoring networks. This includes developing a well inventory and registration program. The studies and estimated costs are described in detail in the following subsections.

Table 7-1. Summary of GSP Implementation Studies

Study	Description
Expand Shallow Groundwater Level Monitoring Network	To expand the shallow groundwater monitoring network, additional monitoring wells must be evaluated. This includes existing monitoring wells and suitable locations for the construction of new monitoring wells.
Expand Water Quality Monitoring Network	This study will evaluate and expand additional groundwater quality monitoring wells.
Colusa Subbasin Western Boundary Investigation	This study will evaluate data to better understand the physical characteristics and groundwater conditions of the principal aquifer along the western margin of the Subbasin.
Westside Streams Monitoring Program	Streams originating from the Coastal Range west of the Subbasin will be evaluated for potential recharge volumes, water quality, and the interconnectedness of the streams and the groundwater system within the Subbasin.
Groundwater Well Monitoring Program	This pilot program will evaluate the costs and benefits of continuous groundwater monitoring data collection via six irrigation production wells. Program expansion throughout the Subbasin will be considered based on the data utility and costs of the pilot program.
Groundwater Financial Incentives Investigation	This analysis will quantify the total costs of groundwater use and switching to surface water. The analysis will also identify grower financial incentives for in-lieu recharge and options for structuring those incentives.

[1] Fee Study for the Glenn Groundwater Authority, May 2019 and Fee Study for the Colusa Groundwater Authority, May 2019.

Table 7-1. Summary of GSP Implementation Studies

Study	Description
CV2SimFG-Colusa Model Updates and Enhancement	This program will implement the periodic model data updates necessary to adequately represent near-term and future conditions within the Subbasin, and to support annual and five-year periodic GSP reporting to the DWR.
Well Inventory Program	This program will inventory the estimated 20% of groundwater wells unaccounted for within the Subbasin, and would seek to identify wells that are no longer active.
Well Registration Program	This study will evaluate the potential of a program for landowners to inventory their well data. This will complement the well inventory program.
Increasing GSA Involvement in County Well Permitting and Land Use Planning	CGA and GGA will explore options for allowing GSA input to the counties' well permitting processes and land use planning. The objective of GSA input would be to ensure that wells are permitted and land uses are planned in a manner consistent with sustainable groundwater management according to the GSP.
GSA Coordination with Water Quality Coalitions and Regulatory Agencies	GSAs will coordinate with the various water quality coalitions, water stakeholders, and regulatory agencies regarding GSP and other regulatory program implementation. This will include helping to identify and address water quality problems across the Subbasin, including those affecting disadvantaged communities (DACs) and severely disadvantaged communities (SDACs), and consideration of opportunities to expand public water systems and consolidate small public systems to improve drinking water quality delivered to DACs and SDACs.
Sutter Buttes Rampart Water Quality Interbasin Working Group	The CGA, GGA and the GSAs in the Butte, Sutter, Yolo, North Yuba and South Yuba Subbasins should participate in an interbasin working group focused on collaborative discussions, consensus-building and planning to address groundwater quality matters associated with the unique geology of the Sutter Buttes area.
Participation in Interagency Drought Task Forces	The CGA and GGA should coordinate their responses to droughts with their respective county and state agency partners through existing Interagency Drought Task Forces established in each county by the Colusa and Glenn County Boards of Supervisors.
Sacramento Valley Subsidence Interbasin Working Group	The CGA and GGA should consider participating in a Sacramento Valley Subsidence Interbasin Working Group with DWR, the other GSAs in the Sacramento Valley and federal partners. The working group would provide a forum for collaborative discussions, consensus-building, and planning to address inelastic land subsidence in the Sacramento Valley.
Evaluate Infrastructure Sensitivity to Subsidence	This study will evaluate the sensitivity of infrastructure in the Subbasin to potential subsidence rates.

7.1.2.1 Expand Shallow Groundwater Level Monitoring Network

The shallow groundwater monitoring network will be used to monitor groundwater levels and groundwater quality of the unconfined portion of the principal aquifer. Additionally, groundwater levels in shallow groundwater monitoring wells within five miles of major surface water features will be used to monitor stream-aquifer interactions and groundwater dependent ecosystems (GDEs). Understanding the flow relationships between the shallow groundwater aquifer and surface waters can assist in evaluating any possible occurrences of surface water depletions or riparian habitat. Monitoring wells with multiple completions (i.e., boreholes with more than one well casing installed, each casing screened at different depth intervals, and sealed between screens) can be used to characterize aquifer properties such as vertical hydraulic conductivity and transmissivity. Better understanding the flow mechanics of the

principal aquifer system improves the integrated hydrologic model, increases understanding of water flow relationships throughout the Subbasin, and can enable stakeholders to be more informed during their decision-making processes.

The current groundwater monitoring network contains 104 wells in 48 boreholes, of which 30 completions in 24 boreholes are screened at depths less than 200 feet and are considered to be in the shallow groundwater aquifer. The majority of these shallow wells are in the lowlands of the Subbasin. There are reports of domestic wells going dry in the western portion of the Subbasin, specifically near the uplands west of the City of Orland. Including additional shallow groundwater monitoring wells to the monitoring network in this area would be beneficial for monitoring and understanding the conditions of the shallow aquifer.

The representative surface water depletion monitoring network is comprised of a subset of the 30 shallow groundwater monitoring wells and includes 12 completions in 12 boreholes to monitor conditions within Stony Creek, the Sacramento River, and the Colusa Drain. Some of the wells are within range of more than one surface water feature, and will therefore be used to monitor conditions within multiple surface waters. Expanding the shallow groundwater monitoring network to include shallow wells closer to each specific surface water feature will provide better insight into how groundwater is influencing flows in their respective surface water feature.

This study proposes to evaluate additional existing wells to include in the shallow groundwater monitoring network and identify suitable locations for the construction of new monitoring wells. Evaluation of existing wells to add to the shallow groundwater monitoring network will cost approximately $50,000 and will include evaluation of existing wells and coordination. Newly constructed shallow wells will cost approximately $40,000 each and include planning through construction phases. It is anticipated that no more than ten new shallow wells will be considered.

7.1.2.2 Expand Water Quality Monitoring Network

The groundwater quality monitoring network is comprised of 25 wells, all of which are already being monitored for salinity under existing groundwater quality monitoring programs. Four wells are part of the Sacramento Valley Water Quality Coalition (SVWQC) monitoring network. Ten wells are part of the California Rice Commission (CRC) monitoring network. Eleven wells are municipal wells and are monitored under State Water Resources Control Board (SWRCB) Division of Drinking Water (DDW) regulations. The SVWQC and CRC wells are regulated by the Regional Water Quality Control Board.

Data gaps in this monitoring network are described in Chapter 4 and include lack of deep aquifer monitoring for upwelling of brackish connate waters and low spatial density of monitoring locations. The CRC wells are all shallow and may represent conditions of percolating water from rice ponds instead of groundwater conditions. Additionally, since these wells are included in existing monitoring programs managed by other agencies, the GSAs currently have no say on the frequency or continuation of monitoring beyond what the existing monitoring entities have already planned.

This study proposes to evaluate including additional wells as groundwater quality monitoring wells. Existing wells in appropriate locations with appropriate construction in existing monitoring programs will be prioritized over drilling new wells. Wells that are in close proximity and/or are most representative of groundwater quality conditions experienced by DACs, domestic wells, tribes, and GDEs will also be prioritized. Existing wells in appropriate locations with appropriate construction will be considered to either be requested additions to existing monitoring programs managed by other entities or included in a new monitoring program managed directly by the GSAs.

Establishing a new monitoring program managed by GSA staff, and potentially in coordination with DWR, will cost approximately $50,000 for implementation and coordination and an additional approximate $50,000 annual fee (assuming quarterly sampling from 30 well completions). Adding existing wells to existing programs will be approximately $5,000 per well, annually, and includes evaluation of wells and monitoring coordination with GSA staff, property owner, and the monitoring agency. Drilling new multiple-completion monitoring wells, including planning through construction phases, will be approximately $120,000 per well. Sites for new wells would need to be evaluated for property access, proximity to areas of concern, and suitability. It is anticipated that no more than ten existing or new wells will be considered.

7.1.2.3 Colusa Subbasin Western Boundary Investigation

Geologic and groundwater condition data is sparse throughout the western margin of the Subbasin. This includes the uplands west of the City of Orland in the north, southward along the Coast Ranges, and into the extension of the Dunnigan Hills west of the Arbuckle area in the south. There are few wells drilled in these areas that can provide information regarding the subsurface lithologic or groundwater conditions. The wells that do exist are shallow domestic wells with little, if any, historical record.

DWR is conducting an airborne electromagnetic survey (AEM) that will provide subsurface information regarding lithologic interfaces and potentially water level and saline water interface depth information. The survey for the Subbasin is not yet scheduled but is expected to occur before 2023. The GSAs intend to coordinate with DWR in determining the AEM flight paths to ensure coverage of the western margin of the Subbasin.

This study will be an evaluation of future existing data to better understand the physical characteristics and groundwater conditions of the principal aquifer along the western margin of the Subbasin. Lithologic interfaces will be updated using geophysical data from oil and gas wells, potentially new exploratory boreholes in key areas of interest, AEM survey data, and new well logs available from DWR. Future revisions of the Colusa Subbasin GSP will be updated to reflect the new information. This study is estimated to cost $100,000. New boreholes will be addressed during the study and are not reflected in the above estimate.

7.1.2.4 Westside Streams Monitoring Program

The CGA and GGA, in coordination with landowners and other agencies, would design and implement a monitoring program to collect data on the westside streams that originate in the Coastal Range to the west of the Subbasin and flow eastward into the Subbasin. The monitoring program would include monitoring flow, water quality parameters, and sediment loads. The objectives of the program would be to evaluate potential recharge volumes and water quality and to evaluate the interconnectedness of these streams and the groundwater system within the Subbasin.

The total cost estimate for planning, installation, and first year of monitoring is estimated at $225,000. Annual monitoring is $105,000.

7.1.2.5 Groundwater Well Monitoring Program

The CGA and GGA are currently implementing a pilot program to collect continuous groundwater monitoring data (e.g., water levels, pumping volumes) at six selected irrigation production wells spread across the Subbasin (three each in Colusa and Glenn counties). The objective of the pilot program is to test the utility of these data, and to evaluate installation and maintenance costs in order to estimate the costs and benefits of expansion of the program throughout the Subbasin. Estimated costs are presented for continued operation and maintenance of the pilot program, as well as for expansion of the program with an estimated per well cost. Measurement of groundwater pumping by some means will be needed to support implementation of a groundwater extraction fee, if the GSAs decide to do so.

The total cost estimate for planning, installation, and first year of monitoring is estimated at $265,000. Annual monitoring is estimated at $130,000.

7.1.2.6 Groundwater Financial Incentives Investigation

Sixteen (16) planned, ongoing, or potential PMAs included in the Colusa Subbasin GSP would provide in-lieu recharge benefits in targeted areas of the Subbasin (see Chapter 6). Water sources for in-lieu recharge are expected to include a mix of water transfers and utilization of existing district contract supplies. Successful in-lieu recharge projects will require growers being willing to pay for surface water and forgo groundwater pumping. Some of the perceived advantages of using groundwater over delivered surface water include the growers' convenience of having a clean, reliable, on-demand supply from their groundwater wells. Therefore, the effective cost of surface water must be less than that of groundwater. This study will include two phases to: (i) establish crop production costs under groundwater and surface water systems and (ii) and develop potential grower incentives structures for in-lieu recharge in selected areas of the Subbasin.

The initial phase of the study will quantify the total cost of groundwater use and the cost to switch to surface water. Total costs will include all direct costs (e.g., energy, equipment, and labor) in addition to indirect costs associated with each system (e.g., convenience, irrigation scheduling, frost protection, other perceived benefits). It is anticipated that this would include interviews with growers, agricultural engineering assessment of on-farm costs, and establishment of baseline crop budgets for groundwater and surface water irrigation for selected areas and crops. The initial phase of the study would provide a full cost comparison of groundwater and surface water.

Incentivizing the use of district surface water in-lieu of pumping would require paying at least the difference between district surface supply and the variable cost of pumping groundwater. The results of the baseline cost assessment will be used to establish potential incentives needed to encourage growers to switch from groundwater to surface water. This will include establishing the growers' willingness to pay for groundwater relative to surface water deliveries and establishing potential financial incentive structures. Incentive structures will also consider existing district rate structures. As of 2021, many Central Valley Project (CVP) contractors in the Subbasin have converted their contracts to repayment contracts, thus paying off and removing the capital component from their CVP water rates. The new repayment rates are allocated to land assessments and volumetric charges, which vary by district. The financial incentive analysis will consider the ability to shift district rates between fixed and variable costs to reduce the effective cost of surface water relative to pumping groundwater. The output of this second phase of the analysis will be a summary of grower financial incentives for in-lieu recharge and options for structuring those incentives for different in-lieu recharge areas.

The estimated cost of the study and cost assumptions are:

- The incentives investigation would consider up to two specific crops based on the crop mix in the in-lieu recharge areas; a preliminary assessment suggests walnuts or almonds would be the primary candidate crops.
- Interviews would be limited, coordinated by the GSA, and targeted to the key crops in the study.
- The focus areas would target Planned PMA in-lieu recharge projects but could be scaled up (or down) to consider incentives for additional (or fewer) areas.
- The estimated cost of the study is $165,000.

7.1.2.7 CV2SimFG-Colusa Model Updates and Enhancement

The C2VSimFG-Colusa model is an integrated hydrologic flow model (IHM) based on DWR's Central Valley Groundwater-Surface Water Simulation Model – Fine Grid Beta2 (C2VsimFG) released in May 2019 with updates, enhancements, and calibrations made to better represent local conditions in the Subbasin. The model is being used to support development and implementation of the Colusa Subbasin GSP, including characterization of historical, current, and projected water budgets, and evaluation of potential projects and management actions. The model is currently calibrated for the period 1990 through 2015 and needs to be updated periodically to adequately represent near-term and future conditions in the Subbasin. Calibration challenges were encountered during model development, leading to identification of several additional, potential model refinements including: adjustment of model layering in the northwest and southwest portions of the model domain to better represent local geology, adjustments to the vertical distribution of groundwater pumping, improved representation of westside tributary streams, and evaluation of inter-basin groundwater flows in coordination with neighboring GSAs.

These refinements may include:

- **Extension of time series data past Water Year 2015**. With the calibrated model, extending time series data (e.g., precipitation, land use, stream inflows, evapotranspiration, surface water diversions, urban demand, groundwater pumping) allows for use of more recent data and improved accuracy of the model for predicting near-term and future conditions in the Subbasin.
- **Model layering**. Model layer thicknesses may be adjusted locally, primarily in the southwest and northwest areas of the model, to better represent local geologic conditions and potential faults in these areas.
- **Distribution of groundwater pumping between layers**. Model layer thicknesses may be refined such that distribution of groundwater pumping between model layers better matches groundwater extraction from different depth and layers of the aquifer.
- **Small watersheds**. The water coming from the foothills is simulated using small watersheds representing small streams and groundwater flowing into the western side of the Subbasin. Theseephemeral streams may need explicit representation and simulation in the model to better control recharge and flows from the foothills as some observed groundwater levels near the foothills show signs of recharge from nearby small streams.
- **Interbasin flows**. C2VSimFG-Colusa model is well calibrated along the eastern boundary of the Subbasin and the five-mile zone on the eastern side of this boundary. Quantification of Sacramento River recharge along the eastern boundary of the Subbasin and subsurface groundwater underflow across this boundary into and out of Colusa, Butte and Vina

Subbasins will be useful in building consensus for management of groundwater by these neighboring subbasins.

- **Model Grid Resolution**. The observed groundwater level data show high spatial gradients in the northwestern and southwestern areas of the model. The model grid may be refined in these areas to better simulate these local high groundwater gradients.

The estimated cost for the model updates and enhancements is $225,000.

7.1.2.8 Well Inventory Program

Both Glenn and Colusa Counties have existing initial inventories and geographic information system mapping (GIS) of many of the water supply wells in each respective county. The mapping and associated databases were developed to gain a better understanding of well development over time in each county and to provide data for earlier water management efforts and initial SGMA planning efforts. Both well databases are based on information from public sources, including primarily well completion reports available from the DWR and in Glenn County, records from the County Environmental Health Department were also utilized.

While these initial efforts were extremely valuable, there remain many data gaps that will be necessary to fill. It is estimated that only about 80 percent of existing wells have well logs on file with DWR, so approximately 20 percent of the wells in the Subbasin remain to be identified and inventoried. It is also unknown how many of the inventoried wells are no longer in operation. Additionally, for SGMA purposes, the two County maps will need to be merged and refined to fit within the Subbasin boundaries.

The proposed well inventory program would complete further analysis of well logs and county well permits, ground truth actual well locations, and identify wells that are no longer active to ensure a complete and accurate well inventory exists. Additional data from well completion reports could also be entered into the well database to improve the understanding of the hydrogeology of the Subbasin. This will require a great deal of time and effort, especially given the size of the Subbasin. It will also be necessary to set up protocols for keeping the inventory updated as new wells are installed and as wells are decommissioned. These activities could be complemented by a well registration program where landowners submit information about their wells through an online portal, if this is determined by the GSAs to be an effective, acceptable means of well data acquisition.

This program would improve the accuracy and reliability of this dataset through additional data collection and outreach to improve both the quantity and quality of data in the well inventory.

A comprehensive, reliable well inventory is a pre-requisite for implementation of the following activities:

- Gaining a complete picture of groundwater development in the Subbasin
- Potentially initiating a per-well fee and/or extraction fee to fund SGMA implementation and PMAs
- Identifying potential new monitoring sites to help fill data gaps
- Improving the understanding of the hydrogeology of the Subbasin by conducting hydrogeologic investigations (AEM and similar)

The estimated cost of the program and cost assumptions are:

- Program conducted by GSA staff members with outside, on-call technical support
- Five-year period to develop the complete well data base at an estimated cost of $100,000 for the first year and $50,000 per year for years 2-5, totaling $300,000
- Annual updates to add new wells and delete old wells at an estimated cost of $20,000 per year

7.1.2.9 Well Registration Program

A well registration program could be developed for landowners to enter well information via an online portal to improve the accuracy of the current well inventory, including well location, well construction details (if known), and well type/use. The amount of information collected could be scaled up or down depending on the needs of the Subbasin. The registration program has the ability to provide the necessary information to improve the well inventory database, improve the understanding of the Subbasin hydrogeology, provide information to support potential future fee structures, and provide information to support specific future projects. The well registration program could be implemented on an annual timescale or some other timescale that is determined appropriate.

Other pertinent data potentially reportable through the well registration program could include information subject to change from year to year, such as the acreage (or number of people or livestock) served by a well, the crops irrigated and irrigation systems used (if the well is operated for agricultural use), and the volume of water pumped. This information could potentially feed into design and implementation of projects and management actions.

The estimated cost of the program and cost assumptions are:

- Program conducted by GSA staff members with outside, on-call technical support
- Two-year period to design and implement the on-line registration system and conduct public outreach at an estimated cost of $90,000 per year
- Three-year period to maintain outreach, compile data, and merge data into the well inventory database at an estimated cost of $40,000 per year
- Ongoing program implementation and maintenance cost of $15,000 per year

7.1.2.10 Increasing GSA Involvement in County Well Permitting and Land Use Planning

For this study, the CGA and GGA will explore options for allowing input to the counties' well permitting and land use planning processes by the GSAs. The objective of GSA input would be to ensure that wells are permitted and land uses are planned in a manner consistent with sustainable groundwater management according to the GSP. This could include consideration of:

- Well spacing, well construction, or other appropriate measures needed for well permitting
- Potential impacts to existing wells, springs, GDEs, water quality and recharge areas due to proposed development projects and changes in land use designation and zoning

Additionally, the GSA could provide information to the prospective well owners regarding the GSP and potential projects and/or management actions that may require the owner to report specific information or management actions that affect the ability of the well to be used (i.e., pumping restrictions).

The estimated cost of the program and cost assumptions are:

- Program conducted by GSA staff members with on-call technical support and legal counsel
- Two-year period to investigate, publicly vet, establish, and implement coordination protocols and procedures at an estimated cost of $75,000 per year
- Ongoing program implementation and maintenance cost of $15,000 per year

7.1.2.11 GSA Coordination with Water Quality Coalitions and Regulatory Agencies

GSAs intend to coordinate with the various water quality coalitions, beneficial users, water stakeholders, and regulatory agencies. These would include CRC and SVWQC, the municipal and small public water systems, and domestic well owners and users within the Subbasin. Coordination would ensure consistency regarding monitoring locations, monitored chemical constituents, monitoring procedures and frequencies, management plans and actions for out-of-compliance constituents, and responsible agencies for each management action. GSAs may need to get involved with management actions depending on any occurrence of undesirable results or input from the different regulatory boards.

The CGA and GGA recognize that disadvantaged communities and small water systems are disproportionately affected by degraded groundwater quality. As documented in Chapter 2, many of the communities within the Subbasin are considered Disadvantaged or a Severely Disadvantaged Communities (DACs and SDACs). Nearly all of the Subbasin is considered an Economically Distressed Area (EDA) because it is rural, has a low population density and has a low median household income. The CGA and GGA will coordinate with the regulating agencies, regulated entities, municipalities, small public water systems, and residential well owners and users to help identify and address potential water quality problems across the Subbasin, including those affecting DACs and SDACs. This will include consideration of opportunities to expand public water systems and consolidate small public systems to improve drinking water quality delivered to DACs and SDACs. This study will be an ongoing process. Costs for staff time are estimated at $20,000 per a year.

7.1.2.12 Sutter Buttes Rampart Water Quality Interbasin Working Group

The CGA, GGA, and the GSAs in the Butte, Sutter, Yolo, North Yuba, and South Yuba Subbasins intend to participate in an interbasin working group focused on collaborative discussions, consensus-building, and planning to address groundwater quality matters associated with the unique geology of the Sutter Buttes area. The goals of the working group should be to:

- Identify and prioritize groundwater quality conditions
- Coordinate with local, state and federal agencies
- Develop data and information needs
- Conduct high-level planning for groundwater studies and projects to protect or improve groundwater quality as needed
- Identify and pursue grant funding opportunities for groundwater studies and projects
- Provide a forum supporting cooperation, collaboration, and information sharing during implementation of studies and projects

It is expected that groundwater studies identified by the interbasin working group would be grant funded and implemented by research entities, such as U.S. Geological Survey (USGS) or DWR. If projects are identified to protect or improve groundwater quality, they would be led and implemented by local entities

such as the counties, agricultural water districts and agencies, municipalities, and other public water suppliers using a variety of funding sources, as described under Section 7.6.

Although the surface expression of the Sutter Buttes Rampart is limited to the Sutter Subbasin, the subsurface extent of volcanic deposits and associated geologic structures is greater and may influence groundwater quality in the adjacent Butte, Colusa, Yolo, North Yuba, and South Yuba Subbasins. Groundwater in the volcanic sediments of the Sutter Buttes Rampart has arsenic concentrations that frequently and significantly exceed the drinking water standard. The formation of the Sutter Buttes has resulted in the uplift of basement rocks, and corresponding reductions in the depth to the base of fresh groundwater. Faults may provide conduits or otherwise influence the movement of poor quality groundwater.

Objectives of the working group and the to-be-identified studies are to:

- Propose studies to:
  - Improve knowledge of the subsurface extent of the Sutter Buttes Rampart
  - Improve the understanding of local hydrogeology and faulting in the Sutter Buttes Rampart area
  - More fully characterize arsenic geochemistry within the subsurface extent of the Sutter Buttes Rampart
  - Improve knowledge of the depth to the base of freshwater and the structural features (folds and faults) that control the depth to the base of freshwater and groundwater movement in the area
  - Assess the risk of upwelling, or movement along faults, of saline or brackish connate groundwater
  - Assess the potential for mobilization of arsenic and/or connate waters beyond the subsurface extent of the Sutter Buttes Rampart
- Provide a forum for local entities to propose and develop projects to protect or improve groundwater quality

Participation in the working group will be an ongoing process. The estimated cost for GSA staff time is included in the GSAs' annual operating budget.

7.1.2.13 Participation in Interagency Drought Task Forces

The CGA and GGA intend to coordinate their responses to droughts with their respective county and state agency partners through existing Interagency Drought Task Forces established in each county by the Colusa and Glenn County Boards of Supervisors.

The Colusa County Interagency Drought Task Force consists of representation from the following entities:

- County Community Development Department
- County Water Resources Division
- County Office of Emergency Service (OES)/Sheriff's Office
- California OES
- DWR

- County Board of Supervisors
- County Administrative Officer
- Public Works Department
- Environmental Health Department
- City of Colusa
- City of Williams

The GGA participates in meetings of the Glenn County Drought Taskforce which are open to the public and consist of representation from a variety of entities, including:

- Planning and Community Development Services
- County OES/ Sheriff's Office
- California OES
- DWR
- County Board of Supervisors
- County Administrative Officer
- County Counsel
- Agricultural Commissioner
- Health and Human Services Agency
- UC Cooperative Extension
- Artois Community Services District
- City of Orland
- City of Willows
- California Water Service Company
- Water Agencies (Water Districts, Irrigation Districts, Reclamation Districts, Orland Unit Water Users Association, Stony Creek Water Master)
- Groundwater Sustainability Agency representatives
- California Legislator representatives
- Glenn County Farm Bureau
- Glenn County Resource Conservation District
- County Public works
- Fire Departments
- State Board Division of Drinking Water
- Members of the public

The drought task forces in both counties are ad hoc committees of the Board of Supervisors that meet in times of need such as the 2014 and 2021 drought emergencies. The primary purposes of the task forces are to:

- Coordinate the responses to drought at the local and state level
- Identify and track water supply instability, including dry wells and other drought-related issues
- Identify and make available resources that may be used to assist residents and businesses impacted by the drought
- Promote public awareness of the severity of the drought and the need for water conservation

The task forces implement the following coordinated functions at the county level:

- Education and outreach for drought preparedness
- Reporting and tracking of dry or impaired wells
- Identifying and applying for funding resources for programs to assist residents impacted by the drought
- Venue to share drought related experiences, challenges, and potential solutions

The task forces coordinate with the California Office of Emergency Services (OES), Department of Water Resources Northern Region Office, and the State Water Resources Control Board.

When households or small water systems in Colusa County experience a water shortage, they should fill out a "Well Outage Report" form and send that to the Colusa County Water Resources Division. The Water Resources Division verifies the information with the reporter and forwards the information to Colusa County OES.

When households or small water systems in Glenn County experience a water shortage, they should fill out a "Well Incident Report" form and send that to the Glenn County OES.

The respective County OES departments determines if assistance is available and coordinates with the California OES regional coordinators. The State (OES, DWR, SWRCB) provides funding for regional programs and short- and long-term solutions for water systems, and the drought task forces in each county work to procure funding for drought relief programs from these and other sources. Colusa and Glenn Counties are in Mutual Aid Region III of the Inland Administration Region of California OES.

Because the CGA and GGA will jointly implement the Colusa Subbasin GSP, their participation in the two drought task forces will help provide a coordinated response throughout the Subbasin and across the county line.

The CGA and GGA recognize that drought emergencies have a disproportionate effect on disadvantaged communities and small water systems. As documented in Chapter 2, many of the communities within the Subbasin are considered DACs or a SDACs. Nearly all of the Subbasin is considered an Economically Distressed Area because it is rural, has a low population density and has a low median household income. The CGA and GGA anticipate coordinating with the members of the Colusa and Glenn Interagency Drought Task Forces to address the effects of drought across the Subbasin and throughout these communities. The CGA and GGA also expect to coordinate with the members of the Colusa and Glenn Interagency Drought Task Forces to consider DWR's recommendations for drought and water shortage contingency planning

in Small Water Systems and Rural Communities Drought and Water Shortage Contingency Planning and Risk Assessment (DWR, 2021c).

Participation in the two drought task forces will be an ongoing process. The estimated cost for GSA staff time is included in the GSAs' annual operating budget.

7.1.2.14 Sacramento Valley Subsidence Interbasin Working Group

The CGA and GGA intend to participate in a Sacramento Valley Subsidence Interbasin Working Group with DWR, the other GSAs in the Sacramento Valley, and federal partners. The working group would provide a forum for collaborative discussions, consensus-building, planning and remedial actions where called for, to address inelastic land subsidence in the Sacramento Valley. The goals of the working group could include:

- Identify and prioritize areas of concern for inelastic land subsidence
- Identify and prioritize data collection efforts needed to fill data gaps
- Coordinate with local, state, and federal agencies
- Conduct high-level planning for data collection and implementation of projects to address or mitigate inelastic land subsidence
- Identify and pursue grant funding opportunities for data collection and project implementation
- Provide a forum supporting cooperation, collaboration, information sharing, and public outreach during implementation of data collection and projects

The Sacramento Valley Subsidence Network was last surveyed in 2017 and showed inelastic subsidence had occurred in the Sacramento Valley, including in the Subbasin, between 2008 and 2017. A key objective of the working group should be to confirm and reassess the locations and rates of historical subsidence identified based on the 2008 and 2017 surveys of the network. This new information about the locations and rates of inelastic subsidence would be used to reevaluate sustainable management criteria (SMCs) for inelastic land subsidence and help to guide the implementation of projects needed to address inelastic land subsidence.

It is expected that data collection needs identified by the interbasin working group would be grant-funded and implemented by state and federal agencies, such as DWR or USGS. If projects are identified to address or mitigate inelastic land subsidence, they would be led and implemented by local entities such as the counties, agricultural water districts and agencies, municipalities, and other public water suppliers using a variety of funding sources, as described under Section 7.6.

Participation in the working group will be an ongoing process. The estimated cost for GSA staff time is included in the GSAs' annual operating budgets and actions taken by the working group would be documented in subsequent annual reports.

7.1.2.15 Evaluate Infrastructure Sensitivity to Subsidence

The CGA and GGA have proposed a local assessment of infrastructure sensitivity to subsidence in the Subbasin. This study is proposed as one measure to close data gaps related to subsidence and its potential effects on beneficial uses and users in the Subbasin. The study would allow the GSAs to better characterize surface beneficial uses and users that may be susceptible to substantial interference as a result of

subsidence, and plan for actions to expand monitoring and mitigation of potential subsidence. The study would provide the GSAs better understanding of the infrastructure that is most at risk of interference from potential subsidence, and the possible impacts of interference on social, economic, transportation, and other activities in the Subbasin. The study should evaluate infrastructure Subbasin-wide to provide a comprehensive understanding of sensitivity to subsidence, though the study could be phased or structured to initially focus on areas of the Subbasin where the potential risk of subsidence and severity of impacts could be the greatest. Outcomes of the study could include:

- Identification of infrastructure (e.g., canals, pipelines, roads) most at risk of interference (e.g., damage, diminished capacity, loss of use) from subsidence, prioritized by severity of potential interference and severity of potential consequences of that interference on activities in the Subbasin.
- Identification of potential impacts that may result from infrastructure damage or loss of use, especially social, economic, transportation, and sustainability-related impacts.
- A plan for expanding subsidence monitoring to examine changing land subsidence conditions that may lead to potential adverse effects on infrastructure in the Subbasin.
- A plan for actions to respond to changing land subsidence conditions to resolve or mitigate potential adverse effects on infrastructure in the Subbasin.

The study would be a cooperative effort with infrastructure owners and other stakeholders in the Subbasin. The GSAs could, but do not necessarily need to, lead the assessment. It is expected that data collection and analysis in this study would be grant-funded, though local funding sources could also be used. This study would likely be interconnected with work completed through the Sacramento Valley Subsidence Interbasin Working Group (Section 7.1.2.14) and ongoing work to install additional subsidence benchmarks and expand subsidence monitoring in the Subbasin.

7.1.3 GSP Annual Reports and Periodic Evaluations

The GSAs will manage annual reports and periodic (five-year) GSP evaluations. It is anticipated that the cost for annual reporting will be substantially lower than the cost of the five-year evaluations. However, the GSAs will engage in required monitoring and technical studies that are required for the five-year evaluations. For example, it is anticipated that the necessary updates to the Subbasin groundwater model would commence prior to applying the model for the five-year periodic evaluation.

Annual Reports. 23 CCR §356.2 requires GSAs to prepare and submit annual reports to DWR. GSAs will prepare required technical analysis, data, summary material, and provide a report on sustainable management objectives. GSAs expect that annual reports will also require inter- and intra-GSA coordination as well as stakeholder outreach. See Section 7.6 for a description of annual report elements. The estimated cost for annual reports is between $40,000 and $60,000 based on the cost of similar services for Critically Overdrafted subbasins. A conservative cost estimate of $46,000 per year is applied and split equally between the GSAs.

Periodic Evaluations. 23 CCR §356.4 requires GSAs to prepare and submit five-year evaluation reports. In contrast to the annual report, this report requires additional evaluation of sustainability conditions, objectives, monitoring, and documentation of new information that is available since the last update to the GSP. See Section 7.7 for a description of five-year update elements. The estimated cost for periodic evaluations is substantially greater than the annual reports because of the additional analysis and full updates to the GSP. The estimated cost is between $200,000 and $250,000. A conservative cost estimate

of $226,000 per year is applied and split equally between the GSAs. This does not include the costs of GSP studies that are required for the five-year evaluations (e.g., updates/calibration to the groundwater model and groundwater monitoring). Those costs are reported separately (and described above) under GSP Studies.

7.1.4 Contingency

An additional contingency cost is included in estimated GSA budgets for planning purposes. Contingencies could include legal challenges or additional investigations required to support GSP implementation. A contingency cost of $50,000 per year for each GSA is added to the estimated costs.

7.2 GSA COSTS FOR GSP IMPLEMENTATION SUMMARY

The following subsections summarize estimated costs for each GSA to implement the GSP. Costs are presented for each of the four cost categories identified above. In practice, GSAs record expenses in different ways, and as such, may list different categories. Studies, annual reports, and five-year updates that apply to the entire Subbasin are split evenly between the CGA and GGA, though some details on the cost allocation between the GSAs remain to be finalized.

It is emphasized that costs are preliminary estimates based on the information available at the time of GSP development. As the GSP is implemented the GSAs will evaluate progress and adjust accordingly. It is anticipated that the GSP financing plan (see Section 7.4 for a summary of funding and financing approaches) would consider the cost-effectiveness of the GSP implementation plan, including planned PMAs and other GSA activities to support implementation. A cost-effective implementation plan would achieve GSP implementation benefits at the lowest feasible cost. Actual costs incurred will be made available in annual reports and yearly financial statements released by the GSAs.

7.2.1 Colusa Groundwater Authority GSA

Table 7-2 summarizes estimated CGA costs. The CGA estimated annual costs for GSP implementation averages approximately $780,000. This does not include PMA-specific costs (see Section 7.3). Several planned studies are assumed to begin in 2022. As such, estimated costs are greatest in 2023.

Table 7-2. Colusa Groundwater Authority GSA Estimated Implementation Costs

Cost Category	2022	2023	2024	2025	2026	2027+
GSA Administration	$322,000	$342,000	$322,000	$322,000	$322,000	$322,000
GSP Studies	$520,000	$560,000	$343,000	$230,000	$230,000	$315,000
GSP Updates	$23,000	$23,000	$23,000	$23,000	$23,000	$113,000
Contingency	$50,000	$50,000	$50,000	$50,000	$50,000	$50,000
Total	**$915,000**	**$975,000**	**$738,000**	**$625,000**	**$625,000**	**$800,000**

7.2.2 Glenn Groundwater Authority GSA

Table 7-3 summarizes estimated GGA costs. The GGA estimated annual costs for GSP implementation averages approximately $945,000. GGA costs are slightly greater than CGA estimated costs based on the 2019 rate studies and actual expenditure summaries in the 2020 audited financial reports. This does not include PMA-specific costs (see Section 7.3). Several planned studies are assumed to begin in 2022. As such, estimated costs are greatest in 2023.

Table 7-3. Glenn Groundwater Authority GSA Estimated Implementation Costs

Cost Category	2022	2023	2024	2025	2026	2027+
GSA Administration	$445,000	$499,000	$499,000	$499,000	$499,000	$499,000
GSP Studies	$520,000	$560,000	$343,000	$230,000	$230,000	$315,000
GSP Updates	$23,000	$23,000	$23,000	$23,000	$23,000	$113,000
Contingency	$50,000	$50,000	$50,000	$50,000	$50,000	$50,000
Total	**$1,038,000**	**$1,132,000**	**$915,000**	**$802,000**	**$802,000**	**$977,000**

7.3 PLANNED PMA IMPLEMENTATION COSTS

The costs for PMAs, described in Chapter 6, are reported separately from other GSP implementation costs. In addition, the costs of PMAs may be allocated to different entities or the Subbasin more broadly (see Section 7.5 and Appendix 7A).

There are currently five planned PMAs that the GSAs or other project proponents are working to implement (as described in GSP Section 6.3). Costs for ongoing and potential PMAs are not shown. This is because these projects are already underway (and therefore funded) or will not be implemented unless required by changing groundwater conditions in the Subbasin.

Table 7-4 summarizes planned PMA capital and initial study costs and ongoing operation and maintenance (O&M) costs. Capital and initial study costs are one-time expenses to build or design a project. For example, the Orland-Artois Water District (OAWD) land annexation project includes an initial capital cost for distribution system construction. OAWD is currently working to refine the estimated construction cost. Other PMAs include one-time expenses for studies to develop the project. O&M costs are annual costs after the project is implemented. The total estimated cost for capital and studies is approximately $20.6 million. Estimated annual O&M costs are approximately $6.7 million per year at full implementation of the planned PMAs.

Table 7-4. Planned Projects and Management Actions Estimated Implementation Cost Summary

Cost Category	2022	2023	2024	2025	2026	2027+
Colusa Subbasin Multi-Benefit Groundwater Recharge						
Capital/Studies	$328,000	-	-	-	-	-
O&M	-	$246,000	$246,000	$246,000	$246,000	$246,000

Capital/Studies	$100,000	-	-	-	-	-
O&M	-	$1,736,000	$1,736,000	$1,736,000	$1,736,000	$1,736,000
Total (Planned PMAs)						
Capital/Studies	**$556,000**	**$20,000,000**	**-**	**-**	**-**	**-**
O&M	**-**	**$4,033,000**	**$6,675,000**	**$6,675,000**	**$6,675,000**	**$6,675,000**

7.3.1 Planned PMA Benefits

Figure 7-1 illustrates the expected gross average annual benefits of planned PMAs at full implementation. The gross average annual benefit to the Subbasin from planned PMAs is approximately 61,000 acre-feet in 2022 and will increase to 84,000 acre-feet by 2027 when planned PMAs are fully implemented.

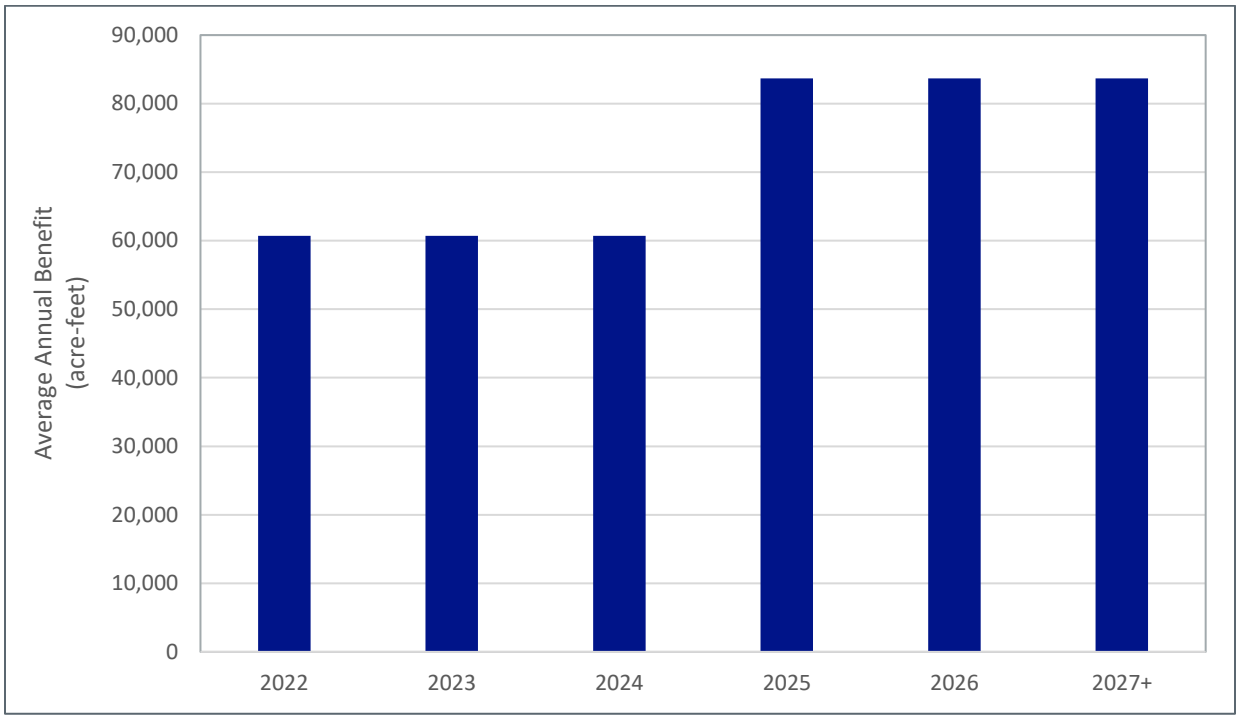

Figure 7-1. Colusa Subbasin Project Estimated Gross Benefit Timeline

7.4 GSP ANNUAL IMPLEMENTATION COST SUMMARY

The total GSP implementation costs include the sum of GSA costs (Section 7.2) and PMA costs (Section 7.3). These costs are expressed on an annual basis and summarized in Table 7-5. Estimated annual GSP implementation costs increase from approximately $1.5 million to around $9.5 million per year (including annualized capital costs). A substantial share of the total cost is attributable to surface water purchase costs for in-lieu recharge PMAs. Cost categories include:

- **Other Capital/Studies** includes one-time capital costs incurred from PMA implementation and GSP Study costs (See Section 7.1.2 and 7.3)
- **Debt-Financed PMA Capital Repayment** includes the estimated debt service for the OAWD District Land Annexation and In-Lieu Groundwater Recharge project capital costs (See Section 7.3). Capital costs for PMAs are annualized assuming repayment on a 30-year bond at 3 percent interest. All other costs are already annual expenses and reported as such
- **PMA O&M** costs are ongoing annual costs incurred after the first year of a PMA's implementation (See Section 7.3). These costs include annual surface water purchase costs. It is noted that this is the majority share of annual costs associated with each PMA
- **GSA Admin/Studies** costs are ongoing annual costs incurred by the GSAs that are not project specific (See Section 7.2)

Table 7-5. Total Estimated Cost Summary of GSP Implementation

Cost Category	2022	2023	2024	2025	2026	2027+
Other Capital/Studies	$556,000	$1,120,000	$685,000	$460,000	$460,000	$630,000
Debt-Financed PMA Capital Repayment	-	$1,020,000	$1,020,000	$1,020,000	$1,020,000	$1,020,000
PMA O&M	-	$4,033,000	$6,675,000	$6,675,000	$6,675,000	$6,675,000
GSA Admin/Studies	$914,700	$987,900	$968,200	$968,200	$968,200	$1,148,200
Total	**$1,470,700**	**$7,160,900**	**$9,348,200**	**$9,123,200**	**$9,123,200**	**$9,473,200**

7.5 IMPLEMENTATION SCHEDULE

Figure 7-2 illustrates the estimated implementation schedule for the GSP. The GSP implementation schedule allows time for GSAs to develop and implement projects and management actions to achieve the Subbasin sustainability goal. It is anticipated that Planned PMA implementation will commence in 2022, with initial project studies and project development. The GSP implementation schedule also shows mandatory reporting and updating for the GSP, including annual reports and five-year periodic evaluations prepared and submitted to DWR.

Task Name	2022	2023	2024	2025	2026	2027	2028	2029	2030	2031	2032	2033	2034	2035	2036	2037	2038	2039	2040	2041	2042

Figure 7-2. Colusa Subbasin Implementation Schedule

7.6 GSP FINANCING AND FUNDING MECHANISMS

Administering the GSP and monitoring and reporting progress is projected to cost approximately $9.5 million per year once all planned PMAs are implemented. Costs are expected to be higher during years in which a five-year periodic evaluation and report is prepared, and slightly lower during other years when an annual report is prepared. These include all costs required for implementation, including for example, PMAs implemented by individual water agencies. To fund GSA operations and GSP implementation, GSAs are developing a financing plan that will include one or more of the following financing approaches:

- **Grants and low-interest loans**: GSAs will continue to pursue grants and low interest loans to help fund planning studies and other GSA activities. However, grants and low-interest loans are not expected to cover most GSA operating costs for GSP implementation.
- **Groundwater extraction charge**: A charge per acre-foot pumped could be used to fund GSP implementation activities.
- **Other Fees and charges**: Other fees may include permitting fees for new wells or development, transaction fees associated with contemplated groundwater markets, or commodity-based fees, all directed at aiding with sustainability objectives. Depending on the justification and basis for a fee, it may be considered a property-related fee subject to voting requirements of Article XIII D of the California Constitution (passed by voters in 1996 as Proposition 218) or a regulatory fee exempt from such requirements.
- **Assessments:** Special benefit assessments under Proposition 218 could include a per-acre (or per-parcel) charge to cover GSA costs, or other fees under Proposition 26.
- **Taxes:** This could include general property related taxes that are not directly related to the benefits or costs of a service (ad valorem and parcel taxes), or special taxes imposed for specific purposes related to GSA activities.

The GSAs are considering a combined approach, targeting available grants and low interest loans, and considering a combination of fees, assessments, and charges to cover operating and program-specific costs. Costs borne by individual water agencies will be allocated and recovered within that agency based on its policy decisions and customer preferences. As required by statute and the Constitution, GSAs and agencies would complete an engineer's report, rate study, and other analyses to document and justify any rate, fee, or assessment. For example, both the CGA and GGA have prepared rate studies to fund near-term (fiscal years 2019/20 through 2023/24) administrative costs as property-related service charges under Proposition 218. Appendix 7A provides a summary and additional discussion of the funding and financing options available to GSAs and other local entities in the Subbasin.

Some cost recovery approaches can affect the cost of water for specific uses in the Subbasin. Agencies supplying surface water recognize that recovering GSP related costs as part of their surface water charge can be counter-productive by disincentivizing surface water use. All agencies are concerned that any fees, charges, or assessments will affect business (farm) income and, if large, may affect cropping decisions and farming practices in the Subbasin. Based on groundwater monitoring, land use changes, and other future conditions, the GSAs will reconsider or adjust fees/assessments as needed to complete required PMAs and activities that are required to achieve sustainability.

An important consideration for GSA financing plans is the allocation of different types of costs to entities or areas. Cost allocation is a multi-step process that determines how costs of GSP implementation

components would be spread among and recovered from entities and areas covered by the GSP. For example, the implementation plan includes several categories of activities that must be paid for: administration, projects and management actions, monitoring, and studies. The categories may have their costs spread in different ways (among different entities and areas) depending on discussions and policy decisions. Considerations would include who is responsible for a cost, who benefits from an activity, what is fair, what is legally allowed or possible, what are the requirements for determining and justifying a cost allocation. Appendix 7A provides a summary overview of cost allocation concepts.

7.7 ANNUAL REPORTS

The GSP regulations require annual reports to be submitted to DWR by April 1 of each year following the adoption of the GSP (23 CCR §356.2). The GSAs will prepare and submit annual reports that comply with the requirements of §356.2. It is anticipated that the GSAs and their member agencies will need to develop independent analyses and data (e.g., quantifying surface water use within a particular GSA and/or member agency) as well as joint analyses (e.g., estimating the Subbasin-wide change in groundwater storage) in order to develop the required components of each annual report. The GSAs will work together to complete the annual reports.

Annual reports must provide general information about the Subbasin (23 CCR §356.2(a)) in addition to detailed, technical information that includes (23 CCR §356.2(b) and (c)):

- Groundwater elevation data from monitoring wells, analyzed and represented in:
  - Groundwater elevation contour maps
  - Groundwater elevation hydrographs
- Groundwater extractions in the preceding water year
- The surface water supply used or available for use in the preceding water year, including for groundwater recharge or other in-lieu uses
- Total water use in the preceding water year
- Change in groundwater storage, including maps and graphs
- A description of progress towards implementing the GSP, including achievement of interim milestones and implementation of PMAs

The following subsections provide a general outline of what information will be provided in each annual report. Each annual report submitted to DWR will fully comply with the requirements of §356.2.

7.7.1 General Information (§356.2(a))

General information provided in each annual report will include an executive summary that highlights the key content of the annual report. The executive summary will include:

- A description of the Subbasin sustainability goal
- A description of ongoing, newly implemented, and other planned GSP projects
- An updated implementation schedule
- A current map of the Subbasin

Any important changes or updates to the Subbasin, GSAs, or GSP implementation since the last annual report will be noted and described.

7.7.2 Subbasin Conditions (§356.2(b))

The Subbasin conditions section of each annual report will provide an update on groundwater conditions, surface water conditions, and water use in the Subbasin during the preceding water year.

Technical information will include a summary of current groundwater conditions in the Subbasin with respect to the Subbasin sustainability goal. The GSAs will summarize the groundwater monitoring network data and report the current groundwater elevation and change in groundwater elevation at monitoring sites. Data will be summarized in hydrographs and groundwater elevation contour maps for each aquifer in the Subbasin, tailored to specific hydrogeologic conditions across the region. This information will show seasonal high and low conditions within the current season and show historical data from at least January 1, 2015, to the current reporting year.

Groundwater extractions in the preceding water year will be summarized (in tabular and map form) by water use sector, and the method of measurement will be identified (e.g., metering, satellite analysis, crop-based evapotranspiration [ET] estimates, etc.). All data and methods used to characterize extractions and levels will follow best practices and be described in the annual report.

The surface water supply used or available for use in the Subbasin will be reported based on data that describes the total surface water diversions and total surface water inflows used or available for use in the Subbasin. The summaries will indicate whether the surface water supply was used or available for use for direct or in-lieu recharge, and will identify all data sources for each GSA.

Total water use from all sources will also be summarized by water use sector and water source type, with identification of the measurement method used to quantify all uses. Consumptive water use will also be summarized based on evapotranspiration of applied water (ET_{aw}) volumes, parsed into ET_{aw} of surface water and ET_{aw} of groundwater using the available information on applied surface water. All water use information will be collected using the best available measurement methods and data sources, which will be described in the annual report.

The Subbasin groundwater system water balance described in Chapter 3 will be used to estimate the change in groundwater storage each year. Change in storage will be summarized in tabular form and as a map for each principal aquifer in the Subbasin. A graph will show the water year type, groundwater use, annual change in storage, and cumulative change in storage for the Subbasin using historical data, including data from at least January 1, 2015, through the current reporting year.

7.7.3 Plan Implementation Progress (§356.2(c))

Each annual report will summarize the progress made over the past year in GSP implementation, including implementation of PMAs and other GSA-related activities. Each annual report will also describe progress toward established interim milestones and planned sustainability objectives. It will summarize sustainability conditions in the Subbasin.

7.8 PERIODIC EVALUATION (FIVE-YEAR UPDATES)

At least every five years, DWR will review the progress that GSAs have made toward meeting the GSP sustainability goals. Required components of the periodic evaluations are identified in 23 CCR §356.4. The GGA and CGA will prepare the periodic evaluation (or five-year update) at least every five years to summarize the status of GSP implementation, whether the GSP is meeting sustainability goals, and progress toward implementation of PMAs. An evaluation will also be made whenever the GSP is amended. Each periodic evaluation will fulfill all the requirements of 23 CCR §356.4. A summary of the general information that will be included in each periodic evaluation is provided in the following subsections.

7.8.1 Sustainability Evaluation (§356.4(a) - §356.4(d))

Each periodic evaluation will summarize current groundwater conditions for each applicable sustainability indicator and describe overall progress towards sustainability. Groundwater conditions will be evaluated and described in relation to interim milestones, measurable objectives, and minimum thresholds. If any minimum thresholds are found to be exceeded, the GSAs will investigate probable causes and implement actions to avoid undesirable results and correct groundwater conditions, as warranted.

Implementation of all PMAs will be documented and described in relation to the adaptive management strategy for the Subbasin. This description will include a summary of implementation timelines compared to the proposed timeline (Figure 7-1) and PMA implementation schedules described in Chapter 6. The description will also summarize the effect of the PMA on groundwater conditions in the Subbasin. If groundwater conditions are improving faster or slower than projected, the reason for the difference from the projection will be evaluated. If conditions are improving slower than projected because any PMAs are not being implemented according to the specified timeline, the deviation from the original plan will be documented and to the extent possible, corrective actions will be taken to speed implementation and/or implement other PMAs for adaptive management of the Subbasin.

The periodic evaluation will also analyze and describe the effects of PMAs on Subbasin sustainability indicators and compare those to the estimated gross benefits of the PMAs presented in Chapter 6. If differences are identified, those will be described in the periodic evaluation. If PMAs are not performing as expected, the periodic evaluation will describe steps the GSAs will take to implement additional PMAs or initiate demand management, if warranted. Those steps would include public outreach, notification, and other processes described in Chapter 6 for those PMAs. Any changes to the implementation schedule of PMAs will be described in the periodic evaluation.

As PMAs are implemented, monitoring data may indicate unanticipated effects. Also, land uses and economic conditions will change in ways that have not been anticipated or evaluated at this time. It may be necessary to revise the GSP to account for these changes. Elements of the GSP, including the basin setting, management areas, undesirable results, minimum thresholds, and measurable objectives will be reconsidered by the GSAs during the periodic evaluation. Any revisions will be proposed and documented in the evaluation.

7.8.2 Monitoring Network Description (§356.4(e))

Chapter 4 describes the planned monitoring network and protocols. The effectiveness of the monitoring network and overall GSP implementation depends on timely, accurate, and comprehensive data. The GSP includes Data Management System (DMS) protocols, as well as expanded monitoring wells and data collection. However, as described in Chapter 4, data gaps still exist in the Subbasin that will require expanding the monitoring network.

The periodic evaluation will include a description of the monitoring network within the Subbasin, will identify data gaps, and will identify any applicable areas within the Subbasin that are represented by data that does not satisfy the requirements established in the GSP regulations. A plan will be developed to improve the monitoring network, consistent with 23 CCR §354.38.

Additional data gaps may be identified in future GSP updates. The periodic evaluations of the GSP will assess changes to the monitoring program needed to acquire additional data sources, and how the new information will be used and incorporated into any future GSP updates. The installation of new data collection facilities and analysis of new data will be prioritized in the GSP.

7.8.3 New Information (§356.4(f))

The CGA and GGA will continue to monitor Subbasin conditions throughout GSP implementation. The DMS will allow GSAs to identify additional data gaps and implement procedures to secure additional data. Land use and economic incentives for farming and other water uses in the Subbasin will continue to change as the GSP is implemented. GSAs expect that new information about groundwater conditions, projects and management actions, and sustainability objectives will continue to be available. An adaptive management approach will be applied to identify, review, and incorporate all new information into the GSP.

Any significant new information available since GSP adoption, amendment, or the last periodic evaluation will be described. The evaluation will also clearly evaluate and indicate whether that new information warrants any changes to the GSP, including reassessment of the basin setting, measurable objectives, minimum thresholds, or the criteria that defines undesirable results.

7.8.4 GSA Actions ((§356.4(g) - §356.4(h))

The GGA and CCA will continue to monitor, manage, and collaborate to meet the sustainability goals specified in the GSP. Within their allowed authorities, if necessary, the GSAs will evaluate new regulations or ordinances that could be implemented to help achieve sustainability objectives. Any changes in regulations or ordinances will be summarized in the periodic evaluation.

The periodic evaluation will include a summary of state laws and regulations, or local ordinances related to the GSP that have been implemented since the previous periodic evaluation, and address how these may require updates to the GSP. Enforcement or legal actions taken by the GSAs in relation to the GSP will be summarized along with how such actions support sustainability in the Subbasin.

7.8.5 Plan Amendments, Coordination, and Other Information (§356.4(i) - §356.4(k))

Any proposed or completed amendments to the GSP will be described in the periodic evaluation. This will also include a summary of amendments that are being considered or developed at that time. Any changes to the basin setting, measurable objectives, minimum thresholds, or undesirable results will be described.

Any changes to applicable agreements will be documented and summarized in the periodic evaluation. GSAs will summarize any other information deemed appropriate to support the GSP and provide required information to DWR for review of an amended GSP.

7.9 DATA MANAGEMENT SYSTEM (§352.6)

The Subbasin DMS has been developed as an integrated network of digital file folders, databases and linked programs and tools. Each element is directly or indirectly linked the C2VSimFG-Colusa groundwater model and related water budget databases and tools that are used to calculate and summarize the Subbasin water budget (Figure 7-3). Inputs to the water budget are organized into inputs that are managed and implemented at the Subbasin-level and inputs that are managed at the GSA-level (or member agency-level). Subbasin-level inputs include:

- **Time series**: time series data managed in a database structure and used to quantify surface water inflows/outflows and groundwater levels
  - USGS station data
  - DWR-compiled data (Water Data Library [WDL] and California Data Exchange Center [CDEC])
- **Weather:** weather data managed in a database structure and used to quantify reference evapotranspiration and precipitation, and to support root zone water budget calculations (crop evapotranspiration, infiltration, runoff)
  - California Irrigation Management Information System (CIMIS) station data
  - National Oceanic and Atmospheric Administration's (NOAA's) National Centers for Environmental Information (NCEI) station data
  - PRISM Climate Group data
- **eWRIMS**: Electronic Water Rights Information Management System (eWRIMS) stores water rights diversion records managed publicly in a database structure and used to help quantify surface water supply utilized for irrigation
- **GIS:** spatially-defined geographic data managed in GIS and used to support land use analyses and spatial water use by sector
  - DWR spatial data (Subbasin boundaries, GSA boundaries, land use survey spatial coverages, Land IQ land cover classification and analysis)
  - DWR interpolation tool results (spatial and temporal interpolation of spatial coverages, using Ag Commission reports)
  - Local land use data comparison and validation

Inputs to the Subbasin water budget that are managed at the GSA or member-agency level include:

- **Time series:** time series data relating to GSA or member agency-specific inflows that are managed in a database structure and used to quantify surface water inflows/outflows
- **Local Data:** local data managed in spreadsheets and used to quantify GSA or member agency-specific inflows/outflows (diversions and deliveries not recorded in Subbasin-level data sources)
- **Deliveries**: Water district delivery data managed in a database structure and used to quantify surface water supply utilized for irrigation

The GSAs will manage data related to GSP project implementation within their boundaries. GSAs are continually working to refine data, identify data gaps, and incorporate additional information characterizing groundwater conditions in the Subbasin.

The GSAs are currently planning to review, update, and refine the current DMS to improve organization and more efficiently store, manage, and retrieve data. This will formalize the DMS, which will be developed to meet the requirements in the GSP Regulations, including 23 CCR §352.4, 23 CCR §352.6, and 23 CCR §354.4. The data will be managed so that appropriate tables, graphs, and maps supporting the GSP annual reports and periodic evaluations can be queried and provided to DWR.

Appendix 1A

Glossary of Terms

(THIS PAGE LEFT BLANK INTENTIONALLY)

GLOSSARY

This Glossary includes terms from a variety of legal and administrative sources relevant to SGMA and GSP development. These sources include:

- California Water Code Section 10721, Sustainable Groundwater Management Definitions (CWC Section 10721)
- California Code of Regulations Title 23 Section 341, Groundwater Basin Boundaries Definitions (23 CCR Section 341)
- California Code of Regulations Title 23 Section 351, Groundwater Sustainability Plan Definitions (23 CCR Section 351)
- DWR Bulletin 118 Definitions, updated 2003 (B118, 2003)
- Locally defined terms used in the GSP

The source of each term is provided in the citation following that term. Page numbers are included when a definition is not found in the referenced document's definitions or glossary. Additional information regarding each source are summarized at the end of this glossary.

Adjudication Action	The action filed in the superior or federal district court to determine the rights to extract groundwater from a basin or store water within a basin, including, but not limited to, actions to quiet title respecting rights to extract or store groundwater or an action brought to impose a physical solution on a basin. **(CWC Section 10721)**
Administrative Adjustment	The basin or subbasin boundary adjustment by the Department that either (1) amends existing basin or subbasin boundary data files to accurately reflect an unambiguous written basin or subbasin boundary description as defined in Bulletin 118 or amended pursuant to this Part, or (2) restates the description of a basin or subbasin boundary to more precisely reflect a mapped basin or subbasin boundary consistent with the original description. **(B118, 2003)**
Agency	The groundwater sustainability agency as defined in the Act. **(23 CCR Section 351)**
Agricultural Water Management Plan	The plan adopted pursuant to the Agricultural Water Management Planning Act as described in Part 2.8 of Division 6 of the Water Code, commencing with Section 10800 et seq. **(23 CCR Section 351)**
Alternative	The alternative to a Plan described in Water Code Section 10733.6. **(23 CCR Section 351)**
Annual Report	The report required by Water Code §10728. **(23 CCR Section 351)**
Aquifer	The three-dimensional body of porous and permeable sediment or sedimentary rock that contains sufficient saturated material to yield significant quantities of groundwater to wells and springs, as further defined or characterized in Bulletin 118. **(B118, 2003)**
Baseline or Baseline Conditions	The historical information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin. **(23 CCR Section 351)**

Basin	Defined in the Sustainable Groundwater Management Act as a groundwater basin or subbasin identified and defined in Bulletin 118. Unless the context indicates otherwise, those terms are further defined as follows: (1) The term ***basin*** shall refer to an area specifically defined as a basin or ***groundwater basin*** in Bulletin 118, and shall refer generally to an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom, as further defined or characterized in Bulletin 118. (2) The term ***subbasin*** shall refer to an area specifically defined as a subbasin or ***groundwater subbasin*** in Bulletin 118 and shall refer generally to any subdivision of a basin based on geologic and hydrologic barriers or institutional boundaries, as further described or defined in Bulletin 118. **(B118, 2003)**
Basin Setting	The information about the physical setting, characteristics, and current conditions of the basin as described by the Agency in the hydrogeologic conceptual model, the groundwater conditions, and the water budget, pursuant to Sub article 2 of Article 5. **(23 CCR Section 351)**
Beneficial Use	Water in Bulletin 118 references 23 categories of water uses identified by the State Water Resource Control Board and are listed and briefly described in Appendix E. **(B118, 2003)**
Best Available Science	The use of sufficient and credible information and data, specific to the decision being made and the time frame available for making that decision, that is consistent with scientific and engineering professional standards of practice. **(23 CCR Section 351)**
Best Management Practice	The practice, or combination of practices, that are designed to achieve sustainable groundwater management and have been determined to be technologically and economically effective, practicable, and based on best available science. §351. **(23 CCR Section 351)**
Board	The State Water Resources Control Board. **(23 CCR Section 351)**
Bulletin 118	The department's report entitled "California's Groundwater: Bulletin 118" updated in 2003, as it may be subsequently updated or revised in accordance with § 12924. **(CWC Section 10721)**
CASGEM	The California Statewide Groundwater Elevation Monitoring Program developed by the Department pursuant to Water Code Section 10920 et seq., or as amended. **(23 CCR Section 351)**
Condition of Long-Term Overdraft	The condition of a groundwater basin where the average annual amount of water extracted for a long-term period, generally 10 years or more, exceeds the long-term average annual supply of water to the basin, plus any temporary surplus. Overdraft during a period of drought is not sufficient to establish a condition of long-term overdraft if extractions and recharge are managed as necessary to ensure that reductions in groundwater levels or storage during a period of drought are offset by increases in groundwater levels or storage during other periods. **(CWC Section 10721)**
Coordination Agreement	The legal agreement adopted between two or more groundwater sustainability agencies that provides the basis for coordinating multiple agencies or groundwater sustainability plans within a basin pursuant to this part. **(CWC Section 10721)**
Data Gap	The lack of information that significantly affects the understanding of the basin setting or evaluation of the efficacy of Plan implementation and could limit the ability to assess whether a basin is being sustainably managed. **(23 CCR Section 351)**

Existing Stored Groundwater	Groundwater that is already underground from centuries of accumulated native groundwater. Historic pumping has been diminishing the existing stored groundwater at rates greater than the native groundwater can sustain, causing overdraft and unsustainable conditions. If more water is pumped from a basin than what is added from Native Groundwater and Introduced Groundwater, this water comes from the Existing Stored Groundwater. Continuing to use this previously stored groundwater will continue to exacerbate overdraft conditions. Temporarily using some of this water during the transition to sustainability will likely continue to cause lowering of groundwater levels.
Groundwater	Water beneath the surface of the earth within the zone below the water table in which the soil is completely saturated with water but does not include water that flows in known and definite channels. **(CWC Section 10721)**
Groundwater Basin	The groundwater basin or subbasin identified and defined in Bulletin 118 or as modified pursuant to Water Code 10722 et seq. **(23 CCR Section 351)**
Groundwater Dependent Ecosystem	The ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. **(23 CCR Section 351)**
Groundwater Flow	The volume and direction of groundwater movement into, out of, or throughout a basin. **(23 CCR Section 351)**
Groundwater in Storage	The quantity of water in the zone of saturation. **(B118, 2003)**
Groundwater Overdraft	The condition of a groundwater basin in which the amount of water withdrawn by pumping exceeds the amount of water that recharges the basin over a period of years during which water supply conditions approximate average conditions. **(B118, 2003)**
Groundwater Recharge or Recharge	The augmentation of groundwater by natural or artificial means. **(CWC Section 10721)**
Groundwater Storage Capacity	The volume of void space that can be occupied by water in a given volume of a formation, aquifer, or groundwater basin. **(B118, 2003)**
Groundwater Sustainability Agency	One or more local agencies that implement the provisions of this part. For purposes of imposing fees pursuant to Chapter 8 (commencing with Section 10730) or taking action to enforce a groundwater sustainability plan, ***Groundwater Sustainability Agency*** also means each local agency comprising the groundwater sustainability agency if the plan authorizes separate agency action. **(CWC Section 10721)**
Hydrogeologic Conceptual Model	The description of the geologic and hydrologic framework governing the occurrence of groundwater and its flow through and across the boundaries of a basin and the general groundwater conditions in a basin or subbasin. **(23 CCR Section 341)**
Interconnected Surface Water	The surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. **(23 CCR Section 351)**
Interested Parties	The persons and entities on the list of interested persons established by the Agency pursuant to Water Code Section 10723.4. **(23 CCR Section 351)**
Interim Milestone	The target value representing measurable groundwater conditions, in increments of five years, set by an Agency as part of a Plan. **(23 CCR Section 351)**
Introduced Groundwater	Water that is added to the sustainable yield of groundwater supply derived from percolation of imported surface water. This can be the directly through groundwater replenishment projects or groundwater banking or can be indirectly through percolation from irrigation and unlined canals.

Management Area	The area within a basin for which the Plan may identify different minimum thresholds, measurable objectives, monitoring, or projects and management actions based on differences in water use sector, water source type, geology, aquifer characteristics, or other factors. **(23 CCR Section 351)**
Measurable Objectives	The specific, quantifiable goals for the maintenance or improvement of specified groundwater conditions that have been included in an adopted Plan to achieve the sustainability goal for the basin. **(23 CCR Section 351)**
Minimum Threshold	The numeric value for each sustainability indicator used to define undesirable results. **(23 CCR Section 351)**
Monitoring Protocols	Designed to detect changes in groundwater levels, groundwater quality, inelastic surface subsidence for basins for which subsidence has been identified as a potential problem, and flow and quality of surface water that directly affect groundwater levels or quality or are caused by groundwater extraction in the basin. The monitoring protocols shall be designed to generate information that promotes efficient and effective groundwater management. §10727.2. Required Plan Elements. **(CWC Section 10721)**
NAD83	The North American Datum of 1983 computed by the National Geodetic Survey, or as modified.
Native Groundwater	Water naturally infiltrating into the groundwater from precipitation and runoff. This is the average quantity of water annually added to the groundwater budget from rain, rivers, and streams, and reflects the portion of estimated sustainable yield of the groundwater supply that is not derived from imported surface water.
NAVD88	The North American Vertical Datum of 1988 computed by the National Geodetic Survey, or as modified. **(23 CCR Section 351)**
Plain Language	The language that the intended audience can readily understand and use because that language is concise, well-organized, uses simple vocabulary, avoids excessive acronyms and technical language, and follows other best practices of plain language writing. **(23 CCR Section 351)**
Plan	The groundwater sustainability plan as defined in the Act. **(23 CCR Section 351)**
Plan Implementation	The Agency's exercise of the powers and authorities described in the Act, which commences after an Agency adopts and submits a Plan or Alternative to the Department and begins exercising such powers and authorities. **(23 CCR Section 351)**
Plan Manager	An employee or authorized representative of an Agency, or Agencies, appointed through a coordination agreement or other agreement, who has been delegated management authority for submitting the Plan and serving as the point of contact between the Agency and the Department. **(23 CCR Section 351)**
Planning and Implementation Horizon	The 50-year time period over which a groundwater sustainability agency determines that plans and measures will be implemented in a basin to ensure that the basin is operated within its sustainable yield. **(CWC Section 10721)**
Principal Aquifers	The aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. **(23 CCR Section 351)**
Qualified Map	The geologic map of a scale no smaller than 1:250,000 that is published by the U. S. Geological Survey or the California Geological Survey, or is a map published as part of a geologic investigation conducted by a state or federal agency, or is a geologic map prepared and signed by a Professional Geologist that is acceptable to the Department. **(23 CCR Section 341)**
Recharge Area	The area that supplies water to an aquifer in a groundwater basin. **(CWC Section 10721)**

Reference Point	The permanent, stationary and readily identifiable mark or point on a well, such as the top of casing, from which groundwater level measurements are taken, or other monitoring site. **(23 CCR Section 351)**
Representative Monitoring	The monitoring site within a broader network of sites that typifies one or more conditions within the basin or an area of the basin. **(23 CCR Section 351)**
Safe Yield	The maximum quantity of water that can be continuously withdrawn from a groundwater basin without adverse effect. **(B118, 2003)**
Saturated Zone	The zone in which all interconnected openings are filled with water, usually underlying the unsaturated zone. **(B118, 2003)**
Seasonal High	The highest annual static groundwater elevation that is typically measured in the Spring and associated with stable aquifer conditions following a period of lowest annual groundwater demand. **(23 CCR Section 351)**
Seasonal Low	The lowest annual static groundwater elevation that is typically measured in the Summer or Fall and associated with a period of stable aquifer conditions following a period of highest annual groundwater demand. **(23 CCR Section 351)**
Seawater Intrusion	The advancement of seawater into a groundwater supply that results in degradation of water quality in the basin and includes seawater from any source. **(23 CCR Section 351)**
Statutory Deadline	The date by which an Agency must be managing a basin pursuant to an adopted Plan, as described in Water Code Sections 10720.7 or 10722.4. **(23 CCR Section 351)**
Sustainability Goal	The existence and implementation of one or more groundwater sustainability plans that achieve sustainable groundwater management by identifying and causing the implementation of measures targeted to ensure that the applicable basin is operated within its sustainable yield. **(CWC Section 10721)**
Sustainability Indicator	The effects caused by groundwater conditions occurring throughout the basin that, when significant and unreasonable, cause undesirable results, as described in Water Code §10721(x). **(23 CCR Section 351)**
Sustainable Groundwater Management	The management and use of groundwater in a manner that can be maintained during the planning and implementation horizon without causing undesirable results. **(CWC Section 10721)**
Sustainable Yield	The maximum quantity of water calculated over a base period representative of long-term conditions in the basin and including any temporary surplus, that can be withdrawn annually from a groundwater supply without causing an undesirable result. **(CWC Section 10721)**
Technical Study	The geologic or hydrologic report prepared and published by a state or federal agency, or a study published in a peer-reviewed scientific journal, or a report prepared and signed by a Professional Geologist or by a Professional Engineer. **(23 CCR Section 341)**
Uncertainty	The lack of understanding of the basin setting that significantly affects an Agency's ability to develop sustainable management criteria and appropriate projects and management actions in a Plan, or to evaluate the efficacy of Plan implementation, and therefore may limit the ability to assess whether a basin is being sustainably managed. **(23 CCR Section 351)**

Undesirable Result	One or more of the following effects caused by groundwater conditions occurring throughout the basin: (1) Chronic lowering of groundwater levels indicating a significant and unreasonable depletion of supply if continued over the planning and implementation horizon. Overdraft during a period of drought is not sufficient to establish a chronic lowering of groundwater levels if extractions and groundwater recharge are managed as necessary to ensure that reductions in groundwater levels or storage during a period of drought are offset by increases in groundwater levels or storage during other periods. (2) Significant and unreasonable reduction of groundwater storage. (3) Significant and unreasonable seawater intrusion. (4) Significant and unreasonable degraded water quality, including the migration of contaminant plumes that impair water supplies. (5) Significant and unreasonable land subsidence that substantially interferes with surface land uses. (6) Depletions of interconnected surface water that have significant and unreasonable adverse impacts on beneficial uses of the surface water. **(CWC Section 10721**
Urban Water Management Plan	The plan adopted pursuant to the Urban Water Management Planning Act as described in Part 2.6 of Division 6 of the Water Code, commencing with Section 10610 et seq. **(23 CCR Section 351)**
Water Budget	The accounting of the total groundwater and surface water entering and leaving a basin including the changes in the amount of water stored. **(CWC Section 10721)**
Water Source Type	The source from which water is derived to meet the applied beneficial uses, including groundwater, recycled water, reused water, and surface water sources identified as Central Valley Project, the State Water Project, the Colorado River Project, local supplies, and local imported supplies. **(23 CCR Section 351)**
Water Use Sector	The categories of water demand based on the general land uses to which the water is applied, including urban, industrial, agricultural, managed wetlands, managed recharge, and native vegetation. **(23 CCR Section 351)**
Water Year	The period from October 1 through the following September 30, inclusive. **(CWC Section 10721)** or the period from October 1 through the following September 30, inclusive, as defined in the Act. **(23 CCR Section 351)**
Water Year Type	The classification provided by the Department to assess the amount of annual precipitation in a basin. **(23 CCR Section 351)**
Wellhead Protection Area	The surface and subsurface area surrounding a water well or well field that supplies a public water system through which contaminants are reasonably likely to migrate toward the water well or well field. **(CWC Section 10721)**

Selected General Plan Goals and Policies

(THIS PAGE LEFT BLANK INTENTIONALLY)

Table 1. Selected Colusa County General Plan Goals and Policies

Goal or Objective	Policy or Action
Agriculture Element	
Goal AG-2: Maintain and enhance agriculture as the County's most critical land use, economic sector, and resource.	**Policy AG 2-1:** Agricultural-related industrial support operations shall be permitted on agricultural lands. Such uses may include, but are not limited to, processing, assembly, distribution and warehousing of agricultural materials and commodities and alternative energy systems that provide energy for on-site uses. These uses should be permitted on agricultural lands as principal permitted uses subject to the standards of the Zoning Ordinance provided the following findings are made: *d. The operational or physical characteristics of the use will not have a significant adverse impact on water resources or the use or management of surrounding agricultural properties within at least a one-quarter (1/4) mile radius.*
Objective AG 2-C: Preserve and Protect Water, Soil, and Natural Resources Necessary for Agricultural Operations	**Policy AG 2-8:** Support and promote water development projects which provide additional sources of water for agricultural uses. Policy AG 2-9: Support the procurement of expanded and additional water rights which provide for contractual supply reliability for agricultural use. **Policy AG 2-10:** Seek to increase the County's influence regarding water rights and distribution legislation at the state and federal level, to the greatest degree feasible for both surface water and ground water sources. This may occur through County support for local farm interest groups seeking to influence water-related legislation at the state and federal levels. **Policy AG 2-11:** Assist landowners in resolving water rights, water delivery, and water supply issues with other agencies such as the California Department of Fish and Game, the U.S. Army Corps of Engineers, the U.S. Bureau of Reclamation, and the California Department of Water Resources. Policy AG 2-12: Within conservation easements and habitat conservation lands, preclude the practice of fallowing fields for the purpose of water export. **Policy AG 2-13:** Encourage the reuse of treated wastewater for agricultural purposes. **Policy AG 2-14:** Preserve water resources for agriculture, both in quantity and quality, from competition with development, non-agricultural uses, mitigation banks, and/or interests from outside of the County. **Policy AG 2-15:** Promote best management practices in agricultural operations (including animal operations) to reduce emissions, conserve energy and water, and utilize alternative energy sources. **Policy AG 2-16:** Promote wildlife-friendly farm practices, such as tailwater ponds, native species/grasslands restoration in field margins, hedgerows, ditch management for riparian habitat, and restoration of riparian areas in a manner consistent with ongoing agricultural activities, water delivery systems, reduction of pesticides, and other appropriate measures.
	Action AG 2-F: Coordinate with irrigation districts to identify cost-effective and feasible Best Management Practices for the application and use of water resources that address the range of agricultural activities in Colusa County. Work with entities such as the irrigation districts, Agricultural Commissioner, UC Extension Office, the Colusa County Resource Conservation District, and the Natural Resources Conservation Service to distribute Best Management Practices information to agricultural operations in the County. **Action AG 2-G**: Collaborate with water suppliers and wastewater treatment plant operators to increase the availability of treated or recycled water for agricultural purposes.
Community Character	
GOAL CC-2: Ensure that New Growth Addresses the Needs, Challenges and Opportunities Unique to Each Community	**Policy CC 2-6:** Require new residential development to connect to municipal water and sewer services. **Policy CC 2-19:** Prohibit lot splits or subdivision of land into new parcels smaller than two acres until centralized water and wastewater services are available. **Policy CC 2-24:** The use, expansion and development of private or mutually owned water and wastewater systems serving large-scale commercial and industrial land uses or multiple users shall be supported within the Sphere of Influence, provided that the systems meet the requirements outlined in Policy PSF 1-26 and all applicable State regulations. **Policy CC 2-25:** Encourage urban residential development within the City's Sphere of Influence to connect to municipal sewer and wastewater service and discourage the use, expansion and development of private or mutually owned water and wastewater systems serving residential uses within the Sphere of Influence. **Policy CC 2-42:** Require new urban development in Maxwell to connect to the municipal water and wastewater systems. **Policy CC 2-47:** Require new residential development in Princeton to connect to the municipal water and wastewater systems. **Policy CC 2-57:** Require applicants requesting land subdivisions or parcel splits in the Stonyford Lodge area to provide proof of adequate water supply for domestic use and fire protection. Additionally, sewage disposal meeting the County's standards and frontage for each parcel on a road built to County standards shall be ensured. **Policy CC 2-60:** Allow the subdivision of land designated Agriculture Transition (AT) and zoned Upland Conservation, 10 acre minimum (UC-10) into 10 acre parcels, provided that the project can demonstrate sufficient roadway access, water supply, septic capacity, no significant aesthetic impacts, and that no significant risk associated with wildland fires or slope stability would occur. **Policy CC 2-67:** Encourage urban residential development within the City's (Williams) Sphere of Influence to connect to municipal water and wastewater service. **Policy CC 2-69:** Discourage the use, expansion and development of private or mutually owned water and wastewater systems serving residential uses within the Sphere of Influence (Williams)

Table 1. Selected Colusa County General Plan Goals and Policies	
Goal or Objective	Policy or Action
Conservation Element	
Goal CON-1: Conserve and protect Colusa County's ecosystem.	**Policy CON 1-4:** Encourage conservation, rather than preservation, through the active management of natural resources, including wildlife, water, air, minerals, forests, and land. Conservation and management techniques include replacing trees, crops, and other renewable resources at a pace that ensures they are not consumed more quickly than they can be replaced; use of non-renewable resources in a manner that ensures the resources are not depleted but available to future generations for use; strategic forest thinning and fuels management to prevent wildfires; making resource areas accessible to the public while protecting resources from being diminished to non-recoverable levels; reducing incompatible wildlife/agricultural interface; and increasing public understanding and responsible use of resource conservation areas.
	Policy CON 1-7: Conserve and enhance those biological communities that contribute to the County's rich biodiversity including, but not limited to, blue oak woodlands, annual grasslands, mixed chaparral, pine woodlands, wetlands, riparian areas, aquatic habitat, and agricultural lands.
Objective CON-1B: Protect Endangered, Threatened and Special-Status Plant and Animal Species, their Habitats, and Other Sensitive Habitats	**Policy CON 1-13:** Sensitive habitats include oak woodlands, wetlands, vernal pools, riparian areas, wildlife and fish migration corridors, native plant nursery sites, waters of the U.S., and other habitats designated by state and federal agencies and laws. **Policy CON 1-14:** Require any proposed project that may affect special-status species, their habitat, or other sensitive habitat to submit a biological resources evaluation as part of the development review process. Evaluations shall be carried out under the direction of the Colusa County Department of Planning and Building and consistent with applicable state and federal guidelines. Additional focused surveys shall be conducted during the appropriate season (e.g., nesting season, flowering season, etc.), if necessary. **Policy CON 1-15:** Require that impacts to wetlands and riparian habitat protected by State or Federal regulations be avoided to the greatest extent feasible. If avoidance is not possible, fully mitigate impacts consistent with applicable local, State and Federal requirements. **Policy CON 1-16:** Require new development projects to incorporate measures that eliminate or avoid direct impacts to lakes, reservoirs, rivers, creeks, streams, wetlands, and other waterways to the greatest extent feasible. Measures may include, but are not limited to, appropriate setbacks or the implementation of best management practices approved by the Department of Planning and Building. **Policy CON 1-17:** All discretionary public and private projects that identify special-status species or sensitive habitats in a biological resources evaluation shall avoid impacts to special-status species and their habitat to the maximum extent feasible. Where impacts cannot be avoided, projects shall include the implementation of site-specific or project-specific effective mitigation strategies developed by a qualified professional in consultation with state or federal resource agencies with jurisdiction (if applicable) including, but not limited to, the following strategies: *a. Preservation of habitat and connectivity of adequate size, quality, and configuration to support the special-status species. Connectivity shall be determined based on the specifics of the species' needs.* *b. Project design measures, such as clustering of structures or locating project features to avoid known locations of special-status species and/or sensitive habitats.* *c. Provision of supplemental planting and maintenance of grasses, shrubs, and trees of similar quality and quantity to provide adequate vegetation cover to enhance water quality, minimize sedimentation and soil transport, and provide adequate shelter and food for wildlife.* *d. Protection for habitat and the known locations of special-status species through adequate buffering or other means.* *e. Provision of replacement habitat of like quantity and quality on- or off-site for special status species.* *f. Enhancement of existing special-status species habitat values through restoration and replanting of native plant species.* *g. Provision of temporary or permanent buffers of adequate size (based on the specifics of the special-status species) to avoid nest abandonment by nesting migratory birds and raptors associated with construction and site development activities.* *h. Incorporation of the provisions or demonstration of compliance with applicable recovery plans for federally listed species.* *i. Monitoring of construction activities by a qualified biologist to avoid impacts to on-site special status species.*
	Action CON 1-C: Review development project proposals, infrastructure projects, long range planning projects, and other projects that may potentially impact special-status species and sensitive resources to determine whether significant adverse impacts will occur. Where adverse impacts are identified, develop appropriate mitigation measures, in conformance with General Plan policies and relevant state and federal laws, to reduce or avoid impacts to the maximum extent feasible and practical. **Action CON 1-D**: Update the Zoning Ordinance to include standards to address significant impacts to special-status species and sensitive habitats consistent with Policies CON 1-13 through 1-18.
Objective CON-1C: Protect and Enhance Local Fisheries and Riparian and Aquatic Habitat	**Policy CON 1-21:** Protect riparian habitat along the Sacramento River in order to maintain suitable habitat for anadromous fish species, including salmon and steelhead trout, and for native sportfishing species
	Action CON 1-E: Coordinate with the California Department of Fish and Game to identify adversely impacted aquatic habitat within the County and to develop riparian management guidelines to be implemented by development, recreation, and other projects adjacent to rivers, lakes, reservoirs, and streams.

Table 1. Selected Colusa County General Plan Goals and Policies	
Goal or Objective	Policy or Action
Objective CON-1D: Protect Surface Water Quality in the County's Lakes, Streams, Creeks and Rivers	**Policy CON 1-22:** Maintain lakes, rivers, streams, creeks, and waterways in a natural state whenever possible. These water features may be actively managed and/or improved or modified in order to function as natural flood protection and storm water management features during storms and flooding events. **Policy CON 1-23:** Protect and enhance streams, channels, seasonal and permanent marshland, wetlands, sloughs, riparian habitat and vernal pools through sound land use planning, community design, and site planning. **Policy CON 1-24**: If a proposed project may result in impacts to wetlands or other Waters of the U.S., require the project proponent to consult with the appropriate regulatory agency and implement all applicable permit requirements as a condition of project approval. **Policy CON 1-25:** Balance the needs of aquatic and riparian ecosystem enhancement efforts with flood management objectives. Policy CON 1-26: Discourage development within 50 feet from the top of banks for all lakes, perennial ponds, rivers, creeks, sloughs, and perennial streams unless County-approved best management practices have been incorporated into the project's design in order to protect water quality and shoreline resources. Appropriate uses within the setback areas may include, but are not necessarily limited to: a. Fire and flood protection areas b. Maintenance of riparian habitat c. Recreational trails d. Vegetated landscaping e. Boat launch facilities Levees g. Docks h. Irrigation pumps **Policy CON 1-27:** Encourage agricultural land owners to improve on-site storm water retention features and implement feasible Best Management Practices (BMPs) to reduce site runoff and provide for natural removal of water pollutants. **Policy CON 1-28:** Support non-regulatory programs for protection of streams and riparian habitat, including education, technical assistance, tax incentives, and voluntary efforts to protect riparian resources. **Action CON 1-F:** Continue to require implementation of the County's Grading Ordinance. Review projects to ensure that BMPs are implemented during construction and site grading activities as well as in project design to reduce pollutant runoff into water bodies.
Objective CON-1E: Ensure a Sustainable and Long-Term Supply of Safe and Reliable Water to Support the Needs of County Residents, Businesses, and Agricultural Operations	**Policy CON 1-29:** Support water development, treatment, and storage projects that are needed to meet existing and future local and regional demand. **Policy CON 1-30:** Ensure that regional, state, and federal water projects, including proposed Sites Reservoir, protect local water rights and areas of origin. **Policy CON 1-31:** Encourage municipal water purveyors to install water meters and abandon flat-fee water use rate structures where feasible. **Policy CON 1-32:** Demonstrate leadership in water conservation by including water-efficient plumbing and landscaping at all new County facilities, and by reducing the County's own water use to the extent possible. **Policy CON 1-33:** Require new development and expansion of existing uses to incorporate best management practices for water use and include water conservation measures. **Policy CON 1-34:** Encourage the use of water conservation measures for agriculture and in existing residences and businesses. **Policy CON 1-35:** Encourage the use of water conservation measures, including low flow plumbing; reclaimed wastewater for non-potable uses; dual plumbing that allows grey water from showers, sinks, and washers to be reused for landscape irrigation in new developments; and native and drought-tolerant landscaping. **Action CON 1-G:** Adopt a Water Efficient Landscaping Ordinance for residential, park, recreational, and commercial uses, based on the state model ordinance as amended to address local concerns. The ordinance should address: 1. Water-efficient landscape designs using low water-use plants. 2. Efficient irrigation systems. 3. Minimized turf areas. 4. Soil improvements and mulch. 5. Regular maintenance and adjustment of irrigation systems. 6. Scheduling irrigation during early or late hours. 7. Water budgeting, when necessary. 8. Education of residents, customers and employees regarding the importance of efficient water use. **Action CON 1-H:** Continue to implement the policies, actions, and Basin Management Objectives (BMOs) contained in the Colusa County Groundwater Management Plan. Action CON 1-I: Continue to cooperate with Butte, Glenn, Tehama, Shasta and Sutter Counties through the Northern Sacramento Valley Integrated Regional Water Management Group, and continue to foster regional cooperation with other counties and water purveyors.

Table 1. Selected Colusa County General Plan Goals and Policies	
Goal or Objective	**Policy or Action**
Housing Element	
Goal HO-2: Provide Adequate Sites and Infrastructure to Accommodate the County's Housing Needs	**Policy HO-11:** Implement all policies and programs of the Housing Element with adequate consideration given to the protection of the County's agricultural and groundwater resources, and maintaining consistency with the County's Conservation Element of the General Plan.
	Program HO 2-5 Provision of Public Services The County will make every effort to ensure that infrastructure is available in a timely manner to accommodate development of its fair share of regional housing needs. Particular effort will be made to provide adequate infrastructure to accommodate the R-2, R-3, and R-4 sites in Arbuckle, Maxwell, Princeton, and the unincorporated area of Colusa. The County will coordinate with the local water and sewer agencies to assist in planning for adequate water and sewer service. The County will take the following actions, as needed, to provide service to developing areas: <u>All Service Providers</u> • Each water and sewer provider will be mailed a copy of the Housing Element, upon its adoption, along with a letter that includes: 1) the text of Government Code Section 65589.7 requiring water and sewer providers to grant priority for service allocations to proposed developments that include housing units affordable to lower (including very low and extremely low) income households; 2) a summary of the County's regional housing needs allocation; and 3) specific actions the provider should take to ensure adequate service (see below for actions specific to each district/area in the County). <u>Rural Areas</u> • Review potential treatment technologies that could be developed to provide water and sewer service for rural market-rate and affordable housing; develop performance standards for potential treatment technologies to assist public and/or private sewer and water providers in determining which will be most feasible in their locations within the County. • Allow a wide range of feasible alternative system sizes and treatment technologies to provide water and sewer service for rural market-rate and affordable housing. Program HO 2-6 Adequate Water and Wastewater Service for Subdivisions Revise the Zoning Ordinance to ensure parcel map or subdivision map approval is dependent on demonstrated ability to provide potable water and meet septic capacity requirements.
	Policy HO-18: Give priority for water service connections to extremely low, very low, and low income housing units in areas receiving water service from the County. Encourage local water and sewer providers to give priority to these lower income developments pursuant to Government Code Section 65589.7. Provide a copy of the Housing Element Update to local water and sewer providers upon its adoption.
Land Use Element	
Goal LU-1: Maintain the efficient and harmonious use of land in the county, promoting a well organized and orderly development pattern, avoiding random, haphazard growth, protecting public health and safety, and accommodating the orderly and sustainable growth of employment and population.	**Policy LU 1-4**: Locate lands designated for future development based on constraints associated with natural features, such as soil, slope, and drainage, preservation of the County's resources, including agriculture, open space, and scenic views, and by public service availability, such as sewer and water capability; policies and actions related to these requirements are set forth in more detail in the Safety, Conservation, and Public Facilities and Services Elements.
	Action LU 1-D: Review development projects, consistent with the requirements of the California Environmental Quality Act and other applicable laws, to identify potential impacts associated with aesthetics, agriculture, air quality, circulation, community character, natural and cultural resources, greenhouse gases, public health and safety, water quality and supply, public services and facilities, and utilities and to mitigate of adverse impacts to the maximum extent that is feasible and practical.
Objective LU-1C: Ensure a Streamlined and Equitable Process for Project Permitting and Outside Agency Coordination without Compromising the Enforcement of Local Land Use Regulations	**Policy LU 1-27:** Participate in countywide, regional and other multi-agency planning efforts related to agriculture, water supply, tourism, open space, air quality, housing, green infrastructure, recreation, habitat conservation, energy, emergency preparedness and flood protection to ensure that the needs of the County's residents and businesses are not overlooked.
Goal LU-3: Ensure that Future Development Achieves the County's Goals of Agricultural Conservation, Rural Character, Growth Focused Around Existing Communities and Uses Sustainable Practices through Application of Development Requirements	**Policy LU 3-1:** Require proposed urban and rural residential development to be consistent with the following: <u>Rural Residential</u> • The soil is determined to be suitable for septic tank use by the Environmental Health Department • Groundwater is determined to be sufficient to support a well by the Environmental Health Department • The parcel can be made accessible from a public street • It can be demonstrated that the development is compatible with surrounding uses and will not have a significant, adverse effect on adjoining properties. • The area is accessible for fire protection and can meet fire resistance guidelines if located in a high hazard area. • It can be demonstrated that potable water is available. <u>Urban Residential</u> • The community utility systems, including water, drainage, and sewer, if available, can accommodate the additional demand. • The area has access to a major transportation route. • The impact of the development on local streets can be mitigated to acceptable levels. • Adequate fire protection measures are provided. • The site adjoins existing urban (residential, commercial, public facility, etc.) development. • The project avoids the repetition of residential facades/designs within subdivisions. • The development is compact, is sensitive to natural resources, public safety, efficiently uses water and energy, maximizes bicycle and pedestrian opportunities, provides multimodal connections to nearby neighborhoods, bike/pedestrian routes and trails, and provides direct, safe routes to services, schools, and shopping.

Table 1. Selected Colusa County General Plan Goals and Policies	
Goal or Objective	Policy or Action
Objective LU-3B: Ensure that Reasonable Development Standards and the County's Rural Character and Quality of Life are Not Compromised in Efforts to Attract Commercial and Industrial Growth	**Policy LU 3-24:** Require proposed industrial development to be consistent with the following: • The area can be readily hooked up to public sewer and water facilities where these facilities are available, or to private sewer and water facilities where utilities do not yet exist. • If the industry uses community utilities, that community systems can accommodate the added demand without additional costs to the existing community. • If the project is to be served by groundwater wells, that reliable, scientific data be provided in the project development application that demonstrates that groundwater will be available under all conditions, including drought, that surrounding the wells will not have appreciable adverse effects on the quality and quantity of existing domestic and agricultural water supplies, and that private sewage disposal systems can comply with Environmental Health Department standards. • The project will not significantly contribute to air, water, light, and noise pollution.
Open Space Element	
Objective OSR 1-B: Balance Open Space Preservation with Economic Development Needs	**Policy OSR 1-9:** Maintain open space for future water and drainage projects.
Public Services and Facilities Element	
Objective PSF-1A: Provide Safe, Reliable, and Environmentally Sound Water Services to Existing County Land Uses and Areas of Planned Growth	**Policy PSF 1-3:** Coordinate with water providers throughout the County to manage water supplies in a way that ensures adequate supplies for existing residents, agricultural uses, and businesses, and for projected growth, and avoids groundwater overdraft, water quality degradation and other adverse environmental impacts. **Policy PSF 1-5:** Facilitate, and to the extent feasible, assist with the development of new and reliable sources of water, consistent with County land use plans and regional water needs. **Policy PSF 1-7:** Priority is given to serving existing water uses over new water uses. **Policy PSF 1-8:** Require proof of an adequate (as defined by the County Environmental Health Division) potable water supply to serve the entire project prior to approval of any division of land or use permit. **Policy PSF 1-11:** New residential development on parcels two acres in size or smaller shall be required to connect to a public water system, with the exception of existing Rural Residential and Rural Service Center parcels which may be allowed to have an on-site well if approved by the County Department of Environmental Health.
Safety Element	
Objective SA 1-D: Take Appropriate Steps to Reduce the Risks to Life, Property, and Public Services Associated with Flooding.	**Policy SA 1-27:** Maintain adequate lands that can be used for groundwater recharge and storm water management. These lands may include parcels designated Agriculture General (AG), Designated Floodway (DF), and Resource Conservation (RC). **Policy SA 1-35:** Encourage and accommodate multi-benefit flood control projects that incorporate recreation, resource conservation, preservation of natural riparian habitat, and scenic values of the County's streams, creeks and lakes. Where appropriate and feasible, the County shall also encourage the use of flood and/or stormwater retention facilities for use as groundwater recharge facilities.

Table 2. Selected Glenn County General Plan Goals and Policies	
Goal or Objective	**Policy or Action**
Natural Resources	
Agriculture/Soils	
NRG-1 Preservation of agricultural land	**NRP-3:** Recognize the value of ricelands for waterfowl habitat, watershed management, and for groundwater recharge in an effort to preserve such lands and to maintain necessary water supplies in Glenn County. **NRP-4:** Support efforts underway to explore the potential to utilize ricelands as temporary storage reservoirs in the winter months, thus increasing groundwater recharge and supplies of surface water for both agriculture and wildlife, and potentially providing an alternative to rice straw burning. **NRP-19:** Support the erosion control programs, resource management programs, and agricultural conservation efforts of the Glenn County Resource Conservation District that benefit the county as a whole. Implementation Strategies, Programs and Priorities **NRI-3:** Encourage rice growers as well as other agricultural crop growers and cooperative to emphasize the value of rice land for waterfowl habitat, air quality enhancement, and groundwater recharge through promotions and advertisement. **NRI-4:** Monitor and participate in efforts of State and federal agencies and private conservation groups to find alternatives to rice straw burning, including winter flooding of fields. **NRI-16:** Establish a County notification process for requests to convert land from agricultural and grazing use to wetlands.
Water Resources	
NRG-2 Protection and management of local water resources	**NRP-22:** Oppose the exportation of groundwater resources outside the county. **NRP-23:** Support legislation which will provide for a locally controlled Glenn County groundwater management district. **NRP-24:** Recognize the following local priorities when dealing with questions of ground and surface water use: • Highest: 1) Household/Domestic, 2) Agriculture, 3: Industrial/Commercial, 4) Wildlife/Conservation Lowest: 5) Exportation **NRP-25:** Protect groundwater recharge areas in the county from overcovering and contamination by carefully regulating the type of development which occurs within these areas. **NRP-26:** Discourage onsite sewage disposal systems in areas with high groundwater recharge potential and eliminate existing concentrations of septic tanks in such areas through construction of community sewage treatment and disposal systems. **NRP-27:** Prohibit uses with the potential to accidentally discharge harmful groundwater pollutants in areas of high groundwater recharge, unless appropriate mitigation measures have been incorporated into the operation of such uses. **NRP-28:** Identify and monitor potential sources of groundwater pollution, including harmful agricultural practices. **NRP-29:** Limit structural coverage and impervious surfaces within areas of high groundwater recharge through application of zoning that recognizes the importance of this feature. **NRP-30:** Protect important watershed areas from poor development practices and potential degradation. **NRP-31:** Monitor actions taken at the State and federal level which impact water resources in order to evaluate the effects of these actions on the county's resources. **NRP-33:** Carefully study the potential impact that any future reservoir construction may have on groundwater recharge areas in Glenn County. **NRP-34:** Recognize the value of irrigation system infrastructure by discouraging development within established irrigation district boundaries which would prematurely reduce the utility of such systems. **NRP-35:** Encourage the development of water conservation programs by water purveyors for both agricultural and urban uses. **NRP-36:** Encourage development of educational programs to increase public awareness of water conservation opportunities and the potential benefits of implementing conservation measures and programs. **NRP-37:** Recognize that efforts to reserve water in Glenn County for wildlife may also bring long-term benefits to the effort to retain water resources locally. **NRP-38:** Recognize the impacts of gravel extraction on groundwater quantity and quality and encourage extraction methods that preserve and enhance groundwater resources. Implementation Strategies, Programs and Priorities **NRI-18:** Establish a local groundwater management program including strategies for advancing State legislation supportive of a locally controlled groundwater management district. **NRI-19:** Apply the priorities for water consumption included in this General Plan when reviewing discretionary actions. **NRI-20:** Establish an overlay designation to provide appropriate protections for areas of the county where groundwater recharge occurs, such as limitations on overcovering of soils with impervious surfaces. To provide for appropriate groundwater protection, new zoning proposals that could result in residential lots less than one acre should not be approved until a sewer system is available. Consult with the State Department of Water Resources, the Glenn County Health Department and the Glenn County Planning Department, and incorporate protective measures into the *Glenn County Zoning Code.* **NRI-22:** Work with State and federal agencies to improve local groundwater pollution detection and monitoring. **NRI-23:** Amend County ordinances to include development standards, as contained in this *General Plan,* which protect watershed areas, and coordinate application of the standards with the U.S. Forest Service and other agencies. **NRI-24:** Monitor and participate in efforts of the Bureau of Reclamation and Army Corps of Engineers to study the impacts of additional reservoir construction and of reservoir siltation. **NRI-25:** Develop and actively seek funding to develop water conservation and educational programs.

Table 2. Selected Glenn County General Plan Goals and Policies

Goal or Objective	Policy or Action
Biological Resources	
NRG-3 Preservation and enhancement of the county's biological resources in a manner compatible with a sound local economy.	**NRP-39:** Approach the retention and enhancement of important habitat by preserving areas or systems which will benefit a variety of species or resources rather than focusing on individual species, resources or properties. **NRP-41:** Preserve natural riparian habitat, especially along Stony Creek and the Sacramento River and Butte Creek. **NRP-42:** Eliminate the E-M (Extractive Industrial) Zone from areas containing natural riparian vegetation/habitat and replace it with a category affording greater protection to stream courses and riparian habitats. **NRP-46:** Promote protection of native biological habitats of local importance such as riparian forests, foothill oak woodlands, Stony Gorge and Black Butte Reservoirs. **NRP-50:** Recognize the Sacramento River corridor, the Sacramento National Wildlife Refuge, migratory deer herd areas, naturally occurring wetlands, and stream courses such as Butte and Stony Creeks as areas of significant biological importance. **NRP-53:** Direct development away from naturally occurring wetlands to the extent such policy is consistent with the concept of compact and contiguous development. **NRP-61:** Support efforts to improve water availability and management when the potential exists to benefit fish and wildlife in cooperation with Glenn County agricultural water users. Implementation Strategies, Programs and Priorities **NRI-27:** Amend the *Glenn County Zoning Code* to include a Streamside Protection Zone and rezone those areas along stream courses currently zoned E-M (Extractive industrial Zone) in accordance with a locally prepared riparian zone management plan. **NRI-32:** Meet with the U.S. Fish and Wildlife Service to determine if there is interest in establishing buffer areas around the Sacramento National Wildlife Refuge and other areas of biological importance, and how the federal government would participate in their formation. **NRI-34:** Identify biologically important areas, such as the Sacramento River Corridor, Sacramento National Wildlife Refuge, deer herd ranges, naturally occurring wetlands, and stream courses such as Butte and Stony Creeks, and show them as constraints to development in this *General Plan* (Reference Biological Importance Overlay and Restorable Wetlands Overlay).
Public Safety	
Water Quality	
PSG-6 Protection and enhancement of water quality.	**PSP-43:** Support ongoing regulatory and compliance efforts at the federal and State level for the protection of water quality. **PSP-45:** Zone floodways and stream channels in a manner that promotes protection of water quality. **PSP-47:** Support the preparation of area groundwater studies to the protection of groundwater and to ensure that the holding capacity of the area is not exceeded. Implementation Strategies, Programs and Priorities **PSI-42:** Sponsor and assist with educational efforts which have as a goal greater public awareness and compliance with established water quality standards.
Community Development	
Land Use/Growth	
CDG-2 Avoidance of land use conflicts in agricultural areas.	**P-45:** Discourage urban growth in floodplains, aquifer recharge areas, scenic and historic sites, or other sensitive areas as specified in this General Plan. **CDP-17:** Encourage agricultural water suppliers to make changes in their service requirements to increase the minimum sized parcel to be served in agricultural areas to ten (10) acres, and recommend that new parcels created within water supply district boundaries which are less than ten (10) acres in size be detached from the district(s), except for the Orland Unit Water Users' Association, for which the minimum size shall be 5.01 acres. **CDP-18:** Within the Orland-Artois Water District, approve no zone changes allowing parcels smaller than twenty (20) acres in size, and approve no tentative maps for parcels less than twenty (20) acres in size. Implementation Strategies, Programs and Priorities **CDI-10:** Contact agricultural water suppliers and formally request establishment of a ten (10) acre minimum parcel size for agricultural water service. **CDI-11:** Apply zoning to properties located within the Orland-Artois Water District that reflects a minimum parcel size of twenty (20) acres or larger.
Public Services and Facilities	
CDG-17 Provision of adequate and cost-effective public services.	**CDP-129:** Maintain coordination and cooperation between the County and water purveyors, and encourage special districts to comply with State law by referring capital projects to the County for review and evaluation for consistency with the General Plan. Implementation Strategies, Programs and Priorities **CDI-83:** Convene a task force composed of representatives of Glenn County and the cities of Willows and Orland to formulate a memorandum of understanding which establishes uniform polities and standards for building construction, public utility connections, sewer and water service, and other matters related to cost-effective development of unincorporated areas within city urban limit lines. **CDI-88:** Request LAFCO to initiate and undertake studies of existing special districts and cities which include inventorying those agencies and determining their maximum service area and service capacities. **CDI-89:** Request LAFCO to adopt standards and procedures for the evaluation of service plans submitted by cities and special districts with annexation/reorganization applications. **CDI-94:** Request the Environmental Health Department to review minimum parcel size standards for areas without public or community water service for adequacy as new information becomes available e.g. soil surveys, new regulations.

Table 3. Selected City of Colusa General Plan Goals and Policies

Goal or Objective	Policy or Action
Land Use Elements	
Comprehensive Planning	
Goal LU-6: To provide a comprehensive, logical land use planning process rather than an incremental, piecemeal approach.	**Policy LU-6.3:** Growth shall be managed to ensure that adequate public facilities and services are planned for and provided in a manner that protects the public's health, safety, and welfare.
	Implementing Actions Implementing Action LU-6.3.e: Water Master Plan The City will adopt and implement a Water Master Plan. Development projects will be evaluated for consistency with this plan. The plan will provide a framework for timed capital improvements and facility expansion projects and will aid the City in identifying and establishing funding sources beyond monthly service charges to finance improvements related to water quality, supply, recycling, distribution, and water conservation. Municipal water is discussed is discussed in detail in the Municipal Facilities and Services Element. Implementing Action LU-6.3.f: Wastewater Master Plan The City will adopt and implement a Wastewater Master Plan. Development projects will be evaluated for consistency with this plan. The plan will provide the framework for timed capital improvements and facility expansion projects and will identify funding sources beyond monthly service charges to finance improvements related to expansion and upgrades to wastewater capacity, flow, treatment, and reclamation. The City will refer to this plan when constructing improvements and upgrades to the Wastewater Treatment Plant as needed to accommodate existing customers and any approved development. Wastewater is discussed in detail in the Municipal Facilities and Services Element. Implementing Action LU-6.3.g: Storm Drainage Master Plan The City will adopt and implement a Storm Drainage Master Plan. Development projects will be evaluated for consistency with this plan. The plan will identify drainage facilities that will be constructed to eliminate drainage problems in the City and will describe the means for financing the improvements. The Storm Drainage Master Plan will address Regional Water Quality Control Board water quality standards, including Best Management Practices for storm drainage management. Storm drainage is discussed in detail in the Municipal Facilities and Services Element.
Community Character and Design	
Environmental Sustainability	
Goal CCD-2: To ensure that new development respects the natural environment.	**Policy CCD-2.2:** New development shall respect the contours of drainage ways as important recognizable features of the City.
	Implementing Actions Implementing Action CCD-2.2.c: Improvement Standards The City will update and adopt improvement standards to be applied to improvements and private works to be dedicated to the public and accepted by the City for maintenance or operation, as well as improvements to be installed within existing rights of-way and easements. These standards shall serve to regulate and guide the design and preparation of plans for street construction, alleys, drainage, sewer, street lighting water supply facilities, and related public improvements.
	Policy CCD-2.5: The City shall ensure that infrastructure improvements demonstrate sensitivity to any natural systems affecting a project site.
	Policy CCD-2.5: The City shall ensure that infrastructure improvements demonstrate sensitivity to any natural systems affecting a project site.
	Implementation Actions Implementing Action CCD-2.5.b: Development Review Impacts of proposed new development will be evaluated with each proposal. Mitigation of significant impacts to the natural environment, including biological resources, water quality and air quality, will be required as part of the development review process. Mitigation measures to minimize impacts on these natural resources will be implemented as appropriate.
Safety Element	
Goal SAF-2: To minimize the potential for loss of life and damage to property due to flooding.	**Policy SAF-2.2:** The City shall minimize the potential for flood damage to buildings and other structures, particularly from storm water runoff.
	Implementing Actions Implementing Action SAF-2.2.a: Storm Drainage Master Plan The City will adopt a Storm Drainage Master Plan for Colusa. The Master Plan will identify drainage facilities that will be constructed to eliminate or mitigate drainage problems in the City, and describe the means for financing the proposed improvements. The Storm Drainage Master Plan will be consistent with any Capital Improvements Plan prepared by the City and will address Regional Water Quality Control Board water quality standards, including Best Management Practices for storm drainage. Implementing Action SAF-2.2.b: Development Review The City will require new development to ensure that the cumulative rate of peak runoff does not exceed pre-development levels. New development and redevelopment of existing sites will provide storm water detention or retention facilities (on- or offsite), if necessary, to prevent flooding due to runoff or where existing storm drainage facilities are unable to accommodate increased storm water drainage. Implementing Action SAF-2.2.c: Ordinance and Regulation Review and Update The City will review and revise its Subdivision Ordinance as needed to incorporate specific data and design requirements related to storm water drainage that are contained in this General Plan update.

Table 3. Selected City of Colusa General Plan Goals and Policies	
Goal or Objective	**Policy or Action**
Parks, Recreation and Resource Conservation	
Water Quality and Water Conservation	
Goal PRC- 9: To manage and protect the City's water resources.	**Policy PRC – 9.1:** The City shall require natural drainage flows be maintained in new development projects to the greatest extent feasible.
	Implementing Action Implementing Action PRC-9.1.a: Development Review As part of the development review process, the City will review individual projects to determine the setback requirements that will adequately buffer natural drainage corridors from development. The City will require that new development protect natural drainage corridors and other watercourses from the adverse effects of construction activities and urban runoff.
	Policy PRC- 9.2: The City shall periodically review the status of the City's groundwater resources.
	Implementing Action Implementing Action PRC-9.2.a: Water Resources Report The City will prepare a Water Resources bi-annual report to the City Council. This report, in part, will include an analysis of groundwater resources, including groundwater quality. The City will use this report to ensure groundwater resources are protected from contamination and overdraft. As part of the bi-annual Water Resources Report, the Public Works Department will analyze the quality of drinking water in the City. The City will encourage activities that maintain and improve drinking water quality.
	Policy PRC – 9.3: The City shall maintain its ability to meet its water supply requirements. Implementing Action PRC-9.3.a: Development Review As part of the development review process, the City will evaluate the incorporation of water conservation techniques in all new development.
	Implementing Action Implementing Action PRC-9.3.b: Development Impact Fees (see Implementing Action MFS-1.1.b).
	Policy PRC-9.4: The City shall encourage the use of treated wastewater and other non-potable water sources for irrigation and groundwater recharge.
	Implementing Actions Implementation Action PRC-9.4.a: Landscape Ordinance The City will adopt and implement a landscape ordinance, which will establish standards for water-conserving landscaping in order to reduce water use in developed areas. Requirements will specify the use of reclaimed water, trees, and other vegetation. This ordinance will be applied in the design and development of private and public development projects and will be consistent with the provisions of the General Plan. Implementation Action PRC-9.4.b: Interagency Coordination In cooperation with the Colusa County Water District, the City will identify and develop opportunities for reuse of non-potable water, including reclaimed water, for non-domestic uses.
Municipal Facilities	
Water System	
Goal MFS – 7: To maintain and enhance a water system that meets the needs of existing and future residents of Colusa.	**Policy MFS-7.1:** The City shall establish development standards and plans to ensure that the water treatment and delivery system is not unduly burdened by new development.
	Implementing Action Implementing Action MFS-7.1.c: Water Master Plan The City will prepare and implement a Water Master Plan to provide a framework for timed capital improvements and facility expansion projects. The plan will aid the City in identifying and establishing funding sources beyond monthly service charges to finance improvements related to water quality, supply, recycling, distribution, conservation, and other issue areas identified issue areas identified by the City and the plan. The plan will evaluate the depth, size, recharge rate, and capacity of the aquifer to accommodate the City's projected future growth. The plan will also make determinations regarding the need to develop additional water sources during the planning period of this General Plan.
	Policy MFS-7.2: To minimize the need for the development of new water sources and facilities and to minimize sewer treatment needs, the City shall promote water conservation in City operations and in private development. The City shall annually monitor water usage to assess the effectiveness of the water conservation program.
	Implementing Action MFS-7.2.a: Water Master Plan The City will implement a water conservation program, to be defined and incorporated in its Urban Water Management Plan, to be prepared with the Water System Master Plan. If groundwater levels decline and/or if the "moderate" program does not achieve its intended results, the City will implement the "aggressive" or "maximum" water conservation program as defined in the Water Management Plan.
	Policy MFS-7.3: The City shall, to the extent practical, require the use of drought-tolerant plant species and water efficient irrigation systems in the landscaping of new public and private open space areas, common areas, and parks.
	Implementing Action MFS-7.3.a: Development Review Through review of development projects, the City will condition development, where practical, on water conservation practices.
Stormwater Drainage System	
Goal MFS – 9: To provide adequate stormwater drainage for all existing and future development.	**Policy MFS-9.1:** The City shall ensure its stormwater drainage system is upgraded in phases to adequately accommodate drainage resulting from new development prior to project construction.
	Implementing Action Implementing Action MFS-9.1.a: Storm Drainage Master Plan The City will prepare and adopt a Storm Drainage Master Plan for Colusa. The Master Plan will identify drainage facilities that will be constructed to eliminate existing drainage problems and avoid future drainage problems in the City and describe the means for financing the improvements. The Storm Drainage Master Plan will be consistent with any Capital Improvement Program prepared by the City and address Regional Water Quality Control Board water quality standards, including Best Management Practices for storm drainage.

Table 4. Selected City of Williams General Plan Goals and Policies	
Goal or Objective	**Policy or Action**
Land Use and Character	
Achieving a Quality Community Character	
	Policy 3.27: The land use plan and zoning districts will address for the character of development, which accounts for the design/intensity of development, the arrangement of buildings and parking areas, and the preservation of open space. Actions **3.hh.** Establish minimum open space standards within each district, which may be used for storm water detention, resource protection (e.g. riparian buffers along streams), bufferyards, and/or parks, trails, and open space. The amount of private or common open space relates to the character of development. For instance, in the Agriculture and Estate Residential districts, there is a high proportion of private open space whereas the Suburban Residential and Urban Residential districts have increasing percentages of common (public or semipublic) open space. **3.jj**. Incorporate development options within each zoning district. Different lot sizes and percentages of open space maintain the district character while allowing market flexibility and adjustment to site conditions. In other words, a smaller lot may be used and clustered to set aside adequate open space to preserve agricultural resources, such as the orchards, or to fulfill the City's storm water management objectives. A comparable density and character is achieved.
Service Provision	
	Policy 3.41: The City's land use pattern shall focus new development and significant redevelopment where adequate public services and utility capacity are already in place or projected for improvement, including streets, water, wastewater, and drainage infrastructure.
Environmental Sensitivity, Resource Protection, and Flood Prevention	
	Policy 3.45: Sensitive resources, including floodplains, wetlands, riparian buffer areas along stream channels, and valued view sheds, will be protected and preserved. **Policy 3.50:.** The City will consider the location of natural resources to be used for groundwater recharge and stormwater management.
Public Safety	
Flood Protection	
	Policy 4.9: The design of drainage improvements will be sensitive to community aesthetics, aquatic habitat, recreation (trails, playing fields), wetlands, and water quality mitigation. **Policy 4.10:** The City will encourage design strategies to reduce the impact of impervious surfaces on storm water quality through the use of water gardens, rain barrels or cisterns, pervious pavement, vegetated swales, swale blocks, and green roofs, among others. Actions **4.d.** Maintain a Flood and Drainage Master Plan that addresses the following, at a minimum: • Storm water and drainage improvements for all sections of the City that are needed to accommodate planned growth; • Coordination with irrigation districts, the County and other affected flood control agencies to develop uniform standards for irrigation and storm water conveyance infrastructure; and • Standard measures used for new development to address localized flooding, such as measures to avoid off-site drainage impacts from adjacent agricultural operations. **4.e.** At the time the City reaches a size by which it is required to comply with Section 402(p) of the Federal Clean Water Act, prepare a Storm Water Management Plan (SWMP) to fulfill the requirements for improving the quality of storm water discharges from Small Municipal Separate Storm Sewer Systems (MS4) for Phase II municipalities. **4.f.** Begin identifying Best Management Practices (BMPs), particularly construction site storm water runoff control and post-construction storm water management, to reduce the discharge of pollutants to the storm water system. These should be integrated as standards into the City's subdivision regulations. **4.g.** Through improved land development practices and regulations, establish a hierarchy for managing storm water with the following priorities: minimize impervious surfaces, attenuate flows by use of open, vegetated swales and natural depressions and preserve existing natural stream channels, infiltrate runoff 3, provide storm water retention and then detention structures, provide velocity dissipation structures or channel design, and construct storm sewers. **4.m.** Investigate the feasibility of the alternatives outlined in the Preliminary Technical Memorandum for Flood Hazard Mitigation Study Project Alternatives. The structural alternatives include improving the conveyance capacity of Freshwater and Salt Creeks and the supporting network of drainage laterals, replacing bridge crossings to remove obstructions, constructing diversion dams to channel flows away from the City, constructing flood detention and multi-purpose flood retention reservoirs, constructing levees to the west and north of the City with removable floodwall sections, and elevating existing structures. The non-structural alternatives include land acquisition, cropland storage, channel restoration, upland re-vegetation, and improved maintenance of stream channels.

Table 4. Selected City of Williams General Plan Goals and Policies	
Goal or Objective	Policy or Action
Public Facilities	
Water, Wastewater, and Storm Drainage	
	Policy 5.1: The City of Williams will provide utilities concurrently with development. Actions **5.b.** Continue developing the City's Capital Improvement Program (CIP) to repair and replace aging and deteriorated sewer lines, which will improve the flow efficiency, reduce inflow and infiltration into the collection and treatment systems, and help to mitigate ground water impacts. **5.c.** Execute plans to install a new water well. **5.d.** Further develop plans for a second water storage tank. **5.e.** Amend the zoning ordinance to include ground water protection measures in site development standards. Include open space provisions in the density standards. **5.f.** Amend the subdivision ordinance to include ground water protection measures in future subdivisions. **5.g.** In accordance with AB 1881, the Water Conservation Landscape Act of 2006, develop water efficient landscaping standards for new development to include: • Requirements for specific species of plantings; • Prohibition of invasive species; • Submittal requirements for landscaping and irrigation plans (and requirement for both to be installed per approved plans); • Landscaping and hardscaping to be designed based on "hydrozone" specifications; • Provision for recirculating and recycling water systems; • Requirements for a soil report with recommendations regarding the most efficient types of planting and irrigation for the specific soil types existing on a site; • Specific "plant factors" in compliance with state standards for high, medium and low water using plantings; and • Irrigation to be designed according to hydrozone needs. **5.k.** Incorporate into City standards and specifications means for addressing storm water quality, including a first preference for nonstructure best management practices such as bioretention, vegetated swales and buffer strips, constructed wetlands, and other environmentally sensitive design and construction practices.
Open Space and Conservation	
Vegetation	
	Policy 7.24: Preference will be given to native and drought-tolerant plant species to reduce water consumption, minimize invasive species, and preserve the appearance of the natural landscape. Actions **7.zz** Consider provisions in the subdivision regulations may require riparian buffers around all naturally occurring water bodies and wetlands. The standards shall restrict septic systems within the buffer area and include requirements for planting indigenous plants and trees to enhance the buffer's absorption and filtering potential. 7.aaa Include the use of bio-swales and permanent water features for drainage management to reduce the volume and rate of stormwater runoff from new developments. 7.bbb Support green roofs on new developments as a method of stormwater mitigation, as well as reduction of the urban "heat island" effect. For new construction, the use of green roofs shall result in a reduction in the extent of stormwater facilities that need to be constructed to meet standards. 7.ccc The City will identify areas that may accommodate floodwater for the purposes of groundwater recharge and stormwater management.

Table 5. Selected City of Orland General Plan Goals and Policies	
Goal or Objective	**Policy or Action**
Safety Element	
Subsidence	
	Policy 4.6.C: Applications for projects that extract groundwater, oil, or gas shall include a report evaluating the potential for resulting subsidence. Reports shall discuss appropriate mitigation measures to reduce the potential for subsidence.
Open Space, Conservation, and Public Facilities Element	
Water Quality	
Goal 5.6: Conserve, enhance, and manage water resources, protect their quality, and ensure an adequate long-term supply of water for domestic, agricultural, industrial, and recreational use.	**Policy 5.6.A:** Ensure that new development complies with State and federal regulations and standards in order to maintain and improve water quality. Program 5.6.A.1: The City shall require applicants for new development projects to adhere to RWQCB discharge standards, including identifying specific measures for minimizing project related erosion and resulting siltation of surface water features. Programs Program 5.6.A.2: The City shall require that a grading and erosion control plan be submitted with each tentative parcel and tentative subdivision map prior to action by the City. Standard RWQCB best management practices (BMPs) shall be incorporated in these plans as a means to control runoff and minimize erosion impacts. Program 5.6.A.3: The City shall ensure that new development has a minimal impact on natural drainage channels and flow capacity. **Policy 5.6.B:** Reduce the potential for sediment and other pollutants to contaminate surface and ground water resources. Programs Program 5.6.B.1: Where feasible, the City shall maintain the natural condition of waterways and floodplains and protect watersheds to ensure adequate ground water recharge and water quality. Program 5.6.B.2: The City shall require that new development at a density greater than one unit per acre and commercial and industrial areas annexed to the City be connected to the City's wastewater collection system. Existing residential development and individual homes where septic systems have failed also may be connected to the system. Program 5.6.B.3: The City shall review City standards for drainage structures and, if determined appropriate, adopt requirements for grease and sediment traps for roads and parking lots to improve water quality of urban runoff. **Policy 5.6.C:** Explore the use of pervious concrete/pavement to allow the continued filtration of groundwater into the soil. **Policy 5.6.D:** Encourage the use of site design techniques for non-residential uses that provide for the discharge of on-site stormwater into landscaped basins or swales prior to discharge to the City's storm drainage system. **Policy 5.6.E:** Encourage water conservation as a means of conserving not only water but also minimizing energy consumption and costs associated with pumping and delivery systems.
Water Supply	
Goal 5.7: Protect the quantity and quality of community water supplies	**Policy 5.7.A:** Ensure that groundwater resources in the vicinity of Orland are protected from contamination. Programs Program 5.7.A.1: The City shall require wells located on land annexed to the City and served by City water service to be properly abandoned or all possibility of cross connection with the City water system eliminated in accordance with Glenn County Health Department guidelines. Program 5.7.A.2: The City shall ensure that all City wells are operated and maintained to meet California Department of Health Services standards for public drinking water supplies. **Policy 5.7.B:** Avoid the wasteful use of water within the planning area. Program 5.7.B.1: The City shall promote the use of water-conserving devices and practices in both new construction and major alterations and additions to existing buildings.
Stormwater Drainage System	
Goal 5.9: Provide for the collection, transport, and stormwater in a safe manner to protect people and property from damage arising from storm drainage.	**Policy 5.9.A:** Require new development to ensure that the cumulative rate of peak runoff does not exceed pre-development levels. Programs Program 5.9.A.1: New development and redevelopment of existing sites should provide storm water detention or retention facilities (on- or offsite), if necessary, to prevent flooding due to runoff or where existing storm drainage facilities are unable to accommodate increased storm water drainage. Program 5.9.A.2: The City shall review and revise its Zoning and Subdivision Ordinances, as needed, to incorporate specific data and design requirements related to stormwater drainage that are contained in this general plan. Program 5.9.A.3: The City shall complete its Storm Drainage Master Plan. **Policy 5.9.B:** Minimize the potential for flood damage to buildings and other structures, particularly from storm water runoff. Programs Program 5.9.B.1: The City shall explore the use of pervious concrete and pavement to assist in the return of water to the regional aquifer and to assist in the management of storm drainage. Program 5.9.B.2: The City shall encourage the use of landscaped bioswales to filter oil and other pollutants from stormwater drainage. Program 5.9.B.3: The City shall consider the use of filtered storm drainage inlets to screen pollutants from drainage waters.

Table 6. Selected City of Willows General Plan Goals and Policies	
Goal	**Objective, Policy or Implementation**
Land Use Element	
Development	
DPS-1 Goal: Accommodate and plan for new growth.	Objective: During the life of this plan, maintain flexibility and responsiveness to the changing conditions and opportunities for development. Policy: The City should only approve development proposals that are consistent with this plan.
Community Services, Facilities, and Infrastructure	
DPS-4 Goal: Adequate community services, facilities, and infrastructure.	Objective: Maintain existing services, facilities, and infrastructure, and provide for expansion, extension, or upgrades to meet the needs of new development without adversely impacting existing levels of service or the revenues required to provide them. Policy: Before approving a development proposal, the City should determine through the California Environmental Quality Act (CEQA) process that a proposed project will not adversely impact existing community services, facilities, and infrastructure The City Council should determine that revenues are, or will be, available to maintain and/or expand, extend, or upgrade services related to new development.
High Groundwater	
DPS-13 Goal: Protect water quality.	Objective: Prevent septic system failure and ground water contamination in high groundwater areas. Policy: The City Council should only approve projects in the high ground water areas that will be served by city sewers.

1	7/6/2020	Ben King	Land Owner	Email	Connate Water	My concern is that the connate seawater under the Sutter Buttes is contaminating groundwater and drinking water quality….My suggestion would be to pick up where the SWRCB left off in 1952 and examine salt water and arsenic levels within a 15 mile circumference around the Buttes and set up a monitoring network to monitor changes in ground water quality going forward. This would not only focus on the southern part of the Buttes but within the whole circumference.*	https://app.box.com/s/auy1v5yuwgoesm5dttz489jg41r7zl5b	General Input	Response included in Administrative Record Files
2	8/9/2019	Brian Cahill	Land Owner		Projects	While there will be private landowner sites for groundwater recharge ponds, private sites would be most effective if they augment a public effort by Colusa county to revamp road crossing drainage culverts such that storm flows are re directed to intermittent streams like Salt creek via trenching the side road ditches. At present, the road culverts facilitate storm flows crossing the public road (necessary) but because there is no attempt to re-direct the storm flows the volumes accumulate such that the volumes arriving on private property are difficult to manage.		General Input	Comments will be logged for consideration when the PMAs portion of the GSP is being developed. Will need to coordinate also with land use entities.
3	10/20/2020	Ben King	Land Owner	Email	Water Quality	I want to highlight the C 14 dating results and trace metal contamination levels for IASC 21 generally. See the Tables for IASC 21 at the end of the Report. (Referencing USGS Middle Sacramento Valley 2006 Water Quality Report)...Perhaps we can work with the USGS to expand its network around the Sutter Buttes. Even if we get USGS testing every 10 years that may be enough to detect water quality trends. We just need a baseline because this may be 100 year issues. My concern is how the increased pumping to support permanent crops may effect the lateral and upward movement of natural contaminants. I think that recharge probably can mitigate this and may have contained the issue before the levees were built. With recharge we can tactically simulate some of the the natural benefits of the historical benefits of flooding in the Sacramento Valley while benefiting from the State's investment in flood control and reclamation.*	https://app.box.com/s/45i9kz30hb3ci2qxah7r66dgrvi8s0iy	General Input	Response included in Administrative Record Files

Colusa Subbasin Groundwater Sustainability Plan
Development Outreach Comment Tracking Table - General Input

Comment Categories: General Input, Comment, Question, Request, Suggestion, Clarification.

#	Date Submitted	Commenter Name (if available)	Commenter Organization (if applicable)	Venue Received	Subject	Comment	Link to Full Comment/ Reference Materials (if applicable)	Categorized Comment	Response Needed
4	11/18/2019	Ben King	Land Owner	Email	Water Quality	I am concerned about the potential for further later movement of the salt water northward towards the Butte Sink that may be cause by future groundwater substitution on east side of the Sacramento River near Colusa. As you know Colusa, Grimes, Sutter and Meridian use groundwater. The other issue that came to my mind was the potential for further deterioration due to future earthquake activity. Perhaps – this area might be a good candidate for an Aerial mapping if the mapping could detect higher chloride levels in the groundwater? References: SWRCB Bulletin #6 (1952), Hydrogeology of the Sutter Basin (George Curtin 1920), USGS Geochemistry of groundwater in the Sacramento Valley (1984), USGS Late Cenozoic Tectonism of the Sacramento Valley (1987) *	https://app.box.com/s/7l3fswdsa97yzxm84zjdnwylf18jze29	General Input	Response included in Administrative Record Files
5	12/9/2020	Ben King	Land Owner	Email	Water Quality	I want to make the point that the current law is that the SWRCB will curtail Sacramento River and Sacramento River tributary diversions during critically dry years. This is the legal status quo after the 2015 year drought and the curtailments should be included in the Water Budget. The reason I am making this point is the recent decision regarding diversions from Deer Creek during the 2014/15 drought.This litigation was appealed to the California Appellate court which confirms the current power to curtail water supplies for the Colusa Basin. The California Supreme Court declined to review the Appellate Courts decision on September 23, 2020. I have attached the Appellate Court decision confirming existing law and current limitations of surface water supplies for the Colusa Basin. Just to reiterate the current law gives the SWRCB to enforce the current instream minimums under the Bay Delta Plan. Any voluntary settlement that may be less restrictive is speculative and does not represent the in stream requirements currently enforced.		General Input	
6	12/9/2020	Member of the Public	N/A	Public Meeting	Aquifer Depths	Has the consultant team ground-truthed the freshwater aquifer depths across the basin? Due to the seawater aquifer under the subbasin's groundwater system, these depths are an important consideration. The interplay between the two has resulted in areas where there are no wells due to water quality being impacted by the saltwater.		Question	Answer provided in 12/09 public meeting. See meeting summary for full response.
7	12/9/2020	Ben King	Land Owner	Public Meeting	Water Quality	I am concerned about drinking water quality and availability in Colusa county including arsenic contamination.*	https://app.box.com/s/xf8ke3p5morjfcmy870xays1lignnzwp	General Input	
8	12/9/2020	Ben King	Land Owner	Email	Subsidence	I would suggest that our most critical infrastructure is the transportation infrastructure of I-5 and the residential infrastructure of Arbuckle including the Arbuckle cemetery. The cemetery is very close to the greatest level of subsidence and I -5 crosses adjacent to the area of greatest subsidence. I believe we have to look at the potential for multi-feet subsidence over decades and we need to look at the subsidence potential in the context of historical events. *	https://app.box.com/s/jgjdb714deysi7rn3ofevevelu7egu8v	General Input	

Colusa Subbasin Groundwater Sustainability Plan
Development Outreach Comment Tracking Table - General Input

9	12/9/2020	Member of the Public	N/A	Public Meeting	Funding	What type of studies might be done with Proposition 68 funds?		Question	Answer provided in 12/09 public meeting. See meeting summary for full response.
10	12/9/2020	Member of the Public	N/A	Public Meeting	Water Supply	Under the Bay-Delta Plan, aren't we going to have only 40-50% of the surface water we had in the past? Have you tracked how much water we lose from the basin through water transfers? How much do we pump for groundwater substitution? These do not appear to be included in the budget.		Question	Answer provided in 12/09 public meeting. See meeting summary for full response.
11	12/9/2020	Member of the Public	N/A	Public Meeting	Water Supply	Do models show any significant variation in storage in some parts of the subbasin compared to others, and if so, would some areas have more issues than others?		Question	Answer provided in 12/09 public meeting. See meeting summary for full response.
12	12/9/2020	Member of the Public	N/A	Public Meeting	Water Budgets	Have zone water budgets been created at this point for sub areas of the basin and if not, are they are planned?		Question	Answer provided in 12/09 public meeting. See meeting summary for full response.
13	12/9/2020	Leslie Nerli	GGA Board Member Alternate	Public Meeting	Thresholds	Since conditions vary between wet years and dry years, will you take into account dry years vs wet years when setting thresholds? Can you set multiple thresholds?		Question	Answer provided in 12/09 public meeting. See meeting summary for full response.
14	12/9/2020	Member of the Public	N/A	Public Meeting	Water Supply and Quality	The residents in Colusa County rely on groundwater for drinking water. The County faces issues around water availability, such as when domestic wells run dry in critically dry years as a result of competition with agricultural use. Domestic use should be the priority and that use should grow in a reasonable way. Colusa County also faces issues around maintaining groundwater quality in critically dry years. The U.S. Environmental Protection Agency standard for arsenic is ten parts per million, and there are areas that exceed that. This issue will continue due to the connate water coming out of Sutter Buttes and can't be mitigated. In the future, Colusa County may need water from the Sacramento River, which is very expensive, but may be a good investment.		General Input

15	12/9/2020	Member of the Public	N/A	Public Meeting	Sites Project	Regarding his concerns about the Sites Reservoir project and the proposed interconnect between the Tehama-Colusa Canal and Colusa Basin Drain, the speaker stated that this project should be in Colusa County, because Sites Reservoir is in Colusa, and it needs to promote safe drinking water supply in Williams and Arbuckle. It should be close to Williams and Arbuckle. The Tehama-Colusa Canal jags southeast of Arbuckle. One of the closest distances between the canal and drain is south of Arbuckle. The County needs to push for the interconnect to be in Colusa County.		General Input	
16	12/10/2020	Member of the Public	N/A	Public Meeting	Groundwater Dependent Ecosystems	The Nature Conservancy (TNC) cuts off groundwater dependent ecosystems at a depth of 30 feet. However, the U.S. Department of Agriculture notes that Valley Oak groves can tap into groundwater as deep as 80 feet and are groundwater dependent. Thus, the GSP should take into consideration that Valley Oak woodlands may be tapping deeper than the TNC guidelines suggest. This information has also been presented to the Butte County Department of Water and Resource Conservation and should be shared in the upcoming Interbasin Coordination Group meeting.		General Input	
17	12/10/2020	Member of the Public	N/A	Public Meeting	Interbasin Coordination	There have been discrepancies between basin setting and water budget reports during the initial stages of groundwater sustainability planning. The Interbasin Coordination Group stated in their December 1st meeting agenda that they would review compiled data, identify significant differences, and discuss potential ways to reconcile those differences. Has there been an update? For example, is there an update on reconciling the discrepancies from the various water models used, since consistency is critical to the foundation of groundwater planning.		Question	Answer provided in 12/10 public meeting. See meeting summary for full response.
18	12/10/2020	Member of the Public	N/A	Public Meeting	Groundwater Dependent Ecosystems	Was the map on groundwater ecosystem also based on soil mapping based on the lines along with west side of the basin?		Question	Answer provided in 12/10 public meeting. See meeting summary for full response.
19	12/10/2020	Member of the Public	N/A	Public Meeting	Subbasin Mapping	Are the 38 subareas tools for data collection for management of the whole basin or 38 separate Management Areas?		Question	Answer provided in 12/10 public meeting. See meeting summary for full response.
20	12/10/2020	Member of the Public	N/A	Public Meeting	SGMA	Are other regions in the state where the State of California has taken over the monitoring--the thing we are trying to avoid?		Question	Answer provided in 12/10 public meeting. See meeting summary for full response.

21	12/10/2020	Mathew E. Jones	T&P Farms	Email	Subbasin Mapping	In regards to the 38 subbasins, how can we access the interactive mapping for these? How were they determined etc.*	https://app.box.com/s/c4xl3rj9tdsfpr4ailf91gnp5ta90tz8	Question	Byron Clark followed up directly with Mathew Jones
22	12/10/2020	Mathew E. Jones	T&P Farms	Email	Recharge	Recharge was touched upon in the public meeting. I did not see or hear discussion regarding banking of in-lieu or recharged water within the basin. I am sure it would be a minimal amount, but may think about using within the water budget. Is banking being addressed in the GSP? *	https://app.box.com/s/c4xl3rj9tdsfpr4ailf91gnp5ta90tz8	Question	Byron Clark followed up directly with Mathew Jones
23	12/10/2020	Antionette Marsh	N/A	Public Meeting	Groundwater Dependent Ecosystems	Was the map on groundwater exosystem also based on soil mapping? Based on the lines along the West side?		Question	Answer provided in 12/10 public meeting. See meeting summary for full response.
24	12/17/2020	Karen Biane	"Stakeholder" in the Glenn County subwatershed basin	Email	Outreach Approach	I have attached a memo outlining my commentary on specific areas about the presentations and plans. I am aware of the incredible complexity and challenges the planning and implementation of the program will involve. The ideas presented are designed to potentially improve the communications to, and understanding by, the water community. *	https://app.box.com/s/8gnkuuq4xnuznj5e13cjxv028xjlkdxa	General Input	
25	12/17/2020	Sharon Wiggin	N/A	Email	General Input	One of our concerns is on Sand Creek. 50 years ago, that Creek spread out very wide and we believe that gave us recharge for out underground runs very fast. We can't do anything about it because of the California Department of Fish and Wildlife. They will allow some low berms as long as one side has no berm. This isn't much help.		General Input	
26	1/12/2021	Mathew E. Jones	T&P Farms	Email	Management Areas	Wanted to follow up regarding "management areas". It is a tough discussion and should include laying out the facts regarding areas of concern. I vague statement regarding an area does not do anybody justice and leads to speculation and possibly inaccurate conclusions. The attached maps paint a clearer picture of "areas" of concern, but more importantly it emphasizes how our basin is interconnected and impacts of "areas" not within the "management areas"? I would also like to follow up regarding recharge and banking. I am trying to get an understanding of how it will play a roll in the GSP or if it will be addressed within the GSP.*	https://app.box.com/s/c4xl3rj9tdsfpr4ailf91gnp5ta90tz8	General Input

27	2/2/2021	Ben King	Land Owner	Email	Geographical Features	I believe that it is important to have the correct location of the Willows Fault regarding the proximity of the Fault to the City of Colusa. As you will see in the attached Figure 7 from the Sutter County GMP it looks like a wishbone like structure near the City with one fork trending south east away from the City on the east side of the Sacramento River and another fork on the west side of the River nearer to the City trending more in a north south direction... The reason I think it is important to get the best information on this fork in the Willows Fault is the potential for the movement of arsenic contamination along the Willows Fault from the desorption of arsenic from the metal and iron oxides in the volcanic rock of the Sutter Buttes. So far the public water supply for the City does not seem to be contaminated but the location of this fork may be problematic for the future risk profile. *	https://app.box.com/s/lan700issfbfqeis565rjz6caxrarzqj	General Input	
28	2/8/2021	Ben King	Land Owner	Email	Geographical Features	The location of the Willows Fault appears to have a fork north of the Colusa State Park and ironically appears to run under the Colusa County Courthouse. I have included three photos from the link. https://maps.conservation.ca.gov/cgs/fam/app/ I believe this is a different location than set out in the Geologic Figure in the HCM. It seems to be very close to the City of Princeton and the Colusa Rancheria. It actually runs through Colusa and towards Grimes and Meridian along Hwy 20. As I mentioned before I wanted to raise the issue of the Fault as the mechanism whereby the arsenic and seawater contamination from the Sutter Buttes may be translocating.*	https://app.box.com/s/k6l7gg1slg0qhv23gx343pafk3tx0o8j	General Input	
29	2/27/2021	Ben King	Land Owner	Email	Maps	I wanted to point out that there are two different versions of the Presentation for the 2/17/21 on the CGA Website*	https://app.box.com/s/s0wz3qrux0gvolnabxdkn97h9u4uloyd	Clarification	
30	2/28/2021	Ben King	Land Owner	Email	Water Quality	I was finally able to get access to Stephen Springhorn's paper on the Sutter Buttes Rampart.I want to make sure that Mr. Clark and Mr. Loy are aware of his recommendations and concerns as they draft the Basin Setting for the Colusa Basin especially in light of the work highlighted in a recent USGS Paper on arsenic contamination.*	https://app.box.com/s/fw2ie13mxvwqctb5zw9i0n29isg5wszx	General Input

31	4/8/2021	William Vanderwaal	RD 208	Email	Hydrographs	Jim Wallace, Derrick Strain, Lewis Bair, Hilary Reinhard and I looked through these last week and we had some questions. We really like and appreciate the Google Earth set up. There are two potential controlling factors that determine the MT. Please label which controlling feature it is that controls for each well. I see from a cursory look at the package for the upcoming meeting that you've included MO's but we noted on these there were not MO's. We would like to see the MT/MO compared with the historical well data. We requested and appreciate seeing these compared to the model runs but also want to see how they compare to actual historical. Some MT's seem extremely deep on the initial look. It would be helpful to also see the number of wells per polygon for each well. That would help us understand the magnitude of wells that could be impacted if the controlling feature is the 20% of domestic wells criteria. I've attached a screen shot of what Yolo has provided in the past that shows domestic well density as an example of what could be helpful. We have some questions about the water budgets (we were looking through those also). We noticed in CCWD, that the change in storage and the net recharge numbers don't seem to align with what we'd expect. For example, change in storage increases in 'Dry' years, but decreases in 'BN' and 'Critical' years. Also, net recharge is greater (or less extreme) in 'Dry' vs 'BN'. Is there any known explanation for that? Also, this doesn't just occur in CCWD, we're not picking on them, it's just where we noticed it first.*	https://app.box.com/s/jq7totuwt0sxxb9l1fu9ccinrlgbwnrj	Request	
32	3/20/2021	Ben King	Land Owner	Email	Subarea Water Budgets	Can I get a map of all the model subarea in the Colusa County portion of the Colusa Basin? Also – Does the example on Page 24 tie into real numbers? The numbers and graph on the left side of Page 24 seem different than the graphs on Page 20 for example? Could I get the data tables for Subareas CDMWC and COLGWE? Thanks for your assistance. *	https://app.box.com/s/phbj56zzpmzf0ife7zmnpdeb6arksi6d	Request

33	4/12/2021	Donald Bills	USGS	Email	Subsidence	A couple of points were made during the discussion on subsidence in the TAC meeting on Friday April 9th. I had comments to add to the discussion but was having difficulty with an unstable ZOOM connection and was unable to contribute. Please feel free to pass this on to however is most appropriate. The points I wanted to comment on are: 1.—Subsidence in the regional aquifer is mostly going to be due to dewatering of clays. Little subsidence occurs related to dewatering of sand and gravels. 2.—Subsidence is largely a surface problem. 3.—There is a significant lag time between groundwater withdrawals and subsidence. 4.—What is critical infrastructure? 5.—Surveyed subsidence monuments every 5 years is not enough. *	https://app.box.com/s/zmjnrgcy6lsfag9wrh7eoo7bc134swpw	General Input	
34	4/26/2021	Donald Bills	USGS	Email	Invasive Phreatophytes	As I was thinking about evasive phreatophytes that could result in a significant GW savings, eucalyptus occurred to me. They were imported to California from Australia as a source of wood for RR ties in the mid to late 1880's before anyone realized that the wood splits easily. Since then, they have become obliquitous in the state. The tree has an extensive root structure that is capable of reaching 50 ft or more to access groundwater. I was hesitant to suggest this during the meeting because I did not know if it had been addressed in the past, or who I should suggest it to for further consideration. As with my comments on land subsidence, if you could pass it on, or not, as appropriate.		General Input	
35	7/2/2021	Jim Wallace			Data	Not sure if your challenge getting transfer data from reclamation is intentional or not, but a clear and complete picture of the water dynamics affecting the basin is a fundamental requirement to successful management. We can't manage what we don't understand. So ultimately, the business of water transfers, both inside and outside the basin, has to be transparent and well understood by the CGA. Gathering that data directly from USBR(as opposed to trying to collect from 33 separate districts/agencies) seems the most efficient way to do this. Perhaps a conference call with USBR that includes some CGA staff or board member to inquire how the CGA might best organize a formal request to gather this this information would help your efforts. Ultimately, a FOIA request might be necessary, but hopefully, USBR staff will be responsive to a reasonable request for the information relevant to the CGA's responsibilities.		Suggestion	Responded to by email Wednesday, July 7, 2021 8:02 AM

36	7/2/2021	Jim Wallace			Baseline	I am not sure what kinds of practices or processes you have considered for capturing data and quantifying a recharge project, but establishing a baseline seems like it will be an important part of the process. A typical CDMWC shareholder, for example, uses a mix of well water and surface water in any given year. Once implemented should a recharge project consider all of the surface water diverted to be in-lieu recharge or only that portion in excess of some historical baseline diversion?		Question	Responded to by email Wednesday, July 7, 2021 8:02 AM
37	7/2/2021	Jim Wallace			Legal	I have read and re-read a few times the December 18, 2020 memo directed to the Vina GSA from its Administrator, Paul Gosselin, and Legal Counsel, Valerie Kincaid that was circulated during a recent CGA TAC meeting. Admittedly, there is much in this memo that I do not yet fully understand. But what is clear, is that recharge projects will potentially have legal implications that affect stakeholders across the sub-basin and that we (CGA) should consider these implications as part of our project development. I attached this memo here in case you have not yet seen it. I would be interested in a meeting with CGA counsel to review this memo (or perhaps a white paper of our counsels own origination) to better understand these issues and then discuss potential policies and priorities that CGA should consider to address these issues.		Request	Responded to by email Wednesday, July 7, 2021 8:02 AM
38	7/29/2021	Ben King	Land Owner	Public Meeting	PMAs	Ben King asks for clarification on process of approving PMAs. He also wants to know what it means when an action was recommended by the board. Response: This will be addressed in the next section of the presentation.		Question	Answer provided at the 7/29/2021 meeting. See comment section.
39	7/29/2021	Ben King	Land Owner	Public Meeting	PMAs	Ben King's question on the status of public approval and if the SMCs/PMAs been vetted through the TAC or had an approval process. Response: Presentations on the PMAs were presented to the Joint TAC along the way, but the full list of 33 PMAs were not formally approved by the TAC		Question	Answer provided at the 7/29/2021 meeting. See comment section.
40	7/29/2021	Ben King	N/A	Public Meeting	PMAs	Ben King would like to know who ranked the PMAs. Response: Lisa Hunter commented that they aren't ranked, but the top five are included because they are in process and ready to go. The ones that are in planning stage are in the next tier. Mary Fahey added that the PMA submittal process was very open and transparent and that projects are accepted on an ongoing basis. Ben King wanted there to be a TAC discussion for ranking, and including more PMAs possibly, as well as a process in place for adding and ranking them.		Question	Answer provided at the 7/29/2021 meeting. See comment section.

41	7/29/2021	Joe Carancho	N/A	Public Meeting	TAC	Joe Carancho wanted transparency in who is on the TAC committee and what decisions they are making. Response: Dave Ceppos responded that TAC members are listed on the websites. Thirteen TAC Meetings were held and publicly noticed, and the PMA list is available in the matrix within the PMA chapter.		General Input	Answer provided at the 7/29/2021 meeting. See comment section.
42	7/29/2021	Joe Carancho	N/A	Public Meeting	PMAs	Joe Carancho wanted more ideas for PMAs from local farmers and ranchers. Response: John Amaro let him know that people on the TAC and GSA Boards are local and any decisions the TAC makes have to be approved by the full board. This led to introductions of board and TAC members who were present to show they were local and involved in agriculture/local activities.		General Input	Answer provided at the 7/29/2021 meeting. See comment section.
43	7/29/2021	Darrin Williams	N/A	Public Meeting	MTs	Darrin Williams asks about the timing for MTs. Stating that there is a two-year period before we reach an UR. He asks when the two-year period starts – is it on January 31, 2022 or has it already started? Response: Grant Davids and Ken Loy clarified that the two-year period would only start when 25% of the wells get below the MT. Darrin Williams is concerned that some MTs for some of the wells may be something we will reach too quickly.		Question	Answer provided at the 7/29/2021 meeting. See comment section.
44	7/29/2021	Lester Messina	N/A	Public Meeting	Slide 16	Lester Messina asks a question about the hydrograph on Slide 16. Are there any wells in the monitoring network that stopped being monitored in the 2015 drought, and will they be monitored in 2022? Response: Ken Loy said there are one or two wells in the current monitoring network that have not had recent measurements and he is not sure why. They will be reviewed		Question	Answer provided at the 7/29/2021 meeting. See comment section.
45	7/29/2021	Sharon Ellis	Land Owner	Public Meeting	Well Monitoring Network	Sharon Ellis asks who is responsible for monitoring the 48 wells in the Monitoring network. Response: Ken Loy responded that the GSAs are making use of existing monitoring wells and DWR currently does the monitoring.		Question	Answer provided at the 7/29/2021 meeting. See comment section.
46	7/29/2021	Sharon Ellis	Land Owner	Public Meeting	Undesirable Results	**Sharon Ellis** asks who is in charge of alerting DWR if we are experiencing UR, is it the County? Response: Ken Loy responded that the Groundwater Authorities will take the monitoring data and prepare annual and 5-year reports to DWR.		Question	Answer provided at the 7/29/2021 meeting. See comment section.

47	7/29/2021	Sharon Ellis	Land Owner	Public Meeting	Dry Wells	Sharon Ellis expresses concern over dry wells on her property and drying of Stony Creek. She asks who to notify or who will address these concerns. She and Emil Cavagnolo discuss why people chose to use groundwater instead of surface water in a dry year. There is then a discussion of GSAs and the fact that they are the regulatory agency that has authority to take action. Sharon is implying that locally we are already experiencing UR.		General Input	Answer provided at the 7/29/2021 meeting. See comment section.
48	7/29/2021	Joe Carancho	N/A	Public Meeting	General Input	Joe Carancho mentions that farmers shouldn't be told how to farm. John Amaro comments that we have a fine line to walk to work locally to keep the management local.		General Input	Answer provided at the 7/29/2021 meeting. See comment section.
49	7/29/2021	Member of the Public	N/A	Public Meeting	GSP	Unknown person asks if we have to wait for the GSP to pass before taking action and moving forward with actions. He also asks who will police actions that will be needed if we fall below MTs. Does GSA have authority to place usage restrictions, etc.? Response: Darrin Williams responded that there can be self-regulation through the GSA and there should be regulation before MTs are reached. The goal is to operate at the MO. "SGMA has very few 'shalls', and very many 'mays'".		Question	Answer provided at the 7/29/2021 meeting. See comment section.
50	7/29/2021	Ben King	Land Owner	Public Meeting	General Input	Ben King mentions that the PMA section needs to be scrutinized as the Demand Management PMA will affect income and jobs in Colusa and Glenn County. He mentions the tomato subsidy to manage land and therefore use less water. Response: Grant Davids responded that there are 2 demand management actions in the Plan, but they are not preferred. In the end, it is one of the tools in the tool box that the GSAs can pull from as situations warrant actions. Just because it is in the toolbox does not mean it will be used. Discussion followed that Demand Management isn't the first choice for our area.		General Input	Answer provided at the 7/29/2021 meeting. See comment section.
51	7/29/2021	Member of the Public	N/A	Public Meeting	Surface Water Use	**Unknown person** addressed Emil Cavagnolo and asks if the GSAs have the power to have people use surface water to the extent its available before pumping? And can the price of the water be subsidized? Response: **Emil Cavagnolo** mentions that his district already works to lower surface water costs and make it more enticing to use it first. Discussion follows that surface water absolutely has to be used first to allow for recharge along with additional recharge projects. It was answered that a GSA can build incentive programs into it to encourage surface water, and use all available surface water.		Question	Answer provided at the 7/29/2021 meeting. See comment section.

52	7/29/2021	Member of the Public	N/A	Public Meeting	Surface Water Cost	Unknown person asked how to reduce surface water costs? And how to keep discrepancies between districts low? Emil Cavagnolo offers an explanation of where Orland-Artois Water District comes from and how expensive transferred water is, as well as how different districts have access to different water.		Question	Answer provided at the 7/29/2021 meeting. See comment section.
53	7/29/2021	Sharon Ellis	Land Owner	Public Meeting	Undesirable Results	Sharon Ellis asks to address her original question. If we get significant UR who is responsible? Response: Ken Loy described how a landowner would want to communicate with your GSA board member and they would make sure DWR has the most up to date data. Emil Cavagnolo pointed out that there is a monitoring well near Sharon's house and she can see that data.		Question	Answer provided at the 7/29/2021 meeting. See comment section.
54	7/29/2021	Ben King	Land Owner	Public Meeting	Recharge	**Ben King** asks if the board would consider giving incentives for people participating in recharge.		Question	N/A
55	7/29/2021	Darrin Williams	N/A	Public Meeting	General Input	Darrin Williams comments that he is happy to see new people at the meeting. We are really fortunate that we are in this subbasin and that we have had dry years since 2015 but aren't terribly bad off. He is positive about the projects on the horizon and the future. He states that using 100% of available surface water needs to be at the top of the list to protect groundwater.		Comment	Answer provided at the 7/28/2021 meeting. See comment section.
56	7/28/2021	Pete Carr		Virtual Public Meeting	Table 5.1	Pete Carr noted that Chapter five describes the methodology of how those minimum thresholds are established, but the practical result then as illustrated by the sample monitoring well hydro graph in figure five dash one shows that well levels can at least this well, I will could get all the way down to 208 feet before it exceeds the minimum threshold, so that would suggest unless i'm misunderstanding this that a domestic well or municipal well that's a 200 feet is still acceptable and not considered unreasonable, in other words, I mean 200 feet would run most domestic wells and half of our municipal wells dry and yet that's not exceeding the threshold I don't understand how that could be. Response: Ken Loy responded that the minimum thresholds are not like the example that we showed that's just for that specific well. Each one of the 48 representative monitoring network wells has its own on site specific minimum threshold and measurable objective.		Question	Answer provided at the 7/28/2021 meeting. See comment section.

57	7/28/2021	Member of the Public		Virtual Public Meeting		In the PMA you have a couple of these that are predicated on having an available surface water, and it was even brought into the equation that you have it tough to have the economics for the surface water. is maybe, as are more affordable than the groundwater and so when you bring this into the equation, knowing that it's outside of the base and where those economics are established i'm just wondering how that works. Response: Grant Davids responded that there are some entities with surplus water at times. Under the settlement contracts and some surplus project water and philosophically they might be predisposed to keeping that water in the sub basin for for local benefit rather than letting it go out but. Others, maybe not so much. I can't tell you how it's going to play out, but I think it comes down to negotiation and it depends kind of on the philosophy of the folks with the available surface water. Jeff Sutton added that project water held by the settlement contractors is only available for sale pursuant to section 3405 within the area of origin, so that water is not available to be sold outside of basin.		Question	Answer provided at the 7/28/2021 meeting. See comment section.
58	7/28/2021	H Brich		Virtual Public Meeting		H. Birch asked in the chat: You mentioned groundwater's impact on ecosystems, but can we say more specifically that groundwater is impacting forests, and that (lack of) groundwater is a contributing cause to the increased numbers and intensity of fires in CA? Response: Ken Loy responded that forests are not in the bounds of the ground water basin and to the extent that there are plants that are groundwater dependent that is something that we do look at, and we look at the routing depth of those plants that are generally along the riparian corridors of the sacramento river and other streams in the groundwater basin not up in the foothills that are you know up in the in the Highlands that are part of the counties that's those areas are not part of of the groundwater basin as defined by the Sigma regulations.		Question	Answer provided at the 7/28/2021 meeting. See comment section.

59	7/28/2021	Scott Bradford		Virtual Public Meeting		Scott asked in the chat: Please briefly discuss the water balance. What are the present values of groundwater outputs to inputs? How long will the proposed recharge projects take to bring groundwater into balance? Will recharge projects have adverse impacts on groundwater quality? Response: Grant Davids responded You know the the system is going to be fairly well unbalanced, meaning that there's no large negative or positive change in groundwater storage. 01:40:35So that's what we think about the future, you know, in the near term or in the present we've got and looking backward in time we've got. 01:40:43Obviously, declining groundwater levels in a couple of areas within the sub base and even more generally throughout the seven days in which we feel is primarily a consequence of drought. 01:40:54And then the extension of that would be that you know if drought debates and we get some good water years back on the books that the groundwater levels would recover.		Question	Answer provided at the 7/28/2021 meeting. See comment section.
60	7/28/2021	Arne Gustafson		Virtual Public Meeting		It sounds as if the management of issues that arise but don't yet meet the standards of Undesirable Results is critical to the success of SGMA. Can you speak a little more specifically to how those activities will be addressed? Response: Grant Davids responded that how you balance that and where you begin to take action, all depends on decision making and policies at the board level and let them know what you think.		Question	Answer provided at the 7/28/2021 meeting. See comment section.
61	7/28/2021	Pete Carr		Virtual Public Meeting		Pete asked in the chat: Plan is based on an assumption of 26-140 maf of underground aquifer volume, and that this has only been depleted 5% in recent years. How confident are we that at least 26 maf actually exists? How stable and reliable is this data? Response: Ken Loy responded the best place to go for the that water budget information is in chapter three of the groundwater sustainability, where the plan authors talk about the water budget which is really a flux, it changes its water moving through the system it's not a static number.		Question	Answer provided at the 7/28/2021 meeting. See comment section.
62	7/28/2021	Pete Carr		Virtual Public Meeting		Pete asked in the chat: 1/2 foot per year of subsidence may be acceptable out in the county, but even a couple of inches in a year could/would be devastating to municipal services like sewer, water and storm drainage underground infrastructure. How can subsidence of up to 1/2 foot / year be considered not significant or unreasonable enough to trigger action? Response: Ken Loy responded that in Chapter Chapter three you'll see that there is very little subsidence up in the Orland area, if that were to change, then that would be the whole adaptive management part of this, then the the GSA would be looking for the local feedback on on what's going on in that area and then what's the right thing to do to mitigate it.		Question	Answer provided at the 7/28/2021 meeting. See comment section.

63	7/28/2021	H Brich		Virtual Public Meeting		H Brich asked in the chat: Re Slide 24: you said it was dependent upon how many farmers sign up for the (Sacramento River?) program. How do farmers find out about what programs are available to them to participate in? We have a farm manager and several owners. Response: Lisa Hunter responded that you should email either LHunter@countyofglenn.net or mfahey@countyofcolusa.com and sign up for the interested parties list.		Question	Answer provided at the 7/28/2021 meeting. See comment section.
64	7/28/2021	H Brich		Virtual Public Meeting		H Brich asked in the chat: Re: Slide 17, how does the groundwater become electrically conducting when it is "degraded"? Is it full of metal contaminants? Response: Ken Loy responded that the Groundwater does become more electrically conducted as the salinity goes up and we want to pay attention to that, but it doesn't mean that it's full of metal contaminants you could have high conductivity and and low metal contaminants or vice versa, you could have low electrical conductivity and high metal contaminants you can't correlate one with the other necessarily.		Question	Answer provided at the 7/28/2021 meeting. See comment section.
65	10/13/2021	Shelly Morris		Virtual Public Meeting		What does "state intervention" include if "undesirable results"? Response: Ken Loy responded the State Water Resources Control Board can take over management and levy fines and fees.		Question	Answer provided at the 10/13/2021 meeting. See comment section.
66	10/13/2021	Erik Kolderup		Virtual Public Meeting		Is there precedent for the DWR not accepting the minimum thresholds established by local authorities? Are they likely to accept this plan? Response: Grant Davids responded of the four plans submitted so far 2 were not accepted. Pat Vellines recommended checking DWR website as the next round of GSP approvals will be out soon. Mary Fahey added that		Question	Answer provided at the 10/13/2021 meeting. See comment section.
67	10/13/2021	John Monroe		Virtual Public Meeting		How is this Sites project, which is in this subbasin taken into account, is it considered to be a PMA? Response: Grant Davids responded I believe it is a potential source of water for in lieu recharge. In ieu recharge is when you have got groundwater pumping going on, and you can deliver surface water, instead of pumping the groundwater.		Question	Answer provided at the 10/13/2021 meeting. See comment section.
68	10/13/2021	Anonymous		Virtual Public Meeting		One of the PMAs was ground water extraction fees. How would those fees be set and how frequently could those fees be increased. Response: Grant Davids responded that will be decided by the GSA once the GSP is adopted.		Question	Answer provided at the 10/13/2021 meeting. See comment section.
69	10/15/2021	Del Raymond		In-Person Public Meeting		Would be better to work to keep surface water in the area. Surface water users should not pay as much as ground water pumpers. Response: Grant Davids responded that the GSA will decide fees that it outside the scope of this plan.		Comment	Answer provided at the 10/15/2021 meeting. See comment section.
70	10/15/2021	Reimers		In-Person Public Meeting		Plan is to technical for average person to understand. Written so only an expert can understand. Trees are dying for lack of water. Only allowed to irrigate every 21 days instead of 14 days.		Comment	
71	10/15/2021	Anonymous		In-Person Public Meeting		Willing to pay an assessment to keep the GSA running but not to pay for projects to solve problems that I did not cause.		Comment	
72	10/15/2021	Ben King		In-Person Public Meeting		SIGMA regulations are a trojan horse. This is a way to turn our subbasin into a Sacramento water market.		Comment	

Colusa Subbasin Groundwater Sustainability Plan
Development Outreach Comment Tracking Table - General Input

73	10/15/2021	Ben King		In-Person Public Meeting		Request that the bylaws from the GSA require proof of residency to be on the board.		Comment	
74	10/15/2021	Anonymous		In-Person Public Meeting		When will the PMAs be reviewed? Response: Lisa Hunter responded that they have been reviewed by the TAC.		Question	Answer provided at the 10/15/2021 meeting. See comment section.
75	11/1/2021	Mary Fahey	CGA	Email	PMAs	Regarding the South Valley Water Resources project, the comment is that this project should be removed because it includes sending water out of the basin to the San Joaquin Valley		Comment	
76	11/1/2021	Mary Fahey	CGA	Email	PMAs	Regarding the Glenn-Colusa Irrigation District (GCID) Water Transfers to TCCA CVP Contractors – The comment on this project proposal is to update it to include all Settlement Contractors since there are many that transfer to the TCCA.		Suggestion	
77	10/30/2021	Ben King		Email		As discussed over the last couple of days the GSP Maps and Budget Subareas need to be adjusted to include the correct boundary and surface water delivery area for the CDMWC. The CDMWC delivery area on the west side of the Colusa Basin Drain south of Hahn Road needs to be included in the CDMWC Budget Subarea in Figure 3-6. Likewise the boundary for the CDMWC has to be adjusted throughout the GSP Maps in Chapter 2 and elsewhere.		Suggestion	
78	10/25/21	Holly Dawley	GCID	Letter		We ask that as GSAs move from planning to implementation and continue to look for opportunities to leverage surface water over groundwater, you consider those members and partners with senior water rights and stable contracts that contribute to our shared aquifers and provide high quality environmental habitat. We look forward to better identifying and quantifying this benefit for the subbasins during implementation. Further, we ask that GSAs work with their County partners to consider land use planning and accountability.		Request	
79		Ashley Driver	Driver Performance Improvement	Email		Was follow-up information provided on how the groundwater pumping fees will be calculated? Response: Mary Fahey responded there have been no decisions regarding a pumping fee. Those discussions will start happening early next year. It is still to be determined how/if fees will be instated. Those discussions and decisions will happen at public GSA Board meetings. There may be other subcommittee meetings where recommendations for the Boards will be developed.		Question	Response included with comment.

80	11/4/2021	Ashley Driver	Driver Performance Improvement	Email		Also, how easy is it to adjust our compliance markers (e.g. minimum thresholds)? Is there a formal process, is the public included, and does the state have to approve changes? Response: Mary Fahey responded The GSAs are required to report annually on their progress and to update the Plans every five years. They can adjust the Sustainable Management Criteria during these updates. Any adjustments will need to be justified to DWR with data and reasoning, and DWR will have to approve any changes. It will be a public process, likely similar to what has been done the last couple years with information coming to the Technical Advisory Committees at public meetings and then to the Boards at their public meetings for final decisions.		Question	Response included with comment.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
1	Emil Cavagnolo	GGA/OAWD	2	2.1.2	2-4			Monroeville is a Groundwater District	Comment acknowledged. Monroeville is a water district formed to give its landowners (groundwater pumpers) a voice during the SGMA process. Table 2-2 contains municipal public potable water suppliers while Table 2-3 contains ag or other non-municipal water suppliers. Monroeville WD falls into the latter category and is included in Table 2-3.
2	Emil Cavagnolo	GGA/OAWD	2				2-3	OAWD's service area is currently just under 30,000 acres	Comment addressed in the GSP section indicated.
3	Emil Cavagnolo	GGA/OAWD	2	2.2.1.1	2-16	4		OAWD's latest WMP I 2020	Comment addressed. The 2020 WMP was used.
4	Emil Cavagnolo	GGA/OAWD	2	2.5.1.2	2-29	1		Colusa Subbasin now Chowchilla	Comment addressed in the GSP section indicated.
5	Emil Cavagnolo	GGA/OAWD	2	2.5.1.3	2-32	5		The public meeting in Orland was at the Glenn County Fairgrounds	Comment acknowledged. There was no meeting held at the fairgrounds, to our knowledge.
6	Emil Cavagnolo	GGA/OAWD	2	2.5.1.3	2-33	6		I do not remember this type of meeting in Glenn County	Comment acknowledged.
7	Emil Cavagnolo	GGA/OAWD	3	3.3.3.3	3-83	last		Agricultural Water Demand is a heading and should be Bold Print	Comment addressed in the GSP section indicated.
8	Leslie Nerli	GGA Board	2	2.1.2	Plan Area	1	2	The obvious and probably already corrected is….primary urban….Colusa & William in Glenn Co…wrongly printed for both counties	Comment addressed in the GSP section indicated.
9	Leslie Nerli	GGA Board	2	2.4	23		3	Water purveyors along TC Canal Re: 0%-100% depending on available water - truly dependent on what Bureau feels to allow each year and is announced very early in year.	Comment acknowledged. The text has been updated to reflect the agency responsible for the allocation volume.
10	Leslie Nerli	GGA Board			32			Areas of sustainability concerns: Glide Water District Please see attached MAP of what I believe to be an excellent area of land to recharge. First off, the land owner of the property has changed hands from Pete Galaya to: RD 45 , LLC , 1380 East Ave, Ste 124, Chico, CA, Parcel number 020-240-0140 There is 41.5 acres of Glide water district in the block of Habitat. Not sure what plain ole Habitat is but definitely good percolation in this area. Of course this is a statement made only by experience and not as a geologist/hydrologist which would have to be confirmed by science. A rice farmer to the west of the proposed property for recharge used almost 10 acre feet one year for his crop. Again, the cost of water and other crop costs combined with returns have forced this farmer to sell part of his land using the sale of his land from many generations in his family to develop orchards so that he can keep some of the remaining 4rth or 5th generation family farm. From what I was told by Mike Alves regarding there are 41.5 acres of glide district land within the 300+/- acres of Habitat. When available from the Bureau, water can be surface water that can be purchased at each year's allocation rate for the only the 41.5, but not more than the allocation for each year. In addition to the glide surface water yearly allocation, any Bureau excess flow water could be captured in the 41.5 acres and remaining property acres as well. So using the Glide	Comment acknowledged. This would make a great addition to the list of "potential PMAs" in Section 6.5 of the GSP, and will be considered for inclusion in the GSP. We also invite everyone to submit suggestions for PMAs through the Colusa Subbasin PMA Submittals portal: https://colusagroundwater.org/projects-and-management-actions-submittals/.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
11	Leslie Nerli	GGA Board			32			in "excess flows available" Of course, they still charge a fee and Glide a fee as well, but usually at a more reasonable price. Because this property lies between the 2 creeks, it does flood during wet years. So, maybe some improvements could be made to capture more of the flood water that flows so quickly away and allow for more time to capture excess flood water to our groundwater storage. Maybe it will be so simple and cost effective as placing Check damns? and/or doesn't need them just some drainage management. I do not know who the RD 45 LLc people are or if they would even consider working with the ground water recharge project. Even to the north of Wilson Creek is land in the habitat. It is a very large piece of property. 300 +/- acres.	Please see the response to comment 10.
12	Mary Fahey	CGA	1	Cover Page	Cover Page	N/A	N/A	1. Title: Change to Colusa Subbasin Groundwater Sustainability Plan. 2.Add logo to page 3.Under "Prepared for", change Colusa GSA and Glenn GSA to: Colusa Groundwater Authority and Glenn Groundwater Authority 4.Make these same changes on the second page	Comment addressed in the GSP section indicated.
13	Mary Fahey	CGA	All Chapters	Entire Document – footer				Change footer to read: Colusa Groundwater Authority and Glenn Groundwater Authority Colusa Subbasin Groundwater Sustainability Plan	Comment addressed in the GSP section indicated.
14	Mary Fahey	CGA	1	1.3.1	1-3	1		Please specify that there are **two** Private Pumper Representatives from the Colusa County Groundwater Commission, **appointed by the Colusa County Board of Supervisors**	Comment addressed in the GSP section indicated.
15	Mary Fahey	CGA	1	1.3.1	1-3	4		Second Sentence, please edit as follows: **Except for the Private Pumper representatives**, Board members are chosen in public meetings by the respective governing boards of the Member Agencies…. **Private Pumper representatives on the CGA Board are recommended by the Colusa County Groundwater Commission and appointed by the Colusa County Board of Supervisors**.	Comment addressed in the GSP section indicated.
16	Mary Fahey	CGA	2	2.1.1	2-1	4		Glenn and Yolo County boundary should be **Colusa** and Yolo County boundary	Comment addressed. The GSP has also been revised to include the new RD 1004 subbasin boundary line.
17	Mary Fahey	CGA	2	2.1.2	2-4	1		Fourth line – Change water pumpers to groundwater pumpers: …and two appointed private groundwater pumpers…	Comment addressed in the GSP section indicated.
18	Mary Fahey	CGA	2	2.1.2	2-4	2		Orland and Willows are in Glenn County. Colusa and Williams are in Colusa County.	Comment addressed in the GSP section indicated.
19	Mary Fahey	CGA	2		2-4		Table 2-2	Grimes water district should be: Colusa County waterworks district #1 – Grimes Also in Colusa County: Colusa County waterworks district #2 - Princeton	Comment addressed. Colusa County Waterworks Districts for Grimes and Princeton have been added to Table 2-2. Del Oro Black Butte District was also added.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
20	Mary Fahey	CGA	2				Fig. 2-3	The map is titled Colusa Subbasin GSA Member Agencies but does not show/list Colusa County or Glenn County Under Note 1: There are two private pumpers from the Colusa County Groundwater Commission on the CGA Board There are no private pumpers on the GGA Board	Comment addressed. Edits were made to the note section that Colusa and Glenn Counties are member agencies but are not shown on the map.
21	Mary Fahey	CGA	2	2.2.1.1	2-15	6		(NSV IRWM) last sentence, add year that the update was adopted. In March, 2021….	Comment addressed in the GSP section indicated.
22	Mary Fahey	CGA	2	2.2.1.1	2-18	2		Second bullet states "The following GSAs have readily available MSRs:" Don't you mean "The following GSA Member agencies…"?	Comment addressed in the GSP section indicated.
23	Mary Fahey	CGA	2	2.2.1.2	2-19	1		I believe CCWD has a SCADA system. There may be other districts as well that are not listed.	Comment acknowledged. USBR funded the project in 2014.
24	Mary Fahey	CGA	3	3.1.7.3.1	3-32	5		Faults: Second to last sentence, Zamora Fault should be listed along with the others that were analyzed.	Comment addressed in the GSP section indicated.
25	Mary Fahey	CGA	3	3.1.10.2	3-42	1		Primary Users, first sentence – can this be re-worded. It sounds like there are only 20 Stakeholders in the basin.	Comment addressed. The text was changed to include the total count of water service agencies within the Colusa Subbasin based on DWR's GIS dataset.
26	Mary Fahey	CGA	3	3.1.11.2.3	3-45	2		– The TNC project is better described as an on-farm multi-benefit managed aquifer recharge and shorebird habitat program. Where it says migratory birds, please specify migratory shorebirds.	Comment addressed. The section title has been changed as suggested.
27	Mary Fahey	CGA	3				3-19	Water source layer missing for Colusa County portion	Comment acknowledged. Water source was not surveyed for water use by DWR in Colusa County during the displayed survey year. Land and water use surveys are constantly being conducted, so more recent information will be included in GSP annual reports and/or periodic GSP evaluations and updates.
28	Mary Fahey	CGA	4	4.1	4-1	1+		Should monitoring for GDEs be mentioned in the discussion about the monitoring networks?	Comment acknowledged. GDEs have been included in the write up as part of the stream-aquifer monitoring.
29	Mary Fahey	CGA	4	4.2.2.2	4-4	1		Will this section be expanded to include more details?	Comment addressed. The monitoring protocols now include protocols that are used by the GSAs.
30	Mary Fahey	CGA	4	4.2.3.3	4-17	1		Suggest spelling out Irrigated Lands Regulatory Program (ILRP) in first sentence	Comment addressed in the GSP section indicated.
31	Mary Fahey	CGA	4					General chapter 4 comment: This Chapter will need to be updated based on recent activities/discussions/decisions, especially regarding monitoring and filling data gaps for stream interactions and GDEs. Also, information about the coordination efforts taking place along basin boundaries between the neighboring subbasin GSAs should be expanded. Overall, this chapter reads light on describing the Colusa Subbasin monitoring network and heavy on listing excerpts from the regulations.	Comment addressed. We have included a section on the representative monitoring networks for groundwater levels and stream-aquifer interaction, of which the latter includes monitoring for surface water depletions and impacts to GDEs. All monitoring protocol sections have been revised to include more information regarding protocols used by the monitoring agencies and not just the requirements listed under SGMA regulations. The requirements listed in the BMPs have been summarized instead of comprehensively listed.
32	Evan Markey/Michael Bolzowski	GGA/Cal Water	2	2.1.2.1	8	4	-	The plan states Willows used 1.6 MGD. Our records show and average of 1.2 MGD for the same time.	Comment addressed. This typo has been corrected. The volume listed in Table 2-2 also equates 1.2 MGD (1,044 AFY = 1.16 MGD).

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
33	Evan Markey/Michael Bolzowski	GGA/Cal Water	Appendix	2.7.3	121	-	2-4	Table shows Willows average per capita as 231 Gallons per Capita Per Day from 1990 to 2015. Our current average 2015 to 2020 is much lower, 143 Gallons per Capita Per Day. The model maybe overestimating our demands for the basin.	Comment acknowledged. The C2VSimFG-Colusa model inputs and results are finalized for GSP development. This and other concerns would be addressed in future revisions of the model, and incorporated into GSP annual reports and/or periodic GSP evaluations and updates.
34	Lester Messina	Colusa Glenn Subwatershed Program (SVWQC)	2	2.2.1.2	2-20	2		Recommended Change: Irrigated Lands Regulatory Program The Central Valley Regional Water Quality Control Board (CVRWQB) has adopted waste discharge requirements (WDRs) for discharges from irrigated commercial croplands to protect both surface water and groundwater supplies. When land is in agricultural production it is irrigated and fertilized. It is assumed that portions of the soil amendments, particularly fertilizer, is converted to nitrate which has the potential to percolate into groundwater The ILRP regulates such discharges, growers can minimize the percolation of nitrate to groundwater through the implementation of effective management practices. Commercial irrigated lands, including managed wetlands are required to obtain regulatory coverage.	Comment addressed in the GSP section indicated.
35	Ben King	Land Owner	2	2.1.1				How were the vertical boundaries of the annexed area of the previous West Butte Subbasin determined since the HCM did not cover this area during previous data collection?	Comment acknowledged. The 2016 preliminary hydrogeologic investigation included the entire groundwater aquifer system within Colusa and Glenn Counties, including the portions of the previous West Butte Subbasin and current existing Corning Subbasin. Vertical boundaries of subbasin were defined using the same information regarding depths to relatively impermeable geologic formations, interpretation of geologic formations, and the estimated freshwater-brackish water interface.
36	Ben King	Land Owner	2	2.1.1				The lateral extent is not bounded by the Sacramento River to the east but it is bounded by the western boundary of RD 1004.	Comment addressed in the GSP section indicated.
37	Ben King	Land Owner	2	2.1.2.1				How many wells and what is the volume for Del Oro Arbuckle?	Comment addressed. There are two wells, the second well was installed and operational in October 2015. The average annual volume in 2016-2020 was 48.35 AFY.
38	Ben King	Land Owner	2	2.3				Why is Colusa Drain Mutual Water Company only on the map in Yolo County? All of Colusa County CDMWC is missing from the Map.	Comment acknowledged. Our understanding is that CDMWC/CDWUA has a shared service area with many other water districts and agencies. CDMWC/CDWUA was included on the map, but was drawn "underneath" the other agency boundaries. Figures 2-3 and 2-4 have been revised to better identify the CDMWC/CDWUA service area in those shared locations. Figure 2-3 has been revised to show the CDMWC everywhere that it exists.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
39	Ben King	Land Owner	2		2-9		Table 2-3	There are no entries for Surface Water Supply or Volume Descriptions for CDMWC or RD479. If there is some valid reason for the omission it should be explained in a footnote rather than just omitted.	Comment addressed. Surface water supply available to CDMWC is variable and consists of the Colusa Drain and its tributaries. The major water source available during the irrigation season is return flow or drainage water from districts in the northern part of the Colusa Basin that divert water from the Sacramento River and discharge their return water to the Colusa Drain. RD 479 conveys drain water and relies on the RD 2047 to convey drainage water to the Sacramento River.
40	Ben King	Land Owner	2	2.8	2-21		Table 2-6	Relating to Table 2-3 above there are no diversions cited for Model Input as Diversions attributable to CDMWC acreage. What is the impact of this omission?	Comment acknowledged. Please refer to Figure 3-6 and Table 3-2.
41	Ben King	Land Owner	2		2-21		Table 2-6	The USEPA SDWIS system reports violations and maintains a log of monitoring events. This monitoring data and time line of violations does not seem accessible on the Waterboards site. The EPA link should be included. Why isn't the Drinking Water Open Data Portal referenced as it is in 2.6?	Comment addressed. The EPA SDWIS website has been added to the list as another resource. The California Open Data Portal has also been added to Table 2-6. These different websites contain slightly different, but also duplicate information regarding public drinking water supply requirements and monitoring information.
42	Ben King	Land Owner	2		2-21			The CV Salt information is not online? How do stakeholders access this data. Where can Stakeholders access GAMA data? Where is the Sacramento Valley Water Coalition Data? Where is the groundwater quality data relating to wells used for groundwater substitution accessible? It is part of the Appendix of the Environmental Assessment for Tehama-Colusa Canal Authority In-Basin Water Transfers.	Comment acknowledged and addressed. Stakeholders can obtain data from programs that do not post data online by contacting the responsible agency and requesting the data. In some cases, data from these programs are available on other data repositories, such as USGS or GeoTracker websites. In the case of the SVWQC, data is available via GeoTracker GAMA and from Luhdorff & Scalmanini, their monitoring entity. Websites to the individual programs, through which contact information for all of the agencies and coalitions participating in those programs can be accessed, were added to Table 2-6. Groundwater quality data relating to wells used for groundwater substitution is not currently included in the groundwater monitoring network, other than those wells that are part of other existing monitoring programs. For example, the environmental assessment for the Tehama-Colusa Canal Authority In-Basin Water Transfer Initial Study evaluated groundwater from wells included in the GAMA program, which is already listed in Table 2-6.
43	Ben King	Land Owner	2					According to the City of Colusa Policy PRC –9.2-The City will prepare a Water Resources bi-annual report to the City Council. The Public Works Department will analyze the quality of drinking water in the City. The description of the General Plan is incomplete because it does not mention that water quality is addressed and included in this bi-annual report to the City Council for the City of Colusa.	Comment addressed. Table 3 of Appendix 2A has been reworded to clarify this statement.
44	Ben King	Land Owner	2					The Human Right to Fresh Water should be addressed somewhere in 2.3 or 2.4. Ultimately this will affect the priority of beneficial use, management actions and minimum thresholds to comply with the requirements of this Law.	Comment addressed. Section 2.4, Additional GSP Elements, and Section 2.2.1.3, Groundwater Monitoring and Management, now include references to Water Code Section 106.3 text and related actions taken by the GSAs.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
45	Ben King	Land Owner	2		2-30			Don't understand the reference to Human Right to Water as described. Doesn't this Right apply to all residents in the Colusa Subbasin and all water systems?	Comment acknowledged. The stakeholders listed in Table 2-8 are just a shortlist of sample stakeholders, not a comprehensive list of all stakeholders that apply to that category of interest. The stakeholders listed in Table 2-8 for the "Human Right to Water" topic are those that are most vulnerable to losing access to clean drinking water.
46	Ben King	Land Owner	Table 3-1					What change in Data Sources were used to incorporate the annexed area from the West Butte Basin? What sources were used for Geochemistry and water quality?	Comments acknowledged and addressed. The Colusa Subbasin boundary was revised along its eastern edge to follow the Sacramento River or the western boundary of RD 1004. Basin boundary modifications were redrawn in coordination with CGA and RD 1004 staff and submitted to DWR for approval. A previous basin boundary modification had the eastern edge of the Colusa Subbasin follow the county boundary, regardless of whether it was east of the Sacramento River or not. Digital data sources for mapping the water chemistry have been added to Table 3-1. Table 3-1 is not a full list of all data and information sources, please refer to Chapter 8 References, Chapter 3.2 Groundwater Conditions, and Chapters 2 and 4 for more information regarding the different sources of water quality data and informative reports that were downloaded and used.
47	Ben King	Land Owner	3.1.5		3-7			The Hydrology of the Colusa Subbasin is also influenced by the Geochemistry and underlying Faults. Since the Subbasin water quality is influence by the volcanic rock of the Sutter Buttes and influences from the marine and lacustrine geologic history of the Subbasin – can Hydrology be determined without Geochemistry? Faults are known to influence Geochemistry and water quality since there may be anoxic water upwelling and lateral movement of naturally occurring contaminants via faults like the Willows Fault.	Comment acknowledged. Section 3.1.5 only discusses physical surface hydrology, specifically, surface waters that exist within the Subbasin. The section introduction has been revised to include a statement regarding water chemistry and refers the reader to the groundwater quality discussion sections found later in the chapter.
48	Ben King	Land Owner	3.1.5		3-11		Figure 3-6	Why is part of the CDMWC delivery area included in ColGGWS? The CDMWC on the west side of Colusa Basin Drain south of Hahn Road receives surface water deliveries as the rest of the CDMWC. There are CDMWC subarea components on multiple sides of this area but for some reason this jurisdictional area of the CDMWC is treated differently. This area is also part of the flood zone and receives significant seepage during seasonal winter flows.	Comment acknowledged. The subareas labeled in Figure 3-6 are collections of C2VSimFG-Colusa model elements that approximately represent water supplier service areas based on GIS mapping. CDMWC has a discontinuous service area along the Colusa Drain, and so is represented by several model subareas. The representation of water supplier service areas is limited by the spatial resolution of model elements. Service areas were modeled to capture the best representation of the service area alignment possible, while also simulating a total acreage that is closest to the actual acreage of that service area.
49	Ben King	Land Owner			3-16		Table 3-2	What assumptions are included in Model Diversion ID 113? As mentioned above a portion withing the jurisdictional boundaries of the CDMWC and a CDMWC surface water delivery area is left out of the CDMWC budget subarea.	Please see the response to comment 48. Per Table 3-6, the diversion records (input files) that came with DWR's C2VSimFG Beta2 model were used without adjustment for this diversion in the C2VSimFG-Colusa model.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
50	Ben King	Land Owner	3.1.7				3-3	See Springhorn Page 22 – Table 2.1 and Page 93 Table 3.3, Need to incorporate Turlock Lake Lacustrine influence to document Corcoran like clay components to the Lithology and also need to incorporate the formation of the Sutter Buttes Rampart and Geomorphic influence of the Sutter Buttes volcanic structure. Both Springhorn and Harwood and Helly differentiate the lithology of the Pliocene and Pleistocene periods this way. Water quality and subsidence issues are related to this geologic history. Figure 3-10 is probably the most complete Geologic Map I have seen for the region – excellent!	Comment acknowledged and addressed. The extent of the Turlock Lake Formation is unknown within the Colusa Subbasin west of the Sutter Buttes. Many of the boreholes used by Springhorn southwest of the Sutter Buttes did not encounter the Turlock Lake Formation, though there were some lithologies that may be related to it.
51	Ben King	Land Owner					3.11, 3.14 &3.15	See Springhorn Page 113 Figure 4.4. This Geologic Crossection needs to be incorporated in Cross Section C-C on Figure 3-11. Otherwise the Cross section leaves out the influence of the most unique Geomorphic Unit in the Sacramento Valley which is the Sutter Buttes. Also there is a critical need to address the Cross Section next to the City of Colusa because of the interrelationships of the Willows Fault, Sutter Buttes Rampart, Colusa Dome and Sacramento River. As it now stands Cross Section C-C is not consistent with the robust Geology set out in Figure 3-10 which seems to be a recent update since it references Springhorn. Regarding 3.14 how can you have a 3 Dimensional Model that omits the geology of the Sutter Buttes? Regarding 3.15 – it is important to map the area of the Corcoran like clays deposited by the Turlock Formation to know the potential area of impact for future subsidence.	Comment acknowledged. The 3D HCM representation focuses on the shallow marine and continental sedimentary geologic formations. It excludes the relatively more impermeable underlying plutonic and metamorphic formations. The 3D representation also fits slightly inside of the Colusa Subbasin boundary. Permeable subsurface volcanic formations that far west of the Sutter Buttes are thin at the scale being shown. Intrusive igneous formations related to the Sutter Buttes exist deeper than what the 3D representation shows. It is recommended to include more subsurface mapping of the permeable volcanic deposits and relatively impermeable plutonic formations, and to expand the 3D HCM beyond the subbasin boundaries in future HCM revisions. Cross Section C-C' has been revised a bit to include the Willows Fault zone near Colusa.
52	Ben King	Land Owner	3.1.9.2					See USGS Circular 1358 "Water Quality in Basin-Fill Aquifers of the Southwestern United States: Arizona, California, Colorado, Nevada, New Mexico and Utah, 1993-2009. Thiros,Paul, Bexfield and Anning 2014.(USGS Thiros et al 2014) See Page 56 – it is clear that arsenic contamination occurs and translocates along fault zones like the Willows Fault as is currently is the case in the Middle Rio Grande Basin. The water system for the City of Colusa could have the same fate as the water system for the City of Albuquerque.	Comment acknowledged and addressed.
53	Ben King	Land Owner	3.1.8.2		3-35	2nd and 3rd		The base of freshwater should not include brackish water which is defined by the USGS and others at 1000 ug/L. Water quality definitions should be consistent with the California Human Right to Fresh Water. Brackish water is not potable. The reference to brackish water in the Upper Princeton Valley is inconsistent with the outdated Olmstead and Davis referenced in paragraph 2 . See Springhorn Page 149 for additional references.	Comment acknowledged. The base of fresh water presented in the GSP are based on historical reports, of which many regulatory agencies use differing concentrations to define brackish versus fresh water. Data gaps regarding the lateral base of fresh water mapping or regarding discrete location well depth information for wells with measured water quality issues have been expanded upon in the Section 3.1.12.

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
54	Ben King	Land Owner			3.37		3.17	The Base of Freshwater Depths in the annexed area from the old West Butte Basin seem incorrect based on the vertical depths included in Springhorn's Cross Section work. Also the area west of Colusa on Lurline near Roberts Ditch is known to have lower fresh water base levels. Levels are probably in the 300 to 400 ft levels or less in both areas.	Please see the response to comment 53.
55	Ben King	Land Owner	3.1.10.2		3-39			The potential for vertical movement via abandoned gas wells and faults needs to be mention since it most likely will lead to aquifer degradation in areas where the subsurface groundwater have elevated TDS levels and/or anoxic conditions.	Comment acknowledged and addressed.
56	Ben King	Land Owner	3.1.10.3		3-42			Arsenic contamination at the abandoned Del Oro Walnut Ranch well and the well at the CIP site which was cited by SWRCB show arsenic contamination has been found in the Colusa City limits. The USEPA reports also show arsenic contamination in the Princeton water supply system.	Comment acknowledged.
57	Ben King	Land Owner	3.1.12.1		3-50			Additional Areas of Uncertainty: 1. See Springhorn Page 165 Figure 6.1 Areas where subsurface information is needed regarding the area outlined west of the Sutter Buttes, 2. Research regarding the vertical and lateral movement of saline water within and across the Willows Fault as generally described on Page 56 of USGS Thiros et al 2014, 3 The predicted desorption of arsenic from a volcanic structure like the Sutter Buttes in Figure 6-5 of Thiros on Page 58, 3. The breadth and depth of the Corcoran type clays from the Turlock Lake formation highlighting the potential for future subsidence, 4 – the water quality issues near the Freshwater area west of Williams as described in the Colusa County Groundwater Management Plan.	Comment addressed. Descriptions of these issues of concern and existing data gaps have been incorporated into various sections of Chapter 3.1, HCM.
58	Ben King	Land Owner	3.1.12.1				3-5	The C2VSimFG Model has to incorporate the saline and anoxic seawater around and south of the Sutter Buttes. According to the Sutter- Yuba investigations (SWRB Bulletin No. 6, 1952) a TDS level as high as 10,000 was observed near Robbins. Others including the DWR and Curtin have observed TDS levels from 4,000 to 6,000 south of the Sutter Buttes.	Comment acknowledged.
59	Ben King	Land Owner	3.1.12.3				3-51	What are the statutory obligations to address the Human Right to Fresh Water in the HCM?	Comment acknowledged. The Human Right to Water is not specifically addressed in SGMA regulations. SGMA and the Human Right to Water are intrinsically related, however, as the projects and plans proposed and implemented under SGMA aim to directly address the concerns outlined under the Human Right to Water. Section 2.4, Additional GSP Elements, and Section 2.2.1.3, Groundwater Monitoring and Management, include references to Water Code Section 106.3 text and related actions taken by the GSAs.

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
60	Ben King	Land Owner	3.2.5				3-64	The worst reported arsenic contamination for any public water system in the Sacramento Valley water supply system is in Grimes. The USEPA has documented arsenic contamination in the Princeton public supply system. There has been two incidences of arsenic contamination in supply wells within the boundaries of the City of Colusa. The wide scope of arsenic contamination around the extent of the Sutter Buttes Rampart and south of the Sutter Buttes in the Colusa Basin needs to be disclosed as an area of grave concern. See Springhorn Page 164 highlighting the need for more research about the need for more work regarding the relationship of arsenic contamination and the health risks from arsenic.	Comment acknowledged. Chapter 3 text has been revised to include data gaps regarding characterizing sources of arsenic near and downgradient of the Sutter Buttes and flow mechanics along the Willows Fault.
61	Ben King	Land Owner	3.2.5.1.1				Figure 3-30	What is the source for this data? Is there a time series? Stakeholders should have access to time series for water quality data and it should be included in the Appendix like the hydrograph data concerning water levels. Arguably water quality data should have a higher level of access and transparency due to the Human Right to Fresh Water.	Comment acknowledged. The TDS concentrations shown on Figure 3-30 are those recorded in GeoTracker and USGS website databases, last downloaded in 2020. The mapped TDS concentrations are the historical high at all groundwater sample locations. Historical EC charts are included in Chapter 5 for the representative groundwater quality monitoring network wells. All data taken from existing monitoring programs and data repositories (e.g., GeoTracker, GeoTracker GAMA, DWR WDL, USGS NWIS, CEDEN, etc.) will be evaluated in future GSP annual reports and periodic GSP evaluations and updates. EC/TDS concentration time series charts for all current active monitored wells will also be considered for inclusion in future GSP annual reports and periodic GSP evaluations and updates.
62	Ben King	Land Owner			3-66			According to the 2020 Tehama-Colusa Canal Water Authority Initial Study/Environmental Assessment there were several wells used for Groundwater Substitution with elevated Specific Conductance. As reported in the Appendix for the report GCID, 7 of the 16 reported wells had a consistent annual reported level of Specific Conductance greater than 1000 ug/L. Three of these wells had levels greater than 1500 and the other 4 were between 1000 and 1500. Are these wells included in the data points of Figure 3-30 and the discussion on page 3-66?	Comment acknowledged. Wells were not included in Figure 3-30 unless their TDS measurements were submitted to GeoTracker or USGS before the datasets were downloaded to generate the map in 2020. These wells do not appear to have been submitted before then. The TCC environmental assessment does not include named well locations or additional well identification information. These wells will be evaluated in relevant future projects, GSP annual reports, and periodic GSP evaluations and updates.

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
63	Ben King	Land Owner	3.2.5.2.1		3-67			Where is the location of the well near Grimes with Arsenic at 200 ug/L.? Grimes arsenic levels are reported to be approximately 25 ug/L. The USGS publication by Thiros et al has an extensive discussion of the desorption process of arsenic for volcanic rocks in saline groundwater with PH greater than 8. The USGS predictive model predicts the occurrence of arsenic in basin discharge areas like Robbins and the areas south of Grimes. This USGS publication also highlights how arsenic had moved into the groundwater of Albuquerque via a fault. The Willow fault crosses the Sacramento River at Colusa and runs south towards Grimes and the area where the two arsenic contaminated wells were found at the Del Oro Walnut Ranch site and CIP which is now in the boundary of the City of Colusa. The Sutter GMP includes a Figure showing elevated areas of TDS and Arsenic with levels as high as 370 ug/L. There is discussion of a biotic response that coincides with anoxic groundwater becoming oxidated from soil microbial activity that release arsenic as a bi-product. Arsenic contamination of the Colusa public water supply would be disastrous and a violation of the Human Right to Fresh Water.	Comment acknowledged. The 200 ug/L arsenic concentration near Grimes was a typo and should be 28 ug/L. References and discussion regarding Human Right to Water have been added to Chapters 2 and 3. Groundwater flow along faults is discussed in Chapter 3.
64	Ben King	Land Owner	3.2.6				Figure 3.31	Figure 3.31 should overlay the area of the Corcoran like clays from the Turlock Lake geological formation to show a potential relationship of subsidence and the presence of this clay formation	Comment acknowledged. Data is lacking regarding the lateral extent of the Turlock Lake Formation west of the Sutter Buttes. This has been added to the data gaps section of the HCM and additional commentary has been included in the regional geology discussion.
65	Ben King	Land Owner			3-72			The relationship between the Corcoran like clay formation and the presence of inelastic subsidence should be discussed based off the history in the San Joaquin Valley.	Comment acknowledged. The text has been revised to address the comparison.
66	Ben King	Land Owner	3.3.3	3-80			Table 3-9	Using only 2013 and 2015 water diversion data would lead to a wrong outcome if the diverter did not use surface water available during those years. It is an extremely small and not representative data set. Landowners could have not diverted during those years because they were trying to help other landowners out with their surface water allocations since they had wells or the landowner could have been converting land for orchard development with a new filter system.	Comment acknowledged. The point of the comment is understood; however, use of 2013 and 2015 land use and water supply conditions for all but the historical water budget scenario is driven by the GSP regulations. Those regulations state: "Projected water demand shall utilize the most recent land use...", and "Projected surface water supply shall utilize the most recent water supply information..." Since the historical model runs up through 2015, the "most recent" information would be 2015. However, 2015 (and 2014) was a Shasta Critical year, so for the projections 2015 was used to represent Shasta Critical years, and 2013 was used to represent Shasta Non-Critical years. This assumption was reviewed with several district managers and deemed as reasonable. Note that the 2013 TCCA allocation was 75%, equal to the average 1990-2015 allocation.
67	Ben King	Land Owner		3-81,2				Using Land Use data only for the years of 2003,2009 and 2014 is not representative if there was a conversion from rice to row crops or row crops to orchards. The impact of this narrow assumption set could lead to incorrect Budget Subareas.	Comment acknowledged. These are the years when DWR land use surveys are available. Years in between are interpolated to develop the best historical land use characterization.

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
68	Ben King	Land Owner	3-4	3-102				Management Areas should not be set until the GSP is approved and implemented for several years. The history and genesis of the Colusa Groundwater Authority JPS was for collective management of the Subbasin and there is no basis to change the jurisdictional management of the Subbasin in contravention of those principals. Stakeholders and property owners who are paying Prop 218 Assessments must know there is a rational basis for any changes in jurisdictional oversight within the Basin to maintain confidence in the GCA's governance. What should not happen are actions which may lead to a perception that a few powerful members have manipulated the process for their own benefit.	Comment acknowledged. Management Areas were not defined for the Colusa Subbasin.
69	Ben King	Land Owner	4.2.3.3		4-17		Table 4-4	The Monitoring Network is woefully inadequate to protect against groundwater quality degradation and to protect the Human Right to Fresh Water. All wells used for Groundwater Substitution should be used to collect water quality samples and to preserve public accountability against over pumping. There is an incentive for quantity rather than quality and Stakeholders should be entitled to publicly available water quality data from groundwater substitution wells. In order to protect Colusa County Resident's Human Right to Fresh Water Monitoring Wells should be placed in the study area suggested by Springhorn as referenced in the Comments on Section 3. Springhorn raised concerns about high Saline TDS levels and arsenic levels in a large area west and southwest of the Sutter Buttes. Several monitoring wells should be placed in this area. Monitoring wells may also need to be placed around the City of Williams to provide a historical time series to monitor TDS levels over time. If water banking activities start with the development of Sites, this enhanced Monitoring Network and time series will become critical to protect the water supply for the City of Williams.	Comment addressed. The text has been revised to include a better description of the data gaps in the groundwater quality monitoring network.
70	Ben King	Land Owner	4.2.3.4		4-19			Springhorn highlighted a wide area where there are water quality monitoring data gaps. Monitoring wells should be placed in this area in consultation with the DWR and Springhorn's personal input since he highlighted this concern in the first place. Additional monitoring wells may be needed around the City of Williams and any potential water banking sites that could cause degradation of drinking water supplies for on the west side of the Subbasin.	Comment addressed. The text has been revised to include a better description of the data gaps in the groundwater quality monitoring network.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
71	Ben King	Land Owner	4.2.4.4		4-20			One or two Extensometers need to be installed near Arbuckle and Dunnigan. One site should be near the intersection of Bailey Road and Hwy 99 since it is the site of greatest subsidence and because the infrastructure of I-5 is there in addition to the Arbuckle Cemetery and old railroad tracks. The other Extensometer should be installed near Dunnigan working with the Yolo County GSA to choose a site. There are approximately 500 residences in the area and an ever-growing commercial infrastructure.	Comment acknowledged. Colusa County was originally considering installing an extensometer, but has recently been coordinating with DWR (through the CGA) to install a continuous GPS station near Arbuckle instead. We agree that the installation of more real-time monitoring stations both within the heart of current subsidence and along the edges would be beneficial in quantifying the magnitude and rate of subsidence in this area of concern.
72	Donald Bills	GGA-TAC	1	1.2	1.2	2		1.—Sustainable groundwater resources not only preserve, and enhance the economic viability, social well-being and culture of all beneficial uses and users, but also insure the sustainability of water for natural and environmental needs. Especially those of at risk or critical resource value (i.e. springs, wetlands, riparian habitat, and baseflow reached of perennial and/or intermittent streams). I would suggest adding something like this to the stated goal of the Colusa Subbasin GSP. 2.—there is no such thing as sustainable/safe yield. At best the term means planned depletion. I suggest you replace it with sustainable goal.	Comment addressed. The sustainability goal has been updated to precisely match the phrasing adopted by the CGA and GGA, and "sustainable yield" has been changed to "sustainable goal" where it is not text taken directly from DWR or SGMA documentation.
73	Donald Bills	GGA-TAC	1	1.2	1.2	3		1.—Sustainable/safe yield is no longer considered to be a valid term in the context of hydrogeology. The term was originally developed as a legal term to characterize a water budget in balance by relating recharge (from precipitation) with discharge, two terms that are not related. I suggest that you replace it here with sustainable goal.	Please see the response to comment 72.
74	Donald Bills	GGA-TAC	1	1.3	1.2	3		1.—Suggest that you modify Both GSAs in the last sentence to “Both the Colusa and Glenn GSAs…” for clarity.	Comment addressed in the GSP section indicated.
75	Donald Bills	GGA-TAC	1	1.4	1.4	1, bullet 5		1.—Suggest that you add to seawater intrusion, brackish or saline groundwater intrusion. As discussed during TAC meetings, as freshwater is removed from storage in the regional aquifer. The reduced hydraulic head will allow brackish and/or saline water at depth to seep upward into the regional aquifer. Unless monitoring of water quality at depth in the regional is intended to be the monitoring tool for this.	Comment acknowledged. The upwelling or mobilization of brackish or saline connate/deep groundwater is included as part of the "degradation of water quality" undesirable result topic and is monitored via the groundwater quality monitoring program. It is not addressed under the "seawater intrusion" undesirable result topic.
76	Donald Bills	GGA-TAC	1	1.4	4 of 7	Article 5 sub-article 2	1-1, GSP regulation section 354.18, bullet 3	Suggest replacing estimate of sustainable yield with estimate of sustainable goals.	Comment acknowledged. Table 1-1 contains the checklist requirements posted by DWR in 2016. The text and terminology in the "Description" column come directly from that document and were not edited.
77	Donald Bills	GGA-TAC	1	1.4	4 of 7	Article 5 sub-article 2	1-1 GSP regulation section 354.18, surface water supply	Shouldn’t this also include reclaimed water and/or	Comment acknowledged. Table 1-1 contains the checklist requirements posted by DWR in 2016. The text and terminology in the "Description" column come directly from that document and were not edited. Reclaimed water (as "recycled water" or "reused water") is one of the water source types considered under §354.18(b) (as applicable).

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
78	Donald Bills	GGA-TAC	1	1.4	6 of 7	Article 5 sub-article 4	1-1, GSP regulation section 354.36, representative monitoring.	Remote-sensing data was discussed as an additional proxy in addition to groundwater elevations for other sustainable indicators. Should it be mentioned here?	Comment acknowledged. Remote sensing is being conducted by DWR. The schedule and flight paths have not yet been determined for the Colusa Subbasin. Chapter 7 includes DWR's planned airborne electromagnetic (AEM) survey as available data to be used for updating the HCM and potentially evaluating groundwater levels, the interface with deeper brackish waters, and lithologies along fault zones. We do not discuss including remote sensing data as an ongoing recurring monitoring program, other than whatever DWR, USGS, and NASA have already planned or implemented. Existing datasets, however, will be evaluated in each GSP annual report and/or periodic evaluation.
79	Donald Bills	GGA-TAC	1	1.4	6 of 7	Article 5 sub-article 4	1-1, GSP reg section 354.36, Assessment and Improvement of Monitoring Network	Again remote-sensing methods and data are another tool that seems suited for filling data gaps by improving monitoring frequency, accuracy, and density of data sites. Discussion of DWR INSAR and gravity data as possibilities.	Comment addressed. All of the satellite surveys, remote sensing surveys, GPS, gravity surveys, SAR/InSAR, etc. are included under the UNAVO umbrella. The text has been updated to specifically call out InSAR as part of the monitoring network for land subsidence and mention other sources of subsidence or displacement data.
80	Donald Bills	GGA-TAC	3	3.1	3-1	1, first sentence		First occurrence of abbrev. Should be spelled out in text. I.E. This section describes the hydrologic conceptual model (HCM) of the Colusa Subbasin.	Comment addressed in the GSP section indicated.
81	Donald Bills	GGA-TAC	3	3.1.3	3-6		3-3. Note in upper left of plot. Second sentence.	There appears to be missing or jumbled text at the start of sentence 2. " at r y ars missing more that 30 days…". Suggest that it be fixed is needed.	Comment addressed in the GSP section indicated.
82	Donald Bills	GGA-TAC		3.1.4	3-8		3-4	Since land surface elevation is color coded on the Topography map, it might help to identify the very light shade of blue as surface water as it can be easily confused with the very light green (greenish-blue?) that is land surface less than 30 ft.	Comment addressed. Edits have been made to Figure 3-4.
83	Donald Bills	GGA-TAC		3.1.5	3-7	Paragraph2, 1st sentence	3-5	"The regional watersheds and natural waterways are shown on Figure 3-5." Figure 3-5 also shows principal water infrastructure. I suggest it be added to the sentence and the fig. 3-5 title.	Comment addressed. Edits have been made to Figure 3-5.
84	Donald Bills	GGA-TAC		3.1.5	3-10	First paragraph, last sentence		"These streams are intermittent and drain the foothills that border the Coast Ranges to the west." Perennial streams are connected to the regional groundwater table and get most of their base flow by groundwater discharge. Intermittent streams are only seasonally connected to the regional groundwater table and flow seasonally or in response to runoff. Ephemeral streams are not connected to the regional groundwater table and only flow in response to seasonal runoff. Are Foothill streams of the Coast range truly intermittent?	Comment acknowledged. The foothill streams are historically a mix of intermittent and ephemeral streams. However, given the many back-to-back, multi-year droughts that the region has been experiencing over the past two decades, these foothill creeks and streams are most likely all ephemeral until they reach the valley floor, where they may have stretches of connectivity with shallow groundwater aquifers.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
85	Donald Bills	GGA-TAC	3	3.1.5.1.1	3-10			Is there no range of flow data for Stony Creek pre-Black Butte Dam (and even Stony Gorge Dam)? This would give some context to the releases from Black Butte Dam since 1996.	Comment acknowledged and addressed. Stony Gorge Reservoir was constructed in 1928. Black Butte Lake was constructed in 1963. Streamflow measurements in Stony Creek downstream of Black Butte Lake are not available prior to 1941. These post-Stony Gorge Reservoir / pre-Black Butte Lake discharges have been summarized in Chapter 3.
86	Donald Bills	GGA-TAC		3.1.5.1.2	3-13			"Sacramento River stream flows measured at the Ord Ferry-Main Channel stream gauge, in the northern part of the Subbasin, varied between 200 and 160,000 cfs during the 1984 to 2020 time period, with extreme low flows measured in the spring of 1990." Why is the time p3.1.5.1.3eriod limited to 1984 to 2020? If the intent here is to describe natural surface waters, there are documented (USGS) periods of extreme flows greater that this range extending back to the 1920 from stream-flow gaging stations in or adjacent to the Colusa subbasin.	Comment acknowledged and addressed. There are limited stream gauges north of the Sutter Buttes with historical discharge data.
87	Donald Bills	GGA-TAC		3.1.5.1.3	3-13			3.1.5.1.4 Glenn Colusa Canal lists acres serviced. Wouldn't it be appropriate to do the same for the Tehama-Colusa Canal? Also the length of the canal and diversions? I watched the Tehama-Colusa Canal being built less that a quarter-mile away from where I grew up on Co. Rd. 21 south of Orland. I even rode my bike in the bottom of the canal once it was cemented in. I noticed at the time there was a line of one-way valves on the bottom of the canal. I later learned they were there to relieve stress on the canal by allow rising groundwater to move into the canal. Is this something you are accounting for in your groundwater models during those wet years when WLS are very close to the surface?	Comment acknowledged. Commentary has been added to the TCC section. The groundwater model does not currently model TCC as a canal. Surface water supplies and agricultural demand are accounted via diversion and place of use information.
88	Donald Bills	GGA-TAC		3.1.5.1.6	3-15	1		"These foothill drainages and their tributaries are classified as part of the Sacramento-Stone Corral Watershed…". I think you mean the Upper Stony Watershed.	Comment acknowledged. Upper Stony Watershed drains into Stony Creek and Stony Gorge Reservoir. The fringe foothills are part of the Sacramento-Stone Corral Watershed. These foothills drain through the ephemeral and intermittent streams.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
89	Donald Bills	GGA-TAC		3.1.5.1.6	3-15	2		"Runoff in these ephemeral and intermittent streams generally begins in late fall when the rainy season starts and may continue until late spring." Intermittent streams suggest some seasonal contact with the regional groundwater table. Probably not true for many of these streams in the north part of the subbasin. I do not know about those in the southern part of the subbasin. Springs are overlooked in this discussion (or elsewhere). Many of these smaller streams have springs at or near their headwaters that issue from either the Tehama (exposures of pre-Paleogene, would have a QW signature), Riverbank or Modesto Formations. Discuss here?... High elevation areas to the west of Orland/Willows. GW contours do not extend that far west. 3.1.11.3 does not address springs. Black butte Lake overlies mostly Tehama formation. Is there ant possibility of Reservoir water seeping into Tehama and showing up in springs to the south? QW signature, spring flow related to lake level not climate, etc.	Comment acknowledged. The foothill streams are historically a mix of intermittent and ephemeral streams. However, given the many back-to-back, multi-year droughts that the region has been experiencing over the past two decades, these foothill creeks and streams are most likely all ephemeral until they reach the valley floor, where they may have stretches of connectivity with shallow groundwater aquifers. Springs are discussed in Section 3.1.11. We decided not to discuss streams in the Hydrology section given the lack of reported information regarding those springs' discharge and source. Some text has been added regarding the historical presence of springs at the headwaters. Groundwater contours are not shown in the northwestern area of the Subbasin due to lack of published data and lack of wells in those upland areas. This indicates either that there is no groundwater in those areas that is economically feasible to access, that the wells in those areas are old and are not included in the DWR well database, and/or that the wells are not currently being monitored and reported. There is a possibility of groundwater in the Tehama Formation to be discharging into Black Butte Lake; however, given the studies conducted by TNC regarding stream-aquifer interactions, available groundwater level data, and a thalweg analysis that has been added to Chapter 3 for Stony Creek, it seems highly unlikely that that is occurring unless it is shallow groundwater or "perched" shallow recharged waters that are not connected to the main freshwater aquifer system.
90	Donald Bills	GGA-TAC	3	3.1.6	3-18		3-9	The color for soil type C and water bodies on fig. 3-9 (light blue) are so similar it is hard to tell them apart. I suggest you consider using more contrasting colors and adding waterbodies to the explanation to make them easier to tell apart.	Comment addressed in the GSP section indicated.
91	Donald Bills	GGA-TAC			3-27		3-16	Top of Cretaceous rocks contours are in meters MSL, and tops of Cretaceous rocks elevation are in feet MSL. Using both metric and SI units makes them a little difficult to compare. Can they both be in the same units? Also, there are places where the contours do not match the elevations (SE of Black Butte, Artois, Princeton, etc.). I assume this is related to structural offsets. I suggest you consider adding the principal structures (faults) to this map to help with the interpretation.	Comment addressed in the GSP section indicated.

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
92	Donald Bills	GGA-TAC		3.1.7.2.3	3-31	4		During a review of USGS topographic maps that cover the area west of Orland and Willows, I found about 24 marked springs, a few with actual names. Based on their location, these springs appear to be discharging from either the Tehama, Riverbank or Modesto Formations in the northwest part of the Colusa Subbasin, There is little hydrogeologic information shown on the maps of this report for this area owing to a lack or well data. Springs represent a source of hydrogeologic information that can be used in the absence of well data to extend water level contours and improve understanding of groundwater conditions in the area. Any information about these springs from land owners or site inventories by DWR or the USGS will improve the hydrogeologic characterization of this area of the subbasin. Some mention of spring discharge from the Tehama, Riverbank, and Modesto Formations might be appropriate here, with a more complete discussion in groundwater discharge.	Comment acknowledged. Springs are discussed in Section 3.1.11. We decided not to discuss streams in the Hydrology section given the lack of reported information regarding those springs' discharge and source.
93	Donald Bills	GGA-TAC		3.1.8.2	3-36	2-3		?... Base of the Tehama and Tuscan Formation and (or, and/or?) Base of freshwater excluding those areas where post-Cretaceous sediments contain brackish water. Freshwater is defined as 3,000, 2,000, and 1,000 mg/L depending on which reference is used (USGS, DWR, of C2VSim). Which is it? I would also suggest that you define brackish water here as its related freshwater and the freshwater boundary. The vertical extent of these boundaries shown on fig. 3-11 to 3-13 while approximate do not appear to consistently align with either of these definitions. Perhaps it would be appropriate to add queries ("?") where the degree of uncertainty is highest.	Comment acknowledged. The varying definitions for freshwater versus brackish water are among several issues with defining the base of freshwater. DWR is working on a new base of freshwater study, potentially with a threshold of 1000 mg/L. This threshold concentration is anticipated to be adopted as industry standard for the base of fresh water, and will be used for future versions of the HCM. It is recommended that the model be revised to account to for that. Comment on the cross section mapping has been addressed.
94	Donald Bills	GGA-TAC		3.1.9.2	3-38	1		"These basin faults may act as barriers or conduits to fresh groundwater flows." I think it is also important to mention that, if the faults are deep seated, they can also provide conduits for poorer quality (brackish) water from the marine sediments below to migrate up into the freshwater layer. This is particularly true if the hydraulic head of the freshwater layer is consistently reduced owing to groundwater withdrawal.	Comment addressed. The text has been clarified.
95	Donald Bills	GGA-TAC	3	3.1.10, Principal aquifers	3-39			Some text edits for clarity.	Comment acknowledged. It is unclear what text edits this comment refers to. The entire Chapter 3 has gone through several proofreaders since comments were received and prior to issuance of the public draft GSP.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
96	Donald Bills	GGA-TAC		3.1.10.3, water Quality	3-42	1		Electrical conductivity (EC) is not a measure of the quality of the water. It is a measure of how electrically conductive the water is. As a result, there is a nearly direct relationship between EC and total dissolved solids (TDS) in the water. TDS is one general measure of water quality. The more dissolved solids in the water, the more electrically conductive it is and, as a result, the quality of the water is generally poorer. For this reason, I suggest you delete reference to EC in the first sentence of the paragraph.	Comment addressed in the GSP section indicated.
97	Donald Bills	GGA-TAC		3.1.10.3	3-42			Fire retardant used to be manufactured in Orland and included boron with other chemicals known for both their fire suppression properties and as chemical fertilizer. Currently, fire retardant is a mix of ammonium polyphosphate, diammonium phosphate, diammonium sulfate, monoammonium phosphate, attapulgus clay, guar gum known as Phos Chek. Over time, after a fire, this material gets watered into a watershed and may be a concern for the water quality of an aquifer. It is also highly concentrated where manufactured and distributed (Airports like Orland, Willows, and USFS and CDF fire bases).	Comment acknowledged.
98	Donald Bills	GGA-TAC		3.1.10.3	3-42	3		Most drycleaners use both Trichloroethylene (TCE) and Tetrachloroethylene (PCE) (as did the one in Orland). The studies I have seen on this issue for the Orland area refer mostly to TCE.	Comment acknowledged. Documentation from the Department of Toxic Substance Control and EnviroStor that we have seen indicate that PCE is the constituent of concern for the Orland Dry Cleaner Site.
99	Donald Bills	GGA-TAC		3.1.11, Ground water Inflows and Outflow s	3-42 to 48	1		The section heading is groundwater inflows and outflows. The lead sentence begins “Groundwater underflows between the Colusa Subbasin and neighboring groundwater subbasins…”. Groundwater underflow is a specific type of inflow or underflow. I would suggest that a better use of this introductory paragraph would be to list all the relevant GW inflows and outflows to the Colusa Subbasin as discussed in the following subsections. I would also add the Corning Subbasin in the first sentence in relation to groundwater underflow. As water-level contours indicate (fig. 3-19), Stony Creek is not a barrier to groundwater flow.	Comment acknowledged and addressed. The text has been updated to clarify underflows along the Subbasin boundaries.
100	Donald Bills	GGA-TAC		3.1.11.2. 2, GW banking ?	3-43			Groundwater banking. Not in the glossary of terms and it appears to mean something different here (recharge) as opposed to the most common definition (water management mechanism designed to increase water supply reliability through the buying, selling, and storage of surface water and groundwater rights for later use). I would suggest artificial recharge as a alternate term since the main heading (2.1.11.2) is Groundwater Recharge Areas.	Comment addressed in the GSP section indicated.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
101	Donald Bills	GGA-TAC		3.1.11.3, Ground water discharge areas	3-45	2		I suggest that you consider adding a few sentences about springs in the Colusa Basin to this paragraph. Something like: "Most springs in the Colusa Subbasin occur near the western boundary and discharge from the Tehama, Riverbank, or Modesto Formations and stream channel alluvium. About 25 springs can be identified from USGS topographic maps of the subbasin. A number of these springs have been developed for agricultural use by landowners locally (apparent on satellite imagery). The flow, and water quality of these springs may exist in DWR or USGS databases based on past historical inventories." If properly inventoried these springs would represent significant additional information about the occurrence, movement, and quality of ground water in the regional aquifer of the Colusa Subbasin, especially where this information is poorly defined.	Please see the response to comment 92.
102	Donald Bills	GGA-TAC	3	3.1.11.3	3-48	2, 4th sentence		"There are also many unmetered domestic wells located throughout the study area." I suggest adding unmetered small ag wells also: "…unmetered domestic and small agricultural wells…"	Comment addressed in the GSP section indicated.
103	Donald Bills	GGA-TAC				2, 5th sentence		It might be appropriate to add a sentence or two here to briefly explain how the annual rate of withdrawal from domestic wells was determined (estimated). Average pump capacity of all domestic wells, seasonal domestic water use estimates, or other. Adding small unmetered ag. wells to this total would increase significantly I imagine.	Comment addressed. The methodology used to estimate rural residential (domestic) pumping in the GSP has been added. This is the current, best available approach for quantifying domestic groundwater pumping in the Colusa Subbasin.
104	Donald Bills	GGA-TAC		3.1.11.3	3-48	3		I would also add a comment to this paragraph that during years when surface water deliveries are significantly cut back (drought), agricultural lands rely heavily on wells to make up the difference.	Comment addressed. The suggested text has been added.
105	Donald Bills	GGA-TAC	3	3.1.12.1	3-51	4		other methods or data sources: I'd like to suggest passive seismic. The method uses seismic signals already available in the environment, either anthropogenic (i.e. freeway traffic), or natural (i.e. earthquakes, ocean waves, etc). the seismic signals are processed similar to standard reflection and/or refraction surveys but for much larger areas and depths. Ground-based, non-invasive CSAMT (Controlled Source Audio-frequency Magnetotellurics) and TEM (transient electromagnetic or alternately called time-domain EM (TDEM)) surveys can provide detailed subsurface information on stratigraphy, structure, depth to water and water quality in localized areas of interest. Survey lines that pass over or by existing wells provide ground-truth.	Comment addressed. Thank you for pointing out these alternate methods of subsurface mapping. The text has been revised.

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
106	Donald Bills	GGA-TAC	3	3.1.12.1	3-52	1		Different TDS thresholds to define base of freshwater. Part of the problem may also be that water use type has a lot to do with whether water is considered fresh or not. MCL for safe drinking water is 500 mg/L, Livestock can tolerate about 1,500 mg/l. A lot of commercial ag. plants can tolerate 2,000 to 3,000 mg/L. There is also not broad agreement on what constitutes fresh, saline, or brackish water. It seems to me that the standard for what constitutes freshwater should be the same for all subbasins in the Sacramento Valley, if not the entire Central Valley.	Comment acknowledged. Please see the response to comment 92. The idea is to use the upcoming DWR study as the standard TDS threshold for freshwater.
107	Donald Bills	GGA-TAC		3.2.2.1	3-53	2, second sentence		"The most notable recovery period occurred around 1983, which was both a wet year and when water users added more surface water to their supply portfolios." The recovery after the 1987 to 1991 drought seems at least as great if not greater.	Comment addressed. The 1991 recovery is a notable recovery in terms of magnitude while the 1983 recovery is notable in terms of conditions prior to 1983 and after 1983. When surface water supply increased, there was a large rise in water levels.
108	Donald Bills	GGA-TAC			3-53		3-22	It is hard to evaluate temporal trends on this plot referring back to the average annual precipitation plot at the beginning of this chapter. To help understand and evaluate this temporal data it would seem appropriate to add a plot of the annual average precipitation to this graph.	Comment acknowledged. Precipitation was excluded from this hydrograph in the interest of using the two existing vertical axes to show depth to water and elevation. The drought periods are shown on the hydrograph for reference to climatic events. The text has been revised to clarify that the peaks and valleys in the water level hydrograph represent the rainy season and dry season, respectively.
109	Donald Bills	GGA-TAC		3.2.2.1	3-55	1		Besides showing the general direction of flow to the SE, Figure 2 appendix 3-B appears to show Walker Creek to be a gaining stream (i.e. perennial, groundwater contours point up stream) from the NW part of the subbasin to Artois. Comparing land surface contours (fig 3-4) to the groundwater contours for this area seems to indicate that the depth to water is from -10 to -30 ft below the streambed throughout. Is there a discrepancy here that needs to be resolved?	Comment acknowledged. The contours shown are groundwater elevations, not depth to water. The contours point upstream and indicate groundwater flow is in the direction of the drainage. There are a number of potential factors for why it looks like the depth to water is above land surface. These include, but are not limited to, the spatial density of available data, construction of monitored wells, assumptions made during interpolation into contours, and the scale of regional mapping. Many of the multiple completion monitoring wells show an upward gradient within the Subbasin, and most of the monitored wells are constructed in the semi-confined to confined zone of the principal aquifer. It is possible that groundwater is discharging to Walker Creek in this area during the spring of 2006.
110	Donald Bills	GGA-TAC	3	3.2.2.1	3-55	4		"Current groundwater levels are similar to those measured in 2017, indicating that regional groundwater levels have been relatively stable since the end of the previous multiple-year drought." I find this statement a little misleading. What it overlooks is the fact that the combined effect of the 2007-09 and 2012-16 droughts was an average depth to water decline of over 30 ft (fig 3-22) from which the principal aquifer has yet to recover. In addition the 2019 and 2020 was appear to continue trending down, not stable, as cones of depression continue to expand (fig 3-24 and 3-25).	Comment acknowledged. As of the making of the hydrograph, the water levels had somewhat stabilized. Of course, we have entered a period of alternating average and dry or multiple-dry years and this is taking a toll on the aquifer system. In particular, it is taking a toll on the shallow groundwater aquifer system, which is lacking in available water level data. DWR and GSAs have started working to improve monitoring and record-keeping of shallow wells and wells that are going dry, but that has not been evaluated as part of this GSP given the SGMA time constraints. The text has been revised to mention this.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
111	Donald Bills	GGA-TAC		3.2.2.1	3-55	1,3rd sentence		"Impacts due to pumping are the exception to the typical gradients and disrupt both local and regional gradients." I suggest that you add to this sentence or the first sentence of the paragraph a comment on the effects of changing hydraulic parameters on the lateral groundwater gradient.	Comment addressed in the GSP section indicated.
112	Donald Bills	GGA-TAC		3.2.5	2-64	Second		Delete EC. It is not a water quality parameter.	Comment addressed in the GSP section indicated.
113	Donald Bills	GGA-TAC				third		Who monitors and regulates the water quality of municipal supply systems? Worth mentioning here? Regional water quality control boards? Saline connate water? Connate water is water trapped within the pores of sedimentary rocks. For that to happen it would have to be fully confined laterally and vertically and not be faulted or fractured. In the geologic discussion it states that pre-Cretaceous rocks are faulted and fractured. Groundwater is almost always in motion and always flows in response to gravity and/or the hydraulic gradient. The flow rates can be very slow, ft per hundreds to thousands of years or more. The connate water would be in pre-Cretaceous sediments. Has anyone dated the water to see if it is, in fact, greater than 145 million years old, give or take?	Comment acknowledged. The municipal wells are regulated under SWRCB and the Division of Drinking Water. Drinking water quality is submitted to the SWRCB SDWIS Water Watch and GeoTracker systems. This is discussed in Chapter 4, Monitoring Networks.
114	Donald Bills	GGA-TAC		3.2.5.1.1	3-64	1		End of first sentence add "…and/or EC value (EC is a surrogate [estimate of] for TDS because it is more easily measured on site)." There appears to be a discrepancy in the Secondary MCL for TDS; 500mg/L in sentence 2 and 500 mg/L in sentence 4. Fix?	Comment acknowledged. TDS has three MCLs: the recommended limit (500 mg/L), the upper limit (1000 mg/L), and the short-term limit (1500 mg/L). This has been explained in the text.
115	Donald Bills	GGA-TAC		3.2.5.1.1	3-66	1		"Wells screened in the unconfined to semi-confined zone of the aquifer (i.e. in wells less than 200 feet deep) had the highest number of wells with elevated TDS concentrations." I suggest adding "in thew central and southern part of the subbasin" to the end of this sentence.	Comment addressed in the GSP section indicated.
116	Donald Bills	GGA-TAC		3.2.5.1.1	3-66	2		First sentence, …In these areas…. What areas? Suggest replacing with …southwest of Colusa…	Comment addressed in the GSP section indicated.
117	Donald Bills	GGA-TAC		3.2.5.1.2	3-67	1		Anthropogenic source for increasing chloride and sulfide concentrations? Septic systems, landfills, other?	Comment addressed in the GSP section indicated.
118	Donald Bills	GGA-TAC		3.2.5.2.2	3-67	1		Boron. Pre, late 1970's Boron was a component of fire retardant for its fire suppression characteristics. Fire retardant was manufactured in a plant in Orland and stored at firebases (airports) in Glenn and Colusa counties. Is saw wide use in suppressing forest, brush, and grass (at lower elevations) fires in Glenn and Colusa Counties.	Comment addressed.
119	Donald Bills	GGA-TAC		3.2.5.2.3	3-68	1		Known or suspected cause for increases in iron and manganese worth mentioning here? Natural or human caused? Landfill west of Artois? Junk yards? Suggest adding if appropriate.	Comment addressed.
120	Donald Bills	GGA-TAC		3.2.5.2.3	3-68	1		Known or suspected cause for anthropogenic increases in hexavalent chromium worth mentioning here? Landfill west of Artois? Suggest adding if appropriate.	Comment addressed.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
121	Donald Bills	GGA-TAC		3.2.7	3-73	2 and 3 paragraphs		The second paragraph is misleading ("While Stony Creek, Sacramento River, and the Colusa Basin Drain all experience gaining and losing conditions throughout the year,…") and appears to contradict the information provided in the 3rd paragraph. I would suggest deleting the second paragraph entirely and moving the table references to the 3rd paragraph.	Comment addressed in the GSP section indicated.
122	Donald Bills	GGA-TAC		3.2.8	3-74	2nd paragraph	3-34	I do not follow the scoring criteria for GDE. A GDE where groundwater is near the surface has a score of 1; least likely to be GDE when it should be more likely to be a GDE. If a GDE is not near surface water OR crop land it scores a 4; most likely to be a GDE when it should be least likely to be a GDE. How the 30 ft DTW line was derived is explained in paragraph 1 on page 3-75. But I could not find or estimate the 30 ft DTW on any or the other figures in the text or appendix. An approximated 30 ft DTW line for 2006 data on figure 3-19 would run from between Arbuckle and College City, to near the boundary of the subbasin west of Williams, to just west of Artois, ending at Stony Creek just N/NW of Orland. This is nowhere near the line shown on figure 3-35. Using figure 5 in appx 3B I can approximate a 30 ft contour to the 2017 data. But it also does not compare to the 30 ft DTW contour on figure 3-35. The explanation table on figure 3-35 does not reference a time period (2014 to 2018?) for the 30 ft DTW line or any of the other features shown. Finally, there is no reference to springs and the riparian habitat they support at headwater streams in the NW part of the subbasin between Willows and Orland. These would represent some of the most important and species diverse habitat in the subbasin. I would suggest that the entire GDE section be revised so it more clearly and plainly represents GDE's that occur within the subbasin.	Comment addressed. Clarification has been added in the section indicated. The scoring criteria uses an if/then method. If the response to criteria 1 is "yes," then the scoring moves on to criteria 2. If the response to criteria 1 is "no," then that land receives a score of 1 and the scoring ends. GDEs are near shallow groundwater and not near agricultural lands or surface water features.
123	Donald Bills	GGA-TAC	3	3.3 Water budget information	3-77	1		This section describes water budget components in detail but, I did not see a clear statement of what the water budget was for. Water budgets can be used for many things (i.e. GW gains or losses, basin gains or losses, etc). Is there a statement of the purpose of the water budget in the Groundwater Sustainability Plan Emergency Regulations §354.18 that could be added to the introduction here? The name suggests it is to determine groundwater sustainability of the principal aquifer in the subbasin. That implies that all the inflows and outflows are on onside of the equation and +/- change in storage is the result.	Comment addressed. The introduction has been edited to explain the purpose and utility of water budgets.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
124	Donald Bills	GGA-TAC	3	3.3.3	3-80		3-9	What is the Shasta non-critical and Shasta Critical, mentioned on the table? How does it relate to the Colusa Subbasin? I think it is defined two pages later under Land use. But there is still no explanation of what a Shasta critical and Shasta noncritical year is. Reservoir contents? Outflow? Both? Is there a reference for this missing? It would be worth providing a footnote to table 3-9 to define Shasta critical and Shasta non critical.	Comment addressed. An explanatory footnote has been added at the first reference to "Shasta Critical" and "Shasta Non-Critical" years in the text.
125	Donald Bills	GGA-TAC		3.3.3.3	3-83	3, Land Use		"…modified based on planned development according to the Colusa County 2030 General Plan." Is there a 2030 Glenn County General plan worth considering here as well?	Comment acknowledged. The Glenn County General Plan is currently being updated. The current plan is 28 years old, and thus does not have much direct utility for this application.
126	Donald Bills	GGA-TAC	3	3.3.4	3-84	1, bullet 1		Groundwater pumping and stream accretion are described as inflows here. In paragraph 2 second bullet on page 3-85 they are described as outflows. Which is it? I would suggest they are both outflows from the principal aquifer and the text needs to be fixed accordingly.	Comment acknowledged. From the perspective of the surface water system, which is essentially the root zone and surface waterways, groundwater pumping and accretions are inflows. From the perspective of the underlying groundwater system, these same two flow paths are outflows.
127	Donald Bills	GGA-TAC		3.3.4	3-85	3rd bullet of first paragraph (3-84)		Change in Storage is defined as changes in soil moisture storage within the upper several feet of soil in the root zone, as well as changes in storage in surface water bodies within the basin. Neither of these are change in storage. They are either inflows or outflows components that when summed with other inflows or outflows result in a change in storage of the principal aquifer. I would suggest that the text be fixed accordingly.	Comment acknowledged. The volume of water stored in the root zone and surface water bodies (mainly canals and drains) changes over time (seasonally) depending on a variety of factors. But on an annual basis the change from year to year is very small.
128	Donald Bills	GGA-TAC			3- 86 and 3-87		3-10 and 3-11	The tables do a much better job of representing the various SW and GW components of the water budget. Is there some way change the text so it is mere consistent with the tables? Also, In both table 3-10 and 3-11 the column headings for future conditions climate change relate to a specific date (2030 and 2070). It would be useful to the reader if the other columns (historical simulation, current baseline, and future condition no climate change base line) had the time periods they are based on as well. 1990 to 2015, 2015, and 1966 to 2015 respectively.	Comment addressed. The suggested edits have been made.
129	Donald Bills	GGA-TAC		3.3.4.1	3-88	4		I would suggest that ET from the riparian corridor of the Sacramento River as well as evaporation from the rivers surface can also be significant and worth discussing here. Especially during the summer months when ET is at a maximum and daytime temperatures can exceed 100 degrees for weeks at a time. This is important to consider under future climate change scenarios where temperatures and the days per year of excessive heat are predicted to increase.	Comment addressed. A sentence has been added preceding Tables 3-10 and 3-11 noting that Native Vegetation ET includes riparian corridors along streams and rivers.
130	Donald Bills	GGA-TAC		3.3.4.1	3-89		3-38	I would suggest that you add the change in storage (3taf.yr) to the graph. It is not apparent on the graph even though it is color coded in the legend. The columns look equal. In any case it should not be a color-coded box as inflow or outflow. It is the result of both.	Comment addressed in the GSP section indicated.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
131	Donald Bills	GGA-TAC		3.3.4.1	3-90		3-39	The GW change is storage in table 3-12 is shown as a negative number (-27.5 taf/yr, a loss). So, why is it shown as an inflow in this figure? Change in storage is neither an inflow nor a outflow but the result (sum) of both. Showing it this way graphically suggests the inflows and outflows are in balance. They are not. I would suggest that you add the actual change in storage (-27.5 taf/y) to the legend and remove it from the inflow column. I suggest you make similar changes to figures 3-40 to 3-47.	Comment acknowledged. The convention we choose to use is to include change in storage on the chart so the sum of the 2 columns are equal. A negative change in storage results from inflows being less that outflows, so the change in storage gets added to the inflows so that the two columns balance.
132	Donald Bills	GGA-TAC		3.3.4.1.1	3-91	1 and 2	3-12	"The primary sources of surface water in the basin are the Sacramento River and Stony Creek. Surface water supplies are relatively reliable in the basin and represent approximately 74 percent of the total water supplies." Is this statement accurate? How do Shasta critical and non-critical years affect it? I would think that during Shasta critical years SW deliveries would be much and during Shasta non-critical years would be at or near 100 percent. The second paragraph seems to support this.	Comment addressed. We have verified the calculation and the value is 70%. The value has been corrected, and clarification has been added.
133	Donald Bills	GGA-TAC	3	3.3.4.2	3-93	2		Average annual inflows to and outflows from the groundwater system were estimated to be 997 taf/yr during the current conditions baseline simulation period on figure 3-41 are shown as 998 taf/yr not 997. Which is right?	Comment acknowledged. The 1 AFY discrepancy results from rounding. Both numbers as regarded as right, within uncertainty.
134	Donald Bills	GGA-TAC		3.3.4.3.1	3-95	4		"There is negligible change in groundwater storage under the future condition, no climate change baseline water budget." I suggest you add the actual change in parentheses: "…negligible change (+0.6 taf/yr)…"	Comment addressed in the GSP section indicated.
135	Donald Bills	GGA-TAC		3.3.4.3.2	3-97	1		"Average annual inflows to and outflows from the groundwater system were estimated to be 1.0 maf/yr." I suggest you add the type and time period to toe sentence so it is consistent with the title of this section and the figure referenced. "Average annual future conditions 2030 climate change baseline groundwater system inflows to and outflows from the groundwater system were estimated to be 1.0 maf/yr."	Comment addressed in the GSP section indicated.
136	Donald Bills	GGA-TAC		3.3.4.3.2	3-98		3-45	Change in storage is not an inflow as shown…. See previous comments.	Please see the response to comment 131.
137	Donald Bills	GGA-TAC		3.3.4.3.3	3-100		3-47	Change in storage is not an inflow as shown…. See previous comments	Please see the response to comment 131.
138	Donald Bills	GGA-TAC		3.3.5	3-101	1		"Uncertainty refers to a lack of understanding of the basin setting…" Add Water Budget to uncertainty in the first sentence to be consistent with the section title. I.E. "Water budget uncertainty refers to…"	Comment addressed in the GSP section indicated.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
139	Donald Bills	GGA-TAC		3.3.6	3-102	1		"Based on the current conditions and future conditions with no climate change scenarios, which represent long-term average conditions in the subbasin, overdraft conditions are not expected to occur in the Colusa Subbasin." The rest of the paragraph appears to contradict this. I suggest you change not to expected to occur to minor or modest overdraft is expected to occur.	Comment addressed in the GSP section indicated.
140	Donald Bills	GGA-TAC		3.3.7	3-102	1		"As described previously, sustainable yield refers to the maximum quantity of water, calculated over a base period representative of long-term conditions in the basin, and including any temporary surplus that can be withdrawn annually from a groundwater supply without causing an undesirable result." At the beginning of this chapter sustainable yield was also related to a maximum depth below lands surface, 200 ft I believe. I suggest you add that add that condition her also.	Comment acknowledged. Yes, other sustainability indicators need to be brought into the estimate of sustainable yield, particularly streamflow depletion, and effects on GDEs and other beneficial uses and users.
141	Donald Bills	GGA-TAC		3.5, references				I did not attempt to check or verify references…	Comment acknowledged.
142	Donald Bills	GGA-TAC	4	4.2.2.2.1	4-4	1		Groundwater levels should be measured from a pre-established and recorded reference point. — The reference point elevations (RPE) need to have been surveyed to the NAVD 88, feet and shall be accurate to within 0.5 feet, at a minimum (23 CCR §352.4(a)(4). The USGS standard is 0.1 ft. The reasoning is related to the accuracy of GW model results. If the accuracy of GWLs input to GW models are not accurately known, any errors in model results propagate over time through the model runs. As a result, GWL changes and associated changes in inflow, outflow and storage become increasing less certain. In the case of the Colusa subbasin knowing the accuracy of the MP to only 0.5 ft could result in WL changes of +/- 0.5 ft and storage changes of +/- 0.5 ft (100,000s af/y potentially). Also, Accurate to within 0.5 ft at a minimum seems a little ambiguous. Do you mean that 0.5 ft is the least accurate value acceptable but greater values (1.0 ft, 5.0 ft, etc.) are also acceptable? I would suggest you change this phrase to : " accurate to within +/- 0.5 ft (+/- 0.1 ft if you are going to use the more broadly accepted standard). If you make the change here, make it throughout the rest of the text.	Comment addressed. The protocols and requirements have been shortened to include only a summary of the requirements and references for approved protocols. This level of detail is no longer included in Chapter 4.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
143	Donald Bills	GGA-TAC		4.2.2.2.1	4-4	1, bullet 2		"…Equipment should be operated and maintained in accordance with the manufacturer's instructions." The WL measuring equipment should be calibration checked annually to be sure it is still the same as the original manufacture calibration. In addition, if a well probe is stuck in is a well but can be removed. The calibration of the well probe should be verified before the probe is used again.	Comment addressed. Please see the response to comment 142.
144	Donald Bills	GGA-TAC		4.2.2.2.1	4-4	1, bullet 3		Monitoring wells developed in partially confined or confined aquifers can have a pressure gage installed in the well cap as a further indication of potential hydraulic head.	Comment addressed. Please see the response to comment 142.
145	Donald Bills	GGA-TAC		4.2.2.2.1	4-4	1, bullet 4		Near pumping, recently pumping nearby. Nearby stream flowing or not recently following or not, etc.	Comment addressed. Please see the response to comment 142.
146	Donald Bills	GGA-TAC		4.2.2.2.1	4-4	1, bullet 6		Water levels shall be measured to the nearest 0.1 foot, at a minimum (23 CCR §352.4(a)(3). Measurements to the nearest 0.01 feet are preferred and should be used if the equipment allows. — Groundwater elevations (GWE) are calculated as the RPE minus measured depth to water (DTW). See the problem here? It your RPE is only accurate to +/- 0.5 ft, your GWE is now only accurate to +/- 0.6 ft. USGS standard is to measure RPE's to +/- 0.1 ft and WLS to +/- 0.01 ft (depths less than 500 ft) and round to the nearest 0/1 ft. In addition, all depth to water measurements in wells are repeated until you can get three results within 0.1 ft of each other. The average is used.	Comment addressed. Please see the response to comment 142.
147	Donald Bills	GGA-TAC	4	4.2.2.2.1	4-5	2, bullet 5		"Recorded information should include:…" NOTE: The Height of the RPE can and will change over time. That is why it should be checked at least annually, and the new elevation noted if it has changes.	Comment addressed. Please see the response to comment 142.
148	Donald Bills	GGA-TAC		4.2.2.3	4-6		Figure 4-1	Significant cones of depression (GW withdrawal for Ag.) occur to the NW of Orland just south of Stony Creek and to the SW of Orland. Yet, there is only one monitoring well (21N04W12A001-004M) available to evaluate these drawdowns as they develop over time. I would suggest additional monitoring wells be places in these areas. The same is true in the area to the west of Artois and Willows.	Comment addressed. Please see the response to comment 142.
149	Donald Bills	GGA-TAC		4.2.2.3	4-12	2		"Many of the surface waters are near wells included in the current groundwater monitoring network, except for the surface waters within the Colusa National Wildlife Refuge, east of Williams." Suggest you add the following to this: "…east of Williams, N and NW of Orland near Stony Creek, NW of Artois along the middle reaches of Walker Creek, and NW of Willows along the middle reaches of Willow Creek."	Comment addressed. These additional data gap areas are now called out in the GSP.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
150	Donald Bills	GGA-TAC		4.2.2.3	4-12	5		Are the caved-in of casing collapsed wells going to be repaired or replaced?	Comment acknowledged. To the best of our knowledge, there are no plans to repair or replace these damaged wells. The GSP now excludes the damaged wells from the monitoring network and includes recommended replacement wells, as well as recommended locations for new wells to add to the monitoring network.
151	Donald Bills	GGA-TAC		4.2.2.4	4-12	2, item 2		Consider adding: c. Areas of active drawdowns (storage decline) with minimal monitoring well coverage.	Comment addressed in the GSP section indicated.
152	Donald Bills	GGA-TAC	4	4.2.2.5.2	4-14			I would recommend considering adding monitoring wells in the areas mentioned in my comments on page 4-6 and 4.12. Figure 4.2 already shows one well being removed from the network in the areas near Orland mentioned in comments on page 4-6.	Comment addressed. These additional data gap areas are now called out in the GSP.
153	Donald Bills	GGA-TAC		4.2.3	4-14			Irrigated Ag is also known to increase salinity in shallow water-bearing zones as irrigation leaches minerals from the soil. I would also add nitrate as a constituent of concern for the Colusa subbasin. Nitrates resulting from livestock operations and areas with a high density of septic systems are known to also leach in to the subsurface.	Comment acknowledged. The GSAs decided to focus on salinity for their groundwater quality monitoring as nitrate is more heavily regulated, monitored, and required to have management actions if exceedances occur. The GSP annual report and periodic GSP evaluations and updates will evaluate existing nitrate concentrations, but nitrate is not currently a constituent of concern for action from the GSAs.
154	Donald Bills	GGA-TAC		4.2.3.2	4-16	1		Wilde, 2005 has been updated extensively. Newer versions od different chapters of the report were developed in 2008, 2012, 2014, 2018, 2019, 2021 The entire manual is now available online at: https://www.usgs.gov/mission-areas/water-resources/science/national-field-manual-collection-water-quality-data-nfm?qt-science_center_objects=0#qt-science_center_objects 3rd Bullet: Sample integrity, i.e. ppb protocol? Perhaps add a comment about the chain of custody (oops… bullet 14).	Comment addressed. Wilde (2005) is the version recommended in the DWR BMPs. The text was revised to acknowledge this recommendation, but also to allow for more recent versions to be used.
155	Donald Bills	GGA-TAC		4.2.3.2	4-16	2, bullet 2		And the unique identifier should be verified to already exist in the data base so the data has a home and does not end up in a "unknown site" file.	Comment addressed. Please see the response to comment 142.
156	Donald Bills	GGA-TAC		4.2.3.2	4-16	2, bullet 6		During purging of the well field parameters should be monitored until stable to insure the well has been correctly purged. Easy to do with a QW multi meter.	Comment addressed. Please see the response to comment 142.
157	Donald Bills	GGA-TAC		4.2.3.2	4-16	2,bullet 8		Suggest adding dissolved oxygen (DO) to the list of filed parameters. GW typically has low or near zero DO. Water sitting in well casing for a period of time will accumulate concentrations of DO. Represents another good indicator of proper well purge.	Comment addressed. Please see the response to comment 142.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
158	Donald Bills	GGA-TAC		4.2.3.2	4-16	2, bullet 9		Sample labels can be preprinted in the lab with all the appropriate info. Prevents the smearing of hand-written labels using pencil, ink and even waterproof ink (Sharpie). Also be aware that the outside of the sample bottles can "sweat" in coolers or other containers. The result is the label glue will weaken and the labels will come off. Double bag samples is one solution.	Comment addressed. Please see the response to comment 142.
159	Donald Bills	GGA-TAC		4.2.3.2	4-16	2, bullet 10		Field parameter DO is a good indicator of this. Laminar flow may require the use of a variable speed pump so DD is not excessive during collection of the water sample.	Comment addressed. Please see the response to comment 142.
160	Donald Bills	GGA-TAC		4.2.3.2	4-16	2, bullet 11		DQOs? Is this a reference to Quality assurance. If so a number of duplicates, blanks and spike samples will need to be processed either in the lab or on site, depending on the type and number of water samples being collected during an individual field run. Maybe briefly explain here?	Comment acknowledged. The references to DQOs have been removed or reworded, as necessary, as we did not define specific DQOs.
161	Donald Bills	GGA-TAC		4.2.3.2	4-16	2, bullet 12		In this case DQOs appears to be referring to lab detection limits for individual constituents. Correct or no? May need more explanation here.	Comment acknowledged. The references to DQOs have been removed or reworded, as necessary, as we did not define specific DQOs.
162	Donald Bills	GGA-TAC		4.2.3.5	4-19	1		The lead sentence suggesting the existing QW monitoring programs as sufficient contradicts 4.2.3.4 which says they are not sufficient. If the existing monitoring wells are not spatially located enough to address salinity concerns or, not deep enough to detect upwelling of brackish GW from below, they are indeed not sufficient.	Comment acknowledged. The text has been revised to include a more in-depth discussion about the rationale, data gaps, and recommendations for the groundwater quality monitoring network.
163	Donald Bills	GGA-TAC		4,2,3,5	4-19	2		Small diameter monitoring wells pose additional issues for the collection of Value QW samples. Small diameter submersible pumps (less than 2 inches) are few and far in between. Typically, they are limited to lifts of 100 ft or less, and have small pumping rates (~one gpm or less). Bailers (Teflon preferred) are another option and are readily sized to fit in 2-inch monitoring wells. Bailing a well to purge can be difficult depending on the depth. Bailers have to be pre cleaned between each water sample. Bailer sample volumes may be on the order of 1 liter or less meaning several bail volumes to collect a sample. Then there is still the issue if ant of the monitoring wells are deep enough to register upwelling of brackish water from below.	Comment addressed. Please see the response to comment 142.
164	Donald Bills	GGA-TAC		4.2.4.1 lands subsiden ce	4-20	2, bullet 8		Land subsidence should be measured at least as accurately as SWLs if not more accurate. Small changes in land subsidence (tenths of a foot, not half a foot or more) can have a significant impact on the surface and on GW storage. If you are measuring the elevation of ground surface to +/- 0.1 ft and the elevation of your RP to +/- 0.5 ft, again the accuracy of your subsidence measurement is no better than +/- 0.6 ft.	Comment addressed. Please see the response to comment 142.

Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
165	Donald Bills	GGA-TAC		4.2.5.1	4-24	1, bullet 7		Benchmarks at USGS stream-flow gaging stations are surveyed to the nearest 0.01 ft. One-hundredth foot accuracy is critical to development of a good (+/- 5 percent of the actual flow) or better stage-discharge relationship. If not, you risk losing indications of GW supported base flow and any seasonal signature of gaining or losing flow to/from GW. As an aside, the USGS also requires a minimum of 10-years of continuous (every 15-minutes) record for the data to have any statistical significance.	Comment addressed. Please see the response to comment 142.
166	Donald Bills	GGA-TAC		4.2.5.2	4-24	3		Accuracy of stage data is +/- 0.01 ft (required).	Comment addressed. Please see the response to comment 142.
167	Donald Bills	GGA-TAC		4.2.5.5	4-24	1		Figure 4-4 is land subsidence. I think you mean figure 4-5. The legend for figure 4-5 does not provide adequate explanation of the different stream types shown on the map (perennial, intermittent, ephemeral, canals, or drains). The line widths and colors vary from thick to very thin and light blue to very light blue respectively. It needs to be revised.	Comment addressed. Waters in the maps have been adjusted in coloring, as deemed necessary.
168	Donald Bills	GGA-TAC		4.2.5.5	4-25	2		"Additionally, existing stream and drainage reports will be evaluated for additional information on the timing, stage, and magnitude of flows in ephemeral and intermittent streams in the subbasin, if necessary to fill data gaps or support projects and management actions during GSP implementation." There used to be a stream-flow gaging station on Walker Creek at Artois. Still there? Still active? There also use to be a gage on the Glenn-Colusa Canal where it crosses Stony Creek south of Hamilton City. Still there? Still Active? I imagine there are additional discontinued stream-flow gaging stations scattered across the Colusa subbasin. If the structures for these sites are still there, they can be re-established by installing stage recorders and making periodic discharge measurements to verify the old stage discharge relationships. Besides the Colusa Drain, Willow Creek west of Willows is another intermittent/ephemeral stream that would be worth the effort to gage.	Comment addressed. The text has been revised to include a more in-depth discussion about the rationale, data gaps, and recommendations for surface flow and spring monitoring.
169	Donald Bills	GGA-TAC		4.3 Referenc es	4-27			Add Wilde (2005) or most recent reference(s) available. Reference for California Rice Commission? Reference for California Statewide Groundwater Elevation Monitoring Program (CASGEM)?	Comment addressed. The references are included under the consulting agencies name. Wilde (2005) is the version recommended in the DWR BMPs. The text was revised to acknowledge this recommendation, but also to allow for more recent versions to be used.
170	Holly Reimers		1	1.1	1-1	2		The priority being to halt overdraft and bring basins into balance? This is not even close to being complied with. The overdraft is far greater than the recharge with the ground water tables lowering each year.	Comment acknowledged. Halting overdraft and bringing the subbasin into hydrologic balance is a goal. Achieving this goal will take a lot of effort, collaboration, and give-and-take between all of the affected peoples, communities, industries, and environments.
171	Holly Reimers		1	1.1	1-1		1, 2 & 6	Sounds good but is NOT will not work and is not doable.	Comment acknowledged. This bullet list includes the "undesirable results" as defined by DWR and SGMA.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
172	Holly Reimers		1	1.1	1-1	4		Achieving the groundwater management within 20 years WILL BE TOO LATE.	Comment acknowledged. The 20-year timeframe was decided and established through SGMA, and is simply a deadline for sustainability to be reached or improvements to be shown. Ideally, improvements to groundwater and surface water conditions will occur much sooner than the 20-year deadline.
173	Holly Reimers		1	1.2	1-2	1		SEE ABOVE!	Comment acknowledged. The 20-year timeframe was decided and established through SGMA, and is simply a deadline for sustainability to be reached or improvements to be shown. Ideally, improvements to groundwater and surface water conditions will occur much sooner than the 20-year deadline.
174	Holly Reimers		1	354-10	3 of 7		1-1	The whole process has been totally lacking in "public engagement". Nor has the GGA encouraged any "active involvement". As the times we have given input we have been overridden by counsel.	Comment acknowledged. This concern has been conveyed to the public outreach team.
175	Holly Reimers		2	2.1.2	2-4	2.1.2.1		With the Colusa Subbasin depending on ground water for their potable water the ground water for these wells should be closely watched as the number of wells are going dry or having to be lowered at an alarming rate.	Comment acknowledged. Additional text has been added to Chapter 2 to specify private pumper representation in the GSAs and to Chapter 3 to include a data gap concerning groundwater levels in shallow domestic wells.
176	Holly Reimers		2				2-6	The table shows the density of Ag. wells around Orland. Is anyone reporting the number of domestic wells that are being affected by this?	Comment acknowledged. The density of domestic wells is shown in the middle panel of Figure 2-6. Well densities are based solely on DWR's records and may not reflect all existing wells in the Subbasin. Domestic wells impacted by lowering of groundwater levels are not being tracked in this figure. Additional text has been added to the GSP Chapter 3 to include a data gap concerning groundwater levels in shallow domestic wells.
177	Holly Reimers		2	2.2	2-16	2.2.1.1		"Manage and reduce invasive plant populations" This has been one of my main talking points for many years. The Salt Ceder and the Bamboo are non native and are using more water than any other source. Especially in this dry year these plants need to be eradicated!	Comment acknowledged.
178	Holly Reimers		2	2.2	2-17	2.2.1.1		"Ensure long-term Groundwater Sustainability" At the rate this is going and where it is headed the train has left the station and we in Glenn County will have little or no ground water in the very near future. Domestic and livestock wells MUST be protected.	Comment acknowledged.
179	Holly Reimers		2	2.2	2-17	2.2.1.1		The definition of sustainable: "related to, or being a method of harvesting or using a resource so that the resource is NOT depleted or PERMANENTLY damaged". To date all that I have seen and hear coming from the GGA has been a JOKE!!!	Comment acknowledged.
180	Holly Reimers		2		2-23	2.2.4		With 2021 being one of if not the driest years on record to transfer surface water OUT of the subbasin should be at the very least suspended. To transfer serfice water then pump ground water as a substitute should not be allowed.	Comment acknowledged. Much of the surface water that flows within or through Colusa Subbasin is managed by USBR, a federal agency. Local agencies have little to no power to determine the amount of surface water that is transferred out of the Subbasin.
181	Holly Reimers		2		2-29	2.5.1.2		Chowchilla?????	Comment addressed in the GSP section indicated.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
182	Holly Reimers		3		ALL	ALL		Anyone reading this needs a Masters degree in Geology. Anyone looking for something to put them to sleep at night can try this chapter. Most of what is contained is FAR above most people and especially those here in Northern California. Maybe this chapter is necessary but it is way over the top on so much detail that it loses the normal person. It certainly lost me.	Comment acknowledged. All of the topics are either required by DWR and SGMA or are industry-standard supplemental topics that were deemed to be appropriate for inclusion in this Chapter. The goal of Chapter 3 was to meet DWR/SGMA requirements and provide information to GSAs, residents, and other scientists and engineers that may work on future SGMA-related projects. The Executive Summary contains a simplified version of Chapter 3. Chapter 3 is very technical as it describes the physical, chemical, and climatic history of the area designated as Colusa Subbasin, discusses existing conditions of the subbasin (as of 2020), and introduces future scenario model and water budget calculations based on predictions of future conditions. The techniques and tools to characterize aquifer properties, flow mechanics through a substrate, water budgets, etc. require scientific terminology to accurately convey the necessary information.
183	Holly Reimers		4		ALL	ALL		There is no mention of using those locals that are drillers and or anyone that repairs pump and wells. It should be noted that those working in the "field" just might have a better idea as to what is happening to our groundwater than someone sitting at a computer someplace other then in the field in Glenn County.	Comment acknowledged. Additional testing and local data collection is recommended. Chapters 5, 6, and 7 provide suggestions and recommendations for future technical studies, next steps, water management studies, etc. to reach the sustainability goals.
184	Holly Reimers							After reading through this whole draft. Witch I will have to admit was in many places very boring, I see no offers of solutions. Lots of "we will Keep looking at it" but nothing to address what some are saying is a major overdraft of our ground water. Domestic and stock wells are having to be lowered or are running out of water. The word on the street is that the ground water is dropping by over 1' per year and that was BEFORE the current very dry year. To me this is nothing more than a "make someone feel good" and a waste of time and energy of some that are well meaning but this is NOT getting the job done.	Comment acknowledged. The "we will look into it" is primarily due to lack of available information regarding groundwater flow mechanics. Additional testing and local data collection is recommended. Chapters 5, 6, and 7 provide suggestions and recommendations for future technical studies, next steps, water management studies, etc. to reach the sustainability goals.
185	Jim Wallace		3		3-86	Table 3-10		The table lists diversions only from Stony Creek (SC) and the Sac River (SR), and not the CBD.	Comment acknowledged. The table represents a boundary budget for the Subbasin, so only diversions from boundary waterways outside the Subbasin are reported separately (please refer to the table footnote (a)). In an effort to simplify the number of flow paths shown, inflows to the Colusa Basin Drain are included as part of the total "Sacramento River Inflows." A footnote clarifying this has been added to the table (please refer to table footnote (c)). Diversions from the Colusa Basin Drain are internal to the Subbasin, and are thus not shown in this table.
186	Brooke Davis		6	6.2	5	1	Summary of all PMAs	It is clear what Direct Groundwater recharge is, but not clear what In-Lieu Groundwater recharge is to someone not familiar with it. Is it meaning there is recharge happening simply because there is less ground water used?	Comment addressed. Clarification has been added to Section 6.2 to describe all project types. "In-lieu groundwater recharge" refers to projects that offset groundwater pumping by supplying or otherwise incentivizing use of surface water or other water supplies instead.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
187	Ben King		5.3.1.3		5-6			Last paragraph should include impact of SWRCB water curtailments to TC Contractors. The example just refers to Federal curtailments. Comment should also highlight the fact that TC Member groundwater pumpers will have no alternative but to pump groundwater during curtailments because they need to irrigate their permanent plantings.	Comment addressed. The text in Section 5.3.1.1 has been revised to note that both "federal and state water allocation policies," among other factors, could potentially lead to reductions in available surface water supplies.
188	Ben King		5	5.3.1.4				Comment should address the dewatering of small water systems and domestic wells and the impact on DAC and SDAC households in the affected areas. This is not a hypothetical issue – domestic wells in College City and Arbuckle have run dry. This should be highlighted in the GSP.	Comment addressed. We have added a preface to the GSP to acknowledge the current drought conditions and summarize what is known at this time about the severity of well dewatering experienced by water users, including domestic well users and DAC/SDAC/EDA households. Notably, the majority of the populace in the Colusa Subbasin is classified as a DAC, SDAC, or EDA - just as impacts to groundwater conditions affect these communities, ongoing outreach and implementation of the GSP and PMAs will also benefit them. It is noted that ongoing management of the Colusa Subbasin under the GSP will follow an "adaptive management" strategy that involves active monitoring of Subbasin conditions and addressing any challenges related to maintaining groundwater sustainability by scaling and implementing PMAs in a targeted and proportional manner in accordance with the needs of the Subbasin. Annual reports provide an opportunity each year to evaluate current Subbasin conditions and assess needs for further PMAs. During periodic evaluations, the GSP will be reviewed and revised, as needed, as we learn more about the effects of current and future conditions. At this time, prior to completion and adoption of the GSP, drought response efforts in the Subbasin are the responsibility of the counties, cities, and other local agencies. Counties are currently leading a number of efforts to document and address dewatered wells, including putting programs in place to bring water to those users whose wells are dry. Following adoption of the GSP, those responsibilities may shift to or be coordinated with the GSAs. A strategy for guiding potential coordination between the GSAs, counties, cities, and other local agencies is described in Ch 7. Coordination would ensure preservation of public health and safety (purview of counties/cities) and groundwater sustainability (purview of GSAs).
189	Ben King		5	5.3.1.5				Discussion should include the impact on small water systems and domestic wells. The number of reported domestic wells should be recorded and highlighted. It is my understanding that over 19 domestic wells have already ran dry. The impact on households in SDAC and DAC areas should be highlighted.	Please see the response to comment 188.

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
190	Ben King		5	5.3.4.1	5-10			Discussion of the role of the USEPA should be included. The USEPA has cited the small water systems of Grimes and Princeton for arsenic contamination. It is very important that that the discussion includes the degradation of fresh water aquifers caused by upwelling of poor quality water. There is a possibility that over pumping could cause or exasperate this undesired outcome.	Comment addressed. The California Safe Drinking Water Act addresses the regulation and control of public water systems in the State of California, including enforcing provisions of the federal Safe Drinking Water Act. The federal government first granted primary enforcement responsibility to the State in 1978. The State Water Resources Control Board Division of Drinking Water (DDW) is the agency responsible for enforcement in Colusa and Glenn Counties, including the entire Colusa Subbasin. Chapter 5 has been revised to clarify the state and federal regulatory relationship. Grimes and Princeton have had violations of the 10-microgram per liter Primary Maximum Contaminant Level (MCL), which is both the State of California and federal standard. Chapter 3 has been revised to include discussion of arsenic in Grimes and Princeton.
191	Ben King		5	3.4.2	5-11			Impact on SDAC and DAC areas should be identified and discussed by the GSA. Water quality of monitoring wells with multi-completion stages should be documented for each depth stage to identify degraded fresh water aquifers caused by upwelling. We should avoid water quality monitoring cherry picking and record the data for all depth stages and monitor trends over time to identify possible upwelling.	Comment addressed. Chapter 2 has been revised to include discussion and mapping of Disadvantaged Communities (DAC) and Severely Disadvantaged Communities (SDAC). We concur that multiple completion wells should be used for monitoring EC trends when such wells are available. Monitoring and reporting of EC for all completions in multiple completion wells should be included in the monitoring for potential upwelling of brackish or saline water. New monitoring wells used for monitoring upwelling should be multiple completions when feasible.
192	Ben King		5	3.4.3	5-11			If Sites is constructed, water quality may be adversely impacted by the elevation gradient between the elevation of sites and the bowels of wells on the valley flow. This gradient could be 600 to 900 feet of elevation head and may take decades to document. Especially around the Sutter Buttes Rampart we need to monitor for potential effects of a redox reaction when connate water upwells and starts an oxidation process. Arsenic desorption is a predicted outcome when the pH of the connate water is greater than 8. There are also potential biotic outcomes again arsenic related when connate salt water starts the oxidation process. Certain anoxic microbes may add to the arsenic contamination similar to the cause of arsenic contamination in Chesapeake Bay. Earthquake activity could also affect the movement of upwelled contaminants. The west side of the valley has a history of geothermal conditions which could be impacted by earthquakes and earthquakes could also be a catalyst for upwelling via active faults.	Comment acknowledged. The stage of Sites Reservoir will be higher than the intakes of wells in the Colusa Subbasin, and an elevation gradient will exist between the reservoir stage and groundwater levels in wells in the Colusa Subbasin. The reservoir is located in the Coast Range adjacent to the groundwater subbasin. Most of the reservoir will be separated from the Subbasin by at least two miles of Coast Range rocks. Seepage from the reservoir to the groundwater subbasin is expected to be very low because of the low permeability of the Coast Range rocks. Because seepage rates are anticipated to be very low, no significant impact to the pH of groundwater in the subbasin is expected. As documented in Chapter 3, arsenic concentrations are known to be elevated in the vicinity of the Sutter Buttes. The elevated arsenic concentrations are a consequence of the geologic materials comprising the aquifer and the geochemistry of the aquifer and groundwater. The geology and current groundwater geochemistry, along with geothermal activity, earthquake activity and the potential for movement of connate water constitute the existing conditions in the Subbasin.

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
193	Ben King		5	3.4.4.	5-12			How about birth defects, mother health and other arsenic contamination related outcomes Rather than adverse effect to property values – loss homeowner values and loss of housing if a domestic well becomes contaminated.	Comment addressed. Section 5.3.4.4 has been revised to reference public health concerns as "Potential Effects of Undesirable Results" associated with degraded water quality.
194	Ben King		5	3.4.5	5.12			USEPA and SWRCB Citations should be evaluated.	Comment addressed. Chapter 3 has been revised to provide additional information on exceedances of drinking water standards. Please see also the responses to comments 190 and 193.
195	Ben King		5	4.1	5-16			The stakeholder input regarding the 80 pct level should be documented and recorded for future public comment. As you may know there has been over 20 domestic wells reported dry with several in the College City area. The domestic well threshold should be an area of future discussion and stakeholder input as the drought progresses. The advocates of the 80 pct threshold should be documented and disclosed and the issue of domestic wells should have a future public discourse. Was there a GSA vote on the 80 percent level?	Comment acknowledged. The SMC were presented to the public and discussed at Joint TAC meetings. Joint TAC meetings were held approximately monthly, with a total of 13 meetings held between May 8, 2020, and June 11, 2021. SMC were addressed at nine of the 13 meetings, and at all seven meetings held between January 8, 2021, and June 11, 2021. TAC members engaged in a very thorough, thoughtful, and constructive manner, giving consideration to all interests in the Subbasin involved with or affected by groundwater use and management. SMC were ultimately vetted and approved by both the CGA and GGA Boards at open Board meetings. Public notice was given in advance of those meetings. The decision records for the SMC are documented in Appendix 5A, and referenced in Section 5.3 of the GSP.
196	Ben King		5	5.4.1.1.1				The adverse degradation from the redox process for connate salt water will most likely be permanent. Significant lowering of groundwater near Grimes and the East Side of the Sacramento River could be the most vulnerable are for redox and potential adverse biotic outcomes. On the west side where there is natural geothermal pressures the lowering of groundwater levels could affect the hydrologic balance of groundwater and result in more upwelling. Again another reason to measure all water quality at all observable depths.	Comment acknowledged. Please see responses to comments 192 and 234.
197	Ben King		5	5.4.4.1				There should be a Minimum Threshold for Arsenic Contamination. There are two small water supply systems in Colusa County with USEPA Citations, two abandoned wells at the southern part of the City of Colusa and a reported observation of 200 ug/L near Grimes. Trends in arsenic contamination should be monitored over time due to the potential for continued redox of connate salt water and potential movement via faults which could be adversely aggravated by future tectonic activity.	Comment acknowledged. Please see responses to comments 190, 192, 193, 194 and 234.

198	Ben King		5	5.4.4.2				The Measurable Objective for arsenic should be the USEPA MCL of 10 ug/L	Comment acknowledged. Please see responses to comments 190, 192, 193, and 194. The State Water Resources Control Board Division of Drinking Water (DDW) requires drinking water service providers to issue Consumer Confidence Reports (CCRs) to the public on an annual basis. The CCRs must report on detected contaminants on state and federal lists and contaminants exceeding their California Public Health Goals (PHGs) and Primary and Secondary Maximum Contaminant Levels (MCLs). PHGs are non-enforceable goals established by the California EPA's Office of Environmental Health Hazard Assessment (OEHHA). The law requires that where OEHHA has not adopted a PHG for a constituent, the water service providers are to use the federal Maximum Contaminant Level Goal (MCLG). PHGs and MCLGs are health-based standards, which are typically much lower than MCLs. For example, the California PHG and MCL for arsenic are 0.004 micrograms per liter (µg/L) and 10 µg/L, respectively. The regulations also require water service providers to include specific language on the health effects of arsenic in the CCRs if the arsenic concentration is above 5 µg/L, but below or equal to 10 µg/L. Violations must be documented, including an explanation of the violation including, duration of the violation, potential adverse health effects, and actions taken to address the violation. DDW may refer enforcement to the United States Environmental Protection Agency.
199	Ben King		5	5.4.4.4				The Interim Milestone discussion should include the GSA's role in working with the State of California to guarantee the Human Right to Fresh Water to the residents of the Colusa Subbasin. The State has the responsibility to uphold this Human Right and the GSA will likely have to work with the State on targeted solutions or mitigation efforts.	Comment addressed. A specific reference to the Human Right to Fresh Water is now added to Section 5.4.4.4. Additional discussion of the Human Right to Water and its relationship to the GSAs and the GSP is provided in Chapter 2.

200	Ben King		Appendix 6A		1			The potential for In-Lieu Recharge within the service are of the Tehama-Colusa Canal needs to be evaluated on a month by month or week by week basis and at incremental delivery points on the Canal itself. The physical capacity of the Canal and the physical limitations of all the component irrigation systems that use delivered water will constrain the potential for In-Lieu Recharge. Additionally, there is no discussion about how the use of the Canal for groundwater conveyance under the Warren Act. To the extent the Canal infrastructure is used to store groundwater or convey groundwater from one irrigation system to another (potentially against the flow of the Canal) the potential for the use of In-Lieu deliveries will be constrained.	Comment acknowledged and addressed. Considering historical canal operations, Jeffrey Sutton (General Manager, Tehama-Colusa Canal Authority) has expressed his (caveated) opinion that it is likely that conveyance capacity is available to facilitate the in-lieu projects proposed, subject to certain conditions. The exact communication with Jeffrey Sutton is included in a new attachment to Appendix 6A, and footnoted on the reference to the TCC. A monthly, weekly, or daily operations model of the TCC was not readily available, and creation of such was not in the scope or budget for GSP development work at this time.
201	Ben King		Appendix 6A					It was not clear from the analysis if any of these constraints were considered or analyzed in the potential for the target In-Lieu deliveries. Additional constraints may be relevant once the seasonality of water demand is considered and whether or not the cumulative capacity of the connected irrigation systems is considered since it is likely that both groundwater and surface water would be a required supply during peak ET demand periods.	Please see the response to comment 200.
202	Ben King		Appendix 6A					Is there a model for monthly or weekly water availability at the various delivery points down the Canal infrastructure and monthly or weekly cumulative ET demand for the service area as the water flows southward. Currently water available for the CCWD has to traverse all the northern user service areas and also be of sufficient supplies to meet the needs of Dunnigan Irrigation District. If Sites is constructed, the water flows across both CCWD and DID service area will have be of sufficient volume to meet the delivery needs of the TC – Colusa Basin Drain interconnect pipeline.	Please see the response to comment 200.

203	Ben King		Appendix 6B	Introduction				These demand actions are not "backstops" and should not be implemented without full and transparent support the Cities of Colusa, Williams, Willows and Orland and the Board of Supervisors of Glenn and Colusa Counties. If there is a need to implement this type of action it should be done by a member irrigation company and fully paid by the local irrigation company since there are substantial property rights at issue. Rather than a "back stop" the proposed demand actions should be considered the last and least desired option and should only be done extensive public discourse and public meetings. . As discussed on Page 10, any such Demand Action "..should include consideration of legal, economic, engineering, hydrogeologic, and political considerations".	Comment acknowledged. The demand management action is described as a backstop option because it is viewed as an option that would be considered after other available options. This is stated in the second paragraph of Section 6.5.2.3. As summarized in Table 6-47 of the same section, the management action would be considered in consultation with stakeholders and all local governing agencies, including the GSAs.
204	Ben King			Sponsor				There should be a sponsor disclosed for the two proposed demand actions. Grant Davies mentioned that Mary Fahey and Lisa Hunter were the sponsors which is obviously not correct because they are County Employees.	Comment acknowledged. It was the decision of the CGA and GGA to include demand management in the list of potential PMAs. The CGA and GGA are listed as the proponents of these management actions in Table 6-2. The responsibility for implementing specific components of demand management would depend on the precise action selected. However, we reiterate that demand management is viewed as an option that would be considered after other available options (per Section 6.5.2.3).

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
205	Ben King						Table 1	What Does Rice Milling encompass? There are Tree Nut Farming and a Vegetable and Melon Farming, Grain Farming but no Rice Farming. Is Rice Farming part of Rice Milling or Grain Farming. Rice farming and related local jobs should be identified separately since some rice farmers already fallow ground as necessary for organic rice production and/or sell surface water. The data seems to be from 2014 and only one year which happens to be a drought year. Since it is 7 year old data if could be irrelevant and/or unrepresentative because it reflects the economic impact of the last drought. Has this data been assessed against more recent year's data? What kind of volatility is there in the IMPLAN data set? There should be more recent data presented and presented over a multiple year period. It is interesting to note that 3750 or approx. 31% of the 12,255 FTE jobs are local government. The dependent economic relationship between local government jobs and the local economy should be discussed and analyzed. Fallowed land and out of basin water sales and transfers take away local jobs and dimmish the tax base necessary for local government jobs. There is no discussion about seasonal employment and the positive add on revenue derived from unemployment benefits, fringe benefits and retirement/government payments that come with seasonal employment. Many seasonal employees are women and mothers of low to middle income household units that depend on the marginal income, unemployment insurance and other government payments that comes with seasonal employment. This is a critical and necessary component for any economic costs benefit analysis for a program that will lead to fallowing farmable acreage	Comment acknowledged and addressed. IMPLAN sectors for the economy are based on an aggregation of North American Industry Classification System (NAICS) codes. Rice milling includes NAICS 311212. This includes a number of businesses related to the milling of rice. It does not include rice farming. Rice farming is under the Grain Farming IMPLAN model sector. This includes NAICS 111130, 111140, 111150, 111160, 111191, and 111199. It includes rice in addition to other grains. All values shown in the GSP represent current dollars, not 2014 dollars. The 2014 IMPLAN "multipliers" are used to calculate the total value of the industry based on current industry values. Multipliers capture the relationship between a dollar spent in different sectors of the economy. This relationship is generally stable over time. The results of the analysis are sensitive to changes in the value of the crops produced over time, and less so to the use of base IMPLAN data for industry multipliers. Therefore, the values as reported in the GSP reflect current conditions. Comments regarding the number of jobs and different types of employment are noted and would be considered in a benefit-cost assessment. The purpose of the analysis summarized in Table 1, as described in that section, is to demonstrate the economic contribution of agriculture to Colusa/Glenn counties. It is summarizing the value of the current industry. It is not a benefit-cost analysis of a specific or hypothetical demand management program. That would require a different analysis framework that was not developed here. It may be appropriate to develop additional analysis under future GSP implementation that would include these considerations. A sentence was added to clarify that "This section describes the current contribution of agriculture to the Colusa Subbasin economies."

206	Ben King				3	Demand Management Costs		There is no reason to assume that Net Groundwater Pumping reduction assumed would actually provide a physical benefit to the stressed aquafers in the Colusa Subbasin. This type of program may work within irrigation districts but it needs to be applied within the sphere of adjacent wells or at least within an irrigation system. Paying a rice farmer not to plant a rice field near Grimes is not going to mitigate the pumping depletion caused by pumping groundwater to irrigate a tomato field on the west side of I-5. Perhaps this will with the accounting of a water budget but in reality do nothing to mitigate the short term or long term impact of dropping water levels in stressed parts of the aquifers. The most likely outcome of this type of Demand Action would be to pit certain ag industry vs ag industry. Many tomato farmers are tenant farmers who make substantial investment in buried drip lines. Many rice farmers are settlement contractors who can make money selling water especially during critically dry years and some of which are organic rice farmers who need to idle production fields for a growing season and who would have great incentive to idle and receive payment.	Comment acknowledged. The hydrogeologic conditions of the Subbasin affect outcomes for PMAs in different parts of the Subbasin. These would be assessed as part of PMA implementation. As described under Section 6.5.2.4, a demand management program could be targeted to specific areas within the Subbasin. Similarly, other PMAs would be targeted to areas of need so that specific benefits occur in these regions. Broader benefits would accrue to the entire subbasin because the subbasin is viewed as a single unit for groundwater sustainability.

207	Ben King						Figure 3	There is no transparency regarding the methodology, source or assumptions made for the water costs presented.	Comment acknowledged and addressed. The method is briefly summarized on Pages 4 and 5, prior to Figure 2. The section title on Page 4 was changed to "Methods." The paragraphs within that section were edited and two technical references were added. The figure formatting was also corrected so that figures are referenced within the correct sections. The revised paragraphs are: "An economic model of the Colusa Subbasin was applied to evaluate the supply and demand for water and establish the cost of demand management. It reflects the local water supplies and uses, financial data on returns to farming, and current crop market conditions for Sacramento Valley crops. This includes current crop prices and yields. Production costs are representative averages based on University of California Cooperative Extension crop budgets. It The model is calibrated to the GSP water budget (applied water and evapotranspiration of applied water) and geospatial land use data described in Chapter 3 of the GSP. A technical description of the economic calibration method is beyond the scope of this technical appendix. The method applied is a standard, peer-reviewed economic analysis approach that is widely applied for valuation of water supply and water supply projects in California [refs footnote]. This same technical approach was applied for calibration of an economic optimization model of the Colusa Subbasin. The model quantifies the effect of changes in water supply availability and cost on farm income (e.g., net income and gross farm revenues) and simulates how the agricultural sector would respond to changes in water availability and cost. Responses include switching to higher value and/or lower water use crops, adjusting input use, and idling land. The decision to switch crops and/or idle land depends on agricultural market conditions simulated by the model under increasing levels of a range of (hypothetical) demand management. The economic analysis quantifies the direct economic cost of changing crops and idling land under implementation of demand reduction. For this technical appendix, costs are expressed on a per acre-foot basis for comparability to other PMAs in the GSP. " References added to the footnotes include: Department of Water Resources. Water Plan Update. 2009. Data and Tools Technical Appendix. Economic Modeling of Agriculture and Water in California using the Statewide Agricultural Production Model. U.S. Bureau of Reclamation. 2019. CVP Long Term Operations EIS. Appendix 12A: Statewide Agricultural Production Model (SWAP) Documentation.

208	Ben King				8			It is true that a specific allocation " would require careful analysis of the legal, hydrogeologic, economic and engineering implications, and would require vigorous and informed discussion with stakeholders." The Colusa Subbasin stakeholders should first have the opportunity to be informed and then have the vigorous discussion before considering these Demand Actions.	Comment acknowledged. Demand management is a backstop to other PMAs that would only be implemented if determined necessary after analysis of legal, hydrogeologic, economic and engineering implications, and would require vigorous and informed discussion with stakeholders.
209	Ben King				11			The following statemen as it applies to California is false : " Most GSA's in the state….use.. wellhead meters , to track and enforce allocations." Is it really true that the use of crop type and/or ET calculations are less common than wellhead metering. The DWR has spent extensive resources with the LandIQ crop mapping and many water budgets and irrigation systems are built on CIMIS ET Data and crop coefficients. Ultimately drip lines only have so much capacity so a lot can be done without metering especially when there is only one source of irrigation water. Metering for private pumpers with only source of water would seem like an unnecessary burden and regulatory overreach.	Comment acknowledged and addressed. The full statement reads "Most GSAs in the state and groundwater management entities outside the state use some form of measurement, usually wellhead meters, to track and enforce allocations. There are also examples of allocations that use crop type and/or ET calculations to estimate water use and groundwater pumping, but this approach is less common. Estimation versus measurement is a GSA policy decision that can have important effects on the cost and its ability to manage the allocation effectively." The meaning was not to imply all GSAs use meters. Edited for additional clarity as follows: "Most groundwater management entities outside the state use some form of measurement, including wellhead metering, to track allocations. In California, many GSAs are proposing or considering direct measurement or using crop type and/or ET calculations to estimate water use and groundwater pumping. Estimation versus measurement is a GSA policy decision that can have important effects on the cost and its ability to manage the allocation effectively."
210	Ben King				11			Secondary economic impacts SHOULD be considered BEFORE "future iterations" and more importantly any further consideration of the implantation or adoption of the Demand Management PMAs proposed in this Appendix.	Comment addressed. The text has been revised to indicate that these impacts "should be considered" in future iterations of this analysis.
211	Ben King		Appendix 6D					Please consider my comments from Appendix 6A regarding the assumptions for Modeling Parameters as it relates to projects relying on surface water deliveries from the Tehama - Colusa Canal and Colusa County Water District in particular.	Please see the response to comment 200.

212	Holly Dawley	GCID	5	5.1	5 1	N/A		The Sustainability Terminology could use some context. It might be helpful at the end of 5.1 before 5.1.1 to reiterate what the MTs and MOs are and how they relate.	Comment addressed. Additional clarification of terminology has been added to Section 5.1.
213	Holly Dawley	GCID	5	5.1.1	5 2	2nd bullet list		Would be helpful to carry symbols through to the bullet list indicating the five sustainability indicators that are relevant to the GSP	Comment addressed. Symbols have been added to the bullet list in Section 5.1.1.
214	Holly Dawley	GCID	5	5.1	Not specific			Since it has come up, it might be helpful to address that there is a layer of Ancient Seawater but why that does not trigger the indicator.	Comment acknowledged. Connate water and the base of the freshwater are discussed in Chapter 3 of the GSP.
215	Holly Dawley	GCID	5	5.1	5 2	1st after 2 bullet lists		Suggest add sentence after the 1st sentence quickly explaining why those 2 indicators are using proxies.	Comment addressed. A sentence has been added to explain the correlation between groundwater levels and groundwater storage and depletions of interconnected surface water, allowing groundwater levels to serve as a proxy for those sustainability indicators.
216	Holly Dawley	GCID	5	5.2.1	5 3	3rd paragraph		Why are “planned projects” in quotes? This is a title/name not a nickname.	Comment addressed. The quotation marks have been removed.
217	Holly Dawley	GCID	5	5.3.1.1	5 5	2nd		What is “foreseeable?”	Comment addressed. "Foreseeable" has been revised to reference the projected water budget analysis period (2016-2065), both in Section 5.3.1.1 and Section 5.3.2.1.
218	Holly Dawley	GCID	5	5.3.1.3	5 6	Last paragraph in 5.3.1.3		Suggest add “or state” after federal in 1st sentence. Water use in the CVP can be dictated by State, too.	Comment addressed. The text in Section 5.3.1.1 has been revised to note that both "federal and state water allocation policies," among other factors, could potentially lead to reductions in available surface water supplies.
219	Holly Dawley	GCID	5	5.3.4	5 10			Consistency: Add indicator symbols as in other sub-task titles.	Comment addressed in the GSP section indicated.
220	Holly Dawley	GCID	5	5.3.4.1	5 10	3rd paragraph		Suggest clarify “existing regulatory programs.”	Comment addressed. The existing regulatory programs are described in the paragraphs following the referenced paragraph. The following text was added: "The California Safe Drinking Water Act addresses the regulation and control of public water systems in the State of California, including enforcing provisions of the federal Safe Drinking Water Act. The federal government first granted primary enforcement responsibility to the State in 1978. The State Water Resources Control Board Division of Drinking Water (DDW) is the agency responsible for enforcement in Colusa and Glenn Counties, including the entire Colusa Subbasin."

226	Ben King		5A		2	Outreach		Since the majority of the Outreach and Public Involvement Process was done before the severity of the current drought was known the outreach process does not reflect the impact on domestic well users nor does have domestic well users had the opportunity to give their input. The reported number of domestic well problems should be documented and there should be a concerted outreach program to get their input on the Minimum Thresholds and mitigation measures. The GSA has an opportunity to truly understand the impact on domestic wells from lowered groundwater levels and act in a proactive manner to help manage and mitigate adverse outcomes for the future. The current Memorandum does not reflect input from domestic well users.	Comment acknowledged. We have added a preface to the GSP to acknowledge the current drought conditions and summarize what is known at this time about the severity of well dewatering experienced by water users in the Subbasin, including domestic well users. As stated in Appendix 5A, "Members of the public were welcome to attend the Joint TAC and open Board meetings and were encouraged to express their opinions, and suggestions, and comments on the SMCs, as well as other aspects of the GSP. Members of the public attended and participated in most Joint TAC meetings, including those in which SMCs were discussed." It is noted that GSP development has occurred over several years, with continued public outreach and consideration of the most sufficient and credible information and data available for the decisions being made and the time frame available for making those decisions. Ongoing management of the Colusa Subbasin under the GSP will follow an “adaptive management” strategy that involves active monitoring of Subbasin conditions and ongoing public outreach. Data, information, and input from the public will be evaluated, reported, and used to guide GSP implementation. GSP annual reports provide an opportunity each year to check in and evaluate current Subbasin conditions and assess needs for additional PMAs. The first annual report, due April 2022, will evaluate groundwater conditions in the Colusa Subbasin since 2015. During the periodic (five-year) evaluations, the GSP will also be reviewed and revised, as needed, to address new understanding of Subbasin conditions. Please note that Appendix 5A has been changed to Appendix 5B for the final GSP.
227	Ben King		5A			Hydrographs		The hydrograph for 14N02W22A002 does not have any data on the two pages it is presented.	Comment acknowledged. Well 14N02W22A002 is newly constructed and has not yet been monitored. This well is included in the Colusa Subbasin groundwater monitoring network and will be monitored in the future. Please note that Appendix 5A has been changed to Appendix 5B in the final GSP.

228	Ben King		5B		1			The statement " This appendix describes an economic analysis of MT's that was developed and presented to the TAC at the May 13,2021 Meeting" is false. While it is clear that the economic analysis was included in the presentation there is no indication that the economic analysis was presented or discussed at the meeting. The Minutes of the May 13, 2021 TAC Meeting do not reflect any discussion of the ERA proposal and states on Page 8 of the Minutes in Agenda Item 4.b Projects and Management Actions (PMAs) - " This Agenda item was not discussed during the TAC meeting due to time constraints"	Comment addressed. The presentation was given at the next TAC meeting on June 11, 2021. The text was edited to reflect this date. ERA Economics was asked by the GSAs to develop a description of general demand management programs and prepare economic analysis to illustrate initial concepts for the TAC and public. The demand management program is not a PMA proposal developed by ERA. All PMAs were proposed and defined, and will ultimately be implemented, by the GSAs and stakeholders (which includes the TAC and all local entities). Please note that Appendix 5B has been changed to Appendix 5C in the final GSP.
229	Ben King		5B		2			What are the assumed capital cost for refurbishing potentially dewatered domestic wells? What are the assumptions for energy costs caused by additional pumping? What rate schedule? As you probably are aware there are many critical assumptions depending on season and time of use.	Comment addressed. The following sub-paragraphs have been added to summarize cost assumptions: "1.a.The capital cost of well replacement is set at $40,000 per well based on costs for domestic well replacement used in other GSPs . These costs generally include drilling at $40 per foot, a sanitary seal for a $2,500, and a pump for $5,000. This does not include permit costs. Actual costs will vary based on the costs of materials and supply and demand for well drilling services. " "2.a.Agricultural pumping energy cost depends on lift, pump efficiency, and the power rate which varies by time of use and size of load. For purposes here, the analysis used an average over several 2021 PG&E agricultural power rates to get a total variable pumping cost of about $0.52 per acre-foot per foot of lift." Please note that Appendix 5B has been changed to Appendix 5C for the final GSP.
230	Ben King		5B		4		Figure 2	What does the Table Crop and Acres mean? There is not explanation for the inclusion of this table of the documentation for and reference source.	Comment addressed. The following statement has been added to clarify the acreage shown in the figure: "The irrigated acreage within the Thiessen polygon is also shown in the figure. The mix of crops grown affects the cost of demand management. The example polygon is predominantly planted to permanent crops (almonds and olives), which are costly to idle due to higher net return relative to other annual crops and the substantial capital investment required to establish orchards." Please note that Appendix 5B has been changed to Appendix 5C for the final GSP.

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
231	Ben King		5B		2			Why does the economic analysis assume that demand management would be adopted by the GSA? The economic analysis in Chapter 6 appears to be highly speculative and is difficult to assess since the assumptions for the analysis have not been disclosed.	Comment addressed. Appendix 5B uses demand management as an example only, and does not imply it would be implemented. The following sentence was added to make this clearer to the reader: "It is noted that demand management is not a planned PMA in the Colusa Subbasin, and these costs are used as a proxy for the costs of other projects." Two paragraphs were added to the appendix to describe the costs for well drilling and replacement. Please see also the response to comment 229. Please note that Appendix 5B has been changed to Appendix 5C for the final GSP.
232	Ben King		5B		All	General Comment		Regarding the costs of replacing the domestic well it is hard to assess whether or not the analysis is based on representative costs because the assumptions were not disclosed. The analysis seems to make rudimentary assumptions and not real life assumptions. In the crisis of a drought, local drilling capacity and well repair services are very limited and usually focused on serving the biggest and best customers. Domestic well owners are likely to have to wait until the growing season is over and pay for the costs to maintain their personal health and livelihood during the loss of the well. Some domestic well owners may not have access to the capital they need to make the repairs and most would not be able to secure 20 year financing unless they had equity in their houses and could refinance. Having a well run dry and being ablet to get an appraisal for refinancing is probably near impossible and ultimately the loss of a well may mean substantial loss of market value of their house. To make this a meaningful analysis, there is a timely opportunity to contact the County administrators and survey the domestic well users that have lost their wells during the current drought and ask them about direct and consequential economic costs and costs due to loss of income due to their well depletions. There are more than 20 such dry domestic wells in Colusa County alone.	Comment addressed. Two paragraphs were added to clarify the underlying costs applied to the analysis (see response to comment 229). The analysis is developed to support long-run planning for MTs/MOs. The short-run costs listed in the comment are important to consider in severe drought emergencies, such as 2021. The following paragraph was added to the discussion section of the appendix: "The analysis is developed to support long-run planning for setting MTs. PMAs needed to support higher MTs require time to develop and implement and cannot be implemented rapidly in response to severe, unprecedented drought. The short-run costs of wells running dry during severe drought events can include other cost factors that were not explicitly analyzed. For example, in the crisis of a severe drought, local drilling capacity and well repair services can be limited, which can result in higher cost or increased wait times. This can place additional financial stress on households with domestic wells." An expanded analysis working with local well drillers and other parties in the county could be considered as part of GSP implementation. The additional costs of domestic well replacement during a drought emergency are noted.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
233	Ben King		5C	General				Arsenic levels should be included for Grimes and Princeton since the USEPA has continuously reported that observed levels are above the USEPA MCL. Arsenic should also be reported for all the wells for the Colusa Supply system since there has been the Del Oro Walnut Ranch well abandonment and the CIP enforcement action. Also the well near Grimes with the 200 ug/L observation should be included and reported for each observable depth if it is a multi-completion well.	Comment acknowledged and addressed. Public drinking water systems in the Colusa Subbasin are regulated by the State Water Resources Control Board Division of Drinking Water (DDW), and the regulated public systems have the responsibility for monitoring and reporting on drinking water quality for regulated constituents and unregulated constituents requiring monitoring and reporting. As described in Chapter 5, the GSAs will coordinate with the public systems to address water quality issues in the basin but are focusing GSP monitoring efforts on upwelling of brackish or saline water, which is not explicitly addressed under other existing monitoring and reporting programs. Chapter 3 has been revised to include additional discussion of arsenic impairments in the subbasin. The appendix has been updated to include EC plots for Grimes and Princeton. Please note that Appendix 5C has been changed to Appendix 5D for the final GSP.
234	Ben King		5C	General				All of the reported locations should have EC observations for each observable stage if any of the reported locations are multi-completion wells. The new well drilled by the County of Darrin Williams property should be included in the appendix and water quality observations should be tracked for each observable depth. Mr. Williams reported upwelling near the 1000 foot depth and the water quality from the upwelling aquifer should be observed and tracked.	Comment acknowledged. We concur that multiple completion wells should be used for monitoring EC trends when such wells are available. Monitoring and reporting of EC for all completions in multiple completion wells should be included in the monitoring for potential upwelling of brackish or saline water. New monitoring wells used for monitoring upwelling should be multiple completions when feasible. Please note that Appendix 5C has been changed to Appendix 5D for the final GSP.
235	Ben King		5C	General				Overall the Appendix needs to incorporate the wells discussed in Section 3.2.5.11. There is a multicompletion well near Maxwell with 4 stages and TDS levels as high as 1640 mg/L. There is a shallow well west of Grimes with a measurement of 2,040 mg/L. Wells near College City with TDS concentrations greater than 1000 should be of immediate concern since domestic wells are running dry and bowls are being lowered. Where are the measurements for the shallow wells west of Colusa with TDS levels greater than 2000 mg/L.	Comment acknowledged. The appendix provides EC plots for the subset of wells comprising the water quality representative monitoring network. Other water quality monitoring wells exist in the Subbasin. The historical water quality results are discussed in Chapter 3, and water quality results from existing wells and monitoring programs will be evaluated by the GSAs in coordination with the regulated entities during implementation of the GSP. Please note that Appendix 5C has been changed to Appendix 5D for the final GSP.
236	Ben King		5C	General				Generally we should have up to date observations for all reported wells. The data for the Maxwell public supply system ends before 2013. The data for the Princeton public supply system ends before 2014 Arbuckle only has 3 observations ending in 2016. Since the Williams supply system has elevated EC levels, all the supply wells for Williams should be reported so as to avoid cherry picking and also to monitor any adverse trends.	Comment acknowledged. Some of the drinking water compliance sampling is conducted on a two to three year cycle for a given well. The data presented is the latest data available through the State Water Resources Control Board Division of Drinking Water (DDW), as of June 29, 2021. The data, as available from DDW, will be updated annually during implementation of the GSP. Please note that Appendix 5C has been changed to Appendix 5D for the final GSP.
237	Mary Fahey	Colusa County/CGA	5	Intro	5 - 1	1		Second sentence, instead of “Colusa GSAs”, please use either “Colusa Subbasin GSAs” or “Colusa Groundwater Authority and Glenn Groundwater Authority”	Comment addressed. The text has been revised to "Colusa Groundwater Authority and Glenn Groundwater Authority."
238	Mary Fahey	Colusa County/CGA	5	5.3.1.3	5 - 6	3		Type-o, line 3, pumping would have to increase…	Comment addressed. The text has been corrected.
239	Mary Fahey	Colusa County/CGA	5	5.3.4.1	5 - 11	1,2nd bullet		Type-o, increase in the number of...	Comment addressed. The text has been corrected.

Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
240	Mary Fahey	Colusa County/CGA	5	5.4.1	5 - 16	1		Is "Section 0" correct?	Comment addressed. The text has been corrected.
241	Mary Fahey	Colusa County/CGA	5	5.4.7	5 - 33	5		Type-o, Stony Creek	Comment addressed. The text has been corrected.
242	Mary Fahey	Colusa County/CGA	5	5.4.7	5 - 32			If you feel it's appropriate, this is a good opportunity to mention here that the CGA, GGA and neighboring GSAs have been coordinating throughout GSP development and will continue to coordinate and share technical data during GSP implementation.	Comment addressed. This point has been added to Section 5.4.7 with reference to additional coordination activities described in Chapter 7.
243	Mary Fahey	Colusa County/CGA	Appx 5A		2	1-3		It should be noted that the SMC were also vetted and approved by both the CGA and GGA Boards at open, publicly noticed meetings.	Comment addressed. The text has been revised to note this. The SMC decision records have also been added as a new appendix to Chapter 5 (Appendix 5A).
244	Mary Fahey	Colusa County/CGA	Appx 5A		2	3		Members of the public were welcome to attend all of these meetings and were encouraged to express their opinions and suggestions. There was very good stakeholder attendance and participation at these meetings.	Comment addressed. Clarification has been added to reinforce this.
245	Mary Fahey	Colusa County/CGA	6	Section 6 -1	6-4			2nd bullet: Suggest removing the second sentence regarding demand management. This type of PMA is a last resort and should not be highlighted.	Comment addressed. This reference to demand management has been removed.
246	Mary Fahey	Colusa County/CGA	6		6-6		Table 6-2	First project: Colusa Subbasin Multi-Benefit Groundwater Recharge (TNC). This project concludes in the spring of 2021, not 2020.	Comment addressed. The text has been corrected.
247	Mary Fahey	Colusa County/CGA	6	6.3.3.1	6-29			Add a program benefit – Groundwater conditions (via groundwater Recharge)	Comment addressed. This benefit has been added.
248	Mary Fahey	Colusa County/CGA	6	6.3.3.1	6-29			Pilot program concludes in 2021. The program evaluated flooding that would provide habitat benefits for migrating shorebirds, and groundwater recharge. Both (habitat and recharge) are equal goals of the project.	Comment addressed. The text has been revised to clarify these equal goals.
249	Mary Fahey	Colusa County/CGA	6	6.3.3.1	6-30			While the current project is limited to SDAC communities due to grant funding requirements, ongoing, the project would not be limited to benefitting water levels in DACs.	Comment addressed. Clarification has been added to not that other communities may also benefit depending on where the project is implemented.
250	Mary Fahey	Colusa County/CGA	6	6.3.3.2	6-32			Pilot program runs from 2018-2021. Also update dates in Table 6-13.	Comment addressed. The text has been corrected.
251	Mary Fahey	Colusa County/CGA	6	6.3.3.4	6-32			Depending on the farm, there may be installation of monitoring equipment required (flow meters, groundwater level monitoring devices)	Comment addressed. The text has been revised and additional context has been given for potential infrastructure/equipment needs, depending on the field.
252	Mary Fahey	Colusa County/CGA	6	6.3.3.6	6-32			Program completed in 2021	Comment addressed. The text has been corrected.
253	Mary Fahey	Colusa County/CGA	6	6.3.3.6	6-33			Last three bullets should be indented further	Comment addressed. The text has been corrected.
254	Mary Fahey	Colusa County/CGA	6	6.3.3.7	6-33			Could the CGA and GGA also serve permitting roles?	Comment addressed. The CGA and GGA have been added to the list of agencies with potential permitting roles.
255	Mary Fahey	Colusa County/CGA	6	General				General comment – excellent work on this chapter. This is a great set of tools that the GSAs can pull from as they implement SGMA in the Colusa Subbasin.	Comment acknowledged.
256	Zac Dickens	GCID	6	6.2	pg 6-11	N/A	6 - 3	For chapter consistency, in the "Planned" section on the "In-lieu Groundwater Recharge" row, please move "GCID In-lieu Groundwater Recharge" to the "Potential" section on the "In-leu Groundwater Recharge" row.	Comment addressed. The text has been corrected.

Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
257	Zac Dickens	GCID	6 and associated appendix items	Through out				Minor formatting request. Please use Word's find and replace for all instances of "Glenn Colusa Irrigation District" and substitute with "Glenn-Colusa Irrigation District".	Comment addressed in the GSP section indicated.
258	Holly Reimers	West Side Landowner	6	Section 6.1,	Page 6-3			It should be noted that in the past 15 to 20 years the number of orchards has greatly increased while the number of flood irrigated acres had been greatly reduced. Flood irrigation aids in the recharging of the ground water. The number of acres that has been moved from flood irrigation to drip irrigation is quite substantial with the overall drop of the ground water levels. I have seen this personally when my neighbor changed his irrigated pastures to trees and drip irrigation. On property I own to the East of his now drip irrigated fields the old Oak trees started to suffer then die. These trees were in some cases well over 300 years old but had grown accustomed to the supply of water from the surface. When this water was reduced or eliminated they were unable to survive. Also the water level of my domestic well to the East dropped.	Comment addressed. A sentence has been added to Section 6.1 to acknowledge the shift in irrigation practices.
259	Holly Reimers	West Side Landowner		Section 6.2	Page 6-8			Orland Unit Water Users Flood Water Conveyance. I would note that the conveyance is already in place to be able to run any flood waters from the South Canal into the "Low Line Ditch" then into Hambright Creek, just North of the Graves Cemetery. There is also the option to flood acres at the Black Butte Ranch to provide for additional groundwater recharge. Being on the upper end of the water recharge system it has been noted that when there is no surface irrigation waters applied to the grounds at the Black Butte Ranch the ground water levels in the areas to the East start to drop.	Comment addressed. These details have been added to the project description in Section 6.5.1.5 as an example of potential project configurations.
260	Holly Reimers	West Side Landowner			Page 6-9		Table 6-2	There is no mention of Walker Creek of Hambright. Both of these creeks help in the ground water recharge.	Comment addressed. Section 6.5.1.2 has been revised to acknowledge the potential recharge benefits and opportunities along other streams and creeks, including Walker Creek and Hambright Creek. However, it is noted that the westside streams diversion project analysis was confined to the six streams listed because of the availability of monthly flow estimates.
261	Holly Reimers	West Side Landowner			Page 6-10		Table 6-2	OH one of my favorite points. Invasive species and the Eradication of such!! Arundo & Tamarisk, also known as Bamboo and Salt Cedar. Non-native and VERY invasive. Stony Creek has the largest overgrown population of Bamboo in the WHOLE state of California. I'm not sure that the Salt Cedar has been inventoried but it is just as invasive and a major user of ground/surface water. To anyone that is worried about the "riparian" habitat I would suggest they take a drive up 1-5 or drive Hwy. 32 between Orland and Chico. It takes water to make "riparian" habitat at this time there is NO WATER. **These no-native invasive plants need to be destroyed and eradicated.**	Comment acknowledged.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
262	Holly Reimers	West Side Landowner		Section 6.3.2.10			Table 6-11	Why is there even a conversation about water transfers. Especially when that water could be used to recharge our deleted groundwater basin? When there is conversations about putting meters on wells why would water be transferred out of the basin?	Comment acknowledged. Table 6-11 establishes the cost of within basin transfers and is used to support the Planned PMA cost estimates. No water transfers outside of the basin are considered or included in this GSP.
263	Holly Reimers	West Side Landowner		Section 6.5.1.2			Figure 6-10	Should also list Hambright Creek and Walker Creek	Please see the response to comment 260.
264	Holly Reimers	West Side Landowner		Section 6.5.1.5	Page 6-69		Table 6-33	Cost: There should be little cost to this as the conveyance system is already in place the proper gates just need to be opened.	Comment acknowledged. The anticipated costs of this project have yet to be determined and would be reported in GSP annual reports and five-year updates when known
265	Emily Reinhart	Davis Ranches/Sycamore Mutual Water Company	6	5.1.7	6-70	1 (above Table 6-35)		Question: What do you mean by "newly formed water storage district"? We are already within an existing water district (Sycamore Mutual Water Company). Davis Ranches is the participating Landowner within the district that will be hosting the recharge site.	Comment addressed. The text has been revised to correct these details.
266	Emily Reinhart	Davis Ranches/Sycamore Mutual Water Company	6	5.1.7	6-70	1 (above Table 6-35)		Water would be sources from Sacramento River during high flows in the system. Currently, Sycamore Mutual Water Company (a Sacramento River Settlement Contractor). We will be looking to rely on our Riparian water rights in order to do winter flooding (beneficial use). We will not have 215 water from the Colusa Drain. Should project start before Nov. 1, we would use some of our settlement contract water to recharge.	Comment addressed. The text has been revised to correct these details.
267	Emily Reinhart	Davis Ranches/Sycamore Mutual Water Company	6	5.1.7	6-70	1 (above Table 6-35)		Habitat benefits also include winter floodplain habitat for migrating shorebirds/waterfowl as we pulse flood the field	Comment addressed. The text has been revised to correct these details.
268	Emily Reinhart	Davis Ranches/Sycamore Mutual Water Company	6	5.1.7	6-71	Table 6-35	Water Source & Reliability	Source is Sacramento River. Reliability is good, but still unknown at this time.	Comment addressed. The text has been revised to correct these details.
269	Emily Reinhart	Davis Ranches/Sycamore Mutual Water Company	6	3.5.1	6-42	1		30 – 45 days during fall/winter. We aren't tied to a specific start date. There is flexibility built into the project to allow for water availability, etc. The target is Fall/Winter for the habitat benefits as well as availability of water in the system. Settlement contract waters would be used if the project starts before Nov. 1.	Comment addressed. The text has been revised to correct these details.
270	Emily Reinhart	Davis Ranches/Sycamore Mutual Water Company	6	3.5.1	6-42	2		We do not have contract for 215 water. We do have riparian rights that we would be exercising for this project for beneficial use (habitat).	Comment addressed. The text has been revised to correct these details.
271	Emily Reinhart	Davis Ranches/Sycamore Mutual Water Company	6	3.5.1	6-42	2		5,000 acre feet over 10-years is our goal.	Comment addressed. The text has been revised to correct these details.
272	Emily Reinhart	Davis Ranches/Sycamore Mutual Water Company	6	3.5.5	6-44	1		No 215 water.	Comment addressed. The text has been revised to correct these details.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
273	Emily Reinhart	Davis Ranches/Sycamore Mutual Water Company	6	3.5.7	6-45	2		No 215 water.	Comment addressed. The text has been revised to correct these details.
274	Emily Reinhart	Davis Ranches/Sycamore Mutual Water Company	6		6-8		Table 6-2	Diversion of winter flows from Sacramento River (riparian) or settlement contract flows (should project start before Nov.1).	Comment addressed. The text has been revised to correct these details.
275	Donald Bills	GGA/CGA TAC Member	5	5.2.1	5.3	1		Nothing in chapter 6 refers to sustainable yield. Should this be a reference to chapter 1 section 1.2? As I mentioned in my review comments there, sustainable/safe yield has not been considered a valid term by the hydrologic community for close to 20 years now (USGS Circular 1186, 1999 Alley and others., USGS SIR 2013-5079, The journey from safe yield to sustainability, Leake and Alley, 2005, A critical review of the Water-budget myth and safe yield, Zhou, 2009, Groundwater depletion in the U.S. 1900 to 2008), Konikow, 2013, The myth of safe yield Kathleen Ferris and Sarah Porter, May 2021, Kyl Center for Water Policy, . It would be better to confine this discussion in terms of the sustainable goal(s). This year proves the point. Estimates of sustainable yield based on historical records are being broken almost everywhere in the subbasin this year.	Comment addressed. The title of the subsection has been revised to, "Sustainable Operation of the Subbasin". The text of the subsection has been revised and no longer refers to sustainable yield. It now refers to sustainable operation of the subbasin. Sustainable yield must be reported and described, per the GSP regulations. See § 354.18(b)(7) and § 354.18(c)(2)(C)). This requirement is addressed in Chapter 3 of the GSP.

276	Donald Bills	GGA/CGA TAC Member	5	5.2.1	5.3	2		"…it is uncertain that undesirable results will develop in the future." They are occurring now with wells drying up through the basin.	Comment acknowledged. We have added a preface to the GSP to acknowledge the current drought conditions and summarize what is known at this time about the severity of well dewatering experienced by water users in the Subbasin, including domestic well users and DAC/SDAC/EDA households. It is noted that development of the GSP has occurred over several years utilizing the best available science and tools, with the most sufficient and credible information and data available for the decisions being made and the time frame available for making those decisions. Current and historical groundwater conditions and water budgets have been evaluated for the Subbasin in alignment with the GSP regulations, using the most recent and complete hydrologic, water supply, water demand, and land use data available at the time GSP development began. Unfortunately, drought conditions in 2020-2021 have coincided with development of the GSP, a timing that has not permitted complete evaluation and inclusion of data from these years in the GSP at this time. It is noted that ongoing management of the Colusa Subbasin under the GSP will follow an "adaptive management" strategy that involves active monitoring of Subbasin conditions and addressing any challenges related to maintaining groundwater sustainability by scaling and implementing PMAs in a targeted and proportional manner in accordance with the needs of the Subbasin. Data and information collected through ongoing monitoring will be evaluated, reported, and used to guide GSP implementation. GSP annual reports provide an opportunity each year to evaluate current Subbasin conditions and assess needs for additional PMAs. The first annual report, due April 2022, will evaluate groundwater conditions in the Colusa Subbasin since 2015. During the periodic (five-year) evaluations, the GSP will also be reviewed and SMC will be revised, as needed, as we learn more about the effects of current and future conditions.
277	Donald Bills	GGA/CGA TAC Member	5	5.2.2	5.3			"As discussed above, the Colusa Subbasin does not currently have undesirable results, which shows that the Subbasin is being managed sustainably." As of 2021 this is no longer true. It might be reasonable to add a second footnote here to indicate that extreme dry and heat in 2020 and 2021(not seen in the last 1,200 years) has exacerbated the already dry conditions pushing the basin into undesirable results.	Please see the response to comment 276.

278	Donald Bills	GGA/CGA TAC Member	5	5.3.1.1	5.5	2		"…and are not currently occurring. Per the projected water budget (Chapter 3), these effects are not likely to occur in the foreseeable future." I would suggest amending this text possibly by adding reference to the proposed footnote 2 to account for the existing 2020/21 conditions that clearly have exceeded the undesirable result ("…sustained groundwater levels are too low to reasonably satisfy beneficial uses within the Subbasin").	Please see the response to comment 276.
279	Donald Bills	GGA/CGA TAC Member	5	5.3.1.2	5.5	2		"…impact that would potentially harm the "long-term viability" of affected beneficial uses and users in the Subbasin." It may be necessary to re-evaluate this undesirable result given the current conditions in the subbasin. A significant number of domestic wells and shallow irrigation wells are currently dry or close to being dry while the required amount of representative monitoring wells does not appear to show chronic lowering of groundwater levels.	Please see the response to comment 276.
280	Donald Bills	GGA/CGA TAC Member	5	5.3.1.3	5.6			Suggest replacing sustainable yield with sustainable goals as mentioned earlier. I would also suggest adding a third bulleted Cause: Decrease in the annual precipitation and increase in maximin temperature days (above 100 degrees) related to the changing climate ("Climate Crisis").	Comment addressed. The text of the subsection has been revised and no longer refers to sustainable yield. Sustainable yield must be reported and described, per the GSP regulations. See § 354.18(b)(7) and § 354.18(c)(2)(C)). This requirement is addressed in Chapter 3 of the GSP.
281	Donald Bills	GGA/CGA TAC Member	5	5.3.1.4	5.6			I would suggest adding two additional bulleted items here: Permanent loss of crops due to lack of water (farm failure?). Hauling of water to meet minimum household needs.	Comment addressed. These suggested potential effects have been added to Section 5.3.1.4.

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
282	Donald Bills	GGA/CGA TAC Member	5	5.3.2.2	5.7/5.8			"…provided the GSP demonstrates that there is a significant correlation between groundwater levels and the other metrics." The Freshwater zone of the aquifer extends from near the surface to as much as 2,200 ft below the surface with storage estimates of 26 to 140 maf, almost a full order of magnitude difference (chapter 3, section 3.2.3). But most domestic and shallow wells are located within the first 200 ft below the surface where storage is estimated at only about 13 maf. If all these wells were dewatered there would still be significant water in storage (1/2 to 9/10?) not to warrant an undesirable result for GW storage. The 48 monitoring wells represent storage of 1.4 to 7.7 maf… 5 percent of total estimated GW volumes. So, while GW storage is unlikely to see an undesirable result, most of the water wells can go dry anyway affecting beneficial uses and inflicting significant damage to the economy (as we are currently seeing; 2020/21). I realize it is too late in the game to change undesirable results, MTs and MOs now. But I would suggest that consideration for their revision be modified or changed when appropriate to reflect the differences between the unconfined (first 200ft) and confined/ semi-confined (2,000 ft) of the aquifer and more directly link then to climate impacts5.	Comment acknowledged. The referenced subsection has been revised to include the following statement, "As discussed in Section 5.2.1, implementation of the GSP will be based on adaptive management, as required to adapt to changing climatic conditions. The SMCs for groundwater levels and storage will continue to be evaluated and updated as new information about groundwater conditions is acquired and data gaps are filled."
283	Donald Bills	GGA/CGA TAC Member	5	5.3.2.2	5.7/5.8	2		It is unreasonable to use "…groundwater levels ranging from historical lows…". As the current drought and heat crisis is showing us historic ranges can be misleading (e.g. the Colorado River compact based on only 20 years of record) if not used in context.	Comment acknowledged. The sentence reading, "Based on the estimated range of current storage volume in the Colusa Subbasin (Chapter 3) and the small percentage changes in storage estimated to occur over groundwater levels ranging from historical lows to the groundwater levels minimum thresholds, it is anticipated that an undesirable result related to the chronic lowering of groundwater levels would occur before the Subbasin would experience significant and unreasonable effects related to reduction of groundwater storage," has been revised to read, "Based on the estimated range of current storage volume in the Colusa Subbasin (Chapter 3) and the small percentage changes in storage estimated to occur over groundwater levels ranging from current levels to the groundwater levels minimum thresholds, it is anticipated that an undesirable result related to the chronic lowering of groundwater levels would occur before the Subbasin would experience significant and unreasonable effects related to reduction of groundwater storage". Also, please see to the response to comment 282.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
284	Donald Bills	GGA/CGA TAC Member	5	5.3.2.3	5.8	1		"Additional justification and information supporting the criteria used to define when and where the effects of the groundwater conditions cause undesirable results is provided in Appendix 5A." And from Appendix 5, footnote 1 under MTs, "The lack of shallow groundwater data is identified as a data gap and will be addressed along with other data gaps during plan implementation" …And already too late to identify a undesirable condition for 2020/21.	Comment acknowledged. Please see the response to comment 282.
285	Donald Bills	GGA/CGA TAC Member	5	5.3.2.3	5.8	2		"These criteria were determined based on the evaluation of best available data pertaining to the Subbasin's specific conditions and characteristics, as described in the Plan Area and Basin Setting sections of this GSP (Chapter 2 and Chapter 3, respectively),…" Based on 2020/21 conditions it would seem wise to consider adding an interim evaluation to the 5-year period. Suggest every 2 years.	Comment acknowledged. Please see the response to comment 282.
286	Donald Bills	GGA/CGA TAC Member	5	5.3.5.2	5.12	1		As I have commented before and backed up with references from the San Joaquin Valley and Salt River and Tucson Basins in Arizona, 0.5 to 0.6 ft (half a foot…) in a couple months much less 24 is too much to be able to stop or remediate.	Comment acknowledged. The subsidence SMC are being reviewed and will potentially be revised in the final GSP. Additional clarification has also been added to Section 5.3.5.5 to note that: "[...]recognizing that there is uncertainty in Subbasin conditions and that data gaps exist, the GSAs will continue to monitor groundwater levels to identify potential undesirable results as part of GSP annual reports and five-year updates, and adapt GSP implementation, as needed, to avoid undesirable results." Ongoing monitoring and data collection will inform potential updates to sustainable management criteria (including the minimum thresholds, as needed). Potential updates to the GSP will occur during the periodic evaluation process to ensure that the Subbasin is on track to achieve the sustainability goal. Annual reports also provide an opportunity to reassess Subbasin conditions in the interim, and identify whether more urgent evaluation of the GSP is needed.
287	Donald Bills	GGA/CGA TAC Member	5	5.3.5.3	5.13	2		I would suggest adding another potential cause of undesirable result to the list: "decrease in hydraulic conductivity and the resultant increase in well M&O costs."	Comment addressed. These considerations have been clarified in Section 5.3.5.4, as these are viewed more as potential effects of undesirable results.
288	Donald Bills	GGA/CGA TAC Member	5	5.3.6.1	5.13	1		I would suggest adding "Significant and unreasonable impacts to springs".	Comment addressed. The suggested text has been added.
289	Donald Bills	GGA/CGA TAC Member	6	6.2	page 6-12		Table 6.3	"Westside Streams Diversion for Direct or In-lieu Groundwater Recharge…" This type of GW recharge should help mitigate Land subsidence. Suggest you add an "X" to that column.	Comment addressed. The table has been revised to indicate that benefits are expected for land subsidence.

290	Donald Bills	GGA/CGA TAC Member	6	6.5	Page 6-58		Figure 6.9	I would strongly suggest/recommend adding Walker Creek to the map and this section a one of the Westside larger Streams Diversion for Direct or In-lieu Groundwater Recharge. The Walker Creek Watershed drains an area at least as big as the Willow Creek watershed and bigger than either the Logan or Hunter Creek watersheds. In addition, the Walker Creek watershed contains a number of, as yet characterized springs that would be a source of potential recharge.	Comment addressed. Section 6.5.1.2 has been revised to acknowledge the potential recharge benefits and opportunities along other streams and creeks, including Walker Creek and Hambright Creek. However, it is noted that the westside streams diversion project analysis was confined to the six streams listed because of the availability of monthly flow estimates.
291	Donald Bills	GGA/CGA TAC Member	6	6.5.1.2	page 6-61	1	Figure 6.9	Suggest/recommend adding Walker Creek to the list here. See reasons above.	Please see the response to comment 290.
292	Donald Bills	GGA/CGA TAC Member	6	6.5.1.2	page 6-62		Figure 6-10	Suggest/recommend adding Walker Creek to the map.	Please see the response to comment 290.
293	Donald Bills	GGA/CGA TAC Member	6	6.5.1.2	page 6-63		Table 6-29	Water source and reliability: Add Walker Creek.	Please see the response to comment 290.
294	Ben King		1	1.2				This is a question for the DWR. Since the DWR formally adopted a Human Right to Water ("HRTW) Policy in its Department Administrative Manual during April 2021 – does it want to state that it will be including HRTW considerations in the DWR's decision making, program activities and public engagement in SGMA and the GSP development. Wont this statement promote HRTW engagement?	Comment acknowledged. Please note that the Colusa Subbasin GSP does reference the Human Right to Water policy and how that has been factored into GSP development and SGMA-related processes. Please refer to Sections 2.6.1, Human Right to Water, and Sections 2.7.1.2 and 5.4.4.4 of the GSP.
295				1.3.1				Typo for Private Pumpers – appointed by Colusa Groundwater BOS ? Did you mean to say recommended by the Commission and appointed by the BOS? Were there public meetings for the appointment by the Board Members by GSA's? It would be great to know that the GSA's have public meetings. Do they have websites and interested party lists? Please confirm that each GSA has websites and posts notice of meetings at a minimum.	Comment addressed. The description of the Private Pumper Representatives has been corrected as suggested. As described in Section 1.3.1 (in the paragraph following the bulleted list of GGA representatives): "Board members are chosen in public meetings by the respective governing boards of the Member Agencies. Alternates for each Board member are chosen in the same manner by the same Member Agencies." To clarify, member agencies of the CGA and GGA are not GSAs and are not individually held to the requirements of GSAs, but the member agencies do hold public meetings. As described in Section 2.7.3, the CGA and GGA (GSAs) do maintain interested party lists, and do maintain websites that provide notice of meetings, as well as other information and materials related to GSP development. Those websites are: https://colusagroundwater.org/ https://www.countyofglenn.net/dept/planning-community-development-services/water-resources/glenn-groundwater-authority

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
296	Ben King			1.3.3				Are these costs for the Basin as a whole? It would be good to break these costs on a per acre basis and discuss how the costs are allocated to Cities and small water systems. For example – what does the CGA expect the City of Williams to pay going forward? Voters in the Cities need to know. What will the County of Glenn and the County of Colusa be expected to contribute?	Comment addressed. Yes, the costs summarized in Table 1-1 are the total estimated annual GSP implementation costs for the Colusa Subbasin as whole. This clarification has been added to the text in Section 1.3.1. Specific financing plans and cost-allocation approaches are not yet determined, but will be identified and determined with stakeholder involvement following GSP adoption. Those decisions are expected to be made in the coming year. As described in the last paragraph of Section 1.3.1, "The Colusa Subbasin GSAs will develop a financing plan for the overall implementation of the GSP that will specify funding sources and cost-allocation approaches across entities for the different GSP implementation activities (see Chapter 7 and Appendix 7A for a description of existing options)."
297	Ben King		2	2.1			Table 2-3	Table 2-3 is misleading in that it does not reflect the loss in surface supply due to water transfers. There needs to be a table that reflects the historical amount of water transfers for every water purveyor and how much of the water remains in Basin and out of Basin. Without this stakeholders can not assess the available water supply for the Basin.	Comment acknowledged. It is noted that Tables 2-2 and 2-3 are within the Plan Area section of the GSP, and are intended to summarize general information about water purveyors and agencies with water management responsibilities in the Colusa Subbasin (per 23 CCR §354.8). The historical volume of surface water that has remained in the Subbasin is summarized in the water budget (Section 3.3, per 23 CCR §354.18). Please also see the response to comment 298.
298	Ben King		2	2 generally				The Colusa County GMP does a good job discussing water transfers but the GSP is silent on it. Stakeholders need transparency and understanding how water transfers work and how ground water substitution and fallowing work into the available water supply. The transparency and discussion regarding water transfers, fallowing and groundwater substitution also have potential negative DEI and HRTW outcomes because water transferred out of basin and fallowed acreage means less jobs and ground water pumped for ground water substitution could lead to aquifer degradation if the groundwater pumped is pool quality.	Comment addressed. Clarification has been added to Section 3.3.3 (Water Budget Assumptions) to explain how water transfers were factored into the Subbasin water budget. In the historical water budget, surface water supplies were configured to implicitly reflect historical surface water transfers and any effects of transfers on historical groundwater pumping. In the current conditions and future conditions water budgets, it would be highly speculative to characterize possible future water transfers. The approach we used to specify projected surface water supply is consistent with 23 CCR §354.18(c)(3)(C). The uncertainty of future conditions related to surface water supplies is one of many reasons that GSP implementation will be based on adaptive management. As described throughout the GSP, the GSAs are committed to ongoing monitoring and implementation of projects and management actions to respond to changing Subbasin conditions.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
299	Ben King		2					Again there needs to be discussion about surface water transfers and a Table listing the number of acre feet pumped for groundwater substitution and the acres fallowed by each Settlement Contractor. Stakeholders need to know this for HRTW and DEI concerns and also for the general sustainability of economic health of the Subbasin.	Comment acknowledged. Please see the responses to comments 297-298.
300	Ben King		2	2.3.2				There needs to be a discussion regarding groundwater trading markets and how this would impact the potential water demands. The California Water Commission are holding hearings regarding groundwater trading and it is very relevant to the effects on water demands and the economic feasibility and sustainability for the subbasin. To not include any discussion is misleading and could lead stakeholders to misallocate resources or make material economic decisions without full knowledge of a likely outcome. The CWC appears to quite committed to groundwater trading and the PPIC has come out strongly in favor of water markets. It is misleading not to discuss this likelihood especially when there is such a focus on recharge in the PMAs. It would seem that some PMAs may not be economically efficient if water could be traded instead. In June of 2021, Steven Springhorn , Acting Director of SGMA discussed the framework for Water Trading for SGMA Implementation – it seems ingenious to go through this process and not discuss what the Acting Director of SGMA is presenting to the California Water Commission.	Comment acknowledged. The concept of a water market is addressed in the GSP under Section 6.5.2.3, Long-Term Demand Management Action. The market-based concept of financial incentives to encourage the reallocation of groundwater is also a core component of the PMA described in Section 6.5.2.4, Strategic Temporary Land Idling for Drought and Localized Short-Term Groundwater Management. The concept of groundwater markets is further explored in Appendix 6.B, Economic Analysis of Demand Management and Conceptual Allocation Approaches. Page 11 of Appendix 6.B. notes that groundwater trading is a potential option for the subbasin and that other GSAs across the state are currently exploring such options. Appendix 6.B. also presents an economic analysis of potential demand management actions in the Colusa Subbasin. This provides a basis for establishing whether projects are cost-effective relative to other demand management actions, such as a limit on groundwater extractions and a groundwater trading market. However, that type of analysis would be completed as part of future GSP implementation. The GSP acknowledges the potential benefits of a market for improving flexibility for stakeholders that would face limits on groundwater pumping. However, it also acknowledges that developing a market is a substantial undertaking that is beyond the scope of initial GSP development. A market is an institution that would allow willing buyers and sellers of water to make voluntary exchanges. It requires defining property rights to groundwater (e.g., allocation), market and trading rules, administration, and monitoring and enforcement. These may be considered in the future if it is determined to be of interest to the subbasin stakeholders. Any evaluations would be conducted in a public, stakeholder-driven process.

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
301	Ben King		2	2.3.2				There needs to be reference to the ERA Demand Management Actions if they remain in the GSP. If implemented these Management Actions will have the intended effect which is to limited Demand. These PMAs are DEMAND Management Actions and should be referenced and discussed in this section.	Comment addressed. A reference has been added in Section 2.3.2 to indicate that potential demand management actions are discussed in Section 6.5.2.
302	Ben King		2	2.5.1				Discussion about water quality testing, determination of appropriate well depth and what happens if the driller finds poor water quality. I think the answer is that this information is not captured or disclosed and therefore it is a concern for water quality and HRTW issues.	Comment addressed. Section 2.5 provides an overview of coordination of the GSAs' management efforts with existing county and state programs, including county well permitting programs. The following has been added to Section 2.5. "The State recognizes the Human Right to Water pursuant to Water Code Section 106.3, which states, “every human being has the right to safe, clean, affordable, and accessible water adequate for human consumption, cooking, and sanitary purposes.” The human right to water extends to all Californians, including disadvantaged individuals and groups and communities in rural and urban areas (State Water Resource Control Board [State Board], 2021). The GSAs will seek to work with their respective counties, State Board staff and stakeholders in support the State Board’s efforts, “to develop new systems or enhance existing systems to collect data and identify and track communities that do not have, or are at risk of not having, safe, clean, affordable, and accessible water for drinking, cooking, and sanitary purposes (State Board, 2021)."

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
303	Ben King		2	2.6.1				The following was taken verbatim from the DWR's recent Drought Memo. This is from a footnote: DWR formally adopted the Human Right to Water (HRTW) Policy in its Departmental Administrative Manual which outlines how the HRTW should be included in DWR decision-making, program activities, and public engagement. The Water Board adopted a HRTW Resolution, recognizing HRTW as a core value and directing its implementation across programs and activities. The Water Board is also currently drafting a Racial Equity Resolution. There should be a reference to the emerging HRTW and Racial Equity actions by the DRWR and the SWRCB since it is central to Stakeholder HRTW and Diversity Equity and Inclusion (DEI) concerns regarding the GSP and its future implementation.	Comment addressed. Commentary has been added to the existing discussion in Section 2.6.1, Human Right to Water, to reference these emerging efforts.
304	Ben King							I strongly disagree with the statement that the GSA supported and allowed for effective engagement of all stakeholders regarding HRTW and DEI issues. I would urger the DWR to expressing prohibit GSAs taking any action against a stakeholder unless a mediator is brought in especially regarding situations where there are HRTW and DEI or potentially negative racial outcomes.	Comment acknowledged. It is noted that the GSAs created and followed a Communication and Engagement Plan (Appendix 2E) and sponsored, publicized, and conducted numerous engagement opportunities for stakeholders in the Subbasin (Section 2.7.2), including more than 236 separate meetings and workshops. Meetings and workshops have touched on all aspects of GSP development and decision-making, including issues relevant to HRTW and DEI. Meetings and workshops have been open to the public, and meeting notes, materials, and/or recordings have been available to the public. Communication and outreach for these meetings and for GSP development (Appendix 2C) has reached stakeholders of varied backgrounds. All comments related to the GSP have been logged and addressed appropriately (Appendix 2B). The GSAs have made clear and consistent efforts to respectfully engage with stakeholders through robust discussion.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
305	Ben King			Public Engagement 2.7.3.6				The Stakeholder Engagement Process was materially flawed because there was no discussion about the California Water Commissions initiatives around groundwater water trading. It is unreasonable to have no public engagement and submit a GSP without any public discussion of an issue that the DWR Acting Deputy Director of SGMA is presenting at the California Water Commission. As I said, we are spending a lot of time and money considering and debating potential PMAs when we have spent no time regarding the water trading policies being considered by the California Water Commission. Water Trading will have many intended consequences on the allocation of resources and many unintended consequences – some of which could be extremely detrimental to the long term sustainability of the fresh water aquifers of the Sacramento Valley. It seems like the PMA considerations may be a real waste of time – I just found out about the Water Trading discussions of the CWC yesterday which happens to be the last business day for the comment period for this GSP. Where are the GSAs websites. There is a lot of discussion regarding the CGA website but is there any other website. Do they exists for each Member GSA ? If not – why and how can stakeholders gain transparency. Does each Member GSA have an interested person list?	Comment acknowledged. The GSAs have engaged in extensive public engagement, please see the response to comment 304 for additional information. As described in Section 2.7.3, the CGA and GGA (GSAs) do maintain interested party lists, and do maintain websites that provide notice of meetings. Please see the response to comment 295 for more information. The concept of groundwater markets is noted in the GSP. As described under Comment Response 300, the concept of a water market is addressed in the GSP under Section 6.5.2.3, Long-Term Demand Management Action, market-based concept of financial incentives to encourage the reallocation of groundwater under Section 6.5.2.4, Strategic Temporary Land Idling for Drought and Localized Short-Term Groundwater Management, and Appendix 6.B., Economic Analysis of Demand Management and Conceptual Allocation Approaches. It is noted that these groundwater trading discussions have occurred since GSP development began, and draft recommendations for groundwater trading policies will not be available from the California Water Commission until 2022, after GSP adoption. There are various uncertain factors that could affect future water supplies, but would be speculative to define now. The uncertainty of future conditions related to water supplies and potential water trading policies are among the many reasons that GSP implementation will be based on adaptive management. As described throughout the GSP, the GSAs are committed to ongoing monitoring and implementation of projects and management actions to respond to changes in Subbasin conditions. The GSP is a "living document" that the GSAs will review and revise as more information about the basin setting becomes available (per 23 CCR §356.4).

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
306	DEPARTMENT OF FISH AND WILDLIFE			3.2.7; starting page 3-77):				The GSP does not include sufficient detail describing the timing of depletions of interconnected surface water (ISW). a. Issue: Though the GSP discusses annual gains and losses from interconnected surface waters in the subbasin and summarizes net gains by water year type (Table 3-6, page 3-79), the GSP does not include sufficient detail on the timing of depletions as required by 23 CCR § 354.16(f). In order to adequately assess ISW that may be gaining or losing at different times of the year, it is preferential to present net gain/loss values by month, rather than by year. Quantifying depletions by month for each reach will facilitate evaluation of impacts or benefits to environmental beneficial users that rely on surface waters during specific portions of the year. b. Recommendation: The Department recommends including net gains or losses to interconnected surface waters by month, rather than by year.	Comment addressed. A summary of average monthly net gains/losses has been added to Appendix 3G, in addition to the existing summary of annual and average annual net gains/losses. It is noted that these results are summarized from the C2VSimFG-Colusa groundwater model, and therefore carry significant uncertainty. However, at the time of GSP development the model results are considered to be the best available data to describe streamflow depletion. The GSAs have proposed studies to improve model calibration and close data gaps related to depletions of interconnected surface water (please refer to Chapter 7 of the GSP).
307	DEPARTMENT OF FISH AND WILDLIFE			3.2.8; starting page 3-82				Groundwater dependent ecosystem (GDE) identification, required by 23 CCR § 354.16(g), is based on methods that risk exclusion of ecosystems that may depend on groundwater. a. Issues: i. GDE Scoring Criteria: The GSP assigns a rank of '1' (less likely to be a GDE) to '4' (more likely to be a GDE) to potential GDE areas within the Natural Communities Commonly Associated with Groundwater dataset. It is unclear how the rankings are utilized throughout the remainder of the GSP to assess monitoring networks, management criteria, or potential projects. Accordingly, the ranking system has no apparent actionable groundwater management relevance.	Comment addressed. The text in Section 3.2.8 has been revised to clarify that preliminary screening of the potential GDEs within the Colusa Subbasin was conducted to help prioritize areas for further mapping, evaluation and monitoring of GDEs during implementation of the Colusa Subbasin GSP. The preliminary screening supported the assessment of data gaps, evaluation of existing monitoring networks, which could potentially be used for GDE monitoring, and development of PMAs. The GSAs will seek to work with resource agencies, stakeholders, beneficial users and the public to refine the understanding of GDEs in the Colusa Subbasin, fill data gaps and develop PMAs with consideration of GDEs.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
308	DEPARTMENT OF FISH AND WILDLIFE			3.2.8; starting page 3-82				ii. Depth to Groundwater Threshold: The GSP relies on a groundwater level threshold of 30-feet below the ground surface (bgs) to screen potential GDEs within the subbasin. However, mature Valley Oak (Quercus lobata) can access groundwater up to 80 feet bgs (Howard 1992, Lewis & Burgy 1964). The use of a 30-foot threshold may incorrectly result in Valley Oak communities receiving a GSP-imposed score of '1,' indicating that they are least likely to be a GDE.	Comment acknowledged. The GDEs analysis will be refined during GSP implementation. Additional clarification has been added to the GSP Chapter 3 to acknowledge that significant data gaps exist for the precise locations and characteristics of GDEs in the Colusa Subbasin. It is noted that the prioritization, or "scoring," of GDEs is intended as a step toward identifying GDEs using the information available at the time of GSP development. This "scoring" is not seen as a final call on the classification of GDEs, but rather a prioritization for future work to better identify and expand monitoring of potential GDEs. Section 4.2.5.4 has been revised to state that the ISW monitoring network wells may be useful for monitoring groundwater levels near GDEs; however, a dedicated network of shallow monitoring wells will be developed specifically for GDE monitoring during implementation of the GSP. As described in the GSP Chapter 7, the GSAs have proposed a study to investigate expansion of the shallow groundwater level monitoring network for GDEs during GSP implementation. Among other goals, this study is planned to help close data gaps related to identification of GDEs. The prioritization will be refined in this study, and will be factored into decisions for the placement of new monitoring sites to improve the understanding and protection of GDEs.
309	DEPARTMENT OF FISH AND WILDLIFE			3.2.8; starting page 3-82				iii. GDEs Near Surface Water: The GSP assesses whether potential GDE areas are located near surface waters or irrigated cropland, or both. The GSP considers potential GDE areas within 150 feet of surface waters, within 150 feet of irrigated rice paddies, and within 50 feet of other irrigated croplands to have access to surface water; and therefore, the GSP assigns these areas a score of '2' or '3,' indicating they are less likely to be groundwater dependent. The GSP states that "GDEs include vegetation and habitat that are wholly dependent on groundwater" (line 9, page 3-83); however, this narrow definition of a GDE disregards a GDE's adaptability and opportunistic approach to accessing water in which vegetation and ISW may rely on both surface water and groundwater across seasons and years. Furthermore, this GDE definition contradicts an earlier description of GDEs within the GSP, in which the plan states that "a GDE's dependence on groundwater refers to reliance of GDE species and/or communities on groundwater for all or a portion of their water needs" (line 3, page 3-82). Particularly as the GDE areas receiving scores of '2' or '3' have already been determined to be located in areas with depths to groundwater of less than 30 feet, proximity to potential surface waters is insufficient evidence to categorize them as 'less likely' to be GDEs.	Comment acknowledged. Please see the response to comment 308. It is noted that the GDE "scoring" is not seen as a final call on the classification of GDEs, but rather a prioritization for future work to better identify and expand monitoring of potential GDEs. The prioritization will be refined during GSP implementation and will be factored into decisions for the placement of new monitoring sites to improve the understanding and protection of GDEs (see GSP Chapter 7).

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
310	DEPARTMENT OF FISH AND WILDLIFE			3.2.8; starting page 3-82				iv. Data Gaps: The GSP states that there is potential for GDEs to be present in the uplands west of Orland and west of Arbuckle, but that groundwater level data is lacking in these areas and there is insufficient information "to determine their existence" (line 26, page 3-83). Rather than waiting an indeterminate amount of time to gather data to prove groundwater dependence of potential GDE areas and leaving the potential GDEs unclassified in the interim, the GSP should conservatively consider these areas to be GDEs until sufficient data is collected that proves otherwise.	Comment acknowledged. Please see the response to comment 308. It is noted that the GDE "scoring" is not seen as a final call on the classification of GDEs, but rather a prioritization for future work to better identify and expand monitoring of potential GDEs. The GSAs are not discounting that these western areas are GDEs. During GSP implementation, the GSAs are planning to refine the GDE assessment, and have proposed studies to investigate the western boundary of the Subbasin and expand shallow groundwater monitoring to close data gaps in areas where potential GDEs exist. Please see Section 7.1.2 for additional information about these studies.
311	DEPARTMENT OF FISH AND WILDLIFE			3.2.8; starting page 3-82				v. Special Status Species: SGMA defines GDEs as ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface [23 CCR § 351 (m)]. The GSP does not identify or discuss species that may be present within the subbasin that rely on groundwater, groundwater dependent ecosystems, or interconnected surface waters.	Comment addressed. A reference to TNC's analysis of freshwater species located in the Colusa Subbasin has been added to Section 3.2.8 of the GSP (based on analysis of the California Freshwater Species Database version 2.0.9 within the Subbasin boundary). We have also added more text to acknowledge data gaps regarding which of these species are found within GDEs, and references to GSP studies in Chapter 7 to help close those data gaps and expand understanding of GDEs in the Subbasin.
312	DEPARTMENT OF FISH AND WILDLIFE			4.2.5.4; starting page 4-33				The GSP should include additional details related to the plans to improve the monitoring network for GDEs and ISW within the subbasin. a. Issue: The GSP states that the ISW representative monitoring network will also be used to monitor GDEs. The GSP does not present any information or figures to support its assertion that the ISW monitoring sites are located sufficiently near to GDEs to assess shallow groundwater levels in those areas. While the Department appreciates the GSP's acknowledgement of data gaps related to the characterization of GDEs and ISW within the subbasin and the GSP's proposed plan to install up to an additional 10 shallow monitoring wells, the GSP does not provide details on planned locations or timelines for installation of these additional monitoring locations. b. Recommendation: The GSP should include additional detail related to the anticipated timeline for installation of additional wells to further refine ISW and GDE characterization and management. The Department recommends that the GSP assess the locations of special status species within the subbasin to determine which GDE areas likely provide priority habitat. GDE areas and ISW that support special status species or are most at risk of negative impacts due to groundwater pumping should be prioritized for monitoring to inform management actions (See Comment #2(v)).	Comment addressed. Section 4.2.5.4 has been revised to state that the ISW monitoring network wells may be useful for monitoring groundwater levels near GDEs; however, a dedicated network of shallow monitoring wells will be developed specifically for GDE monitoring during implementation of the GSP. The development of a dedicated groundwater dependent ecosystem monitoring network consisting of shallow monitoring wells is discussed in Chapter 6.5.2.9 Potential Management Actions and Chapter 7.1.2.1 GSP Studies. Although the GSAs used the best available scientific data and information to assess potential GDEs within the Colusa Subbasin, significant data gaps exist in the understanding of the GDEs and the associated species. The GSAs will seek to work with resource agencies, stakeholders, beneficial users and the public to refine the understanding of GDEs in the Colusa Subbasin, fill data gaps and develop PMAs with consideration of GDEs.

313	DEPARTMENT OF FISH AND WILDLIFE			5.3.6, 5.4.6 ; starting pages 5-15 and 5-30				Interconnected surface water sustainable management criteria (SMC) may not protect against undesirable results for fish and wildlife beneficial uses and users. a. Issues: i. Minimum Thresholds: Minimum thresholds (MTs) for ISW are set at 10 feet below the measured historical low for each representative monitoring well. The GSP states that establishing MTs below the historic lows is necessary to provide a sufficient margin of operational flexibility during GSP implementation, and that no undesirable results were observed at the historic low; however, the GSP does not include sufficient analysis or discussion to support this claim. In 2015, the second of back-to-back critically dry water years in the Sacramento Valley which resulted in recent historical low groundwater levels, vegetated and aquatic GDEs experienced adverse impacts including stressed or dying riparian vegetation, poor instream habitat availability, and increased water temperatures (DFW 2019). It is unclear what, if any, studies or analyses were completed to assess whether environmental users within the subbasin experienced undesirable results at the historical low groundwater levels, or what metrics the GSP would evaluate to determine the presence of an undesirable result for GDEs or ISW in the event of additional groundwater decline beyond the historic low as the MTs allow. The ISW SMC are also referenced as protective of GDE beneficial users of	Comment acknowledged. The sustainable management criteria for depletion of interconnected surface water were established with the GSAs' understanding that significant data gaps exist in the understanding of stream aquifer interactions in the Colusa Subbasin. Additional studies, more refined numerical models, and additional monitoring will be needed to address these data gaps and uncertainties. Additionally, the GSAs acknowledge that the sustainability thresholds will need to be reviewed and evaluated, and potentially refined, as additional data and information becomes available. The GSAs will seek to work with stakeholders, beneficial users, the public and GSAs representing adjacent subbasins during this process.

313 cont'd								groundwater according to the GSP, but the supporting discussion focuses on groundwater gradients and associated depletions. No analysis is presented that characterizes whether the established MTs are sufficient to maintain water levels that have historically been shallow enough to support GDEs, or if the MTs would permit groundwater levels to fall below root zones, removing groundwater as an available water source to some GDEs. If MTs are not protective of GDE access to groundwater supplies, significant impacts to environmental beneficial users of groundwater will likely be experienced before MTs are reached. Furthermore, the GSP reports annual net values for streamflow depletion from the modeled baseline conditions, baseline conditions with climate change, and baseline conditions with climate change and project scenarios. However, the annual analysis does not provide sufficient detail on the timing of depletions to adequately assess potential impacts to environmental users (See Comment #1). The GSP compares modeled annual depletions to total annual flow in these river systems, and uses this annual normalization to characterize groundwater contributions to ISW as nominal. This coarse annual comparison does not take into account how groundwater contributions to river base flows are often proportionately greater in dry years or during annual low-flow seasons, or how groundwater contributions play a key role in maintaining water quality and temperatures. Properly contextualizing groundwater contributions to surface water is especially important to understanding potential impacts of groundwater depletion on surface waters and their ecosystems, particularly when the GSP states that streamflow accretion is expected to decrease by 38.3% with climate change impacts (line 9, page 6-2). The Department recommends the GSP reselect minimum thresholds that would better protect environmental uses and users of groundwater, rather than enabling declines in groundwater levels over the implementation horizon beyond the historic low. Additional analyses of the specific impacts of the established thresholds on GDE and ISW beneficial users of groundwater should be included.

314	DEPARTMENT OF FISH AND WILDLIFE			5.3.6, 5.4.6 ; starting pages 5-15 and 5-30				ii. Undesirable Results: The GSP requires 25% of ISW representative monitoring wells in the subbasin to fall below their MTs for 24 consecutive months before identifying an undesirable result to GDEs or ISW. While environmental users are adapted to sustain short-term lowering of groundwater levels during dry periods, environmental users may not be able to sustain extended periods of reduced groundwater access that would result from allowing groundwater levels to fall to historic lows for 24 months. By the time an undesirable result is declared, and management actions are triggered in response to the undesirable result, environmental groundwater users will have already experienced significant stress and potentially irreversible mortality. The Department recommends the GSP reconsider the 24-month duration of groundwater levels below MTs required to constitute an undesirable result, recognizing that extended durations of groundwater inaccessibility for environmental users will likely lead to adverse impacts that cannot be easily reversed when groundwater levels recover. At a minimum, the Department recommends identifying physical triggers (e.g., declining Normalized Difference Vegetation Index signals) and associated management actions (e.g., demand reduction) to enable the GSAs to identify and mitigate localized patterns of lowering groundwater or depleted ISW and associated negative impacts before the second year of MT exceedances yields more	Comment acknowledged. The GSAs will conduct local management of the Colusa Subbasin based on measurable objectives and interim milestones with the goal of avoiding exceedances of minimum thresholds and triggering of undesirable results. The GSAs will conduct this local management with consideration of all beneficial users and will seek to work with resource agencies, stakeholders, beneficial users, the public and GSAs representing adjacent subbasins to avoid exceeding minimum thresholds and incurring undesirable results.

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
315	DEPARTMENT OF FISH AND WILDLIFE			6.5.2.3, 6.5.2.4; starting page 6-84				The GSP should include additional metrics and timelines related to the implementation of demand management within the subbasin. a. Issue: The Department appreciates the GSP's identification of both shortand long-term demand management actions that will serve as a "backstop" to the other identified PMAs. As the other PMAs focus largely on implementing recharge projects that may be costly, rely on securing additional surface water supplies, and/or require potentially lengthy permitting processes, demand management may be necessary in instances where a quick response to undesirable results within the subbasin is needed. Though the GSP identifies various demand management strategies, the GSP states that these management actions are in the "early conceptual stage" and as such, no timelines have been determined. b. Recommendation: The Department recommends detailing specific timelines and metrics that would trigger the implementation of the identified demand management scenarios should recharge projects encounter delays or fail to produce the anticipated groundwater benefits to the subbasin.	Comment acknowledged. It is noted that the decisions pertaining to demand management involve major public policy questions that will require evaluations of conditions in a public, stakeholder-driven process. The GSP acknowledges a non-exhaustive list of events that may trigger demand management in Section 6.5.2.3. The precise decisions for whether and how demand management would be applied will be determined by the GSA boards through a stakeholder-driven process during GSP implementation. If demand management is pursued, the establishment of implementation metrics and timelines should be considered.
316	Holly Reimers			ES-14				What happened to the wells between 200' and 2,000'?	Comment acknowledged. The criteria for selecting interconnected surface water monitoring wells are that the wells must be less than 200 feet deep and the wells must be located between 2,000 feet and 5 miles from the surface waters being monitored. Wells that are deeper than 200 feet do not meet the criteria for monitoring interconnected surface waters.
317	Holly Reimers			ES-16		ES-16		Wells falling below their MT should be monitored more often than every 24 months. Every two years allows for a severe lowering of the ground water level that might not be recoverable. Any well falling below it's MT should be checked at least twice a year. Any land subsidence should not be acceptable. This is not something that is recoverable.	Comment acknowledged. As described in Section 4.2.1.3, groundwater level measurements will be collected twice annually, at a minimum, to ensure seasonal trends are well accounted for (23 CCR §354.34(c)(1)(B)). Manual measurements for all network wells should be collected in the spring and fall, at a minimum, unless more frequent measurements are required to characterize changes in groundwater levels.

318	Holly Reimers			ES-17 12-15				" .. not currently occurring ... " WHAT?? Has anyone noted the number of dry and going dry wells in Glenn County? Granting that this is an usually dry year and that Stony Creek has not run all year it is almost amazing that there have not been more dry wells. Yet there are those around the County that continue to pump great amounts of ground water from their deep wells. Sort of like putting a straw on a glass and sucking. The top part of the glass will go dry first as the water is pulling from the bottom.	Comment acknowledged. We have added a preface to the GSP to acknowledge the current drought conditions and summarize what is known at this time about the severity of well dewatering experienced by water users in the Subbasin, including domestic well users and DAC/SDAC/EDA households. It is noted that GSP development - including work to define undesirable results and establish the Sustainable Management Criteria - has occurred over several years utilizing the best available science and tools, with the most sufficient and credible information and data available for the decisions being made and the time frame available for making those decisions. Current and historical groundwater conditions and water budgets have been evaluated for the Subbasin in alignment with the GSP regulations, using the most recent and complete hydrologic, water supply, water demand, and land use data available at the time GSP development began. Unfortunately, drought conditions in 2020-2021 have coincided with development of the GSP, a timing that has not permitted complete evaluation and inclusion of data from these years in the GSP at this time. Ongoing management of the Colusa Subbasin under the GSP will follow an “adaptive management” strategy that involves active monitoring of Subbasin conditions and addressing any challenges related to maintaining groundwater sustainability by scaling and implementing PMAs in a targeted and proportional manner in accordance with the needs of the Subbasin. Data and information collected through ongoing monitoring will be evaluated, reported, and used to guide GSP implementation. GSP annual reports provide an opportunity each year to evaluate current Subbasin conditions and assess needs for additional PMAs. The first annual report, due April 2022, will evaluate groundwater conditions in the Colusa Subbasin since 2015. During periodic GSP evaluations, the GSP will also be reviewed and SMC will be revised, as needed, as we learn more about the effects of current and future conditions.

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
319	Holly Reimers			Ch 2-1				The basin boundaries should be redrawn to exclude those lands that do not have access to groundwater primarily those lands in the western portion of the basin. Not only is there little to no groundwater these lands are receiving no benifit from being in the basin, only an expense.	Comment acknowledged. There are currently no specific plans for submitting a basin boundary modification request to exclude the lands indicated in this comment. At this time, there is insufficient information to determine whether those areas are hydrogeologically disconnected from the Colusa Subbasin. In Section 7.1.2.3 of the GSP, the GSAs have proposed the Colusa Subbasin Western Boundary Investigation to fill data gaps and better define the western fringes of the Subbasin. Also, specific financing plans and cost-allocation approaches are not yet determined, but will be identified and determined with stakeholder involvement following GSP adoption. Please see the response to comment 321.
320	Holly Reimers			3-15 3.1.5.16				Why is Hambright creek not mentioned? When running it is a major source of groundwater recharge.	Comment addressed. Hambright Creek has been added to the list of streams and creeks in Section 3.1.5.1.6.
321	Holly Reimers			6.5.1				The OUWUA is acknowledged as direct Groundwater Recharge. The land owners in the OUWUA should also be acknowledged as having the ability to assist in the ground water recharge. Those that apply only surface water should be given credit and not charges as they are helping the recharge when ever they apply surface water.	Comment addressed. An acknowledgement to participating landowners has been added to the project description in Section 6.5.1.5. Specific financing plans and cost-allocation approaches are not yet determined, but will be identified and determined with stakeholder involvement following GSP adoption. As described in Section 1.3.1, "The Colusa Subbasin GSAs will develop a financing plan for the overall implementation of the GSP that will specify funding sources and cost-allocation approaches across entities for the different GSP implementation activities (see Chapter 7 and Appendix 7A for a description of existing options)."
322	Holly Reimers			7.6	8-23			Charging the landowners on the west side of the basin, with no groundwater, the same amounts as those that have the water under their ground and are pumping for their perennial crops is unfair. Paying a "tax" or "fee" when there is no benefit to the landowner, there should be some benefit but so far we on the west side are seeing none. To place this additional burden on these land owners may force them to look at other uses of their ground to be able to "pay" for your additional fees.	Comment acknowledged. Specific financing plans and cost-allocation approaches are not yet determined, but will be identified and determined with stakeholder involvement following GSP adoption. As described in Section 1.3.1, "The Colusa Subbasin GSAs will develop a financing plan for the overall implementation of the GSP that will specify funding sources and cost-allocation approaches across entities for the different GSP implementation activities (see Chapter 7 and Appendix 7A for a description of existing options)." These considerations will be folded into the financing plan development and discussions.
323	Holly Reimers			Appendix 7A			Table 1	All "fees" should be passed only by a majority approval vote. Any "vote" should be conducted on a per/acre basis and should take into consideration what benefit there is to the landowner(s). You can call it is "fee" BUT if it looks like a duck, quacks like a duck IT IS A DUCK! A "fee" by any other name is still a tax on our property.	Please see the response to comment 322.

324	Holly Reimers		General Comments					It has been said that there are outside groups purchasing ground in the basin with the only purpose of mining the ground water. This is not a supportable option for the basin to be able to sustain its self. NO GROUND WATER SHOULD BE EXPORTED FROM THE BASIN -EVER! Chapters 3, 4 & 5 one needs to have a Doctorate Degree in Hydrology, Geology and Engineering to even start to understand any of this. This should be written so that the general public and landowners would have some kind of understanding as to what some of these proposals are and how they as landowners will be effected. Or at least put in a summary that the landowner can understand, it may be included I might have missed it in all the other "stuff'.	Comment acknowledged. All of the topics are either required by DWR and SGMA or are industry-standard supplemental topics that were deemed to be appropriate for inclusion in these chapters. The goal of Chapters 3 through 5 was to meet DWR/SGMA requirements and provide information to GSAs, residents, and other scientists and engineers that may work on future SGMA-related projects. The techniques and tools to characterize aquifer properties, flow mechanics through a substrate, water budgets, and monitoring require scientific terminology to accurately convey the necessary information. The Executive Summary contains a simplified version of these chapters.

(There are ad hoc committees that did not require Brown Act compliance)	Comment addressed in the GSP section indicated.
358	Lisa Hunter	GGA	2	2.7.1.3	2-38	9-12		the GSAs have adopted a comprehensive table-based GSP comment	Comment addressed in the GSP section indicated.
359	Lisa Hunter	GGA	2	2.7.1.3	2-38	29		~~weekly by GSA staff~~ on a regular basis by facilitation staff and is then included in the agenda packet for each ~~GSP~~ GSA Board meeting beginning in XX (Date)	Comment addressed in the GSP section indicated.
360	Lisa Hunter	GGA	2	2.7.1.3	2-38	32-34		each Board agenda defines said decision as a formal action ~~and further includes an agendized item for~~ which could include discussion by each Board about associated public input recorded in the comments tables that might inform their decision-making.	Comment addressed in the GSP section indicated.
361	Lisa Hunter	GGA	2	2.7.1.3	2-38	41		• ~~Final public comment period prior to adjournment of each meeting.~~ Final public comment is not agendized on Board or TAC meeting agendas- Member comments are. While frequently, final public comments are taken at that time, I suggest removing the general statement because it may not be accurate.	Comment addressed in the GSP section indicated.
362	Lisa Hunter	GGA	2	2.7.2.1	2-39	3-4		thereafter ~~to present~~ September 2021, the parties that make up the CGA and GGA have collectively sponsored, publicized and conducted over 236 separate It may be helpful to note in this section, the meetings referenced were the meetings that are open to the public. Additional ad hoc meetings were held (some of which members of the public attended)	Comment addressed in the GSP section indicated.
363	Lisa Hunter	GGA	2	2.7.2.1	2-39	22-23		Committee and Subcommittee meetings) requiring compliance with the Brown Act, agendas ~~and associated background information~~ are posted no less than 72 hours before a meeting and all materials presented in said meetings. Background material is made available once prepared and distributed to the board.	Comment addressed in the GSP section indicated.
364	Lisa Hunter	GGA	2	2.7.2.1	2-39	29-30		All public outreach meetings were similarly publicized through Facebook and Twitter.	Comment addressed in the GSP section indicated.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
365	Lisa Hunter	GGA	2	2.7.2.1	4-40	15-17		On a regular ~~and publicly noticed~~ basis, inter-basin meetings of representatives from the Colusa Subbasin met with representatives from the adjacent Corning, Butte, Sutter and Yolo Subbasins (and other non-adjacent subbasin representatives) to discuss interconnected	Comment addressed in the GSP section indicated.
366	Lisa Hunter	GGA	2	2.7.2.1	4-40	28		As described above, ~~in~~ in the initial stages of GSA	Comment addressed in the GSP section indicated.
367	Lisa Hunter	GGA	2	2.7.2.1	4-40	35+		There were also 3 meetings in 2015 with general SGMA information co-sponsored by the Glenn County WAC, Glenn County Farm Bureau, and the UC Cooperative Extension.	Comment addressed in the GSP section indicated.
368	Lisa Hunter	GGA	2	2.7.2.2	2-42		Table 2-9	Include the Preface in the Public Draft Review	Comment addressed in the GSP section indicated.
369	Lisa Hunter	GGA	2	2.7.3.1	2-42	15-17		~~Confidentiality~~ sensitive information, actual contact information of interested parties is not appropriate to publish as part of this GSP). Any interested member of the public could be added to the lists by signing up via ~~respective~~ online entry options located on the CGA ~~respective GSA's~~ website~~s~~ and through email sign up options or requesting by phone for each GSA.	Comment addressed in the GSP section indicated.
370	Lisa Hunter	GGA	2	2.7.3.1	2-42	18+		Did we connect with Cortina?	Comment addressed. Clarifications have been added to the GSP.
371	Lisa Hunter	GGA	2	2.7.3.5	4-43	33		to view all outreach events from late 2020 through (ADD DATE) and including public review and subsequent GSA	Comment addressed in the GSP section indicated.
372	Lisa Hunter	GGA	2	2.7.3.6	2-44	9		(when available after ~~Match~~ March 2020)	Comment addressed in the GSP section indicated.
373	Lisa Hunter	GGA	2	2.7.3.6	2-44	22		GSP background documents ~~including Drought Preparedness and Response~~	Comment addressed in the GSP section indicated.
374	Lisa Hunter	GGA	2	2.7				General comment: It would be helpful to define "public meeting". It is referenced frequently and may confusion between Board and/or committee meetings which are open to the public and public outreach meetings which follow a different process, including the outreach done to advertise public outreach meetings (for instance board meetings are not publicized in the social media and via press release, whereas public outreach meetings were)	Comment acknowledged. The general distinction is: "public meetings" are open to the public and allow comments and feedback from the public, but are not exclusively held for that purpose (e.g., Board meetings, TAC meetings), whereas "public outreach meetings/workshops" are open to the public and are primarily designed to engage with the public and stakeholders to solicit their opinions and feedback. This has been clarified in Section 2.7.2
375	Lisa Hunter	GGA	3	3.1.3	3-4	6-May		with periods ~~of~~ exceeding 100-degree Fahrenheit temperatures.	Comment addressed in the GSP section indicated.
376	Lisa Hunter	GGA	3	3.1.5.1.1			Figure 3-7	This comment refers to this figure and other similar figures. The small inset graphic is useful to see the trends; however, the x and y axis labels are not legible- can the labels be clearer? Perhaps darker to facilitate reading them?	Comment addressed in the GSP section indicated.
377	Lisa Hunter	GGA	3	3.1.5.1.3	3-13	21		Missing a "." after Subbasin	Comment addressed in the GSP section indicated.
378	Lisa Hunter	GGA	3	3.1.7.2.1	3-30	33-34		Is the sentence referencing the average yield in the West Butte Subbasin relevant here? If so, should it reference the Butte Subbasin instead? If not, I suggest removing.	Comment addressed in the GSP section indicated.
379	Lisa Hunter	GGA	3	3.7.8.1	3-35	39-40		Also reference the CCWD jurisdictional boundary	Comment addressed in the GSP section indicated.

Colusa Subbasin Groundwater Sustainability Plan

412	Lisa Hunter	GGA	5	5.2.1	5-3	28		Might be useful to indicate the PMAs could be implemented by other partners (not just the GSAs).	Comment addressed in the GSP section indicated.
413	Lisa Hunter	GGA	5	5.3.1.4	5-7			Include stock water impacts (hauling water, selling livestock, etc)	Comment addressed in the GSP section indicated.
414	Lisa Hunter	GGA	5	5.3.2.5	5-10			Include stock water impacts (hauling water, selling livestock, etc)	Comment addressed in the GSP section indicated.
415	Lisa Hunter	GGA	5	5.3.2.6	5-10	27		Updates should not be capitalized	Comment addressed in the GSP section indicated.
416	Lisa Hunter	GGA	5	5.3.4.1	5-12	9		Irrigation or stock water supply	Comment addressed in the GSP section indicated.
417	Lisa Hunter	GGA	5	5.3.6.2	5-15	31		Use GGA and CGA instead of spelling out	Comment addressed in the GSP section indicated.
418	Lisa Hunter	GGA	5	5.3.6.2	5-15	33		will occur utilizing a subset of wells in the Subbasin's groundwater elevation monitoring network selected for	Comment addressed in the GSP section indicated.
419	Lisa Hunter	GGA	5	5.4.1.1	5-19	Not present		In the Minimum Thresholds section #1- when discussing domestic wells, it may be appropriate to reference the Human Right to Water. It may also be useful to note in the section (when discussing that very shallow wells likely do not meet current health standards. At the end of #1, add "contained in the DWR database" after protect 80 percent of domestic wells.	Comment addressed in the GSP section indicated.
420	Lisa Hunter	GGA	5				Figure 5-1 and similar	It would be useful to add which method was used to determine the MT. Could be added on the right hand side under Minimum Threshold: XX ft	Comment addressed in GSP. This only applies to Figure 5-1, as Figures 5-2 and 5-3 represent wells included in the interconnected surface water monitoring network. The method used to determine the MT for the interconnected surface waters is different from the two alternative methods used for the groundwater levels.
421	Lisa Hunter	GGA	5				Table 5-2	It would be helpful to add a column to denote which method was used to determine the MT. It could be simply 1 or 2 with explanation in the footnote section.	Comment addressed in the GSP section indicated.
422	Lisa Hunter	GGA	5	5.4.5.1	5-29	10-Mar		Based on discussion, evaluating infrastructure sensitivity may be a good project for the GSP.	Comment addressed. A proposed study of infrastructure sensitivity to land subsidence has been added to Chapter 7, and is referenced in Section 5.4.5.1.
423	Lisa Hunter	GGA	5	5.4.5.1	5-29	17		Glenn County has data from 2004.	Comment addressed in the GSP section indicated.
424	Lisa Hunter	GGA	5				Figure 5-2 and similar	Minimum Threshold should be ft bgs not ft	Comment addressed in the GSP section indicated.
425	Lisa Hunter	GGA	5	5.4.6.1	5-34	4		better represented local conditions at that time rather than adding an additional 10 feet (in order to be more protective).	Comment addressed in the GSP section indicated.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
426	Lisa Hunter	GGA	5	5.4.7	5-36			Should water quality and subsidence be mentioned in this section?	Comment addressed. Section 5.4.7 of the GSP was revised as follows: "The Colusa Subbasin GSAs and the GSAs in the adjacent subbasins coordinated their approach to developing sustainable management criteria during development of their respective GSPs and will continue to coordinate their efforts during plan implementation. The Colusa Subbasin GSAs and the GSAs in the adjacent subbasins developed similar sustainable management criteria for degraded water quality and inelastic land subsidence. Because of the similarity in these sustainable management criteria across the subbasins, and the ongoing interbasin coordination efforts, it is anticipated that the minimum thresholds established in the Colusa Subbasin for degraded water quality and inelastic land subsidence will help avoid undesirable results for the Colusa Subbasin and the adjacent subbasins. GSP Section 7.1.2 describes implementation activities focused on interbasin coordination for degraded water quality, inelastic land subsidence and other sustainability indicators."
427	Lisa Hunter	GGA	6					This chapter should discuss the PMA submittal process including the online submittal forms to gather stakeholder ideas and ongoing nature of including PMAs in the GSP.	Comment addressed. Additional information has been added to Section 6.1.3 to describe the PMA submittal process.
428	Lisa Hunter	GGA	6				Figure 6-1	The title "Colusa Subbasin PMA" does not seem appropriate for the image and may be unnecessary. The legend indicates blue lines for "Groundwater Basins"- is that correct? It seems to be streams. The legend does not include water districts or what I assume are wells. Those may be helpful to include. Generally, this is quite a busy figure for the purpose. Consider simplifying.	Comment addressed. Map has been simplified and updated as suggested.
429	Lisa Hunter	GGA	6	6.1	6-4	6		Planned PMAs ~~that will~~ are expected to be implemented to primarily address current,	Comment addressed in the GSP section indicated.
430	Lisa Hunter	GGA	6	6.1	6-4	34		Add "The PMAs are not ranked."	Comment addressed in the GSP section indicated.

463	Lisa Hunter	GGA	7	7.2	7-16			It might be appropriate to add that some details on the cost allocation between the GSAs remain to be finalized.	Comment addressed in the GSP section indicated.
464	Lisa Hunter	GGA	7	7.6	7-22	24		GSAs are ~~pursuing~~ considering a combined approach…	Comment addressed in the GSP section indicated.
465	Pamela Plemmons		Executive Summary			22-2		(Executive summary-Line 22-27 and corresponding sections in the text) I believe that the foundational assumptions with the water budgets do not reflect the reality of future climate change and the assumptions of data used as the baseline were not indicative of drought years. In addition, the idea that using a central tendency for climate change is short sighted at best. It seems to me that a "critical' tendency for climate change should also be included in the analysis—one that looks at a serious increase in overall earth temperature above 2.5*C. Otherwise, we are just putting our heads in the sand with regard to future water/crop issues. What mitigation factors could be planned for? How is water distributed equitably in times like that? What future cropping patterns might be considered? (maybe more annual crops when water is available..)	Comment acknowledged. As the commenter acknowledges, there is significant uncertainty in future conditions related to climate, water supplies, and other factors that will impact groundwater conditions and sustainability in the Colusa Subbasin. The uncertainty of future conditions is one of many reasons that GSP implementation will be based on adaptive management. The GSAs' adaptive management strategy for GSP implementation is described extensively in Chapter 6. The GSAs are committed to ongoing monitoring and implementation of projects and management actions to respond to changing Subbasin conditions. Additionally, the GSP is considered a "living document," and will be revised over time, as needed, once more is known about the basin setting through monitoring (Chapter 4) and GSP studies (Chapter 7). It is also noted that use of the 2070CT climate change scenario is consistent with GSP regulations, and assumes that 2070CT climate change effects will occur immediately and continue over the entire projected period. In reality, climate change effects will occur gradually with uncertain interannual changes.
466	Pamela Plemmons		Executive Summary			17-21		(Executive summary-Line 17-21 and corresponding sections in the text)) I also would like to add that the assumptions of surface water use and a reduction in irrigated acreage from Shasta in critical years would be less is actually inaccurate. Since much of the irrigated agriculture in the Glenn and Colusa area are permanent crops (almonds and walnuts), they need to be irrigated no matter what…what it does trigger is a significant increase in ground water use.	Comment acknowledged. Please see the response to comment 465.
467	Pamela Plemmons		Additional Comment					Finally, what I find distinctly disturbing is that in the entire plan there is no individual accountability for ground water use by individual growers, no monitoring of private wells or individuals who are excessive consumers of our precious and shared resource. For example, I am aghast at the practice of almond farmers extensively irrigating to "fatten up" the nuts just prior to harvest. Seriously!!! What a waste of water!!! The extra moisture has to be dried out using more energy in the drying process. Why is there no individual accountability for each well and that each grower pay the price for water just like most consumers have to do? I believe this is something that truly needs to be included in the plan.	Comment acknowledged and addressed. Specific plans for determining accountability and cost-allocation approaches are not yet determined. Cost-allocation approaches and related accountability measures will be identified and determined by the GSA Boards through a stakeholder-driven process following GSP adoption. Those decisions are expected to be made in the coming year. In Chapter 7, GSP studies are also proposed to expand monitoring, which may help to inform these decisions.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
468	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	6	6.5.2	6-81			*(Summary of Comment A.1)* The Draft GSP has a lot of words but little action, except recharge projects. In Chapter 6, the GSP describes an adaptive management approach and projects and management actions that the GSAs **could** implement to ensure that the Colusa Subbasin is operated sustainably (i.e., to avoid undesirable results). The management actions given in Chapter 6 are all "Potential Management Actions", and all are currently in the early conceptual stage, so there is no understanding of the benefits, costs, the funding sources, or specifics about how the actions will maintain sustainable groundwater levels.	Comment acknowledged. As described in Section 6.1, the GSAs recognize that there are data gaps and uncertainties in future conditions (per 23 CCR §354.44(d)), and have planned an adaptive management strategy for PMA development and implementation. The adaptive management strategy involves active monitoring of Subbasin conditions (as described in Chapter 4) and addressing any challenges related to maintaining groundwater sustainability by scaling and implementing PMAs in a targeted and proportional manner in accordance with the needs of the Subbasin. The adaptive management approach is consistent with SGMA (CWC §10728.2, §10733.8), consistent with DWR recommendations, and consistent with GSPs that have been approved by DWR. Notably, the GSAs have proposed several "planned PMAs" (described in detail in Section 6.3) that do provide more specific information, as available, about project benefits, costs, and funding. As described in Section 6.2.2, the "planned PMAs" are expected to provide more than 80 TAF/yr in gross average annual benefits that will offset groundwater pumping and support groundwater sustainability in the Colusa Subbasin. These benefits are expected to address sustainability concerns in the projected future water budget, even under the effects of 2070CT climate change (Table 6-1). The GSAs expect that the planned PMAs will achieve the sustainability goal for the Colusa Subbasin and avoid reaching the minimum thresholds defined in this GSP under future, changing conditions. Nevertheless, recognizing the uncertainty in future conditions, the GSAs have proposed numerous "potential PMAs" that could be implemented if conditions change unexpectedly from the projected future water budgets. These potential PMAs are an essential part of the adaptive management approach, offering the GSAs options to address uncertain future conditions that may be selected and developed further, as needed.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
469	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	6	6.1	6-2		Table 6-1	*(Summary of Comment A.2, part 1)* Section 6.1 of the draft GSP talks about climate change and then gives a selection of water budget values with and without climate change (2070 central tendency). According to Table 6-1, water users will pump 13% more groundwater to make up for evapotranspiration (ET) increase due to climate change, and stream accretion (groundwater that discharges to the steams) will remain positive but will decrease by 48,000 acre-feet / year with climate change, approximately 38% from the future conditions without climate change and approximately 0.5% of the Sacramento River flow.	Comment acknowledged. Clarification has been added to Section 6.1. As indicated in its title, Table 6-1 summarizes key water budget parameters that were evaluated to formulate PMAs. Table 6-1 does not include the benefits of planned PMAs, nor does it summarize the GSAs' plans for future management of the Subbasin. As described in Section 6.2.2 (and clarified in Section 6.1), the "planned PMAs" are expected to provide more than 80 TAF/yr in gross average annual benefits that will offset groundwater pumping and support groundwater sustainability in the Colusa Subbasin. These benefits are expected to address potential sustainability concerns in the projected future water budget (Table 6-1), especially for areas of localized groundwater declines in the Orland and Arbuckle areas.
470	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network						*(Summary of Comment A.2, part 2)* It isn't clear how the stream depletion monitoring program will interact with the stream accretion assumptions. The stream depletion monitoring program only monitors groundwater levels, but it should also include monitoring of stream flow changes, i.e., seepage and accretion changes, to validate the assumptions about climate change and sustainability	Comment acknowledged. The CGA and GGA are coordinating with GSAs in other subbasins through the Northern California Water Association (NCWA). NCWA is leading a Sacramento Valley-wide effort for improved and coordinated streamflow measurement, which will continue during GSP implementation. However, the GSAs' plans for monitoring shallow groundwater levels as a proxy for stream depletion monitoring are consistent with GSP regulations and consistent with recommendations of the Environmental Defense Fund (EDF, 2018). It is also noted that if the GSAs were to measure stream flow changes, as suggested, it is expected that measurement accuracy would limit the ability to differentiate the estimated +/-0.5% of streamflow change in the Sacramento River discussed in previous comments.
471	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	5-6					*(Summary of Comment A.3, part 1)* The groundwater monitoring for sustainability focuses on domestic wells and stream depletion, but not much on subsidence.	Comment acknowledged. Land subsidence in the Colusa Subbasin will not be monitored using the groundwater level monitoring network or wells. As described in Section 4.2.3.2 of the Colusa Subbasin GSP: "The Colusa Subbasin land subsidence monitoring network is comprised of survey benchmarks, benchmarks, continuous GPS stations, extensometers, and remote sensing data."
472	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	5	5.4.1	5-19:5-21			*(Summary of Comment A.3, part 2)* The MTs for domestic well sustainability are developed by taking the greater depth of either the depth where 20% of the domestic wells within the Thiessen polygon around each of the 48 RMN monitoring wells are shallower, or the depth at 50% of the historical range below the deepest groundwater level prior to January 1, 2015 (and sometimes 2016). These GSP standards for the MTs effectively means that domestic wells in the Colusa subbasin can experience groundwater levels deeper than historical levels and still be considered sustainable.	Comment acknowledged. The CGA and GGA Boards made decisions to set the Sustainable Management Criteria for all sustainability indicators through a transparent process in public meetings with extensive stakeholder engagement. The decisions are documented in Appendix 5.A. All decisions were made in meetings open to the public, following technical presentations and discussions, also held in meetings open to the public.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
473	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	5				Tables 5-1 through 5-3	*(Summary of Comment A.4)* The draft GSP establishes different MTs for each monitoring site (except for subsidence benchmarks) and evaluates MTs in sub-groups of sites with a minimum size and minimum duration. The draft GSP requires that all monitoring sites in a sub-group must exceed their respective MTs together before an undesirable result can occur. This requirement implies that the monitoring site with the greatest MT depth will likely control the occurrence of an undesirable result.	Comment acknowledged. The minimum thresholds are applied at each individual monitoring location within the representative monitoring network for each sustainability indicator. There is no predetermined grouping of locations for the purpose of determining whether undesirable results are occurring in the Colusa Subbasin. The occurrence of an undesirable result for each applicable sustainability indicator in the Colusa Subbasin is determined when a defined percentage of the monitoring locations in the corresponding representative monitoring network exceeds minimum thresholds, regardless of where the monitoring locations are within the basin. The undesirable result is judged to occur based on the percentage of locations exceeding their minimum thresholds, not on the magnitude of the minimum thresholds or the magnitude by which the minimum thresholds are exceeded.
474	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	App. 5C					*(Summary of Comment A.5, part 1)* Are there any facts to document that domestic wells in the WCR database are no longer in use or previously dewatered? DWR has a web site where people can volunteer that their well went dry (https://mydrywell.water.ca.gov/report/). The assumption that the wells previously went dry when groundwater was at the lowest pre-2015 point, allows the GSP to reason that an MT that allow loss of up to 20% percent of the shallow domestic wells is cost-effective, and an acceptable balance between avoiding significant and unreasonable impacts to domestic (and other shallow) wells and allowing sufficient flexibility for conjunctive management of Subbasin surface and groundwater supplies. We ask, cost effective to whom?	Comment addressed. The GSP covers the entire Colusa Subbasin, and measures of cost-effectiveness are consequently from that perspective, as is standard practice. The benefit-cost analysis of PMAs and potential dewatered well impacts is additionally defined at the monitoring well Thiessen polygon level. As described in Appendix 5C, it is important to emphasize that groundwater levels in the Subbasin will be managed for MOs, which are generally set substantially above MTs that the economic analysis is based on. Historical low water levels below the total domestic well depth being an indicator for wells that may have been previously dewatered was deemed to be a reasonable assumption, given the data available and data gaps identified in the GSP. The following paragraph was added to the introduction section of Appendix 5C so that assumptions, data limitations, and other potential GSP PMAs are clear to the reader. "The reconnaissance-level economic analysis was based on the data available for GSP development and the simplifying assumptions described in the sections below. Important assumptions include: (i) the analysis was developed for MTs, not MOs that the Subbasin will be managed for and are substantially higher than MTs, (ii) only a subset of costs and benefits (pumping cost, well replacement cost, PMA avoided costs) associated with PMA implementation dewatered domestic were considered, and (iii) the example PMA considered was demand management (reducing pumping). The analysis can be refined and expanded as

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
474 cont'd									GSP data gaps are addressed and additional information becomes available. It is also noted that the GSP includes additional potential actions for monitoring potential impacts to domestic wells, as described in Section 6.5.2.1, Domestic Well Mitigation Program." As documented in Appendices 5B and 5C, for the Subbasin as a whole, approximately 46 percent of the domestic wells in the WCR database are shallower than the pre-2015 historical groundwater levels as defined by the groundwater level representative monitoring network. Many of these shallow wells may no longer be used, or they may have been deepened because they would have otherwise been dry at times prior to 2015. Nevertheless, all wells in the WCR database were considered in the calculation of the groundwater level minimum thresholds. Including these shallow, potentially unused or deepened wells in the analysis of well completions depths resulted in groundwater level minimum thresholds that are shallower than they would have been if the wells had been excluded, and is viewed as a conservative approach to avoiding undesirable results for all users, considering data gaps.
475	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	App. 5C					*(Summary of Comment A.5, part 2)* The economic analysis concludes that groundwater levels will be managed to the higher MOs levels and therefore no harm will occur to domestic wells; but if harm occurs, then the GSAs should develop a domestic well mitigation program (see Chapter 6) that would provide a safety net to potentially compensate for impacts to domestic wells. It appears to AquAlliance that the GSP has decided that the shallow domestic wells can go dry, and the GSAs might find a way to help the well owners, but they aren't ready to commit to the compensation portion.	Comment acknowledged. Please note that the GSAs have revised the MTs for chronic lowering of groundwater levels at several RMS sites, particularly around the Orland area. These revisions have created shallower MTs that are more protective of the 20th percentile depths of domestic wells. The GSAs still propose a potential domestic well mitigation program, though the precise policies, funding, and other factors underlying that program will need to be determined by the GSAs through a public, stakeholder-driven evaluation and decision-making process during GSP implementation. The GSAs also reiterate that they are planning an adaptive management strategy for GSP implementation. Please see the response to comment 468.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table

476	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	4-5				Table 5-1	(Summary of Comment A.6) A 50% range, or Margin of Operational Flexibility (MOF), has been established at each monitoring well to accomodate seasonal fluctuations in groundwater levels. Is the MOF about the MT depth not considered an undesirable result? Isn't the period, presumably summer months, when groundwater drops below the MT an unreasonable result? What happens if the seasonal decline is greater than the 50% range? How many of the domestic wells in the well 22N03W24E001 Thiessen polygon will go dry with groundwater at a depth of 349+ feet?	Comment acknowledged. The minimum threshold for groundwater level declines is based on the lower of 1) the 20th percentile of shallowest domestic well depths in each representative monitoring well's Thiessen polygon, or 2) 50 percent of range below the historical low groundwater elevation measured in each representative monitoring network well. The measurable objective is the mean of most recent five years of available groundwater elevation measurements up to March 2020 in each representative monitoring network well. The margin of operational flexibility is the difference between the measurable objective and the minimum threshold. The GSAs will conduct local management of the Colusa Subbasin based on measurable objectives with the goal of avoiding exceedances of minimum thresholds and triggering of undesirable results. The GSAs will conduct this local management with consideration of all beneficial users and will seek to work with resource agencies, stakeholders, beneficial users, the public and GSAs representing adjacent subbasins to avoid exceeding minimum thresholds and incurring undesirable results.
477	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	5				Table 5-1	(Summary of Comment A.7) The draft GSP appears to plan for subsidence throughout the subbasin to be as much as 10 feet over the next 40 years with a subsidence MO set at 0.25 feet per year for each of 63 survey benchmarks. The subsidence benchmark MTs are set at 0.50 to 0.60 feet per year or as much as 20 to 24 feet over the next 40 years, depending on the current rate of subsidence. There doesn't appear to be any Management Actions other than recharge to mitigate subsidence, and no proposal to create a subsidence mitigation program. Clarification is needed on the maximum rate of subsidence at any point that will trigger an undesirable results and the duration for averaging.	Comment acknowledged and addressed. The CGA and GGA Boards made decisions to reduce the MT and MO land subsidence rates to lower values, consistent with other GSPs in the Sacramento Valley. These revisions are incorporated throughout Chapter 5. The revised MT is 0.5 feet per five years for all sites, and the revised MO is 0.25 feet per five years for all sites. The criteria that an undesirable result is considered to occur is when the Minimum Threshold is exceeded at 20 percent of the land subsidence monitoring benchmarks.

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
478	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network					Figures 3-23, 3-31, 3-32	(Summary of Comment A.8) The draft GSP requirement to consider monitoring sites as a group when determining whether the MTs have been exceeded may create areas where the number of sites are too small to allow for the groups to encompass all monitoring sites, and/or create scientifically logical groups. The draft GSP should give the boundaries of the subsidence and groundwater monitoring well groups.	Comment acknowledged and addressed. Clarification has been added to Chapter 5 to explain the monitoring site subsets. For each monitoring network the subset of locations is not predetermined; rather, it is delineated only as sites collectively exceed their minimum threshold values. The subset of sites may be any combination of monitoring sites subbasin-wide, and do not necessarily need to be located in the same region.
479	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	4-5					(Summary of Comment A.9) The draft GSP should give the boundaries of the Thiessen polygons for the monitoring wells that are used to measure groundwater levels for either domestic wells or stream depletion, and provide a table of the number and depths, with cumulative frequency for domestic wells in each polygon.	Comment acknowledged. Thiessen polygons were not used to develop sustainable management criteria for surface water depletions.
480	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	4					(Summary of Comment A.10, part 1) The depth of the screens for some of the 48 RMN groundwater monitoring wells in Table 5-2 are given in Table 4-2. The draft GSP doesn't explain why the deep screened monitoring wells are selected to monitor shallower aquifers used by domestic wells even, when there is often a shallow monitoring well at the same location.	Comment acknowledged and addressed. Some of the monitoring wells in the representative monitoring network for lowering of groundwater levels are multiple completion monitoring wells, meaning that they have multiple discretely screened intervals at different depths within the aquifer. The completion depths, and therefore the measurable objectives and minimum thresholds, for the multiple completion monitoring wells in the representative monitoring network were misidentified as the deepest completion intervals in Table 5-2 of the public draft GSP. The completions selected for the representative groundwater level monitoring network have been updated to reflect the completions that best represent the median depth of nearby domestic wells. Thresholds, tables, and hydrographs in Chapters 4 and 5, including Table 5-2 and corresponding appendices, have been updated to reflect these changes.

Colusa Subbasin Groundwater Sustainability Plan

Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
481	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	5				Tables 5-2 and 5-3	(Summary of Comment A.10, part 2) Seven of the wells in the domestic well monitoring network are shallow and are also part of the 12-well stream depletion monitoring network. While the MOs for the stream depletion network in the seven shallow wells are nearly equal to the MOs for the domestic well network, the MTs are very different and much deeper. The draft GSP doesn't clearly explain the differences in any Management Actions needed to maintain the sustainability of domestic wells and interconnected surface waters that result from the different MTs at these same shallow monitoring wells.	Comment acknowledged. There are 48 well locations used as representative monitoring locations for groundwater levels and 12 well locations used as representative monitoring locations for interconnected surface waters. The minimum threshold for assessing impacts to chronic lowering of groundwater levels were calculated using the deeper value of either (1) the 20th percentile of shallowest domestic well depths in the monitoring well's Thiessen polygon, or (2) 50% of range below the historical low groundwater elevation at the monitoring location. The minimum thresholds in the representative monitoring network for assessing depletions of interconnected surface waters were calculated by using the historical fall 2015 groundwater elevations and adding 10 feet to that depth. Appendix 5B provides a detailed discussion of the relationship between the sustainable management criteria for groundwater levels and surface water depletions. For locations in which both groundwater level and surface water depletion monitoring network wells exist, along with their well-specific sustainable management criteria, the management of the Colusa Subbasin will be based on the more conservative monitoring well and its associated sustainable management criteria. Sustainable management criteria for depletion of interconnected surface waters allow for the least reduction in groundwater levels, and management actions related to this sustainability indicator will be based on the surface water depletion monitoring network wells.

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
482	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network						(Summary of Comment A.11) The draft GSP proposes to investigate the possibility of compensating domestic well owners for impacts from groundwater production. What is the recommendation in the GSP for how the well owner should determine the depth for the new well? What assurances does the GSP give to the domestic well owner that the depth for the new well will be sufficient to ensure a future domestic water supply? Can the well owner assume that if they follow the GSP's recommended depth procedures for a new domestic well, they will receive compensation if the depth to groundwater is ever exceeded?	Comment acknowledged. It is noted that the domestic well mitigation program proposed in the GSP (described in Section 6.5.2.1) does not state that well owners would receive direct compensation. Funds may be directed toward projects designed to secure reliable water sources for affected domestic well owners (through, for example, public water system consolidations funded by state or federal programs). The precise policies, funding, and other factors underlying that program will need to be determined by the GSAs through a public, stakeholder-driven evaluation and decision-making process during GSP implementation.
483	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network						(Summary of Comment A.12) Will the GSP also include a subsidence mitigation program that financially compensates homeowners and landowners for damage from subsidence? Will there be funds to repair infrastructures such as roads, bridges, levees, stormwater drainage, pipelines, home and building foundations, walls and roofs, domestic, municipal, industrial, and agricultural wells? What are the possible sources of subsidence mitigation funding, a consumption tax, a property tax, a flat tax per well Will the subsidence fund be designed to anticipate the cost of mitigation repairs over the full 40 years, that is, mitigate the planned 10 to 20+ feet of subsidence?	Comment acknowledged. Please see the response to comment 482 regarding the GSP's discussion of how mitigation program funds may be directed. Regarding subsidence, it is noted that the CGA and GGA Boards made decisions to reduce the MT and MO land subsidence rates to lower values, consistent with other GSPs in the Sacramento Valley. Please see the response to comment 477. Additionally, the GSAs have proposed a study of infrastructure sensitivity to land subsidence in Section 7.1.2.15. This study will help to fill data gaps related to infrastructure sensitivity to subsidence and address questions related to needs for subsidence mitigation. If needed, specific mitigation provisions will be developed by the GSA Boards through a public, stakeholder-driven process during GSP implementation.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
484	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	4				Table 4-2	(Summary of Comment A.13) Table 4-2 lists the characteristics of the monitoring wells in the GSP network, a total of 104 completions wells. However, only 48 completions are used for the domestic well network and another 5 for the stream depletion network. Only those 53 domestic and stream depletion wells have sustainability criteria, MOs and MTs. Why weren't MOs and MT calculated for the remaining 51 monitoring wells? Why are the other 51 wells included in the "groundwater monitoring network"? How will measurements in these other 51 wells be used in the groundwater monitoring program?	Comment acknowledged. There are 48 well locations used as representative monitoring locations for groundwater levels and 12 well locations used as representative monitoring locations for interconnected surface waters. The representative monitoring network wells (see Chapter 5) are a subset of wells used for establishing and monitoring sustainable management criteria. Sustainability thresholds such as the MT, MO, and interim milestones are defined at these representative monitoring network sites. Measurements at the representative sites are used to evaluate plan implementation. Measurements from the other monitoring locations are used to support evaluation of the plan implementation and support future decision making regarding sustainability thresholds, projects, and monitoring. The other groundwater monitoring well completions (totaling 104 completions, including the representative monitoring network) will be used to monitor overall groundwater level conditions in the Subbasin. The monitoring sites will be used to demonstrating progress towards during plan implementation, monitoring impacts to beneficial uses and users, monitoring changes in groundwater conditions, and quantifying annual changes in the water budget components (CCR § 354.34).
485	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	App. 5B					(Summary of Comment A.14) The hydrographs in Attachment A of Appendix 5B give the values of the MO and MT and graphically show their implications. Of interest are those wells where the MT based on the 20% shallower wells depth is below the 50% range depth. This occurs at 30 of the 48 wells.	Comment acknowledged. As described in Section 5.4.1.1, the MT is calculated as the deeper value of the 20th percentile of shallowest domestic well depths in the monitoring well's Thiessen polygon, or 50% of range below the historical low groundwater elevation. Also, it is noted that the GSAs have revised the MTs for chronic lowering of groundwater levels at several representative monitoring network sites. These revisions have resulted in shallower MTs that are more protective of domestic wells. See the response to comment 485.
486	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	App. 5B					(Summary of Comment A.15) The selection of the MO and lowest point for the MT appears to use groundwater levels after January 1, 2015 when it produces a lower elevation than measurement before the SGMA Benchmark date. The use of all historical data to calculate the 50% range appears to be continuing the pre-SGMA impacts into the GSP management actions. This seems to invert the concept that the GSP doesn't have to remedy pre-2015 impacts by making the GSP continue the pre-2015 impacts in the determination of sustainability criteria.	Comment acknowledged. The measurable objective is the mean of most recent five years of available groundwater elevation measurements up to March 2020 in each representative monitoring network well. The minimum threshold for groundwater level declines is based on the lower of 1) the 20th percentile of shallowest domestic well depths in each representative monitoring well's Thiessen polygon, or 2) 50 percent of range below the historical low groundwater elevation measured in each representative monitoring well.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
487	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	App. 5C					(Summary of Comment A.16) In Appendix 5C, the economic analysis argues that the maximum number of domestic wells that would go dry at the MT threshold is 12%, but excludes wells with depths shallower than the pre-January 2015 low because it was assumed those wells went dry with the lowest groundwater level and/or are no longer used. The economic analysis doesn't address if these wells recovered, nor document that these wells actually went dry. To evaluate the groundwater level in domestic wells, you need to use a wells screened at the depth of the domestic wells, for example the stream depletion monitoring wells.	Comment acknowledged. The analysis is based on the information available in the WCR database. Data gaps will be addressed in subsequent GSP updates, as described in Chapter 4 of the GSP. In addition, ss noted in the GSP, additional studies of potential domestic well impacts and for development of a program to mitigate for any well impacts is described under Section 6.5.2.1, Domestic Well Mitigation Program.
488	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	App. 5C					(Summary of Comment A.17, part 1) Appendix 5C says that the portion of the wells shallower than the proposed MT is in aggregate 12% of the domestic wells, not 20%. Histograms of RMN and domestic well depths, and cumulative frequency depth statistics are needed to understand the validity and significance of this economic analysis.	Comment acknowledged. We were unable to find a statement in Appendix 5C that says or implies that "the proposed MT is in aggregate 12% of the domestic wells, not 20%." The MTs are based on the lower of 50% below the historical low groundwater level or 20th percentile of domestic well depths, so it is anticipated that the aggregate share of domestic wells shallower than the MT would be less than 20%.
489	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	App. 5C				Table 1	(Summary of Comment A.17, part 2) A review of the statistics in Appendix 5C (Table 1) finds a large range in the percentage of wells that are shallower than the historical low before January 2015, ranging from zero to 97% across the 48 RMN wells. The aggregate for these dry wells is 46%. Does this average give the GSP's estimated future reduction in domestic well reliability within each RMN well polygon? How does the 12% aggregate for 20% shallower dry wells relate to the 46% well shallower than the lowest pre-January 2015 groundwater level? What are the depths, percentiles and the number of wells that could possibly go dry for each of the RMN well polygons where the MTs are based on the 50% range below the historical low, and/or based on the 20% shallower depth?	Comment unclear. The MTs are based on the lower of 50% below the historical low groundwater level or 20th percentile of domestic well depths, so it is anticipated that the aggregate share of domestic wells shallower than the MT would be less than 20%. Table 1 summarizes the available well data for each polygon. As described in Chapter 4 of the GSP, data gaps will be addressed in future GSP updates. The MT set is an input to the analysis described in Appendix 5C. That is, the economic analysis did not set the MT, it evaluated the costs and benefits (as identified in Appendix 5C) of the proposed MT.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
490	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	App. 5C					(Summary of Comment A.18) Obviously, the future cumulative average of dry wells under the GSP will be greater than the 46% of total wells. When 50% of the historical range is subtracted from the lowest pre-January 2015 groundwater level to calculate the MT, it creates a lower-than-the-lowest sustainable threshold. By this logic, the number of wells listed in Appendix 5C (Table 1) will go dry, at minimum, whenever groundwater levels go below the lowest historical elevation, and possibly more when groundwater levels reach the +50% depth threshold. For areas around the monitoring wells where the MT was set at the 20% shallower wells threshold (because that depth was greater than the lowest +50% depth), Appendix 5C (Table 1) shows a "share" less than 20% (0.20). Does this mean that additional wells will go dry in the future if groundwater levels reach the MT?	Comment unclear. We are not able to follow the logic in the comment and the comment appears to reference information that is not in Appendix 5C (e.g., the MT and selection criteria). In general, the MTs are based on the lower of 50% below the historical low groundwater level or 20th percentile of domestic well depths. This calculation is completed for each polygon individually to establish the MT, not for the entire Subbasin in aggregate. The MT were an input to the economic analysis described in Appendix 5C. That is, the economic analysis did not set the MT, it evaluated the costs and benefits (as identified in Appendix 5C) of the proposed MT.
491	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	App. 5C					(Summary of Comment A.19, part 1) Does the Table 1 in Appendix 5C total of 2,925 wells being shallower than the historic low groundwater level before January 2015 agree with the statistics on dry or no longer used wells collected by DWR or any government agency?	Comment acknowledged. The analysis described in Appendix 5C is based on Well Completion Report data published by DWR.
492	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	App. 5C					(Summary of Comment A.19, part 2) Table 1 of Appendix 5C shows that for the RMN well 22N03W24E001 near Orland, 1,589 out of a total of 1,677 wells are shallower than the historic low before January 2015, or 97%. This monitoring well is the closest RMN well to the City of Orland. Did 97% of the domestic wells around Orland go dry at least once sometime before 2015, and/or have they been abandoned? If yes, what is the source of this data?	Comment acknowledged. The economic analysis described in Appendix 5C excluded domestic wells that were shallower than the historic low groundwater level in each polygon. These data are from the DWR WCRs. As described in Chapter 4 of the GSP, data gaps will be addressed in future GSP updates, and this analysis may be refined with new information.
493	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	3, 6	3.3			Tables 3-11, 3-12, 6-1	(Summary of Comment A.20) The draft GSP provides a general background discussion on the surface water and groundwater budgets in Section 3.3. Tables 3-11 and 3-12 provide the average annual values for the surface water and groundwater budget components for all five analysis periods, respectively (pages 3-96 and 3-97). The water budget analysis selected as representative of conditions in the next 50 years is the projected Future Condition with the 2070 Central Tendency Climate Change provided by DWR.	Comment acknowledged.

Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
494	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	3	3.3			Tables 3-11, 3-12	(Summary of Comment A.21) Unfortunately, there appears to be a calculation error in the 2070 Future Conditions outflow, the right-hand column of Table 3-12. The three groundwaterpumping components, Agricultural, Urban and Industrial and Managed Wetlands, have future 2070 values of 548,000, 10,000 and 35,000 AFY, respectively. The sum of these three groundwater components equals 593,000 AFY, not the 559,000 AFY shown. This results in a Change in Storage (Inflow – Outflow) value of -42,000 AFY, not the -7,000 AFY shown. The values of the three groundwater components listed as inflow components in the surface water budget, Table 3-11, have different future 2070 values that sum to 558,000 AFY. This error in the Groundwater Pumping components needs to be corrected.	Comment acknowledged and addressed. We appreciate your identification of this potential issue. Upon review, it was found that the total groundwater pumping and urban groundwater pumping in Table 3-12 are correct, and that the error was an issue with the summary of agricultural and managed wetlands pumping. These two values have been corrected, and now align with the values in Table 3-11. The total Change in Storage (Inflow - Outflow) of -7 taf/yr corresponds to the model results, and is unchanged.
495	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	6				Table 6-1	(Summary of Comment A.22, part 1) In Table 6-1, the change in annual average groundwater storage with the 2070 climate change is a negative 7,900 AFY. This value differs from the -7,000 AFY value shown in Table 3-11, but this may be the result of round-off error in the Table 3-11 values. Note that the error in the total Groundwater Pumping in Table 3-12 could significantly change the rate of groundwater storage in Table 6-1, so it needs to be corrected.	Comment acknowledged. The difference is due to rounding, and has now been noted in Table 6-1. The concern with the change in groundwater storage has been corrected, please see the response to comment 494.
496	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	6				Table 6-1	(Summary of Comment A.22, part 2) Table 6-1 shows that there will be an annual average decrease in Stream Accretion of 48,000 AFY, or 38.3%, in the Net Stream Accretion in the future with the 2070 climate change scenario. The sums listed in Table 6-1 for future without climate change, 125,000 AFY and for 2070 with climate change, 77,000 AFY, don't appear to agree with the sums that would be obtained using values listed in Table 3-11, but the difference is the same - 48,000 AFY.	Comment acknowledged. The difference is due to rounding and slight changes in how values are summarized from the C2VSimFG-Colusa model results between the two summary tables; however, as noted the difference remains the same. This has now been noted in Table 6-1.
497	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	3					(Summary of Comment A.23, part 1) The increase in Groundwater Pumping and the decrease in Net Stream Accretion in the future with the 2070 climate change scenario suggest that the assumptions being made regarding loss of surface water flows during a groundwater substitution transfer are flawed. The decrease in Net Stream Accretion with future Groundwater Pumping suggests that the overall percentage of groundwater being pumped that will be recharged from the streams in the Colusa Subbasin, i.e., stream depletion, with any future pumping increase is significantly greater than the DWR/BOR assumed 13% stream flow loss from a groundwater substitution transfer.	Comment acknowledged. Please see the response to comment 298.

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
498	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	3					(Summary of Comment A.23, part 2) The groundwater budget in draft GSP Table 3-12 shows that more surface water will infiltrate into the groundwater basin to the detriment of the streams, and that the future increase in groundwater pumping will decrease the discharge of groundwater to streams. Under the existing conditions streams gain more water from the groundwater system than they give. With the 2070 climate change scenario, streams will continue to gain more from the groundwater system, but the gain will be less. The decline in Net Stream Accretion with future increased Groundwater Pumping that changes the streams for gaining to losing suggesting that the subbasin maybe at a tipping point where the impacts from future pumping increases are amplified and cause significantly more harm than just the existing condition.	Comment acknowledged. Please see the response to comment 465.
499	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	3					(Summary of Comment A.24) Figures 3-29 and 3-49 graph the cumulative change in groundwater storage across the water budget scenarios. In 2015 the cumulative change in groundwater storage since 1990 is approximately a negative 600,000 AF, lower than in than any time prior to the start of SGMA. This should be the starting point for going forward in an evaluation of the subbasin's groundwater sustainability. If the anticipated future loss in groundwater storage under the 2070 climate change scenario is added to existing loss in groundwater storage, the cumulative loss is groundwater storage for the Colusa Subbasin in 2065 is approximately 1,000,000 AF. The authors of the draft GSP may know this, and that's maybe why many of the groundwater monitoring well MTs are set at 50% of the historical range below the historical low to allow for an additional 400,000 AF of loss in groundwater storage predicted by the 2070 climate change scenario without triggering an undesirable result.	Comment acknowledged. 23 CCR § 354.18(c)(3) requires that a 50-year period of historical data be used as a baseline for estimating future hydrology. The selected, SGMA-required 50-year period is 1966-2015, which includes the effects of the 2014-2015 critical years. However, it would not be correct to start with those conditions and add those years to the record. The basic assumption is that hydrologic patterns will repeat themselves with adjustments made to the records per DWR guidelines to reflect the effects of climate change. It is noted that GSP regulations do require that GSAs use the most recent land use, evapotranspiration, crop coefficients, and surface water supply information as a baseline for estimating future water demand and surface water supply. As described in Section 3.3.3, the Colusa Subbasin GSP does use data from the most appropriate recent years as a baseline for estimating future water demand and surface water supply.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table

500	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network						(Summary of Comment A.25) The existing groundwater contours in the Butte and Colusa subbasins suggest that the current flow of groundwater in the aquifers shallower than 700 feet flow towards the center of the valley with the flow generally north to south aligned with the Sacramento River. There are several sets of monitoring wells that are approximately opposite each other along the north-south boundary between the subbasins. After comparing MTs for sets of west-to-east monitoring well matches, it was found that the MT elevations in the Butte Subbasin are higher in all but one of the 10 sets. This may create a condition where the Butte Subbasin is providing more interbasin groundwater flow to the west in the future. The implications from setting the MT values in the Colusa Subbasin at elevation lower than the MTs in the Butte Subbasin should be analyzed and management action(s) should be included in the GSPs for each other subbasin to maintain sustainable interbasin groundwater flow.	Comment acknowledged. The GSAs coordinated with the GSAs in the adjacent basins during development of sustainable management criteria, including sustainable management criteria for chronic lowering of groundwater levels and depletions of interconnected surface waters. The GSAs will continue to coordinate with the GSAs in the adjacent basins during implementation of the GSP. Groundwater levels in the Colusa Subbasin near the boundary with the Butte Subbasin will be managed to limit potential increases in surface water depletions, meaning that the minimum thresholds for groundwater levels will be superseded by the minimum thresholds for surface water depletions in the Colusa Subbasin near the Butte Subbasin boundary. Appendix 5B provides a detailed discussion of the relationship between the sustainable management criteria for groundwater levels and surface water depletions. For locations in which both groundwater level and surface water depletion monitoring network wells exist, along with their well-specific sustainable management criteria, the management of the Colusa Subbasin will be based on the more conservative monitoring well and its associated sustainable management criteria. Surface water depletion sustainable management criteria allow for the least reduction in groundwater levels, and management actions related to this sustainability indicator will be based on the surface water depletion monitoring network wells. Projects and management actions will be undertaken by the GSAs, agencies and stakeholders in the Colusa Subbasin.
501	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	3-4					(Summary of Comment A.26) The GSP should specifically state that the water quality MOs and MTs for the Colusa Subbasin will follow the requirements of the CVVRWQCB's Sacramento River Basin Plan. In addition, the GSP should maintain the subbasin's water quality so that it meets all required health protective drinking water standards at levels below the Maximum Contaminant Levels (MCLs) for public water systems, and below the public health goals (PHGs). The GSP should specify Management Actions that will maintain and/or improve the subbasin water quality with an emphasis on the known problems.	Comment acknowledged.

Colusa Subbasin Groundwater Sustainability Plan

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
502	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network	7					(Comment A.27) Is voter approval necessary for any fees or taxes levied to raise funding for any of the Mitigation Actions? Who are the actual voters? Are they all landowners in the Colusa Subbasin, only landowners in a GSA, or all citizens of the Colusa subbasin? The GSP actions may need to fund mitigations to municipal or small water systems, so how are these systems represented in the funding decisions? Will the de minimus extractors, a person who extracts, for domestic purposes, two acre-feet or less of groundwater per year, be allowed a vote? How many votes does each eligible voter get? Will the number of votes be based on the acres owned, number of wells owned, volume of groundwater pumped, or some combination of factors? What happens if the economic burden to fund the management actions falls disproportionately on one group, to whom can they appeal? Will mitigation funds go to the de minimus extractor because their wells can go dry like anyone else's, but they are otherwise exempt from SGMA? Are there any statutes that govern how government agencies determine the per capita or per centum rate of a tax or fee?	Comment acknowledged. Developing a finance plan for the Subbasin will be part of GSP implementation and is not part of initial GSP development. As described on page 1 of Appendix 7A, there are a series of activities that the GSAs will need to undertake to continue to fund and finance GSP implementation activities.
503	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network						(Comment A.28) Do the stream depletion MOs and MTs take precedence over the domestic well MOs and MTs when the monitoring well are adjacent? How should the domestic well owner utilize the stream depletion thresholds?	Comment acknowledged. Appendix 5B provides a detailed discussion of the relationship between the sustainable management criteria for groundwater levels and surface water depletions. For locations in which both groundwater level and surface water depletion monitoring network wells exist, along with their well-specific sustainable management criteria, the management of the Colusa Subbasin will be based on the more conservative monitoring well and its associated sustainable management criteria. Surface water depletion sustainable management criteria allow for the least reduction in groundwater levels, and management actions related to this sustainability indicator will be based on the surface water depletion monitoring network wells. Projects and management actions will be undertaken by the GSAs, agencies and stakeholders in the Colusa Subbasin.
504	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network						(Comment A.28) What is the lateral extent that the stream depletion MO and MT applies? Up to 5 miles from the well? Only in the area where the 5 miles zone intersects a stream? Only in the area between the monitoring well and the stream?	Comment acknowledged. Sustainable management criteria (e.g., measurable objectives and minimum thresholds) for depletions of interconnected streams were assigned to each monitoring well in the representative monitoring network based on the historical groundwater levels at that specific monitoring well. During implementation of the Colusa Subbasin GSP, groundwater levels in each monitoring well in the representative monitoring network will be evaluated in comparison to the well-specific measurable objectives and minimum thresholds. Undesirable results will be judged to have occurred when 25 percent of the representative monitoring network wells exceed their well-specific minimum thresholds.

505	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network						(Comment A.28) Is there a map of the 48 Representative Monitoring Network (RMN) Thiessen polygon boundaries? What is the area of each polygon? How many domestic wells are in each polygon?	Comment acknowledged. The density of domestic wells is portrayed in Chapter 2 of the GSP. The GSAs will consider including a map of the Thiessen polygons during future updates to the Colusa Subbasin.
506	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network						(Comment A.28) Do the MO and MT apply to all domestic wells within that well's polygon? How does the requirement to evaluate undesirable results using 12 RMN wells affect the MO and MT at a specific domestic well? Should a domestic well owner be prepared to have a dry well if depth of their well is shallower than the MT in their polygon, or if the depth is shallower than the deepest MT in the group of 12 RMN wells?	Comment acknowledged. Sustainable management criteria (e.g., measurable objectives and minimum thresholds) do not apply to individual domestic wells, only wells in the representative monitoring network for the applicable sustainability indicators. Sustainable management criteria for depletions of interconnected streams were assigned to each monitoring well in the representative monitoring network based on the historical groundwater levels at that specific monitoring well. During implementation of the Colusa Subbasin GSP, groundwater levels in each monitoring well in the representative monitoring network will be evaluated in comparison to the well-specific measurable objectives and minimum thresholds. Undesirable results will be judged to have occurred when a percentage of the representative monitoring network wells exceed their well-specific minimum thresholds. Sustainable management criteria and the corresponding representative monitoring networks for the sustainability indicators applicable to the Colusa Subbasin are designed for sustainable management of the Subbasin as a whole. Groundwater conditions at specific domestic wells are subject to local and well-specific influences, which are uncertain. Domestic well owners are urged to participate with the GSAs, their respective Counties and stakeholders to address domestic well concerns during implementation of the Colusa Subbasin GSP.

507	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network						(Comment A.28) If a domestic well is being installed or replaced, can the well owner rely on the MO and MT depths in their polygon to determine a minimum depth of their new well? Does the GSP offer any advice on the sustainability criteria for the minimum depth of a new well or replacement well? Should the new well be at least the depth of the old well's polygon MT, or the 12-well group MT, to ensure that the well doesn't go dry in the future?	Comment acknowledged. Sustainable management criteria (e.g., measurable objectives and minimum thresholds) do not apply to individual domestic wells, only wells in the representative monitoring network for the applicable sustainability indicators. Sustainable management criteria for depletions of interconnected streams were assigned to each monitoring well in the representative monitoring network based on the historical groundwater levels at that specific monitoring well. During implementation of the Colusa Subbasin GSP, groundwater levels in each monitoring well in the representative monitoring network will be evaluated in comparison to the well-specific measurable objectives and minimum thresholds. Undesirable results will be judged to have occurred when a percentage of the representative monitoring network wells exceed their well-specific minimum thresholds. Sustainable management criteria and the corresponding representative monitoring networks for the sustainability indicators applicable to the Colusa Subbasin are designed for sustainable management of the Subbasin as a whole. Groundwater conditions at specific domestic wells are subject to local and well-specific influences, which are uncertain. Domestic well owners are urged to participate with the GSAs, their respective Counties and stakeholders to address domestic well concerns during implementation of the Colusa Subbasin GSP.
508	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network						(Comment A.28) What advice does the GSP give on how a domestic well owner should interpret the MO and MT values when their well is near the polygon boundary? For example, if a domestic well is installed or replaced in the 22N02W30H002 polygon that's close to the boundary with the 22N03W24E001 polygon, should the depth of the new well be at the deeper MT of the 22N03W24E001 polygon or the shallower 22N02W30H002 polygon?	Comment acknowledged. Sustainable management criteria (e.g., measurable objectives and minimum thresholds) do not apply to individual domestic wells, only wells in the representative monitoring network for the applicable sustainability indicators. Sustainable management criteria for depletions of interconnected streams were assigned to each monitoring well in the representative monitoring network based on the historical groundwater levels at that specific monitoring well. During implementation of the Colusa Subbasin GSP, groundwater levels in each monitoring well in the representative monitoring network will be evaluated in comparison to the well-specific measurable objectives and minimum thresholds. Undesirable results will be judged to have occurred when a percentage of the representative monitoring network wells exceed their well-specific minimum thresholds. Sustainable management criteria and the corresponding representative monitoring networks for the sustainability indicators applicable to the Colusa Subbasin are designed for sustainable management of the Subbasin as a whole. Groundwater conditions at specific domestic wells are subject to local and well-specific influences, which are uncertain. Domestic well owners are urged to participate with the GSAs and their respective Counties to address domestic well concerns during implementation of the Colusa Subbasin GSP.

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
509	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network						(Comment A.28) Will monitoring the RMN wells only 2 to 3 times each year effectively capture the fluctuations in groundwater level? In particular, the periods of maximum decline which have significant influence over domestic wells and stream depletion?	Comment acknowledged. Most of the wells within the Colusa Subbasin groundwater monitoring network are monitored by DWR staff 2 or 3 times per year, usually in the spring and fall to account for seasonal fluctuations. Monitoring twice per year is acceptable per CCR § 354.34. Increased monitoring frequency may be requested or conducted, as needed for plan implementation.
510	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network						(Comment A.28) What is the distribution of the depths of domestic wells associated with each RMN monitoring well? How many of the 20% shallower wells will go dry with each increment of groundwater level decline? Histograms of wells depth and cumulative frequency of depth statistics are needed to understand the validity and significance of the 20% shallower threshold.	Comment acknowledged. The density of domestic wells is portrayed in Chapter 2 of the GSP (Figure 2-7). The GSAs may consider including a map of the Thiessen polygons with domestic well depth statistics during plan and project implementation, or future updates to the Colusa Subbasin GSP.
511	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network						(Comment A.28) Will the construction of deeper domestic wells in the future influence the MO and MT values? If so, how will the MO and MT change, when will the change occur and what measures should a domestic well owner take when and if this change occurs?	Comment acknowledged. Construction of deeper domestic wells in the future may result in changes in the sustainable management criteria for chronic lowering of groundwater levels. The GSAs will evaluate sustainable management criteria during implementation of the GSP, including during periodic updates of the GSP. The GSAs will consider beneficial uses and users during plan implementation and will coordinate with stakeholders, and the GSAs representing the adjacent subbasins during this public process.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
512	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network						(Comment A.28) Will the use of 50% range values in deep aquifers to set the domestic well MTs cause more the wells to go dry and/or for longer periods than if the range in shallower aquifers were used? In other words, will the use of MT developed on deeper data delay actions needed to maintain the sustainability of the domestic wells because they allow greater declines in groundwater level before an undesirable result is acknowledged?	Comment acknowledged and addressed. Some of the monitoring wells in the representative monitoring network for chronic lowering of groundwater levels are multiple completion monitoring wells, meaning that they have multiple discretely screened intervals at different depths within the aquifer. The completion depths, and therefore the measurable objectives and minimum thresholds, for the multiple completion monitoring wells in the representative monitoring network were misidentified as the deepest completion intervals in Table 5-2 of the public draft GSP. The completions selected for the representative groundwater level monitoring network have been updated to reflect the completion that best represents the median depth of nearby domestic wells. Sustainable management criteria and hydrographs in Chapters 4 and 5, including Table 5-2 and corresponding appendices have been updated to reflect these changes. Also, the GSAs will implement the Colusa Subbasin GSP using a public process that includes domestic well owners and other beneficial users with the goal of implementing projects and management actions geared towards achieving and maintaining measurable objectives, and avoiding reaching minimum thresholds.
513	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network						(Comment A.28) Where in SGMA is the standard that 20% dry wells can be determined to be acceptable and non-significant, and therefore not an undesirable result? Where in SGMA does it give the standards for the economic analysis to determine the cost-effectiveness and the acceptable balance between avoiding significant and unreasonable impacts to domestic and other shallow wells in determining the MTs? Is the GSP's sacrifice of a 20% shallower well considered a taking? Does there need to be compensation? What is the value of the compensation, replacement costs of a deeper well, the original cost of the well, the value of the water at the time it goes dry or the change in water quality makes the water unusable, or all of the above.	Comment acknowledged. Please note that the GSAs have revised the MTs for chronic lowering of groundwater levels at several RMN sites. These revisions have resulted in shallower MTs that are more protective of the 20th percentile depths of domestic wells. The GSAs still propose a potential domestic well mitigation program, though the precise policies, funding, and other factors underlying that program will need to be determined by the GSAs through a public, stakeholder-driven evaluation and decision-making process during GSP implementation. Please see the response to comment 482 regarding the GSP's discussion of how mitigation program funds may be directed.

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
514	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network		6.5.2.1				(Comment A.28) The Management Action for the Domestic Well Mitigation Program states that the GSP (GSA) is in the early conceptual stage. SGMA exempts the GSP from CEQA (WC 10728.6), but requires implementation projects to undergo CEQA review. All eight of the Management Actions given in GSP Chapter 6.5.2 are in early conceptual stage. If the GSP is adopted with this language and no specifics are provided about what actions will be taken, does that mean that any future projects or actions to implement the GPS Management Actions are still CEQA exempt?	Comment acknowledged. Please see the response to comment 482.
515	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network						*(Summary of Comment B, part 1)* The Plan as proposed will degrade the groundwater basin and harm groundwater users who are not involved in conjunctive use, water transfers, or water banking but are reliant on the same groundwater basin.	Comment acknowledged.
516	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network						*(Summary of Comment B, part 2)* The public and SGMA governing bodies and committees have been excluded from NorthState inter-basin discussions. When participants in the Vina Stakeholder Advisory Committee asked staff if discrepancies in inter-basin flow volumes/direction that are estimated in the various GSA Basin Settings had been deliberated within the Inter-Basin Coordinating Committee, they answered that they are too busy, but would examine the issue after the GSPs are submitted in 2022.	Comment acknowledged. Interbasin coordination has occurred throughout GSP development and will continue during plan implementation. The CGA and GGA have engaged in robust interbasin coordination through NCWA and participation in GSP planning meetings in adjacent subbasins. Staff, representatives, and consultants from the Colusa Subbasin and neighboring basins have coordinated for consistency between GSPs, including at meetings open to the public. The GSP process recognizes that data gaps exist, and has built in a structured monitoring and annual/periodic review process to develop clearer understanding of subbasin conditions and progress toward sustainability over time. The GSP is a "living document" that the GSAs will review and revise as more information about the basin setting becomes available (per 23 CCR §356.4).
517	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network						*(Summary of Comment B, part 3)* Achieving sustainability requires local agencies, stakeholders, and water users to make many difficult and potentially contentious decisions. These decisions are prone to conflict, particularly when pumping restrictions are viewed as infringing on property rights or when fees are charged to support local management. The Colusa GSP is not complete without a detailed process and funding to resolve conflicts that arise both within and external to the GSA boundaries.	Comment acknowledged. The GSAs have made clear and consistent efforts to respectfully engage with all stakeholders through robust discussion. Public outreach and engagement is described in the response to comment 304, and is documented in Chapter 2 and associated appendices. The GSAs have also engaged in a transparent and public decision-making process through numerous GSA Board meetings and TAC meetings, documented in Appendix 5A. The GSAs are not searching for conflict, but are prepared to address it if it arises.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
518	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network						(Summary of Comment C, part 1) The Colusa GSP must not assume that local ordinances will in any way protect the population and environment of Glenn and Colusa counties from any transfers and expanded conjunctive use. Water transfers are not protective of the public or the environment, and Think tanks are already encouraging the California Legislature to override local ordinances: "If counties with restrictive groundwater export ordinances fail to amend their laws to conform to SGMA, the legislature should consider preempting local laws that discriminate against out-of-county uses or place undue burdens on groundwater and groundwater-substitution transfers that would not jeopardize sustainable groundwater management of the source aquifer." (comment provides some other examples)	Comment acknowledged.
519	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network						(Summary of Comment C, part 2) Sustainability is not found in the Colusa GSP, let alone equitable sustainability for all residents, farms, businesses, and the environment. The Colusa and Butte GSAs are dominated by large, non-residential landowners, many of whom have sought to play in the lucrative water market already to the detriment of their neighbors, streams, rivers, and species.	Comment acknowledged. The GSAs have made clear and consistent efforts to respectfully engage with all stakeholders through robust discussion. Public outreach and engagement is described in the response to comment 304, and is documented in Chapter 2 and associated appendices.
520	Barbara Vlamis, Jim Brobeck, Bill Jennings, Carolee Krieger	AquAlliance, California Sportfishing Protection Alliance, California Water Impact Network						(Summary of Comment C, part 3) In addition to exports, it is foreseeable that a future GSA will encourage drawdown of the aquifer (based on Los Angeles v. San Fernando) to satisfy massive crop thirst as the drought continues, which will then create extra storage space for imported waters to “recharge” the Basin.	Comment acknowledged. This comment appears to suggest that intentional overdraft will occur because of SGMA. The GSP does not plan for intentional overdraft. The GSP plans for projects and management actions and adaptive management to achieve and maintain sustainability and respond to unforeseen future conditions that may impact sustainable operation of the Subbasin (see Chapter 6). The GSP does not authorize or encourage exports out of the Basin.
521	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	2					(Summary of Comment 1.A, Disadvantaged Communities, Drinking Water Users, and Tribes) The plan fails to clearly document the population of each DAC and the population dependent on groundwater as their source of drinking water in the subbasin. The plan should provide the population of each identified DAC, and identify the sources of drinking water for DAC members, including an estimate of how many people rely on groundwater (e.g., domestic wells, state small water systems, and public water systems).	Comment acknowledged and addressed. We have added additional clarification in Section 2.1.2.1, Water Purveyors, to indicate that municipal and rural domestic water supplies in the Colusa Subbasin largely serve DACs, SDACs, and EDAs, and thus the water sources (groundwater) used to meet all urban (including rural domestic) water needs in the Subbasin are those used by DAC/SDAC/EDA populations.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
522	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	2					(Summary of Comment 1.A, Disadvantaged Communities, Drinking Water Users, and Tribes) The GSP fails to provide depth of domestic wells (such as minimum well depth, average well depth, or depth range) within the subbasin. The plan should include a map showing domestic well locations and average well depth across the subbasin (i.e., a map similar to Figure 2-7 showing average well depth per square mile).	Comment acknowledged. Domestic well densities per one square mile throughout the Colusa Subbasin are discussed in Chapter 2. The GSAs may consider additional evaluations of domestic well depths during GSP implementation, including in the implementation of projects and management actions and during periodic updates of the GSP.
523	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	Appendix 3G					(Summary of Comment 1.A, Interconnected Surface Waters) The identification of Interconnected Surface Waters (ISWs) is insufficient, due to lack of a comprehensive map of ISWs in the subbasin. The plan should provide a map showing all the stream reaches in the subbasin, with reaches clearly labeled as interconnected (gaining and losing) or disconnected. Consider any segments with data gaps as potential ISWs and clearly mark them as such on maps provided in the GSP.	Comment acknowledged. The C2VSim-ColusaFG numerical model was used to determine a subbasin-wide aggregate gain/loss within interconnected surface waters. The model is not currently scaled to determine gains and losses along every ephemeral, intermittent, and perennial stream or canal reach within the Subbasin, but has recently been updated to include a finer timestep. The Stony Creek thalweg analysis discussed in Chapter 3 explores the potential for using groundwater level measurements within shallow wells as a means to determine if stream reaches are connected or not. The thalweg analysis results were compared to the results of the Interconnected Surface Water in California's Central Valley (ICONS) study (TNC, 2021). The results between the two analyses were consistent, but also confirmed data gaps regarding availability of reliable data to evaluate for stream-aquifer connectivity. The GSAs will seek to work with resource agencies, stakeholders, beneficial users and the public to refine the understanding of interconnected surface waters in the Colusa Subbasin, fill data gaps, and develop PMAs with consideration of interconnected surface waters. Future model refinement may be considered to support understanding and quantification of surface water and groundwater connectivity. Additional mapping of surface water connectivity may be included in plan and project implementation reports or future updates to the GSP.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
524	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	Appendix 3G					(Summary of Comment 1.A, Interconnected Surface Waters) While the GSP presents a thorough, comprehensive evaluation of ISWs using the C2VSimFG-Colusa model (Appendix 3G), the plan should confirm those results by overlaying the stream reaches with depth-to-groundwater contour maps and should also discuss stream reaches in the interior of the subbasin (e.g., whether they were included in the groundwater model; their relevant depth to groundwater; whether they are considered to be disconnected, and what data was utilized to support that conclusion).	Comment acknowledged. The GSP includes groundwater elevation contour maps and hydrographs with depth to water in Chapter 3. Depth to water contour maps are not included in this initial Colusa Subbasin GSP but may be included in future revisions or projects completed during plan implementation.
525	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	3					(Summary of Comment 1.A, Groundwater Dependent Ecosystems) The identification of Groundwater Dependent Ecosystems (GDEs) is insufficient. The GSP identified and mapped GDEs using the NC dataset, but incorrectly removed NC dataset polygons in areas adjacent to irrigated fields or due to the presence of surface water supplies. NC dataset polygons adjacent to irrigated land or surface water supplies can still potentially be reliant on shallow groundwater aquifers, and therefore should not be removed solely based on their proximity to irrigated fields or surface water supplies. The plan should provide a comprehensive set of maps for the subbasin's GDEs (e.g., map the NC dataset and label polygons retained, removed, or added to/from the dataset) and discuss how local groundwater data was used to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer.	Comment acknowledged and addressed. The preliminary screening of the potential GDEs within the Colusa Subbasin was conducted to help prioritize areas for further mapping, evaluation and monitoring of GDEs during implementation of the Colusa Subbasin GSP. The preliminary screening supported the assessment of data gaps, evaluation of existing monitoring networks, which could potentially be used for GDE monitoring, and development of PMAs. The GSAs will seek to work with resource agencies, stakeholders, beneficial users and the public to refine the understanding of GDEs in the Colusa Subbasin, fill data gaps and develop PMAs with consideration of GDEs. The GDEs analysis will be refined during GSP implementation. Additional clarification has been added to the GSP Chapter 3 to acknowledge that significant data gaps exist for the precise locations and characteristics of GDEs in the Colusa Subbasin. It is noted that the prioritization, or "scoring," of GDEs is intended as a step toward identifying GDEs using the information available at the time of GSP development. This "scoring" is not seen as a final call on the classification of GDEs, but rather a prioritization for future work to better identify and expand monitoring of potential GDEs.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
526	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	3		3-82			(Summary of Comment 1.A, Groundwater Dependent Ecosystems) The GSP states (3-82): "Average spring groundwater level data from 2014 to 2018 indicates that shallow groundwater levels (i.e., within 30 feet of ground surface) exists throughout most of the subbasin. A depth to water (DTW) of 30 feet based on the average DTW for 2014 to 2018 was used as one of the primary criteria in the initial screening of potential GDEs." While we recognize that the period 2014-2018 represents multiple water year types, we recommend that a longer baseline period (10 years from 2005 to 2015) be established to characterize groundwater conditions. We recommend that a baseline period (10 years from 2005 to 2015) be established to characterize groundwater conditions over multiple water year types.	Comment acknowledged and addressed. The GDEs analysis will be refined during GSP implementation. Additional clarification has been added to the GSP Chapter 3 to acknowledge that significant data gaps exist for the precise locations and characteristics of GDEs in the Colusa Subbasin. It is noted that the prioritization, or "scoring," of GDEs is intended as a step toward identifying GDEs using the information available at the time of GSP development. This "scoring" is not seen as a final call on the classification of GDEs, but rather a prioritization for future work to better identify and expand monitoring of potential GDEs.
527	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	3					(Summary of Comment 1.A, Groundwater Dependent Ecosystems) The GSP does not provide an inventory of the flora or fauna species present in the subbasin's GDEs, except to discuss the four most prevalent vegetation species. The plan should include an inventory of the fauna and flora present within the subbasin's GDEs (Attachment C of this letter lists freshwater species located in the Colusa Subbasin), and note any threatened or endangered species.	Comment acknowledged and addressed. A reference to TNC's analysis of freshwater species located in the Colusa Subbasin has been added to Section 3.2.8 of the GSP (based on analysis of the California Freshwater Species Database version 2.0.9 within the Subbasin boundary). We have also added more text to acknowledge data gaps regarding which of these species are found within GDEs, and references to GSP studies in Chapter 7 to help close those data gaps and expand understanding of GDEs in the Subbasin.
528	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	3					(Summary of Comment 1.A, Groundwater Dependent Ecosystems) The GSP should provide depth-to-groundwater contour maps.	Comment acknowledged. Several depth to groundwater contour maps are included in Chapter 3 (see Figure 3-19, 3-20). It is noted that GSP regulations require groundwater elevation contour maps (§354.16(a)(1)), which are also included in Chapter 3 and Appendix 3B.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
529	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	3				Figure 3-36	(Summary of Comment 1.A, Groundwater Dependent Ecosystems) If insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons as “Potential GDEs” in the GSP until data gaps are reconciled in the monitoring network. It is not clear from the description in the GSP whether NC dataset polygons labeled with a ‘GDE Likelihood Score’ of 1 to 3 on Figure 3-36 are retained as potential GDEs.	Comment acknowledged. Figure 3-36 will be updated during future updates to the Colusa Subbasin GSP. The preliminary screening of the potential GDEs within the Colusa Subbasin was conducted to help prioritize areas for further mapping, evaluation and monitoring of GDEs during implementation of the Colusa Subbasin GSP. The preliminary screening supported the assessment of data gaps, evaluation of existing monitoring networks, which could potentially be used for GDE monitoring, and development of PMAs. The GSAs will seek to work with resource agencies, stakeholders, beneficial users and the public to refine the understanding of GDEs in the Colusa Subbasin, fill data gaps and develop PMAs with consideration of GDEs. The GDEs analysis will be refined during GSP implementation. Additional clarification has been added to the GSP Chapter 3 to acknowledge that significant data gaps exist for the precise locations and characteristics of GDEs in the Colusa Subbasin. It is noted that the prioritization, or "scoring," of GDEs is intended as a step toward identifying GDEs using the information available at the time of GSP development. This "scoring" is not seen as a final call on the classification of GDEs, but rather a prioritization for future work to better identify and expand monitoring of potential GDEs.
530	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	3					(Summary of Comment 1.A, Native Vegetation and Managed Wetlands) The integration of native vegetation and managed wetlands into the water budget is sufficient because the GSP included the groundwater demands of native vegetation and managed wetlands in the historical, current, and projected water budgets.	Comment acknowledged.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
531	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	Appendix 2E					(Summary of Comment 1.B, Stakeholder Engagement during GSP Development) Stakeholder engagement during GSP development is insufficient. SGMA's requirement for public notice and engagement of stakeholders is not fully met by the description in the Stakeholder Communication and Engagement Plan (Appendix 2E). The opportunities for public involvement and engagement with DACs, drinking water users, tribes, and environmental stakeholders are described in very general terms. They include technical and informational workshops and meetings open to the public. No specific outreach targeted to DACs, drinking water users, tribes, or environmental stakeholders is described in the GSP.	Comment acknowledged. It is noted that the GSAs have made clear and consistent efforts to respectfully engage with all stakeholders and interested parties through robust discussion. As described in Section 2.7.2, the CGA and GGA sponsored, publicized, and conducted numerous public engagement opportunities for stakeholders and interested parties in the Subbasin, including more than 236 separate meetings and workshops. Meetings and workshops have been consistently advertised and open to the public, and meeting notes, materials, and/or recordings have been available to the public. Other specific communication and outreach activities are described in Section 2.7.3, including tribal engagement. Communication and outreach has reached stakeholders and interested parties of varied backgrounds, including DACs, drinking water users, tribes, and environmental stakeholders. The GSAs have made clear efforts to reach and engage with all stakeholders and interested parties in the Colusa Subbasin. Notably, the majority of the populace in the Colusa Subbasin is classified as a DAC, SDAC, or EDA (see Section 2.1.2.3). Outreach and communication with communities in the Colusa Subbasin is intrinsically communication with DACs, SDACs, and EDAs.
532	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	Appendix 2E					(Summary of Comment 1.B, Stakeholder Engagement during GSP Development) The Stakeholder Communication and Engagement Plan does not include a plan for continual opportunities for engagement through the implementation phase of the GSP for DACs, domestic well owners, tribes, and environmental stakeholders. The plan should describe efforts to consult and engage with these stakeholders, and should utilize DWR's tribal engagement guidance to comprehensively address all tribes and tribal interests in the subbasin within the GSP.	Comment acknowledged. Engagement strategies listed throughout Appendix 2.E are nearly all expected to be used during GSP "development (or planning) and implementation," which is explicitly stated in several locations. Those engagement strategies apply to GSP implementation. Additionally, Section 2.7.3 of the GSP specifically describes the GSAs' consistent tribal engagement during GSP development. The GSAs are prepared to continue tribal engagement during GSP implementation. Table 4 in Appendix 2.E presents "Educational and Reference Documents for SGMA Implementation" and was used to inform the Communication and Engagement Plan. That list includes DWR's SGMA Engagement With Tribal Governments, thus, said guidance was and continues to be used. Finally, all PMA descriptions in Chapter 6 describe plans for "Notice to Public and other Agencies," summarizing plans for outreach related to implementation of that PMA. As described in Section 2.7.1, the GSAs are committed to periodically update the C&E Plan as conditions warrant, including but not limited to any necessary and beneficial conditions associated with the transition from GSP development to GSP implementation.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
533	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	5					(Summary of Comment 1.C, Disadvantaged Communities and Drinking Water Users) The GSP does not sufficiently describe or analyze direct or indirect impacts on DACs or tribes when defining undesirable results, nor does it describe how the groundwater levels minimum threshold will avoid significant and unreasonable impacts on beneficial users beyond 2015 and be consistent with Human Right to Water policy. The plan should describe direct and indirect impacts on drinking water users, DACs, and tribes when describing undesirable results and defining minimum thresholds for chronic lowering of groundwater levels.	Comment acknowledged and addressed. Section 5.3.1 has been revised to include the following, "As described in Chapter 2, most of the Subbasin is classified as an Economically Disadvantaged Area and has a high proportion of Disadvantaged Communities (DACs), and Small Disadvantaged Communities (SDACs). These beneficial users, along with members of California Native American Tribes (Tribes), including the federally recognized Cachil Dehe Band of Wintun Indians and the Cortina Indian Rancheria of Wintun Indians of California, typically rely on groundwater to meet their drinking water needs. As expressed in California Water Code Section 106.3, "every human being has the right to safe, clean, affordable, and accessible water adequate for human consumption, cooking, and sanitary purposes." The human right to water extends to all Californians, including disadvantaged individuals and groups and communities in rural and urban areas (SWRCB, 2021). Undesirable results caused by chronic lowering of groundwater levels could affect the Human Right to Water by limiting the ability of drinking water beneficial users, including DACs, SDACs and Tribes, to access safe, clean, and affordable water for human consumption, cooking, and sanitary purposes. These drinking water beneficial users could experience cumulative effects of undesirable results caused by chronic lowering of groundwater levels and degraded water quality." Also in Section 5.3.1, the listing of the potential effects of the undesirable results caused by chronic lowering of groundwater levels was revised to include decreased access to safe, clean and affordable drinking water, and additional references to projects and management actions and implementation activities focused on maintaining groundwater levels and mitigating drought impacts to drinking water beneficial users was added. Section 5.4.1 was revised to discuss the Human Right to Water in the context of minimum thresholds for chronic lowering of groundwater levels.

534	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	5					(Summary of Comment 1.C, Disadvantaged Communities and Drinking Water Users) The plan should describe direct and indirect impacts on drinking water users, DACs, and tribes when defining undesirable results for degraded water quality. For specific guidance on how to consider these users, refer to "Guide to Protecting Water Quality Under the Sustainable Groundwater Management Act."	Comment acknowledged and addressed. Section 5.3.4 has been revised to include the following, "Undesirable results caused by degraded water quality could affect the Human Right to Water by limiting the ability of drinking water beneficial users, including DACs, SDACs and Tribes, to access safe, clean, and affordable water for human consumption, cooking, and sanitary purposes. These drinking water beneficial users could experience cumulative effects of undesirable results caused by chronic lowering of groundwater levels and degraded water quality." Also in Section 5.3.4, the listing of the potential effects of the undesirable results caused by degraded water quality was revised to include decreased access to safe, clean and affordable drinking water, and additional references to implementation activities focused on coordinating with drinking water providers and regulatory agencies to support drinking water beneficial uses and users was added. Section 5.4.4 was revised to discuss the Human Right to Water in the context of minimum thresholds for degraded water quality.
535	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	5					(Summary of Comment 1.C, Disadvantaged Communities and Drinking Water Users) The plan should evaluate the cumulative or indirect impacts of proposed minimum thresholds for degraded water quality on drinking water users, DACs, and tribes.	Comment acknowledged and addressed. See responses to comments 533 and 534.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
536	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	5					(Summary of Comment 1.C, Disadvantaged Communities and Drinking Water Users) The plan should provide a summary table for EC that presents the pre-2015 historical maximums, the salinity objective from the Basin Plan, the SMCL, and the resulting minimum thresholds. Ensure that the minimum thresholds do not exceed the salinity objective in the Basin Plan.	Comment acknowledged. Historical salinity, as total dissolved solids, is discussed in Chapter 3. Historical maximum total dissolved solids concentrations, as reported to State and federal agencies, are depicted on Figure 3-30. Historical salinity, as electrical conductance, for the representative groundwater quality monitoring network (public water supply wells) are shown in Appendix 5D and discussed in Chapter 5. The historical electrical conductance measured in the representative groundwater quality monitoring network was used to determine the sustainability thresholds. Existing regulatory programs are currently monitoring and will be addressing salinity concerns in shallow wells throughout the subbasin. The CGA and GGA will coordinate with these programs, the lead regulatory agencies, and the regulated community within the Colusa Subbasin during implementation of this GSP, including during development and implementation of projects and management actions.
537	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	5					(Summary of Comment 1.C, Disadvantaged Communities and Drinking Water Users) The plan should set minimum thresholds and measurable objectives for all water quality constituents within the subbasin that can be impacted and/or exacerbated as a result of groundwater use or groundwater management. Ensure they align with drinking water standards.	Comment acknowledged. MCL exceedances are managed by individual water supply agencies.
538	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	5					(Summary of Comment 1.C, Groundwater Dependent Ecosystems and Interconnected Surface Waters) Sustainable management criteria for chronic lowering of groundwater levels provided in the GSP do not consider potential impacts to environmental beneficial users. When defining undesirable results for chronic lowering of groundwater levels, provide specifics on what biological responses (e.g., extent of habitat, growth, recruitment rates) would best characterize a significant and unreasonable impact to GDEs. Potential impacts on environmental beneficial uses and users need to be considered when defining undesirable results in the subbasin. Defining undesirable results is the crucial first step before the minimum thresholds can be determined.	Comment acknowledged. The development of a dedicated groundwater dependent ecosystem monitoring network consisting of shallow monitoring wells is discussed in Chapter 6.5.2.9 Potential Management Actions, and Chapter 7.1.2.1 GSP Studies. Although the GSAs used the best available scientific data and information to assess potential GDEs within the Colusa Subbasin, significant data gaps exist in the understanding of the GDEs and the associated species. These data gaps include potential undesirable results impacting environmental beneficial users. The GSAs will seek to work with resource agencies, stakeholders, beneficial users and the public to refine the understanding of GDEs in the Colusa Subbasin, fill data gaps, re-evaluate sustainability thresholds, and develop PMAs with consideration of GDEs.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
539	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	5					(Summary of Comment 1.C, Groundwater Dependent Ecosystems and Interconnected Surface Waters) The GSP does not explain how the chosen minimum thresholds and measurable objectives avoid significant and unreasonable effects on surface water beneficial users in the subbasin, such as increased mortality and inability to perform key life processes (e.g., reproduction, migration). When establishing SMC for the subbasin, consider that the SGMA statute [Water Code §10727.4(l)] specifically calls out that GSPs shall include "impacts on groundwater dependent ecosystems".	See response to comment 538.
540	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	5					(Summary of Comment 1.C, Groundwater Dependent Ecosystems and Interconnected Surface Waters) When defining undesirable results for depletion of interconnected surface water, include a description of potential impacts on instream habitats within ISWs when minimum thresholds in the subbasin are reached. The GSP should confirm that minimum thresholds for ISWs avoid adverse impacts to environmental beneficial users. These recommendations apply especially to environmental beneficial users that are already protected under pre-existing state or federal law.	Comment acknowledged and addressed. Section 4.2.5.4 has been revised to state that the ISW monitoring network wells may be useful for monitoring groundwater levels near GDEs; however, a dedicated network of shallow monitoring wells will be developed specifically for GDE monitoring during implementation of the GSP. The development of a dedicated GDE monitoring network consisting of shallow monitoring wells is discussed in Chapter 6.5.2.9 Potential Management Actions and Chapter 7.1.2.1 GSP Studies. Although the GSAs used the best available scientific data and information to assess potential GDEs within the Colusa Subbasin, significant data gaps exist in the understanding of the GDEs and the associated species. These data gaps include potential undesirable results impacting environmental beneficial users and in-stream habitat. The GSAs will seek to work with resource agencies, stakeholders, beneficial users and the public to refine the understanding of GDEs in the Colusa Subbasin, fill data gaps, re-evaluate sustainability thresholds, and develop PMAs with consideration of GDEs.
541	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	3					(Summary of Comment 2, Climate Change) The integration of climate change into the projected water budget is insufficient. The GSP incorporates climate change into the projected water budget using DWR change factors for 2030 and 2070. However, the plan does not consider multiple climate scenarios (e.g., the 2070 extremely wet and extremely dry climate scenarios) in the projected water budget. While these extreme scenarios may have a lower likelihood of occurring, their consequences could be significant and their inclusion can help identify important vulnerabilities in the subbasin's approach to groundwater management.	Comment acknowledged. The GSAs have chosen to evaluate future scenarios of hydrologic uncertainty associated with projections of climate change using the 2030CT and 2070CT scenarios, consistent with GSP requirements (§354.18(c)(3)(A)). However, the GSAs acknowledge that there is significant uncertainty in future conditions related to climate change and other factors that will impact groundwater conditions and sustainability in the Colusa Subbasin. The uncertainty of future conditions is one of many reasons that GSP implementation will be based on adaptive management, described extensively in Chapter 6. It is also noted that the 2030CT and 2070CT climate change effects are simulated over the entire projected period. In reality, climate change effects will occur gradually with uncertain interannual changes.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
542	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	3					(Summary of Comment 2, Climate Change) Imported water should be adjusted for climate change and incorporated into the surface water flow inputs of the projected water budget. The sustainable yield is calculated based on the projected water budget with climate change incorporated. However, if the water budgets are incomplete, then there is increased uncertainty in virtually every subsequent calculation used to plan for projects, derive measurable objectives, and set minimum thresholds.	Comment acknowledged. As indicated in Table 3-9, surface water supplies in the future conditions 2030 and 2070 climate change scenarios were adjusted for climate change with reductions to simulate drought periods. However, the uncertainty of future conditions related to surface water supplies is one of many reasons that GSP implementation will be based on adaptive management. As described throughout the GSP (especially Chapter 6), the GSAs are committed to ongoing monitoring and implementation of projects and management actions to respond to changing Subbasin conditions.
543	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	3, 6					(Summary of Comment 2, Climate Change) The plan should incorporate climate change scenarios into projects and management actions.	Comment acknowledged. As described in Chapter 6 (Section 6.1), PMAs were developed with consideration for the 2070CT climate change scenario. Select planned PMAs were also simulated in the 2070CT climate change scenario to evaluate depletions of interconnected surface water along major waterways in the Colusa Subbasin (see Appendix 3G).

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
544	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	4, 7					(Summary of Comment 3, Data Gaps) The consideration of beneficial users when establishing monitoring networks is insufficient, due to lack of specific plans to increase the Representative Monitoring Sites (RMSs) in the monitoring network that represent water quality conditions and shallow groundwater elevations around DACs, domestic wells, tribes, GDEs, and ISWs in the subbasin. The GSP should ensure that groundwater elevation and water quality RMSs are monitoring groundwater conditions spatially and at the correct depth for all beneficial users, and should plan to increase the number of RMSs in the shallow aquifer across the subbasin as needed to adequately monitor all groundwater condition indicators across the subbasin and at appropriate depths for *all* beneficial users. Monitoring should prioritize proximity to DACs, domestic wells, tribes, and GDEs.	Comment acknowledged and addressed. The GSAs have reviewed and selected new representative completions for several RMN well locations in the groundwater level monitoring network. Completions have been selected to be more representative of domestic well users, including DACs and tribes. Revisions have also created shallower MTs that are more protective of the 20th percentile depths of domestic wells. Section 4.2.5.4 has been revised to state that the ISW monitoring network wells may be useful for monitoring groundwater levels near GDEs; however, a dedicated network of shallow monitoring wells will be developed specifically for GDE monitoring during implementation of the GSP. Although the GSAs used the best available scientific data and information to assess potential GDEs and ISWs within the Colusa Subbasin, significant data gaps exist in the understanding of ISWs, GDEs, and associated species. As described in Sections 6.5 and 7.1.2, the GSAs will seek to work with resource agencies, stakeholders, beneficial users and the public to refine the understanding of GDEs and ISWs in the Colusa Subbasin, fill data gaps, and develop PMAs with consideration of these beneficial users. Plans for expanding the water quality monitoring network (Section 7.1.2.2) have also been revised to clarify that consideration of these beneficial users will be considered in
545	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	4, 7					(Summary of Comment 3, Data Gaps) The GSP should provide maps that overlay current and proposed monitoring well locations with the locations of DACs, domestic wells, tribes, GDEs, and ISWs to clearly identify potentially impacted areas.	Comment acknowledged. Maps of the DACs, tribal lands, GDEs, and surface waters are provided in Chapters 2 and 3. Surface waters are shown on maps in Chapter 4 with the interconnected surface waters and groundwater level monitoring network locations. As more information becomes available during plan implementation, the capability and appropriateness of monitoring sites to accurately and reliably monitoring conditions relative to specific areas of concern may be evaluated and addressed in future reports.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
546	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	4					(Summary of Comment 3, Data Gaps) The GSP should describe biological monitoring that can be used to assess the potential for significant and unreasonable impacts to GDEs or ISWs due to groundwater conditions in the subbasin.	Comment acknowledged and addressed. Although the GSAs used the best available scientific data and information to assess potential GDEs and ISWs within the Colusa Subbasin, significant data gaps exist in the understanding of ISWs, GDEs, and associated species. As described in Sections 6.5 and 7.1.2, the GSAs will seek to work with resource agencies, stakeholders, beneficial users and the public to refine the understanding of GDEs and ISWs in the Colusa Subbasin, fill data gaps, and develop PMAs with consideration of these beneficial users. Section 6.5 described opportunities for evaluating and planning biological monitoring.
547	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	6					(Summary of Comment 4, Addressing Beneficial Users in Projects and Management Actions) The GSP should clarify the planning horizon of the described domestic well mitigation program to ensure that it will proactively monitor and protect drinking water wells through GSP implementation.	Comment acknowledged. It is noted that Glenn and Colusa Counties both track and monitor well problems through a voluntary reporting program (described in the Preface). Additionally, it is noted that the GSAs have revised the MTs for chronic lowering of groundwater levels at several RMS sites, particularly around the Orland area. These revisions have created shallower MTs that are more protective of the 20th percentile depths of domestic wells. The GSAs still propose a potential domestic well mitigation program, though the precise policies, funding, and other factors underlying that program will need to be determined by the GSAs through a public, stakeholder-driven evaluation and decision-making process during GSP implementation. Mitigation could involve actions designed to secure reliable water sources for affected domestic well owners (through, for example, public water system consolidations funded by the GSA).
548	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	6					(Summary of Comment 4, Addressing Beneficial Users in Projects and Management Actions) For DACs and domestic well owners, the GSP should include a discussion of whether potential impacts to water quality from projects and management actions could occur and how the GSAs plans to mitigate such impacts.	Comment acknowledged. Additional text has been added to Section 6.2.2 to describe the anticipated effects of planned PMAs on water quality, including that experienced by domestic well users and DACs.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
549	Ngodoo Atume, Samantha Arthur, E.J. Remson, Amy Merrill, J. Pablo Ortiz-Partida, Danielle V. Dolan, Melissa M. Rohde, Kristan Culbert	Clean Water Action/Clean Water Fund, Audubon California, The Nature Conservancy, American Rivers, Union of Concerned Scientists, Local Government Commission	6					(Summary of Comment 4, Addressing Beneficial Users in Projects and Management Actions) The GSP should develop management actions that incorporate climate and water delivery uncertainties to address future water demand and prevent future undesirable results.	Comment acknowledged. As described in Chapter 6 (Section 6.1), PMAs were developed with consideration for the 2070CT climate change scenario. Select planned PMAs were also simulated in the 2070CT climate change scenario to evaluate depletions of interconnected surface water along major waterways in the Colusa Subbasin (see Appendix 3G). As the comment indicates, there is significant uncertainty in future conditions related to climate, water supplies, and other factors that will impact groundwater conditions and sustainability in the Colusa Subbasin. The uncertainty of future conditions is one of many reasons that GSP implementation will be based on adaptive management. The GSAs' adaptive management strategy for GSP implementation is described extensively in Chapter 6.
550	Samantha Arthur	Audubon California	3					Audubon appreciates that the GSA has identified and specifically included managed wetlands in maps and water budgets, specifically the three primary refuges: Sacramento National Wildlife Refuge, Delevan National Wildlife Refuge, and Colusa National Wildlife Refuge.	Comment acknowledged.
551	Samantha Arthur	Audubon California	3					The future condition water budgets should reflect CVPIA Full Level 4 water supplies being available and delivered to each of the three national wildlife refuges. The use of 2013 to represent unconstrained delivery conditions (e.g. see GSP Table 3-9, page 3-88) reflects deliveries to these refuges that are less than the CVPIA Full Level 4 mandated quantities. Annual Full Level 4 water supplies during unconstrained conditions are as follows: a. Sacramento NWR = 50,000 acre-feet, b. Delevan NWR = 30,000 acre-feet, and c. Colusa NWR = 25,000 acre-feet. During constrained conditions, these same refuges generally are provided 75% of this quantity, as stipulated in their water delivery agreements with the U.S. Bureau of Reclamation.	Comment acknowledged. Table 2-3 has been edited to acknowledge the expected availability of CVPIA Full Level 4 water supplies to the national wildlife refuges. A footnote has been added stating that although CVPIA Full Level 4 supply quantities are known, they were not used in the projected water budgets due to the uncertainty in those quantities actually being provided. In light of these uncertainties, simulating constrained surface water supplies was considered a more conservative approach to GSP planning, as more surface water supply availability would increase groundwater recharge and likely decrease groundwater pumping. It is noted that the GSP is a "living document," and will be revised over time, as needed, once more is known about actual future water supplies. It is expected that the C2VSimFG-Colusa model and water budgets will be updated periodically during GSP implementation to incorporate new information and revised assumptions as we learn more about conditions in the Colusa Subbasin.
552	Samantha Arthur	Audubon California	6				Table 6-2	Audubon appreciates that several of the listed projects included in Table 6-2 include identified opportunities for multi-benefit projects that provide water supply and wildlife habitat benefits.	Comment acknowledged.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
553	Samantha Arthur	Audubon California	2				Figure 2-8	Suggest modifying the color scheme or naming for the category "native" to distinguish the refuges from other "native" areas as the refuges are distinctly different land uses than the traditional native upland areas, for instance, in the southwestern portion of the subbasin. Private managed wetlands and managed wetlands in U.S. Fish and Wildlife Service Management Areas that have federal easements are currently not identified in land use or jurisdictional maps.	Comment acknowledged and addressed.
554	Samantha Arthur	Audubon California	2		page 2-11		Table 2-3	Since the three national wildlife refuges are mandated to receive stipulated quantities (though have yet to achieve them), this table should also list the CVPIA Full Level 4 quantities of: Sacramento NWR = 50,000 acre-feet, Delevan NWR = 30,000 acre-feet, and Colusa NWR = 25,000 acre-feet. While the historic average deliveries are useful for baseline understanding, modeling of future conditions should include the full water supplies for these three refuges.	Comment acknowledged and addressed. Please see the response to comment 551.
555	Samantha Arthur	Audubon California	3		Page 3-13	line 32/33		The term "land" should be added to the end of the sentence to result in "federal wildlife land."	Comment addressed in the GSP section indicated.
556	Samantha Arthur	Audubon California	3		Page 3-88		Table 3-9	The future condition water supplies for the three national wildlife refuges should reflect the CVPIA Full Level 4 water supply. Deliveries in 2013, represented as a Shasta Non-critical year, did not result in Full Level 4 deliveries to these refuges. The CVPIA Full Level 4 quantities include a portion that is labeled "Level 2" that reflects delivery of CVP project water, and a portion labeled "Incremental Level 4" (the difference between Full Level 4 and Level 2) that can come from other sources. The GSP will need to make reasonable assumptions whether the Incremental Level 2 supply will be derived from other surface water sources or from groundwater, though either is possible.	Comment acknowledged. Please see the response to comment 551.
557	Samantha Arthur	Audubon California	3	Section 3.3.3.1 Historical (Water Budget)	Page 3-89			Under "Agricultural Water Demand" the following sentence is included: "For ponded land uses (rice and managed wetlands), pond depths and pond drainage are also considered to simulate demands." Under the "Current Conditions" (Section 3.3.3.2) and "Future Conditions Scenarios" (Section 3.3.3.3) water budget discussions, this same language is missing. Did these budgets recognize managed wetlands in a similar fashion as described for the historical budget? If so, we suggest adding the same sentence to each of the other water budget descriptions for clarity.	Comment acknowledged and addressed. Clarification has been added to Sections 3.3.3.2 and 3.3.3.3 to verify that, yes, the current and future conditions water budgets did recognize managed wetlands in a similar fashion as described for the historical budget.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
558	Samantha Arthur	Audubon California	3		Page 3-96		Table 3-11	As a result of including the CVPIA Full Level 4 water supplies for the national wildlife refuges, the values for the various future conditions for "Sacramento River Diversions" and "Groundwater Pumping – Managed Wetlands" as well as the "Evapotranspiration – Managed Wetlands" may all change. The table should be updated accordingly.	Comment acknowledged. Please see the response to comment 551. It is also noted that adding CVPIA Level 4 supplies to the water budget will increase total surface supply to the subbasin and reduce estimated future groundwater pumping, so the approach used in the GSP water budgets represents a relatively worse case scenario for groundwater sustainability planning purposes.
559	Samantha Arthur	Audubon California	3		Page 3-97		Table 3-12	Similar to the prior comment, values in this table for the future conditions would be expected to change when the CVPIA Full Level 4 water supply quantities are incorporated	Comment acknowledged, please see the response to comment 558.
560	Samantha Arthur	Audubon California	6	Section 6.5.2.3	Page 6-84 to 6-86			Several demand reduction concepts are initially outlined in this section. Audubon suggests the following be considered associated with each suggested method: 1. Allocation: Use of groundwater by managed wetlands should not be restricted without adequate replacement with surface water sources, especially the national wildlife refuges. Managed wetlands in the Colusa subbasin provide invaluable benefits to the Pacific Flyway. 2. Allocation with a market: If a market is created and managed wetlands are assigned an allocation, such parcels should be able to participate in a market to optimize the use of their allocations for achieving habitat objectives, but managed wetlands should not be required to participate in a market to secure the water they need. 3. Land repurposing: Strategic siting of where irrigated lands are retired and others are kept in production should consider the potential benefits to wildlife. Areas surrounding protected areas, such as the Sacramento, Delevan and Colusa National Wildlife Refuges, should be prioritized habitat benefits. 4. Financial incentives: Public beneficial uses such as managed wetlands should not be subject to financial conditions that lesson the public benefit otherwise achieved on the lands.	Comment acknowledged. The following statements were added to Chapter 6, Section 6.5.2.3: "Allocation design may include specific considerations for managed wetlands and other habitat benefits uses of water." "Other market rules might consider habitat and ecosystem service benefits." "Other land repurposing program considerations might consider strategic location of repurposed lands considering proximity to protected areas (e.g., National Wildlife Refuges)." and "Financial incentives could consider public benefits (e.g., habitat) separately from private benefits (e.g., irrigation) of water use."
561		City of Orland	5					Chapter 5 states that the subbasin in is currently being managed sustainably without undesirable result despite over 150 domestic wells going dry this summer alone as 2021 data is not yet included in plan development. It is notable that a key partner in the draft plan explained at the October 13th public meeting. "The current actual drought is more compelling than modeled future sustainability challenges."	Comment acknowledged. Please see the response to comment 318.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
562		City of Orland						The plan's allowance for up to 20% of domestic wells going dry may be understandable in light of the age and depths of most of the wells. However, depletion of up to 5% of groundwater storage (over 5 years) and inelastic subsidence of up to½ foot per year were also considered acceptable in the July version of the draft plan, apparently due to an estimate that we still have 26-140 million AF (acre feet) of water in the aquifer. Consultants to the GGA suggest that 26M AF is reliably established, but the estimate of upwards of 140M AF is more of a projection. We are concerned about any reliance on the 140M AF estimate, and suggest that the subbasin should be more conservatively managed to an assumption of 26M AF.	Comment acknowledged. Please note that the GSAs have since revised the MTs and MOs for subsidence at all RMS benchmarks (please see the response to comment 477) and have updated the MTs for groundwater levels at several RMS wells, including those around Orland (please see the response to comment 564). Change in groundwater storage is monitored and managed in proxy through management of groundwater levels according to these revised SMC. However, recognizing the data gaps in the basin setting and the uncertainty of future conditions, GSP implementation will be based on adaptive management (see the response to comment 468). The GSAs have also proposed a number of studies to close data gaps during GSP implementation (see Chapter 7), including a study of infrastructure sensitivity to land subsidence.
563		City of Orland						We welcome the recent consultant proposal, adopted by the Board October 11th to revise the plan with an amendment tightening the measurable objectives (MO) and minimum thresholds (MT) for inelastic subsidence, as the draft plan's original allowance for excessive subsidence would have exposed municipal services like water, wastewater and storm drainage to unacceptable risk of severe disruption.	Comment acknowledged.
564		City of Orland						City of Orland observes that the draft plan as written does not appear to adequately protect the integrity of domestic and municipal drinking water wells. With most said wells being less han 200' deep, more than 20% would be dry by the time well depth MO were reached and almost all would be dry by the point MT were reached. It would seem that the MO and MT for well depths should be reconsidered and revised to a more conservative and protective standard.	Comment acknowledged. Please note that the GSAs have revised the MTs for chronic lowering of groundwater levels at several RMS sites, particularly around the Orland area. These revisions have created shallower MTs that are more protective of the 20th percentile depths of domestic wells, considering historical groundwater levels since the mid-2000s. The GSP also plans to manage groundwater levels to the higher MO levels, which are shallower than 200 ft bgs at all wells and considerably shallower at most. If harm does occur to domestic wells, the GSAs propose implementing a domestic well mitigation program, though the precise policies, funding, and other factors underlying that program will need to be determined by the GSAs through a public, stakeholder-driven evaluation and decision-making process during GSP implementation. The GSAs also reiterate that they are planning an adaptive management strategy for GSP implementation. Please see the response to comment 468.

Colusa Subbasin Groundwater Sustainability Plan
Document Comment and Response Tracking Table
Last Revised: December 2, 2021

#	Commenter Name (if available)	Commenter Organization (if applicable)	Chapter	Section	Page Number	Paragraph Number (from top of page)	Figure/ Table Number (If Applicable)	Comment	Response
565		City of Orland						Finally, we commend the GGA Board for its many projects in progress, planned and contemplated, as laid forth in Chapter 6. However, there do not yet appear to be real "triggers" that would commit the GGA to certain substantive actions when passing MO and approaching MT. We hope the GGA works with the State and consultants in coming years to develop and specify such triggers as a backstop to recharge projects in order to truly protect the precious drinking water resources on which the people of Orland and Glenn County rely.	Comment acknowledged. The GSAs plan to select and implement PMAs to effectively address the specific concerns that arise in the Subbasin, with regard for the specific sustainability concern and relative costs and benefits. The uncertainty of future conditions is one of many reasons that GSP implementation will be based on adaptive management (see the response to comment 468). Planned PMAs (with a timeline and plans for action) alone are expected to address sustainability concerns over the projected future period (see Sections 6.1 through 6.3); however, other potential PMAs are available as needed. Implementation of many potential PMAs, including demand management, involve major public policy questions that will require evaluations of conditions in a public, stakeholder-driven process. The precise decisions for whether and how potential PMAs would be initiated will be determined by the GSA boards through a stakeholder-driven process during GSP implementation.

Re: Draft Colusa Subbasin Groundwater Sustainability Plan

Dear Ms. Hunter and Ms. Fahey:

AquAlliance, the California Sportfishing Protection Alliance, and the California Water Impact Network (hereinafter AquAlliance) submit the following comments and questions on the draft Colusa Subbasin Groundwater Sustainability Plan ("Colusa GSP" or "Plan"). There are serious weaknesses in the Plan that require significant changes to the document, without which the public and policymakers are truly left in the dark and dangerous consequences are obfuscated.

The information and analysis provided in Section A discuss the future changes described in the draft GSP for the Colusa Subbasin groundwater system and the overlying surface waters, and the implications of the proposed sustainability objectives and minimum thresholds. The draft Colusa GSP presents a rosy scenario suggesting that future precipitation, evapotranspiration, and surface water supplies will adjust to the 2070 Central Tendency climate change scenario provided by DWR and keep groundwater levels stable. However, elsewhere in the Plan is material that indicates the proposed GSP management of the subbasin under the 2070 Central Tendency scenario will cause detrimental changes to both surface waters and groundwater. The 2070 scenario sustainable management of subbasin assumes that annual average groundwater pumping will increase approximately 13%, while allowing declines in groundwater below the historical lows. The groundwater storage will be partially sustained by increases in seepage from overlying streams and a reduction in groundwater accretion to the streams.

Section B demonstrates the serious deficiencies in definitions of and plans to resolve conflicts. This failure will lead to escalating costs to residents, farms, and businesses to protect access to groundwater by deepening wells or drilling a replacement, plus likely legal expenses. Adam Keats and Chelsea Tu discussed this at length in 2016: "[i]f a medium or highpriority [sic] groundwater basin becomes a multi-use basin that includes imported water rights, overlying rights, and interconnected instream rights, the relationship between those rights, and the priority given to each of the rights-holders, remains unresolved by the Act. The responsibility for

identifying and addressing the foreseeable legal and use conflicts between imported water, overlying use, and/or in-stream use where groundwater interconnects with surface water is thus left to the GSAs, or ultimately, the courts."[1]

Section C provides historic information on some of the destructive planning and practices that have transpired in the Sacramento Valley that have caused groundwater basins elsewhere in California to become private assets as opposed to public commons. It is a tragedy in the making to have local government, the cities of Colusa, Orland, Williams, and Willows and the counties of Colusa and Glenn, promote a Plan that accepts the failure of 20 percent of the domestic wells and the loss of almost 1,000,000 AF of groundwater storage by 2070.

A. Sustainability objective and threshold for undesirable results

1. The Draft GSP has a lot of words but little action, except recharge projects. The sustainable operation of the subbasin is described as [*p]rojects and management actions that the GSAs **could** implement to ensure that the Colusa Subbasin is operated sustainably (i.e., to avoid undesirable results) are described in Chapter 6. The Introduction to Chapter 6 describes an adaptive management approach for implementing projects and management actions that will be informed by monitoring of groundwater conditions and will lead to implementation of **additional projects if Measurable Objectives (MOs) are not being maintained and Minimum Thresholds (MTs) are being approached** (emphasis added).*

   > *An adaptive management approach **recognizes that undesirable results do not currently exist in the Subbasin**, and it is **uncertain that undesirable results will develop in the future** (emphasis added).* Section 5.2.1, pages 5-3 and 5-4.

   The sustainability management actions given in Chapter 6 are all "**Potential Management Actions**" (Section 6.5.2, page 6-81), and all are ***currently in the early conceptual stage***, so there is no understanding of the benefits, costs, the funding sources, or specifics about how the actions will maintain sustainable groundwater levels (emphasis added).

2. Section 6.1 on Project and Management Actions Development Approach gives the true goal: **pumping more groundwater, 13% more, to make up for evapotranspiration (ET) increase due to climate change**. The draft GSP talks about climate change and then gives a selection of water budget values with and without climate change, Table 6-1 (page 6-2). See page 1 of AquAlliance Exhibit A. The draft GSP assumes that rainfall will increase with the 2070 climate change scenario to meet 74% of the addition ET from climate change, (75 taf/yr / 102 taf/yr = 0.735). The draft GSP says that stream accretion (groundwater that discharges to the steams) will remain positive with and without climate change, but with the 2070 climate change it decreases 48,000 acre-feet / year (AFY) approximately 38% from the future conditions without climate change. That's a lot of decrease, but that's only 0.5% of the Sacramento River flow, so a cynic might ask, why worry (page 6-2)? It isn't clear how the stream depletion monitoring program will interact with the stream accretion assumptions.

[1] Keats, Adam et al., 2016. *Not All Water Stored Underground is Groundwater: Aquifer Privatization and California's 2014 Groundwater Sustainable Management Act*. p. 98.

The stream depletion monitoring program only monitors groundwater levels, but it ***should*** also include monitoring of stream flow changes, i.e., seepage and accretion changes, to validate the assumptions about climate change and sustainability (emphasis added).

3. The groundwater monitoring for sustainability focuses on domestic wells and stream depletion, but not much on subsidence. The MOs and MTs for domestic well sustainability use point data of historical groundwater depth and hydrographs for 48 Representative Monitoring Network (RMN) wells out of the 104 monitoring wells identified in the subbasin, listed on Table 5-2 and 4-1, respectively. The MOs are defined at the middle of the historical range of groundwater levels. (See pdf pages 56 through 67, and 105 through 116 in Appendix 5B for graphic presentation of MOs and MTs with values from Table 5-2.) The MTs are developed by taking the greater depth of either the depth where 20% of the domestic wells within the Thiessen polygon around each of the 48 RMN monitoring wells are shallower, or the depth at 50% of the historical range below the deepest groundwater level prior to January 1, 2015 (and sometimes 2016) (Section 5.4.1, pages 5-19 through 5-21). These GSP standards for the MTs effectively means that ***domestic wells in the Colusa subbasin can experience groundwater levels deeper than historical levels and still be considered sustainable***.

4. The draft GSP requires that the determination of when an MT is exceeded and creates an ***undesirable result*** for domestic wells, stream depletion, water quality, or subsidence, that the monitoring sites, at either monitoring wells or survey benchmarks, must be evaluated in sub-groups of a minimum size and minimum duration, see Table 5-1 (see page 2 of AquAlliance Exhibit A), and all monitoring sites must **exceed their respective MTs together** before an ***undesirable result*** can occur. The draft GSP identifies the monitoring wells, but doesn't identify the monitoring well groups, or define criteria for the making the groups other than state the minimum number needed in a group. The draft GSP does say that once formed the groupings can't change. Except for subsidence, the MTs for each monitoring site are different, Tables 5-2 and 5-3. See pages 3 through 5 of AquAlliance Exhibit A. The requirement that all monitoring sites must **exceed the MTs together** implies that the monitoring site with the greatest MT depth will likely control the occurrence of an ***undesirable results***. In other words, until the deepest or greatest MT value is exceeded, the group hasn't exceeded the collective MT and therefore no ***undesirable result*** has occurred (emphasis added).

   For example, a group of 12 monitoring wells in the northern portion of the Colusa subbasin surrounding Orland, the last 12 wells listed in Table 5-2, have MTs depths that range from 90 to 356 feet, or elevations from 71 to -108 feet amsl. (See pages 5 and 6 of AquAlliance Exhibit A) The MT listed in column 5 is the greatest value of either of the right two columns in Table 5-2. Note that the MT depth selected for these 12 wells are all at or greater than the depth of the 20th percentile of domestic wells. This means that if these 12 wells are a domestic well monitoring group, then an ***undesirable result*** can't occur until the depth to groundwater at the well with the greatest MT depth, well 21N04W12A004, exceeds 356 feet, or an elevation lower than -108 feet (columns 4 and 5 in Table 5-2) for 24 consecutive months. This maximum depth is significantly greater than the 20th percentile depth for the surrounding domestic wells, column 4 versus column 11.

The ***all-or-none*** requirement makes it possible that the depth to groundwater in the other 11 wells could decline far below their MTs, perhaps even exceed a depth of 356 feet, yet not trigger an ***undesirable result***. In fact, the groundwater elevation contour maps for spring and fall 2020, Figures 3-24 and 3-25 (see pages 8 and 9 of AquAlliance Exhibit A) show that the elevations decline beneath Orland from a high point on the northwest side of the town at approximately 240 to 220 feet in spring and fall 2020, respectively. The groundwater well 21N04W12A004 with the lowest MT elevation, -108 feet, is in southwest of Orland. See page 8 of AquAlliance Exhibit A. The requirement that all 12 RMN wells in the group exceed their MTs before an ***undesirable result*** occurs, seems to allow for the low southwest of Orland to either expand laterally, deepen significantly (decline approximately 190 ft or greater, from current elevation of approximately +80 ft down to the MT of -108 ft) before the MT at well 21N04W12A004 is exceeded when mitigation action(s) would be required. It is possible that another well in the group of 12 will be the last to exceed its MT, but the concept is still the same. The depth to groundwater can exceed the MT depths at 11 out of the 12 RMN wells in a group, and still the groundwater is considered sustainable, regardless of the maximum depth to groundwater in the group's Thiessen polygons (emphasis added).

5. The draft GSP has an economic analysis in Appendix 5C (pdf pages 144 through 155) to apparently reason why the MTs are set at the lowest level of either allowing the shallowest 20% of the domestic wells to go dry and/or 50% of the historical water level range below the lowest depth before January 2015 (or 2016). The GSP states that …*[t]he purpose of the analysis was to establish what share of domestic wells in the WCR database may have been* ***previously dewatered and/or are no longer used***. (see page 3 in Appendix 5C). Are there any facts to document that these wells are no longer in use or previously dewatered? DWR has a web site where people can volunteer that their well went dry (https://mydrywell.water.ca.gov/report/). There are 1,589 wells out of a total of 1,677 wells in the Orland area that are assumed to have gone dry according to Table 1 in Appendix 5C near monitoring well 22N03W24E001 – ***95% of the wells.*** See page 3 of AquAlliance Exhibit A for well locations. The assumption that the wells previously went dry when groundwater was at the lowest pre-2015 point, allows the GSP to reason that an MT that allow loss of up to 20% percent of the shallow domestic wells is ***cost-effective***, and ***an acceptable balance between avoiding significant and unreasonable impacts to domestic (and other shallow) wells and allowing sufficient flexibility for conjunctive management of Subbasin surface and groundwater supplies*** (page 9 in Appendix 5C). The economic analysis concludes on page 9 of Appendix 5C that: (1) MT groundwater levels shouldn't be raised because it's not cost effective. We ask, cost effective to whom?; (2) the groundwater levels will be managed to the higher MOs levels and therefore no harm will occur to domestic wells; but (3) if harm occurs, then the **potential** management action that the GSAs **should** develop a domestic well mitigation program (see Chapter 6) would provide a safety net to **potentially** compensate for impacts to domestic wells. It appears to AquAlliance that the GSP has decided that the shallow domestic wells can go dry, and the GSAs **might** find a way to help the well owners, but they aren't ready to commit to the compensation portion (emphasis added).

6. The *undesirable results* for domestic wells protection are only triggered when the groundwater levels in 25% (12 of the 48 network wells) are continuously below their MTs for 24 consecutive months, Table 5-1. Because groundwater levels naturally fluctuation with season, the 50% range has been established at each monitoring well, this standard seems to also say that the seasonal fluctuation about the MT depth, i.e., the GSP Margin of Operational Flexibility (MOF), is not considered an *undesirable result*? For example, well 22N03W24E001, the closest well to Orland (see Figure 4-2, page 3 of AquAlliance Exhibit A), has a MOF of 79 feet with an MT of 273 feet. See page 5 of AquAlliance Exhibit A.

   Answers to the following questions are crucial for the public, policy makers, and AquAlliance members:
   - If the depth to groundwater seasonally fluctuates for years about say 270 feet, from a depth of 191 to depth of 349 feet, isn't the period, presumably summer months, when groundwater drops to 349 feet an *unreasonable result*? Especially because the 20% domestic well depth is only 90 feet, 259 feet higher than this potential seasonal drop in groundwater.
   - What happens if the seasonal decline is greater than the 50% range?
   - How many of the domestic wells in the well 22N03W24E001 Thiessen polygon will go dry with groundwater at a depth of 349+ feet?

7. The draft GSP appears to plan for subsidence throughout the subbasin to be as much as 10 feet over the next 40 years with a subsidence MO set at 0.25 feet per year for each of 63 survey benchmarks. The subsidence benchmark MTs are set at 0.50 to 0.60 feet per year or as much as 20 to 24 feet over the next 40 years, depending on the current rate of subsidence, Table 5-1. See page 2 of AquAlliance Exhibit A. The subsidence MTs imply that groundwater levels are considered "sustainably" managed until subsidence exceeding 20+ feet over an area of at least 15% of the benchmarks, 9 out of 63 benchmarks. The benchmarks seem uniformly distributed across the subbasin, Figure 3-31(page 10 of AquAlliance Exhibit A), so the area subsidence will likely need to be at least 15% of the total basin area or approximately 138,000 acres (the total subbasin area is 918,380 acres – DWR B118). Section 5.4.5 says that the 9 of 63 benchmarks *must be the same subset of locations not any combination of nine locations*. This seems to say that a large area of subsidence needs to develop before any "action" to stop subsidence will be taken. As with the other network groups, the GSP doesn't identify which benchmark belong to each group of 9.

   The Management Actions in Chapter 6 that affect subsidence include In-Lieu recharge or direct surface water recharge, and reviewing the County well ordinances, see Table 6-3 (page 6-12). The In-Lieu and direct surface water recharge assume that this surface water for recharge is available to divert from the rivers. This assumption needs to be verified given all the other requirements on the river flows. There doesn't appear to be any Management Actions other than recharge to mitigate subsidence, no proposal to **possibly** create a subsidence mitigation program like the **possible** domestic well compensation program. The draft GSP also doesn't appear to be concerned about damage from subsidence to infrastructure, homes, stormwater flood control, or levees that might be impacted by 10+ feet of subsidence. As with domestic wells, the trigger required for an ***undesirable result*** is the ***all-or-none*** monitoring group exceedance of the MT for a group of least 9 benchmarks. This

ignores that fact that subsidence often occurs around a lowest point that then spreads outwards. The draft GSP doesn't give a maximum rate or depth of subsidence allowed for the subsidence group of 9 benchmarks or between the benchmarks, just an annual average. With the advent of InSAR radar to measure changes in ground elevation, Figure 3-32, the subsidence in between benchmarks can now be measured. See page 11 of AquAlliance Exhibit A. The draft GSP doesn't indicate whether the subsidence rate for determining whether an **undesirable result** has occurred will be normalized over the years since 2015, over all 40 years of the GSP plan, over every 5 years with GSP updates, or considered as a separate annual value. Clarification is needed on the maximum rate of subsidence at any point that will trigger an **undesirable results** and the duration for averaging (emphasis added).

8. The draft GSP requirement to consider monitoring sites as a group when determining whether the MTs have been exceeded may create areas where the number of sites are too small to allow for the groups to encompass all monitoring sites, and/or create scientifically logical groups. For example, try creating groups of 9 or more from the subsidence benchmarks in Figure 3-31 that encompass the two known areas of subsidence around Arbuckle and Artois, see Figure 3-32. See pages 10 and 11 of AquAlliance Exhibit A. Now, fill in the rest of the Colusa subbasin with groups of 9+ subsidence benchmarks. Do the shapes of these other subsidence groups make sense? Except for the two around the known high subsidence areas, the other groups are likely very irregular in shape and may not properly encompass the other areas of greatest groundwater pumping, or the other areas with the greatest potential for subsidence, see Figure 3-23 (see page 12 of AquAlliance Exhibit A). To have the necessary minimum numbers to form a subsidence group, more distant and unrelated benchmarks would likely have to be combined. The requirement for a minimum of 9 benchmarks in a group along with the irregular shape of the groups could result an area of subsidence having to be monitored by two or more groups. The draft GSP should give the boundaries of the subsidence and groundwater monitoring well groups to show that this group monitoring scheme to determine a trigger of **undesirable results** is practical and show that it will work (emphasis added).

9. The domestic well monitoring program assigns to each monitoring well a portion of the subarea based on a Thiessen polygon network. The draft GSP doesn't appear to have a map of the shapes of these polygons or list the area of each polygon. The Table 1 in economic analysis of Appendix 5C does lists the total number of domestic wells associated with each monitoring well and the number of domestic wells that are shallower than the depth to the lowest groundwater level before January 2015 (or 2016). There is an assumption that these domestic wells are in the associated monitoring well's polygon, but the spatial distribution of the domestic wells is unspecified. The draft GSP doesn't give a distribution of the depths of these domestic wells for each polygon, such as a histogram or frequency table by depth, so the impact of an incremental decline in groundwater in each polygon as it goes towards the MT, or lower, is unknown. The draft GSP should give the boundaries of the Thiessen polygons for the monitoring wells that are used to measure groundwater levels for either domestic wells or stream depletion, and provide a table of the number and depths, with cumulative frequency for domestic wells in each polygon.

10. The draft GPS assumes and plans to allow domestic wells to go dry even when the MOs and MTs are achieved. The draft GSP says that managing to the MOs through actions yet to be determined, will minimize the number of wells that dewater, i.e., go dry, see Chapter 6.5.2.1 (page 6-81). The depth of the screens for some of the 48 RMN groundwater monitoring wells in Table 5-2 are given in Table 4-2, Chapter 4 pages 7 through 10. Eighteen of the RMN wells are screened deeper than 700 feet below the ground surface (bgs), 15 are screened from 250 to 700 feet bgs, and 15 are screen shallower than 20 feet bgs. ***The draft GSP doesn't explain why the deep screened monitoring wells are selected to monitor shallower aquifers used by domestic wells*** even, when there is often a shallow monitoring well at the same location, see Figures 4-2 and Figure 4-8. See pages 3 and 6 of AquAlliance Exhibit A. Seven of the wells in the domestic well monitoring network are shallow and are also part of the 12-well stream depletion monitoring network, Table 5-3. See page 7 of AquAlliance Exhibit A. The remaining 5 shallow wells in the stream depletion monitoring network appear to have deeper companion wells that are part of the 48 RMN network. While the MOs for the stream depletion network in these seven shallow wells are nearly equal to the MOs for the domestic well network, the MTs are very different and much deeper, (compare values in Table 5-2 to Table 5-3). The draft GSP doesn't clearly explain the differences in any Management Actions needed to maintain the sustainability of domestic wells and interconnected surface waters that result from the different MTs at these same shallow monitoring wells. Perhaps, because the Management Actions are ***currently in the early conceptual stage (emphasis added).***

11. The draft GSP proposes to investigate the **possibility** of compensating domestic well owners for impacts from groundwater production. Whether this compensation program is ever created, a well owner that needs to replace a dry or broken well will need to know the depth for that new well, so that it won't go dry again under the GSP. That depth should be related to the MT of the polygon where the new well will be constructed. However, as discussed above in comment 4, the MT for the well's polygon may not be the maximum future "sustainable" depth of groundwater. It will likely be deeper because of the monitoring group ***all-or-none*** requirement to trigger an ***undesirable result***.

    - So, what is the recommendation in the GSP for how the well owner should determine the depth for the new well?
    - What assurances does the GPS give to the domestic well owner that the depth for the new well will be sufficient to ensure a future domestic water supply?
    - Can the well owner assume that if they follow the GSP's recommended depth procedures for a new domestic well, they will receive compensation if the depth to groundwater is ever exceeded? (emphasis added)

12. The Management Action for the Domestic Well Mitigation Program, Section 6.5.2.1, states that the GSP (GSA) will ***investigate implementing a domestic well mitigation program*** with funding to mitigate dewatered well (based on yet undefined eligibility) (emphasis added).

    - Will the GSP also include a subsidence mitigation program that financially compensates homeowners and landowners for damage from subsidence?

- Will there be funds to repair infrastructures such as roads, bridges, levees, stormwater drainage, pipelines, home and building foundations, walls and roofs, domestic, municipal, industrial, and agricultural wells?
- What are the possible sources of subsidence mitigation funding, a consumption tax, a property tax, a flat tax per well?
- Will the subsidence fund be designed to anticipate the cost of mitigation repairs over the full 40 years, that is, mitigate the planned 10 to 20+ feet of subsidence?

13. Table 4-2 lists the characteristics of the monitoring wells in the GSP network, a total of 104 completions wells (page 4-3). However, only 48 completions are used for the domestic well network and another 5 for the stream depletion network. Only those 53 domestic and stream depletion wells have sustainability criteria, MOs and MTs.

    Answers to the following questions are crucial for the public, policy makers, and AquAlliance members:
    - Why weren't MOs and MT calculated for the remaining 51 monitoring wells?
    - Why are the other 51 wells included in the "groundwater monitoring network?"
    - How will measurements in these other 51 wells be used in the groundwater monitoring program?

14. Attachment A of Appendix 5B shows on 48 hydrographs how the groundwater level thresholds are developed and includes the numbers given in Table 5-2. The hydrographs in Attachment A of Appendix 5B gives the values of the MO and MT and graphically show their implications. Of interest are those wells where the MT based on the 20% shallower wells depth is below the 50% range depth. This occurs at 30 of the 48 wells. ***This seems to say that "sustainability" includes dewatering, drying up, 20% of the domestic wells.***

15. The selection of the MO and lowest point for the MT appears to use groundwater levels after January 1, 2015 when it produces a lower elevation than measurement before the SGMA Benchmark date. For example, monitoring well 21N02W36A002 (hydrograph on pdf page 61 in Appendix 5B; see page 13 of AquAlliance Exhibit A) has significant declines in groundwater elevation during 2015, but the other years have minor seasonal variation. The MO is set as the "average" that appears to include the over pumping in 2015, which doesn't reflect the historical groundwater condition. The 50% range also appears to include the 2015 pumping decline and the lowest point appears to be in 2015, after January 1, 2015. The use of the 2015 overdraft seems to make the post-January 2015 conditions the acceptable standard, rather than require them to be corrected. But even if the proper MO and MT were selected for this well, the 20% shallower groundwater level at 81 feet is approximately 50 feet lower than the seasonal average would be if following the GSP's requirement to take the lowest MT depth. How many of the MTs in the 30 out of the 48 Representative Monitoring Network (RMN) (see page 4 of Appendix 5B) wells are calculated using a post-January 1, 2015 historical low can't be determined because the GSP doesn't clearly tabulate the elevations of the lows used for the MT calculation. In addition, the MT calculation use the entire historical range of groundwater levels rather than the most recent 5 years as is done with the MOs, see Table 5-1. The use of the entire historical record brings the pre-2015 historical decline in groundwater level into the calculation of 50% range, which doesn't represent the actual

current post-January 2015 conditions, see the hydrograph for well 20N03W07E007on pdf page 56 in Appendix 5B, as an example. See page 14 of AquAlliance Exhibit A. The use of all historical data to calculate the 50% range appears to be continuing the pre-SGMA impacts into the GSP management actions. **This seems to invert the concept that the GSP doesn't have to remedy pre-2015 impacts by making the GSP continue the pre-2015 impacts in the determination of sustainability criteria (emphasis added).**

16. MT thresholds assume that the definition of "sustainable" means that up to 20% of the domestic wells can go dry. They make arguments that this number will be less, 12% (see pages 4 and 5 in Appendix 5B). But the economic analysis on page 3 in Appendix 5C apparently removed wells with depth shallower than the pre-January 2015 low (or maybe the analysis included the 2015 low, see comment 15) because it assumes these wells went **dry with the lowest groundwater level and/or are no longer used**. The economic analysis doesn't address if these wells recovered, nor document that these wells actually went dry. Remembering that the 20% depth is taken in a deep well, not a shallow water table well. To evaluate the groundwater level in domestic wells, you need to use a wells screened at the depth of the domestic wells, for example the stream depletion monitoring wells, Table 5-3. Table 1 in Appendix 5C says the subbasin average for wells with total depths shallower than the lowest groundwater level before January 2015 is a "share" of 46%. The "share" around each monitoring well varies widely in Table 1 of Appendix 5C, from zero to as much as 97%.

17. The economic analysis in Appendix 5C also says that the portion of the wells shallower than the proposed MT is in aggregate 12% of the domestic wells, not 20% (see pages 4 and 5). This calculation is apparently saying that the number of wells with total depths greater than the pre-January 2015 low (or maybe pre-2016 low), but less than the maximum of the selected MT depth, is lower if either the 20% shallower depth or the historical low plus 50% range depth. This is 8% fewer wells than when the 20% shallower criteria was used by itself. Histograms of RMN and domestic well depths, and cumulative frequency depth statistics are needed to understand the validity and significance of this economic analysis.

    The rationale for setting the MTs acknowledges that for 30 of the 48 RMN wells there is a possibility that more than 20% or the domestic wells will be shallower and be at risk for dewatering (going dry) (page 4 in Appendix 5B). But then the GSP says that wells shallower than the historical low before January 1, 2015 were removed from the analysis, which then resulted in an "aggregate" of approximately 12 percent of the wells potentially go dry. The GSP states that this is much better than 20% going dry and is viewed as an … *acceptable balance between avoiding significant and unreasonable impacts to domestic (and other shallow) wells and allowing sufficient flexibility for conjunctive management of Subbasin surface and groundwater supplies.* A review of the statistics in Table 1 of Appendix 5C for wells associated with each of 48 RMN wells finds a large range in the percentage of wells that are shallower than the historical low before January 2015, ranging from zero to 97%. The aggregate for these dry wells in Table1 is 46%. Does this average give the GSP's estimated future reduction in domestic well reliability within each RMN well polygon? How does the 12% aggregate for 20% shallower dry wells relate to the 46% well shallower than the lowest pre-January 2015 groundwater level? What are the depths, percentiles and the

number of wells that could possibly go dry for each of the RMN well polygons where the MTs are based on the 50% range below the historical low, and/or based on the 20% shallower depth?

18. When 50% of the historical range is subtracted from the lowest pre-January 2015 groundwater level (maybe pre-2016) to calculate the MT, method selected for 30 out of 48 RMN wells, it creates a ***lower-than-the-lowest*** sustainable threshold. Domestic wells could now experience groundwater levels below the historical lowest depth, and the GSP would still find this condition sustainable, **not an undesirable result**. By this logic, the GSP seems to say that at least the number of wells listed in Table 1 of Appendix 5C will go dry whenever groundwater levels go below the lowest historical elevation and possibly more when the 50% threshold depth sets the MT. As if this isn't enough, the MT levels in 18 of the 48 wells are set at the 20% shallower wells threshold whenever that depth was greater than the lowest+50% depth (see page 4 in Appendix 5B). Does this mean that in those areas around the monitoring wells listed in Table 1of Appendix 5C that have a "share" less than 20% (0.20) and may have additional wells dry whenever the 20% shallower depth is used to set the MT? Obviously, the future cumulative average of dry wells under the GSP will be **greater than the 46% of the total wells** (emphasis added).

19. Does the Table 1 in Appendix 5C total of 2,925 wells being shallower than the historic low groundwater level before January 2015 agree with the statistics on dry or no longer used wells collected by DWR or any government agency? DWR does have a website where dry wells can be reported, which appears to list far fewer dry wells in the area around Orland. As an example, Table 1 shows that for well the RMN well 22N03W24E001 near Orland, 1,589 out of a total of 1,677 wells are shallower than the historic low before January 2015, or 97%. This monitoring well is the closest RMN well to the City of Orland. Did 97% of the domestic wells around Orland go dry at least once sometime before 2015, and/or have they been abandoned? If yes, what is the source of this data?

20. The draft GSP provides a general background discussion on the surface water and groundwater budgets in Section 3.3 (pages 3-85 to 3-97). The water budget analysis uses a 26-year Historical period from 1990 to 2015, a Current Conditions period from 2016 to 2065, and three Future Conditions periods from 2016 to 2065. The hydrology baseline used for the Current and Future conditions is the historical data from 1966 to 2015, see Table 3-9. Tables 3-11 and 3-12 provide the average annual values for the surface water and groundwater budget components for all five analysis periods, respectively (pages 3-96 and 3-97). See pages 15 and 16 of AquAlliance Exhibit A. Table 6-1 (page 6-2) provides a summary of the key water budget parameters that influenced the development of the project and management actions. See page 18 of AquAlliance Exhibit A. The water budget analysis selected as representative of conditions in the next 50 years is the projected Future Condition with the 2070 Central Tendency Climate Change provided by DWR (page 3-92).

21. The groundwater water budget in Table 3-12 shows that during the Historical 26-years from 1990 to 2015 there was an average annual deficit of 28,000 acre-feet per year (AFY). Note that units in Tables 3-11 and 3-12 are thousands of acre-feet per year (taf/yr). With the 2070 Future scenario the deficit is reduced, but there is still a loss of storage of 7,000 AFY.

Unfortunately, there appears to be a calculation error in the 2070 Future Conditions outflow, the right-hand column of Table 3-12.

The sum of the Groundwater Pumping components in Table 3-12 is given as 559,000 AFY. See page 17 AquAlliance Exhibit A. The three groundwater components, Agricultural, Urban and Industrial and Managed Wetlands, have future 2070 values of 548,000, 10,000 and 35,000 AFY, respectively. The sum of these three groundwater components equals 593,000 AFY, not the 559,000 AFY shown. If the 593,000 AFY values is used in calculating the outflows, then the ***total groundwater outflow is now 1,063,000 AFY***. This results in a Change in Storage (Inflow – Outflow) value of -42,000 AFY, not the -7,000 AFY shown. This is a 50% increase in the change in storage from the Historical condition, and essentially a 100% increase from the 1966-2015 Current condition.

The values of the three groundwater components listed as inflow components in the surface water budget, Table 3-11, Agricultural, Urban and Industrial and Managed Wetlands, have future 2070 values or 516,000, 10,000 and 32,000 AFY, respectively (see page 15 AquAlliance Exhibit A). The sum of these values is 558,000 AFY, almost equal to the 559,000 AFY sum listed in both Table 3-11 and 3-12. This error in the Groundwater Pumping components needs to be corrected.

22. Table 6-1 provides the differences in the average annual projections for six key water budgets parameters. These parameters appear to be from Table 3-11 and some of the values are the same in both tables, while others have to be calculated from separate component values listed in Table 3-11. See page 18 of AquAlliance Exhibit A. Note that units in Tables 3-11, 3-12 and 6-1 are thousands of acre-feet per year (taf/yr).

    Table 6-1 shows that with the 2070 climate change scenario groundwater pumping will increase 58,000 AFY, or 12.7%. during the next 50 years. Precipitation and Evapotranspiration (ET) is also expected to increase 75,000 AFY and 102,000 AFY, or 6.3% and 6.8%, respectively. The change in annual average groundwater storage with the 2070 climate change is a negative 7,900 AFY. This value differs from the -7,000 AFY value shown in Table 3-11, but this may be the result of round-off error in the Table 3-11 values. Note that the error in the total Groundwater Pumping in Table 3-12 could significantly change the rate of groundwater storage in Table 6-1, so it needs to be corrected.

    Table 6-1 shows that there will be no change in the average annual total of the Sacramento River and Stoney Creek Diversions to the Colusa Subbasin in the future with the 2070 climate change scenario. Table 3-11 shows that there will likely be a small increase in diversions from the Sacramento River, 4,000 AFY, that's balanced by a 4,000 AFY decrease in Stony Creek diversions. Table 3-11 also shows that the sum of these two diversions will increase approximately 119,000 AFY, or 10.2%, when compared to the 1990-2015 Historical baseline diversion of 116,800 AFY. See page 15 of AquAlliance Exhibit A.

    Table 6-1 shows that there will be an annual average decrease of 48,000 AFY, or 38.3%, in the *Net Stream Accretion* in the future with the 2070 climate change scenario. The *Net Stream Accretion* is the sum of the *Stream Gains from Groundwater (Accretion)* inflow

minus the *Stream Seepage* outflow in Table 3-11. See page 15 of AquAlliance Exhibit A. The sums listed in Table 6-1 for future without climate change, 125,000 AFY and for 2070 with climate change, 77,000 AFY, don't appear to agree with the sums that would be obtained using values listed in Table 3-11, but the difference is the same -48,000 AFY. Note that if a comparison is made between the 1990-2015 *Historical Net Stream Accretion*, 160,000 AFY from Table 3-11 values (366,000 AFY – 206,000 AFY = 160,000 AFY), and the future 2070 climate change of 70,000 AFY from Table 3-11 values (323,000 AFY – 253,000 AFY = 70,000 AFY), the future change in *Net Stream Accretion* is -90,000 AFY, or a 56.3% decline (70,000 AFY - 160,000 AFY = -90,000 AFY; -90,000 AFY / 160,000 AFY = 0.563). See page 19 of AquAlliance Exhibit A.

23. The increase in *Groundwater Pumping* and the decrease in *Net Stream Accretion* in the future with the 2070 climate change scenario suggest that the assumptions being made regarding loss of surface water flows during a groundwater substitution transfer are flawed. The change from any of the baseline water budgets in the *Net Steam Gains from Groundwater (Accretion)* (see page 20 of AquAlliance Exhibit A) that occurs with the increase in groundwater production during the next 50-year with the 2070 climate change scenario is much greater than the DWR/BOR assumed *stream depletion factor* of 13 percent[2]

    The groundwater budget in draft GSP Table 3-12 shows that with the future increase in groundwater pumping under the 2070 climate change scenario, there is an increase in seepage from surface waters to the groundwater ranging from 22,000 AFY to 47,000 AFY with the Historical and Current baseline, respectively. See page 20 of AquAlliance Exhibit A. In other words, more surface water will infiltrate into the groundwater basin to the detriment of the streams.

    The groundwater budget in draft GSP Table 3-12 also shows that with the future increase in groundwater pumping the discharge of groundwater to streams, the *Stream Gains from Groundwater (Accretion)* during the next 50 years will decrease from 366,000 AFY and 349,000 AFY, with the Historical and Current baselines, down to 323,000 AFY under the 2070 climate change scenario. A reduction in Stream Accretion of 48,000 AFY (-11,7%) and 26,000 AFY (-7.4%) from the Historical and Current baseline, respectively (see page 20 of AquAlliance Exhibit A).

    The combined loss of stream flow, or net change, over the next 50 years with climate change from the increased seepage and reduced accretion ranges from 48,000 AFY to as much as 90,000 AFY, from the Table 3-12 Current or Historical baselines, respectively. See page 20 of AquAlliance Exhibit A. This loss of stream flow occurs while groundwater pumping is increasing from 94,000 AFY to 91,000 AFY, Current or Historical baselines, respectively. This is a ratio of the change in *Net Stream Accretion* to the change in *Groundwater Pumping* that ranges from approximately negative 51% to as much as a negative 99%, Current or Historical baselines, respectively (see page 20 of AquAlliance Exhibit A.

[2] https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/State-Water-Project/Management/Water-Transfers/Files/Draft_WTWhitePaper_20191203.pdf

The change in the ratio of *Net Stream Accretion* to *Groundwater Pumping* during the 1990-2015 Historical and Current baseline conditions are positive ranging from positive 31.9% to 23.6%, respectively. In other words, under the existing conditions streams gain more water from the groundwater system than they give. With the 2070 climate change scenario, streams will continue to gain more from the groundwater system, but the gain will be less (see page 20 of AquAlliance Exhibit A).

The decrease in *Net Stream Accretion* with future *Groundwater Pumping* suggests that the overall percentage of groundwater being pumped that will be recharged from the streams in the Colusa Subbasin, i.e., stream depletion, with any future pumping increase is significantly greater than the DWR/BOR assumed 13% stream flow loss from a groundwater substitution transfer. ***In fact, with the Historical baseline, the loss is essentially equal to the volume of groundwater being pumped, which is consistent with stream depletion literature.[3] The decline in Net Stream Accretion with future increased Groundwater Pumping that changes the streams for gaining to losing suggesting that the subbasin maybe at a tipping point where the impacts from future pumping increases are amplified and cause significantly more harm than just the existing condition.***

24. The draft GSP's Figure 3-29 (page 3-66) graphs the cumulative change in groundwater storage from 1990 to 2015 for the Historical condition where the average annual change in groundwater storage was a negative 28,000 AFY. See page 21 of AquAlliance Exhibit A. The figure shows that in 2015 the cumulative change in groundwater storage since 1990 is approximately a negative 600,000 AF.

    The draft GSP gives in Figure 3-49 (page 3-111) graphs of the cumulative change in groundwater storage from 1966 to 2015 for the Current condition and the three future 50-year scenarios. See page 22 of AquAlliance Exhibit A. The figure shows that in 2065 under the 2070 climate change scenario the cumulative change in groundwater storage from the present will be approximately a negative 400,000 AF, which is consistent with the annual average decline of -7,300 AFY given in Table 6-1 (-7,300 AFY x 50 years = -365,000 AF) (see page 18 of AquAlliance Exhibit A).

    If the anticipated future loss in groundwater storage under the 2070 climate change scenario is added to existing loss in groundwater storage, ***the cumulative loss is groundwater storage for the Colusa Subbasin in 2065 is approximately 1,000,000 AF*** (-365,00 AF + -600,000 AF = -965,000 AF).

    The use of the past 50-year Current scenario as the input for the hypothetical future scenarios is reasonable. Repeat the past with the climate changes applied to see what happens. However, the starting point for going forward in an evaluation of the subbasin's groundwater

---

[3] Barlow, P.M., and Leake, S.A., 2012, Streamflow depletion by wells—Understanding and managing the effects of groundwater pumping on streamflow: U.S. Geological Survey Circular 1376, 84 p.
(Also available at *http://pubs.usgs.gov/circ/1376/*.)

sustainability should be at today's conditions, not the average of the past 50 years. The volume of storage at the SGMA benchmark date of January 1, 2015 was near -500,000 AF, which is lower than in than any time prior to the start of SGMA. The additional decline in groundwater storage from the 2070 climate change scenario should be started at the -500,000 AF value of the SGMA Benchmark date, not the zero of 1966. The authors of the draft GSP may know this, and that's maybe why many of the groundwater monitoring well MTs are set at 50% of the historical range below the historical low. The GSP authors want to allow for an additional 400,000 AF of loss in groundwater storage predicted by the 2070 climate change scenario, for a total of 900,000 since the 1990, without triggering an *undesirable result*. The draft GSP doesn't actually say that it's planning to have this amount of groundwater storage loss, but the water balance calculations suggest that it is likely.

25. While this GSP is being developed for the Colusa Subbasin, a GSP is being developed for the Butte Subbasin to the east. A draft GSP for Butte Subbasin was released for public review. The Butte draft GSP also provides MOs and MT for monitoring wells across the subbasin. The monitoring well network for the Butte Subbasin is divided into a Primary Aquifer, wells less than 700 feet depth, and a Very Deep Aquifer, wells greater than 700 feet depth. There are 41 Primary Aquifer monitoring wells in the Butte Subbasin GSP. See pages 23 and 24 of AquAlliance Exhibit A. The MOs and MT for the Colusa Subbasin are given in Table 5-2, pages 4 and 5 of AquAlliance Exhibit A.

    The existing groundwater contours in the two subbasins suggest that the current flow of groundwater in the aquifers shallower than 700 feet flow towards the center of the valley with the flow generally north to south aligned with the Sacramento River (see pages 8, 9, 25, and 26 of AquAlliance Exhibit A). There are several sets of monitoring wells that are approximately opposite each other along the north-south boundary between the subbasins. See page 3 and 24 of AquAlliance Exhibit A. If the MT elevations for these west-to-east sets of wells are compared, knowledge might be gained on how the management of the groundwater in these basins will affect each other. A table is provided on page 27 of AquAlliance Exhibit A that lists the state well numbers and the MT elevations for monitoring wells in the Colusa GSP along with their nearest eastern counterpart monitoring well(s) in the Butte GSP with the MT elevations. Note that sometimes multiple wells are listed for a single well. This is done whenever there is more than one well that aligns along a general west-to-east orientation.

    The right-hand column of the table gives the difference between the Butte GSP well(s) and the Colusa GSP well(s). A positive value indicates that the MT elevation in the Butte Subbasin is higher than the corresponding MT value in the Colusa Subbasin. In all but one of the 10 sets of west-to-east monitoring wells matches, the MT elevations in the Butte Subbasin are higher.

    This suggests that the groundwater elevations in the Colusa Subbasin will be allowed to be deeper under the Colusa Subbasin GSP than in the Butte Subbasin before an undesirable result is declared. This may create a condition where the Butte Subbasin is providing more interbasin groundwater flow to the west in the future. The implications from setting the MT values in the Colusa Subbasin at elevation lower than the MTs in the Butte Subbasin should

be analyzed and management action(s) should be included in the GSPs for each other subbasin to maintain sustainable interbasin groundwater flow.

26. The Draft GSP states that the primary groundwater quality constituent of concern within the Colusa Subbasin is salinity, specifically the upwelling of brackish connate water into the principal aquifer (page 4-15). The water quality sustainable thresholds listed in Table 5-1 only sets MO and MT values for salinity using electrical conductivity (EC). The MO is 700 µS/cm, and the MT is set at the higher of 900 µS/cm or the measured historical high, whichever is greater (Table 5-1 on page 5-18; page 4 in Appendix 5A). In the basin setting discussion, the plan significantly expands on the water quality issues in the Colusa Subbasin noting in Section 3.1.10.3 on pages 3-42 and 3-43 that:

- *Historical groundwater quality concerns within the Subbasin include locally elevated levels of salinity, TDS, adjusted sodium absorption ratio, boron, nitrate, and manganese (DWR, 2006a; Wood Rodgers, 2008) (page 3-42).*
- *Recent groundwater quality concerns within the Colusa Subbasin include salinity, boron, nitrate, heavy metals, including arsenic, and hexavalent chromium. High concentrations of sodium, chloride, and sulfate, all of which are related to salinity have been observed south of Maxwell (CH2MHILL, 2016a; RD 108, 2008) and could negatively impact agricultural applications.*
- *Elevated salinity levels throughout much of Colusa County, nitrates near Orland and Willows, arsenic near Grimes, and iron and manganese near Williams and Colusa are of concern with respect to drinking water MCLs (CH2MHILL, 2016a).*
- *Arsenic, especially, has been a constituent of concern for Grimes, Colusa, and the surrounding area. Local agencies have been working to mitigate arsenic contamination in groundwater in this area.*
- *Drinking water supply wells near Willows, Glenn County, have experienced high concentrations of hexavalent chromium (California Water Service, 2016).*
- *There are also several active groundwater contamination cleanup sites in the Subbasin. These primarily include leaky storage tanks and unauthorized releases of contaminants such as petroleum hydrocarbons, nitrate, pesticides and herbicides including dicamba, and solvents. Most of these cleanup sites impact the unconfined portion of the principal aquifer, but there is a risk that the contamination could migrate into the deeper, more heavily pumped portions of the aquifer.*
- *The largest contamination site is the Orland Dry Cleaner site, a tetrachloroethylene (PCE) plume that extends approximately two miles southeast of the source location in Orland, Glenn County (Department of Toxic Substances Control [DTSC], 2020; SWRCB, 2020b). In 2007, PCE contamination was recorded at depths of 127 feet bgs (DTSC, 2020).*

More details regarding existing and historical groundwater quality issues and trends is provided in Section 3.2. The Draft GSP acknowledges that the *[g]roundwater quality data collected under existing regulatory programs may not be sufficient for SGMA compliance* (page 4-20). The plan indicates that:

- *The GSAs will continue to coordinate and collaborate with other agencies regarding their monitoring programs, including changes to monitoring sites, monitoring protocols or frequencies, and management actions. Data acquisition is not anticipated to be an issue. If necessary, the GSAs **will consider** implementing their own monitoring programs to address concerns over undesirable results, data gaps in the monitoring networks, or GSP project needs* (page 4-15) (emphasis added).
- *The Colusa and Glenn GSAs **will consider** coordinating with the SVWQC, Northern California Water Association (NCWA), and the California Rice Commission in the establishment and ongoing evaluation of these groundwater quality monitoring network sites with the goal of using data collected under the ILRP for SGMA compliance* (page 4-20) (emphasis added).
- *Annual reports and future revisions to the GSP will provide updates on actions taken to address data gaps over the reporting period* (page 4-20).

Although the Draft GSP acknowledges that there are other agencies with water quality monitoring programs with water quality standards, the plan doesn't set or identify any standards for the water quality constituents that are known to impact the subbasin. Water quality standard already exist for the Colusa Subbasin in the Central Valley Regional Water Quality Control Board's (CVRWQCB) Water Quality Control Plan (Basin Plan) for the Sacramento River Basin and the San Joaquin River Basin.[4] The GSP should specifically state that the water quality MOs and MTs for the Colusa Subbasin will follow the requirements of the CVVRWQCB's Sacramento River Basin Plan. In addition, the GSP should maintain the subbasin's water quality so that it meets all required health protective drinking water standards at levels below the Maximum Contaminant Levels (MCLs) for public water systems, and below the public health goals (PHGs).[5,6] The GSP should specify Management Actions that will maintain and/or improve the subbasin water quality with an emphasis on the known problems.

27. Section 7.6 Financing

Is voter approval necessary for any fees or taxes levied to raise funding for any of the Mitigation Actions? Who are the actual voters? Are they all landowners in the Colusa subbasin, only landowners in a GSA, or all citizens of the Colusa subbasin? The GSP actions may need to fund mitigations to municipal or small water systems, so how are these systems represented in the funding decisions? Will the de minimus extractors, a person who extracts, for domestic purposes, two acre-feet or less of groundwater per year, be allowed a vote? How many votes does each eligible voter get? Will the number of votes be based on the acres owned, number of wells owned, volume of groundwater pumped, or some combination of factors? What happens if the economic burden to fund the management actions falls disproportionately on one group, to whom can they appeal? Will mitigation funds go to the de minimus extractor because their wells can go dry like anyone else's, but they are

[4] https://www.waterboards.ca.gov/centralvalley/water_issues/basin_plans/sacsjr_201805.pdf
[5] https://www.waterboards.ca.gov/drinking_water/certlic/drinkingwater/MCLsandPHGs.html
[6] https://www.waterboards.ca.gov/laws_regulations/docs/drinking_water_code_2021.pdf

otherwise exempt from SGMA? Are there any statutes that govern how government agencies determine the per capita or per centum rate of a tax or fee?

28. The following are additional questions about the management actions and procedures in the draft GSP:

- Do the stream depletion MOs and MTs take precedence over the domestic well MOs and MTs when the monitoring well are adjacent? How should the domestic well owner utilize the stream depletion thresholds?

- What is the lateral extent that the stream depletion MO and MT applies? Up to 5 miles from the well? Only in the area where the 5 miles zone intersects a stream? Only in the area between the monitoring well and the stream?
- Is there a map of the 48 Representative Monitoring Network (RMN) Thiessen polygon boundaries? What is the area of each polygon? How many domestic wells are in each polygon?

- Do the MO and MT apply to all domestic wells within that well's polygon? How does the requirement to evaluate *undesirable results* using 12 RMN wells affect the MO and MT at a specific domestic well? Should a domestic well owner be prepared to have a dry well if depth of their well is shallower than the MT in their polygon, or if the depth is shallower than the deepest MT in the group of 12 RMN wells?

- If a domestic well is being installed or replaced, can the well owner rely on the MO and MT depths in their polygon to determine a minimum depth of their new well? Does the GSP offer any advice on the sustainability criteria for the minimum depth of a new well or replacement well? Should the new well be at least the depth of the old well's polygon MT, or the 12-well group MT, to ensure that the well doesn't go dry in the future?

- What advised does the GSP give on how a domestic well owner should interpret the MO and MT values when their well is near the polygon boundary? For example, the MO for well 22N02W30H002 is 104 feet bgs, and the MT at 175 feet, while the MO of the adjacent well 22N03W24E001 is 194 feet bgs and the MT is 273 feet bgs. If a domestic well is installed or replaced in the 22N02W30H002 polygon that's close to the boundary with the 22N03W24E001 polygon, should the depth of the new well be at the deeper MT of the 22N03W24E001 polygon or the shallower 22N02W30H002 polygon?

- Will monitoring the RMN wells only 2 to 3 times each year effectively capture the fluctuations in groundwater level? In particular, the periods of maximum decline which have significant influence over domestic wells and stream depletion?

- What is the distribution of the depths of domestic wells associated with each RMN monitoring well? How many of the 20% shallower wells will go dry with each increment of groundwater level decline? Histograms of wells depth and cumulative frequency of depth statistics are needed to understand the validity and significance of the 20% shallower threshold.

- Will the construction of deeper domestic wells in the future influence the MO and MT values? If so, how will the MO and MT change, when will the change occur and what measures should a domestic well owner take when and if this change occurs?

- Will the use of 50% range values in deep aquifers to set the domestic well MTs cause more the wells to go dry and/or for longer periods than if the range in shallower aquifers were used? In other words, will the use of MT developed on deeper data delay actions needed to maintain the sustainability of the domestic wells because they allow greater declines in groundwater level before an *undesirable result* is acknowledged?

- Where in SGMA is the standard that 20% dry wells can be determined to be acceptable and non-significant, and therefore not an *undesirable result?* Where in SGMA does it give the standards for the economic analysis to determine the *cost-effectiveness* and the *acceptable balance between avoiding significant and unreasonable impacts to domestic and other shallow wells* in determining the MTs? AquAlliance believes that the domestic landowner, or agricultural landowner, that losses a well due to declining groundwater levels might see any loss of a well as *significant and unreasonable*, and disagree with the GSP's criteria for which wells can be sacrificed for the "greater good." This is analogous to a developer directing the stormwater runoff onto adjacent lands without regard to the flooding it might cause, because it's for the economic good of a community to have more homes. This is not allowed in most of California. Is the GSP's sacrifice of a 20% shallower well considered a **taking**? Does there need to be compensation? What is the value of the compensation, replacement costs of a deeper well, the original cost of the well, the value of the water at the time it goes dry or the change in water quality makes the water unusable, or all of the above?

- The Management Action for the Domestic Well Mitigation Program, Section 6.5.2.1, state that the GSP (GSA) will *investigate implementing a domestic well mitigation program* with funding to mitigate dewatered well (based on yet undefined eligibility). This Management Action along with the others is … ***in the early conceptual stage***. SGMA exempts the GSP from CEQA (WC 10728.6, see below), but requires implementation projects to undergo CEQA review. All eight of the Management Actions given in GSP Chapter 6.5.2 are ***in early conceptual stage***. If the GSP is adopted with this language and no specifics are provided about what actions will be taken, does that mean that any future projects or actions to implement the GPS Management Actions are still CEQA exempt?

  WC 10728.6 - Division 13 (commencing with Section 21000) of the Public Resources Code does not apply to the preparation and adoption of plans pursuant to this chapter. Nothing in this part shall be interpreted as exempting from Division 13 (commencing with Section 21000) of the Public Resources Code a project that would implement actions taken pursuant to a plan adopted pursuant to this chapter.

B. Conflict Resolution

State and federal agencies have long viewed the Northern Sacramento Valley as a source of "surplus" water that will one day serve the accelerating water market through conjunctive-use and water banking (more in Section C). Sadly, the Colusa GSP reflects the willingness of the participants[7] to create a destruction model, emulating the demise of the Owens and San Joaquin valleys. As discussed in Section A, the Plan as proposed will degrade the groundwater basin and harm groundwater users who are not involved in conjunctive use, water transfers, or water banking but are reliant on the same groundwater basin.

It is easy to see that newly formed GSAs have layers of potential conflict. Questions regarding authority, streamlined legal and regulatory timelines, a lack of existing precedents, and the need to represent agency and constituent interests have the potential to exacerbate regional conflicts under SGMA. In some cases, where authoritative interpretations of legal authority and truly sustainable limits have not been established yet, litigation may be necessary and warranted.

The public and SGMA governing bodies and committees have been excluded from NorthState inter-basin discussions. Moreover, when participants in the Vina Stakeholder Advisory Committee asked staff if discrepancies in inter-basin flow volumes/direction that are estimated in the various GSA Basin Settings had been deliberated within the Inter-Basin Coordinating Committee, they answered that they are too busy, but would examine the issue after the GSPs are submitted in 2022.

The drama surrounding the nascent Tuscan Water District and highly questionable Minimum Objectives and Minimum Thresholds in this and other plans are examples of "issues" that have already emerged. Achieving sustainability requires local agencies, stakeholders, and water users to make many difficult and potentially contentious decisions. These decisions are prone to conflict, particularly when pumping restrictions are viewed as infringing on property rights or when fees are charged to support local management.

The Colusa GSP is not complete without a detailed process and funding to resolve conflicts that arise both within and external to the GSA boundaries.

C. Water Transfers and Conjunctive Use

The Colusa GSP must not assume that local ordinances will in any way protect the population and environment of Glenn and Colusa counties from any transfers and expanded conjunctive use. Historic facts and current proposals by DWR funded think tanks belie this:

- Water transfers are not protective of the public or the environment. Transfers implement the dreams of the California's Department of Water Resources, the U.S. Bureau of Reclamation, and State Water Project and Central Valley Project water sellers who have

[7] County of Colusa, City of Colusa, City of Williams, Glenn-Colusa Irrigation District, Maxwell Irrigation District, Westside Water District, Princeton-Codora-Glenn Irrigation District, Provident Irrigation District, Colusa County Water District, Reclamation District 108, Reclamation District 479, Colusa Drain Mutual Water Company, Two representatives of private groundwater pumpers. City of Orland, City of Willows, County of Glenn, Glenn-Colusa Irrigation District, Glide Water District, Kanawha Water District, Monroeville Water District, Orland-Artois Water District, Princeton-Codora-Glenn Irrigation District, Provident Irrigation District.

demonstrated over decades that their interests are not the same as the public's interest. Once the state recognized that they were considerably short on water after former Governor and President Ronald Reagan protected North Coast rivers with Wild and Scenic status, it began trolling for other water sources.

- Some of the Butte GSA entities in Butte County sold surface water from Oroville Reservoir to the 1994 Drought Water Bank.[8] This led to an increase in groundwater withdrawals used for irrigating rice, called groundwater substitution transfers. Until the time of the water transfers, groundwater levels had sustained the normal demands of domestic and agricultural users in the region. The 1994 extractions, however, caused the water levels to suddenly fall in shallow domestic wells, water quality to deteriorate in the wells serving the town of Durham, irrigation wells to fail on several orchards, and one farm to enter bankruptcy because it didn't recover from the loss of its crop. Harmed farmers and residents were told to, "Go hire an attorney."
- State and federal water agencies kept exploring how to manipulate groundwater systems during the 1990s to set up conjunctive use programs. CalFed was one such effort. **"**Potential projects at Stony Creek, Butte Basin, and the Cache-Putah Basin (Conaway Ranch) were eliminated because these aquifers are generally full. *Using these aquifers conjunctively would require initial extraction followed by active or passive recharge*. These may prove to be attractive projects in the future if potential third-party impacts are addressed adequately."[9] **(emphasis added)**
- Additional CalFed material recognized that conjunctive use will require an extra 100 feet of aquifer drawdown and "may be an issue." [10]
- Glenn Colusa ID received close to $3,000,000 of public money to study the Stony Creek Fan Conjunctive Water Management Program and Regional Integration of the Lower Tuscan Groundwater formation project.
- Glenn Colusa ID, Western Canal WD, and Richvale ID actively planned to implement conjunctive use schemes: "Ultimately the project evaluated the effects of exercising both the northern Sacramento Valley's deep aquifer system, which is presently relatively undeveloped, and the shallower, regional aquifer, which is more heavily pumped for both domestic and agricultural needs."[11]

- Think tanks are already encouraging the California Legislature to override local ordinances. "Once GSAs establish sustainability plans that address undesirable impacts of

[8] Thomas, Gregory, 2001. Designing Successful Groundwater Banking Programs in the Central Valley: Lessons From Experience. "The Butte County/Basin districts that increased groundwater pumping during the 1991 State Drought Water Bank included: Western Canal Water District, the Joint Water Districts Board (Richvale Irrigation District, Biggs-West Gridley Water District, Butte Water District, and Sutter Extension Water District) Ramirez Water District, Cordua Irrigation District, Hallwood Irrigation Company, and Browns Valley Irrigation District." p. 30.
"Participants in the 1994 State Drought Water Bank were Richvale Irrigation District, Western Canal Water District, Browns Valley Irrigation District, Cordua Irrigation District, and Ramirez Water District." p. 30.
[9] CalFed Bay Delta Program, 1999. *Conjunctive Use Assessment*. p. 6.
[10] CalFed Bay Delta Program. Groundwater Storage Attribute Matrices, Appendix B. p. B-5.
[11] Glenn Colusa ID, et al, 2012. *Feasibility Investigation of Re-Operation of Shasta and Oroville Reservoirs in Conjunction with Sacramento Valley Groundwater Systems to Augment Water Supply and Environmental Flows in the Sacramento and Feather Rivers*. p. ii.

> pumping, it should be possible to ease the coarser restrictions on this practice found in most county ordinances—which effectively preclude trades if they entail water leaving the county. If counties with restrictive groundwater export ordinances fail to amend their laws to conform to SGMA*, the legislature should consider preempting local laws that discriminate against out-of-county uses or place undue burdens on groundwater and groundwater-substitution transfers* that would not jeopardize sustainable groundwater management of the source aquifer."[12] (emphasis added)

Sustainability is not found in the Colusa GSP, let alone *equitable* sustainability for all residents, farms, businesses, and the environment. The Colusa and Butte GSAs are dominated by large, non-residential landowners, many of whom have sought to play in the lucrative water market already to the detriment of their neighbors, streams, rivers, and species. Sadly, SGMA opened this door further: "Non-residential landowners and future banking partners may find it in their common interest to interpret the legislative intent (74)[13] and lax definitions of safe yield and overdraft provided in the Act (75)[14] based on the opinion in *Los Angeles v. San Fernando*, which encourages drawing down basins to create additional storage space and prevent water "wasting."(76)[15] Thus, in addition to exports, it is foreseeable that a future GSA will encourage drawdown of the aquifer to satisfy massive crop thirst as the drought continues, which will then create extra storage space for imported waters to "recharge" the Basin. As a result of future water exchanges and banking, local residents will bear the additional cost of digging deeper wells just to maintain their straws in the aquifer, and will increasingly compete with each other over a diminishing percolated supply while banked supplies increase."

B. Conclusion

By its own admission, the Colusa GSP is bent on pursuing long-held plans to expand conjunctive use through groundwater manipulation, artificial recharge, and potential dam reoperation that will harm the people and environment of the GSA and surrounding region. The draft Plan will not lead to sustainability as required by SGMA, but will allow major groundwater fluctuations,

---

[13] Keats, Adam et al., 2016. *Not All Water Stored Underground is Groundwater: Aquifer Privatization and California's 2014 Groundwater Sustainable Management Act*. Footnote: *2014 Act, § 10720.1(g) (It is the intent of the Legislature "[t]o increase groundwater storage and remove impediments to recharge.").* p. 106.

[14] *Id. Footnote: 2014 ACT, § 10721(v) ("Sustainable yield" is defined as "the maximum quantity of water, calculated over a base period representative of long-term conditions in the basin and including any temporary surplus, that can be withdrawn annually from a groundwater supply without causing an undesirable result."); 2014 ACT, § 10735(a) ("Condition of long-term overdraft" means the condition of a groundwater basin where the average annual amount of water extracted for a long-term period, generally 10 years or more, exceeds the long term average annual supply of water to the basin, plus any temporary surplus. Overdraft during a period of drought is not sufficient to establish a condition of long-term overdraft if extractions and recharge are managed as necessary to ensure that reductions in groundwater levels or storage during a period of drought are offset by increases in groundwater levels or storage during other periods.").*

[15] *Id. Los Angeles v. San Fernando 14 Cal. 3d 199, 280 (1975) ("We agree with plaintiff that if a ground basin's lack of storage space will cause a limitation of extractions to safe yield to result in a probable waste of water, the amount of water which if withdrawn would create the storage space necessary to avoid the waste and not adversely affect the basin's safe yield is a temporary surplus available for appropriation to beneficial use. Accordingly, overdraft occurs only if extractions from the basin exceed its safe yield plus any such temporary surplus.").*

significant well losses, and cost burdens on harmed groundwater dependent farms, homes, and businesses. This was predicted in 2016: "This potential conflict will become acute in the likely scenario where artificial recharge inhibits natural recharge so that it is difficult, if not impossible, to determine the relative quantity of each. Given explicit provisions in the Act and statewide policy favoring storing surface water underground it is not difficult to envision a privately-controlled GSA systematically drawing down percolated groundwater to create storage space in the basin, and then replenishing the basin with imported water, with little consideration of the ability for overlying users to access the basin or the long-term health of the surrounding ecosystem." [16]

Due to the inequity of the Plan for all groundwater dependent residents, farms, and the environment, the deficient presentation of the consequences in the text (see Section A above), and the unacceptable impacts to both ground and surface waters, it should be rejected by the Colusa Subbasin governing body.

Respectfully submitted,

Table 6-1. Summary of Key Colusa Subbasin Water Budget Parameters Influencing Formulation of Projects and Management Actions (average annual volumes, taf/yr)

Water Budget Parameter	Projected Future Conditions without Climate Change	Projected Future Conditions with 2070 Central Tendency Climate Change	Difference (Projected future with 2070 Central Tendency climate change minus without climate change)	Percent Difference[(a)]
Avg. Agricultural Evapotranspiration	1,494	1,596	102.0	6.8%
Precipitation	1,183	1,258	75.0	6.3%
Agricultural Pumping	458	516	58.0	12.7%
Avg. Rate of Change in Groundwater Storage, af/yr	0.6	-7.3	-7.9	-0.8%
Sacramento River and Stony Creek Diversions to Colusa Subbasin	1,287.0	1,287.0	0.0	0.0%
Net Steam Accretion	125	77	-48.0	-38.3%

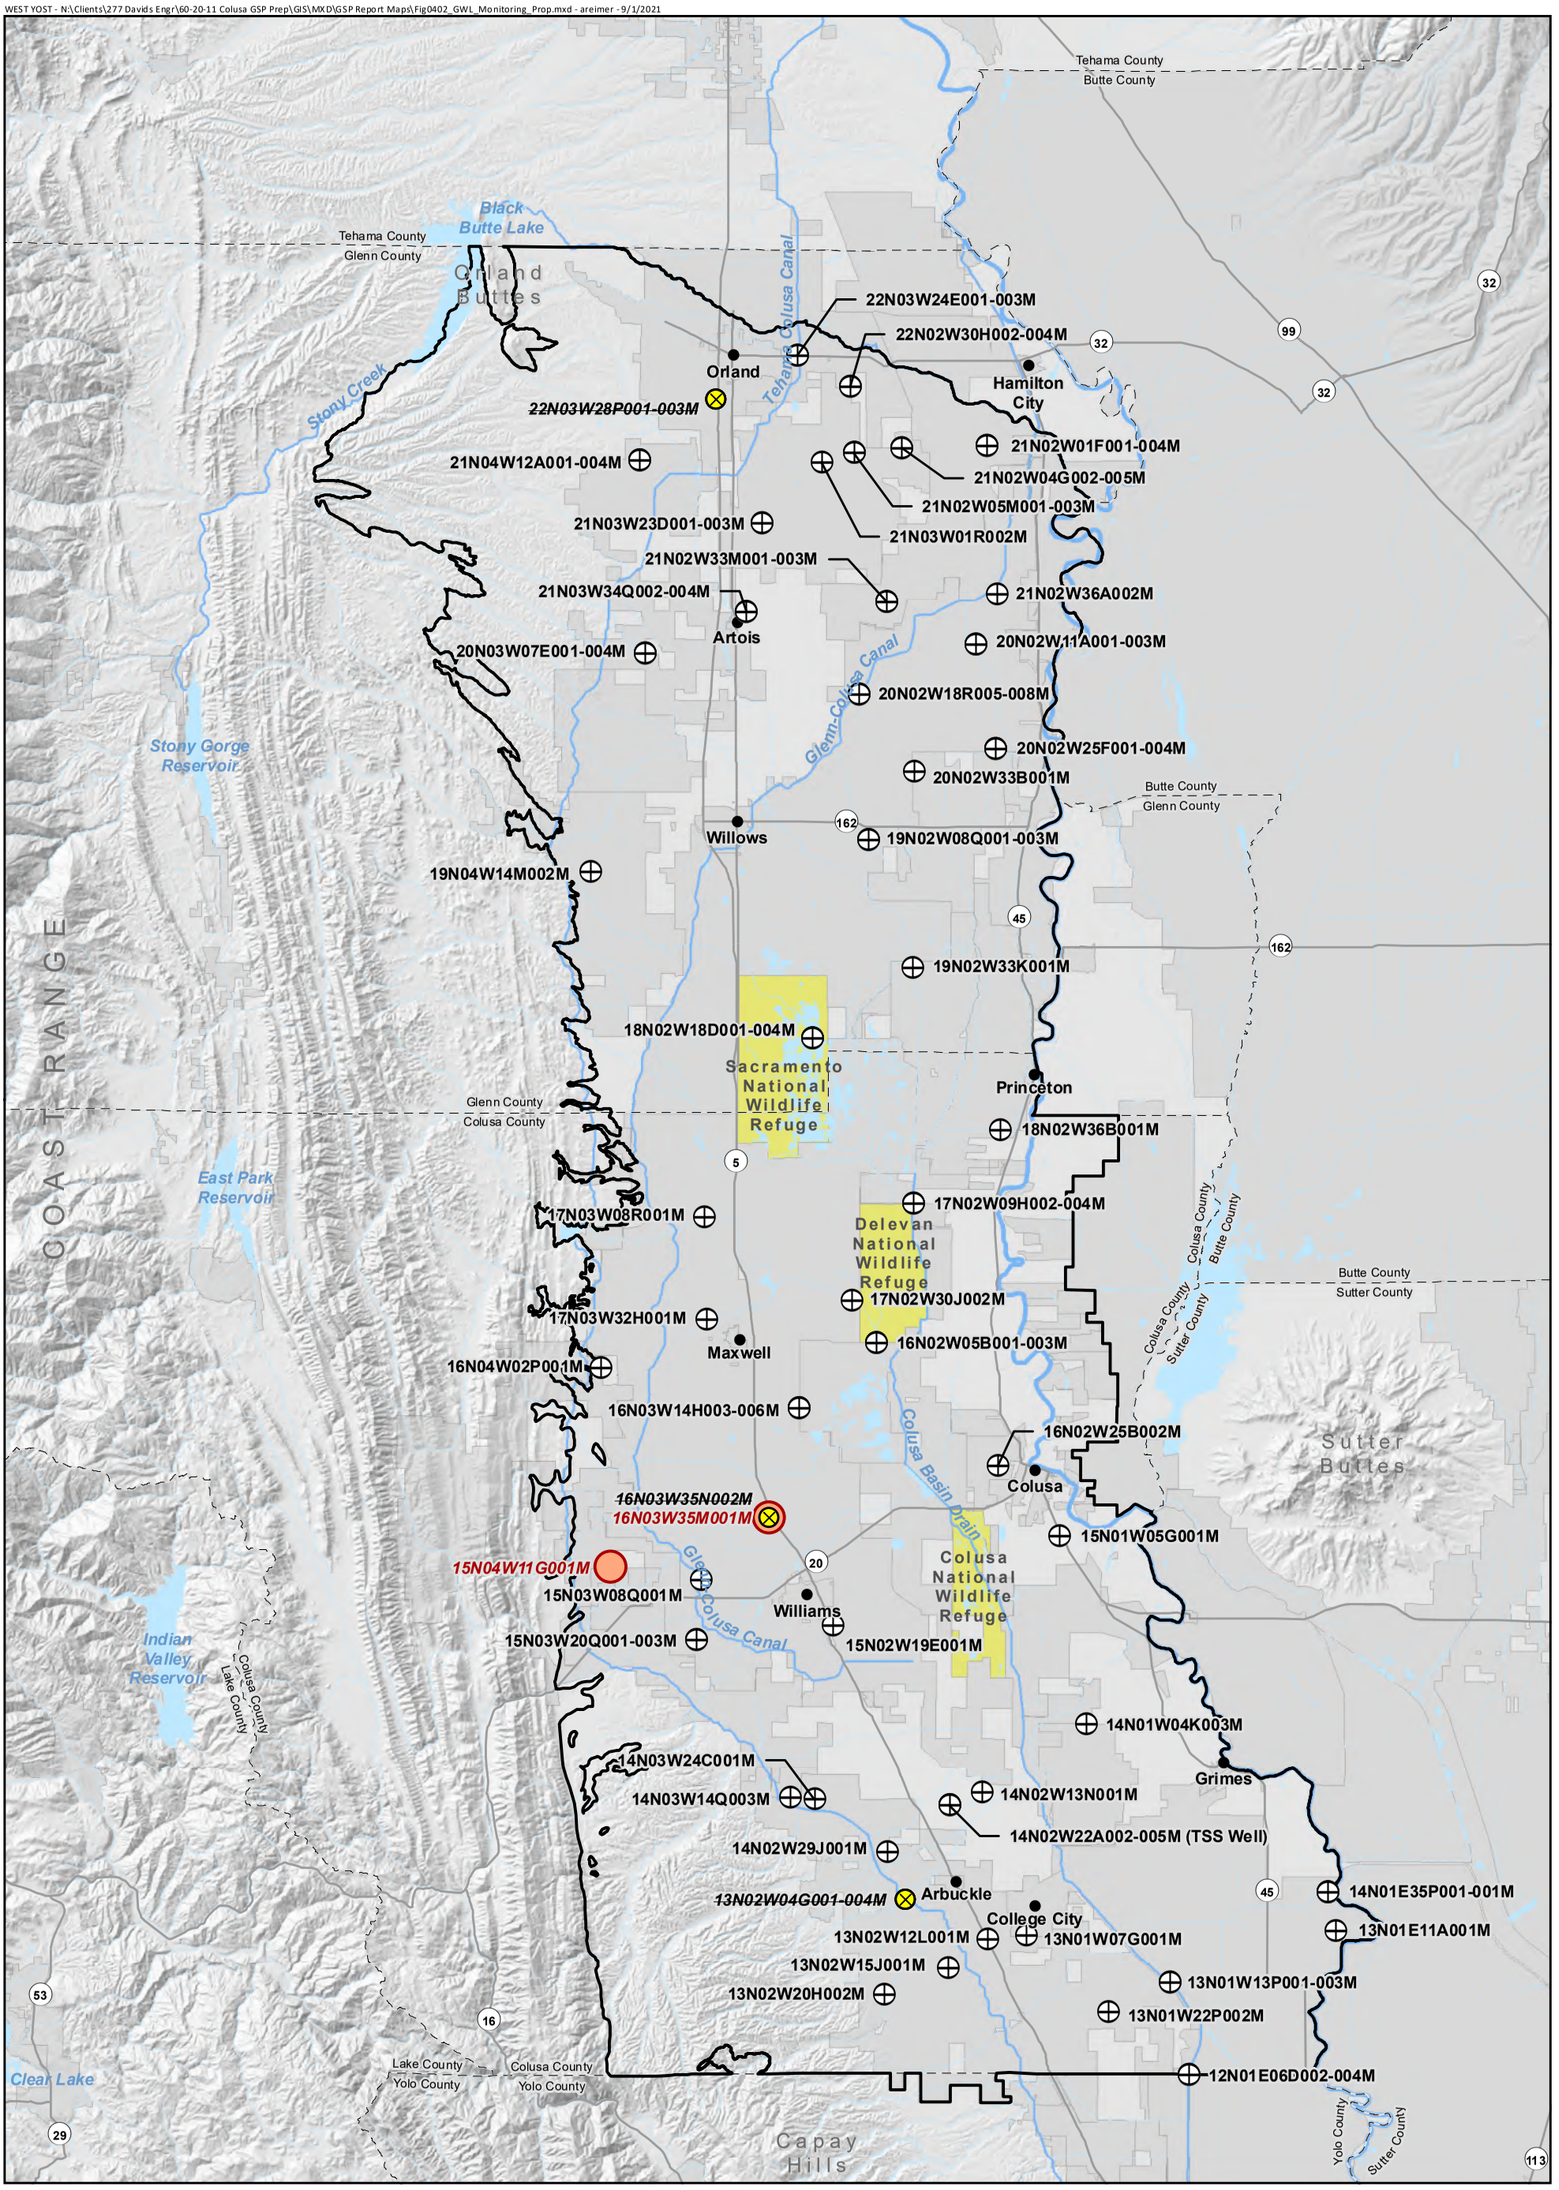
(a) Calculated as the difference in the fourth column divided by the Projected Future Condition without Climate Change quantity in the second column, except for Avg. Rate of Change in Groundwater Storage, for which the percent difference is based on the approximately 1 million acre-feet that flow into and out of the Colusa Subbasin on an average annual basis. Water budget uncertainty is discussed in Chapter 3, Basin Setting, and model uncertainty is discussed in Appendix 3D. The average change in groundwater storage is considered to be within standard modeling error for this type of groundwater model analysis.

Under projected future conditions without climate change, groundwater storage is forecast to increase modestly, at an average rate of 0.6 taf/yr. With 2070 CT climate change and the associated increase in groundwater pumping to meet increased irrigation demands, groundwater storage is projected to decrease at a rate of 7.3 taf/yr. This net change of -7.9 taf/yr is 0.8 percent of the approximately one million acre-feet that flow into and out of the Colusa Subbasin groundwater system annually.

Under projected future conditions without climate change, net stream accretion (stream accretion minus stream depletion) is projected to be 125 taf/yr on average. This aggregate net stream accretion is for the Sacramento River, Stony Creek, and the Colusa Drain combined[2]. With 2070 CT climate change, net stream accretion is projected to remain positive but to decrease by about 48 taf/yr, or by 38 percent, with respect to the without climate change condition. However, viewed in relation to the average Sacramento River flow above the Feather River confluence of approximately 11.7 million acre-feet per year (af/yr) the projected change is roughly one half of one percent.

The aggregate changes in groundwater storage, 0.8 percent, and net stream accretion, 0.5 percent of the average Sacramento River Flow, are considered to be within standard modeling error for this type of analysis. The GSAs will continue to evaluate and review all Subbasin water budget parameters, including net

[2] A more detailed assessment of projected streamflow accretion-depletion is presented in Appendix 3G. The analysis considers the Sacramento River, Stony Creek, and the Colusa Drain individually and collectively, and evaluates temporal accretion-depletion patterns over the 50-year simulation period.



Page 1 - Aqualliance Exhibit A

Table 5-1. Summary of Sustainability Thresholds for All Sustainability Indicators Applicable to the Colusa Subbasin

Sustainability Indicator	Monitoring Network	Undesirable Result	Minimum Threshold (MT)	Measurable Objective (MO)
Chronic Lowering of Groundwater Levels	48 Representative Monitoring Network (RMN) wells monitored at least 2-3 times annually by DWR	25% (12 of 48) RMN wells fall continuously below their MT for 24 consecutive months	The lower of 50% of measured historical groundwater elevation range below the historical measured low elevation and the elevation corresponding to the 20th percentile of domestic well depths in the RMN well's Thiessen polygon, subject to interbasin coordination and consistency to ensure operational compatibility	Mean of last 5 years available groundwater elevation measurements subject to interbasin coordination and consistency to ensure operational compatibility. A fixed value, not a rolling average.
Reduction in Groundwater Storage	48 RMN wells monitored at least 2-3 times annually by DWR (same as Groundwater Level monitoring network)	Use groundwater levels as proxy	Use groundwater levels as proxy	Use groundwater levels as proxy
Seawater Intrusion	Not applicable	Not applicable	Not applicable	Not applicable
Degraded Groundwater Quality	25 RMN wells monitored by others at variable intervals under existing State of California regulatory programs.	Electrical conductivity (EC) in 25 % (6 of 23) of the RMN wells exceeds the MT for two (2) consecutive years.	The higher of EC of 900 microSiemens per centimeter (µS/cm) (the recommended California Secondary Maximum Contaminant Level) OR the pre-2015 historical maximum measured EC.	EC of 700 µS/cm (corresponding to an agricultural water quality objective providing for no yield reduction for crops commonly grown in the Colusa Subbasin).
Land Subsidence[(a)]	Existing Sacramento Valley Height Modernization Project (SVHMP) benchmarks (63 sites)	15% or more (9 of 63) monitoring sites (benchmarks) experience subsidence rates above the MT	Benchmarks with greater than 1 foot historical subsidence (measured between 2008 and 2017): set MT at 0.60 foot/year. Benchmarks with less than 1 foot historical subsidence (measured between 2008 and 2017): set MT at 0.50 foot/year.	Benchmarks with greater than 1 foot historical subsidence (measured between 2008 and 2017): set MO at 0.25 foot/year. Benchmarks with less than 1 foot historical subsidence (measured between 2008 and 2017): set MO at 0.25 foot/year.
Depletions of Interconnected Surface Waters	12 RMN wells less than 200 feet deep and between 2,000 feet and five miles of interconnected stream (Sacramento River, Colusa Basin Drain, Stony Creek)	25% (3 of 12) RMN wells fall below their MT for 24 consecutive months.	Ten (10) feet below the observed fall 2015 groundwater level. (Fall 2015 level is the measured elevation recorded on the date closest to Oct 15.)	Mean of last 5 years available groundwater elevation measurements subject to interbasin coordination and consistency to ensure operational compatibility. A fixed value, not a rolling average.

(a) Sustainable management criteria for inelastic land subsidence are under review and may be revised after publication of this draft GSP.

Page 17 - Aqualliance Exhibit A

Table 6-1. Summary of Key Colusa Subbasin Water Budget Parameters Influencing Formulation of Projects and Management Actions (average annual volumes, taf/yr)

Water Budget Parameter	Projected Future Conditions without Climate Change	Projected Future Conditions with 2070 Central Tendency Climate Change	Difference (Projected future with 2070 Central Tendency climate change minus without climate change)	Percent Difference[(a)]
Avg. Agricultural Evapotranspiration	1,494	1,596	102.0	6.8%
Precipitation	1,183	1,258	75.0	6.3%
Agricultural Pumping	458	516	58.0	12.7%
Avg. Rate of Change in Groundwater Storage, af/yr	0.6	-7.3	-7.9	-0.8%
Sacramento River and Stony Creek Diversions to Colusa Subbasin	1,287.0	1,287.0	0.0	0.0%
Net Steam Accretion	125	77	-48.0	-38.3%

(a) Calculated as the difference in the fourth column divided by the Projected Future Condition without Climate Change quantity in the second column, except for Avg. Rate of Change in Groundwater Storage, for which the percent difference is based on the approximately 1 million acre-feet that flow into and out of the Colusa Subbasin on an average annual basis. Water budget uncertainty is discussed in Chapter 3, Basin Setting, and model uncertainty is discussed in Appendix 3D. The average change in groundwater storage is considered to be within standard modeling error for this type of groundwater model analysis.

Under projected future conditions without climate change, groundwater storage is forecast to increase modestly, at an average rate of 0.6 taf/yr. With 2070 CT climate change and the associated increase in groundwater pumping to meet increased irrigation demands, groundwater storage is projected to decrease at a rate of 7.3 taf/yr. This net change of -7.9 taf/yr is 0.8 percent of the approximately one million acre-feet that flow into and out of the Colusa Subbasin groundwater system annually.

Under projected future conditions without climate change, net stream accretion (stream accretion minus stream depletion) is projected to be 125 taf/yr on average. This aggregate net stream accretion is for the Sacramento River, Stony Creek, and the Colusa Drain combined[2]. With 2070 CT climate change, net stream accretion is projected to remain positive but to decrease by about 48 taf/yr, or by 38 percent, with respect to the without climate change condition. However, viewed in relation to the average Sacramento River flow above the Feather River confluence of approximately 11.7 million acre-feet per year (af/yr) the projected change is roughly one half of one percent.

The aggregate changes in groundwater storage, 0.8 percent, and net stream accretion, 0.5 percent of the average Sacramento River Flow, are considered to be within standard modeling error for this type of analysis. The GSAs will continue to evaluate and review all Subbasin water budget parameters, including net

[2] A more detailed assessment of projected streamflow accretion-depletion is presented in Appendix 3G. The analysis considers the Sacramento River, Stony Creek, and the Colusa Drain individually and collectively, and evaluates temporal accretion-depletion patterns over the 50-year simulation period.

Modified Colusa Draft GSP Table 3-11.

Columns G to J added to original
Bottom two rows added to original

The average annual change in storage was -28 thousand acre-feet per year (taf/yr) over the historical water budget period of 1990 to 2015. This indicates that, on average, more groundwater has left the Colusa Subbasin than entered, resulting in an average net reduction in groundwater stored in the Colusa Subbasin. Figure 3-29 summarizes the annual change in storage and the cumulative change in storage in the Colusa Subbasin aquifer system over the historical water budget period. A decrease in groundwater storage occurred during critically dry (C), dry (D), and below normal (BN) water years. This is most evident between 2007 and 2015, when the region experienced a series of consecutive, multiple-year droughts. While critically dry, dry, and below normal water years almost always correspond with a decrease in storage, above normal (AN) and wet (W) water years do not always result in an increase in groundwater storage. On average, the Colusa Subbasin's storage volume is influenced more by dry years than wet years. This is likely due to both a greater reliance on groundwater supply during dry years when surface water is less readily available and the relatively slow nature of deep percolation to recharge the groundwater system during wet years. Most of the groundwater inflows and outflows within the Colusa Subbasin are exchanged directly with the land and surface water system overlying the Colusa Subbasin groundwater system. More information regarding the groundwater storage calculations can be found in the water budget section of this GSP (Section 3.3) and the model development and calibration Technical Memorandum prepared by Woodard and Curran and Davids Engineering (2021) (Appendix 3D).

Figure 3-29. Change in Groundwater Storage

Page 21 - Aqualliance Exhibit A

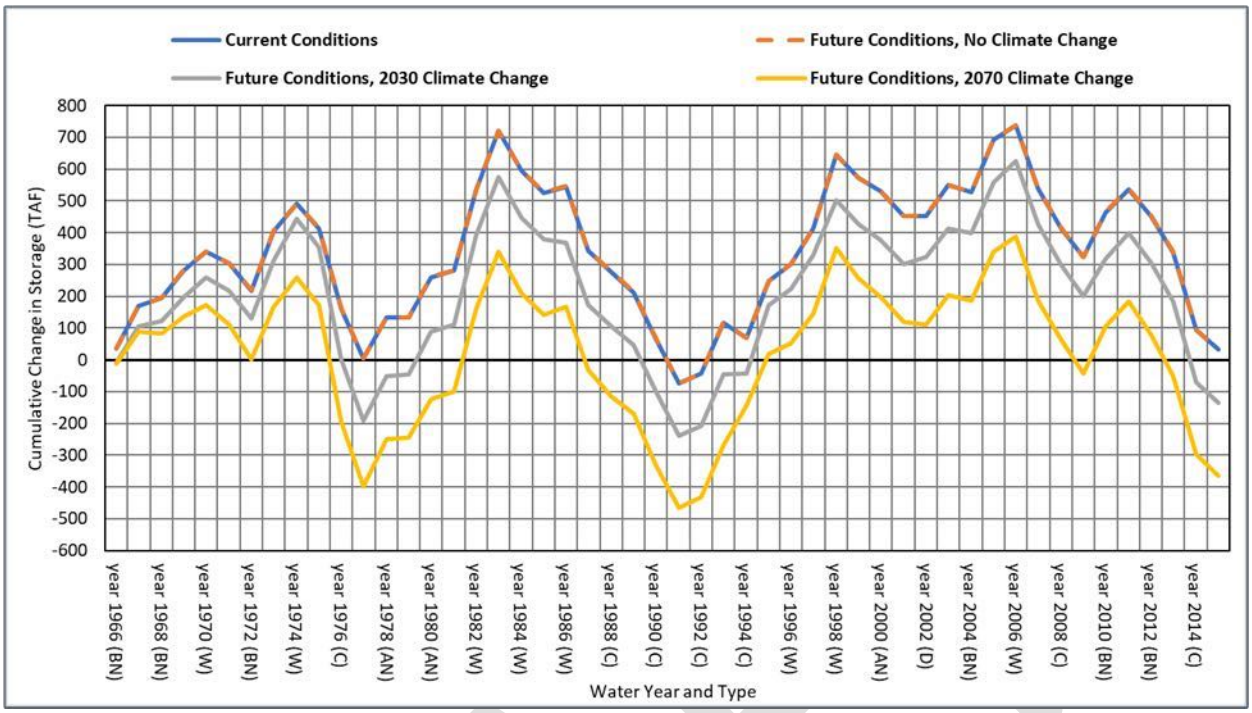

Figure 3-49. Cumulative Change in Groundwater Storage for Current and Future Conditions Baseline Scenarios

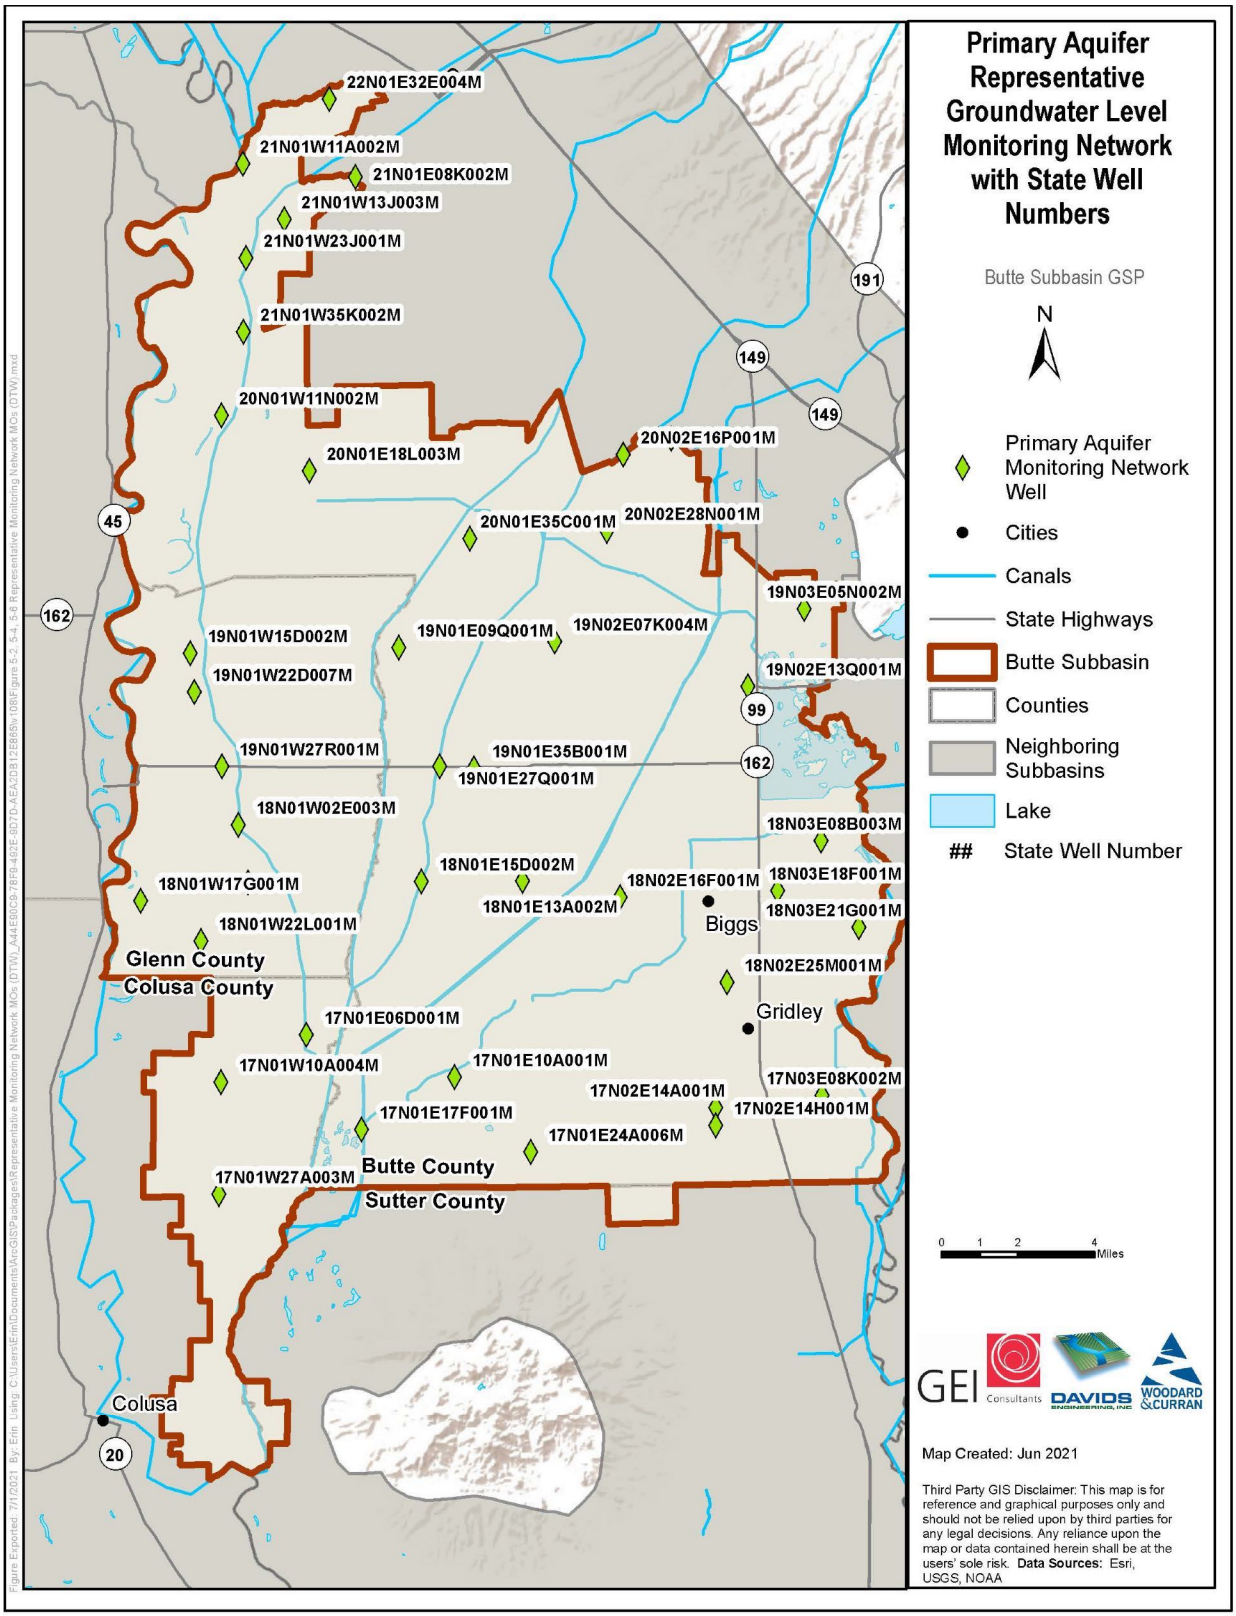
3.3.5 Water Budget Uncertainty



Water budget uncertainty refers to a lack of understanding of the subbasin setting that significantly affects an Agency's ability to develop sustainable management criteria and appropriate projects and management actions in a GSP, or to evaluate the efficacy of plan implementation, and therefore may limit the ability to assess whether a subbasin is being sustainably managed. Substantial uncertainty exists in all components of each water budget component. Substantial uncertainty also exits in the assumptions used to project potential future conditions related to planned development and associated urban demands, as well as, projections of climate change. Consequently, the estimated negligible or very small changes in groundwater storage for current and future water budgets, calculated as total subbasin inflows minus outflows, are highly uncertain. It is anticipated that confidence in model results will be increased over time through additional monitoring and data collection, refinements to C2VSimFG-Colusa input, and coordination with neighboring subbasins.

However, the uncertainties that currently exist do not substantially limit the ability to develop and implement a GSP for the subbasin including the ability to develop sustainable management criteria and appropriate projects and management actions, including improved monitoring, nor the ability to assess whether the subbasin is being sustainably managed over time. GSPs are by nature iterative, and each opportunity will allow for improvements that will (1) lower uncertainty and (2) facilitate more refined analyses of sustainable management criteria and projects and management actions, and (3) refine the GSP implementation.

Re: Comments on the Draft Groundwater Sustainability Plan for the Colusa Subbasin

To Colusa Groundwater Authority and Glenn Groundwater Authority,

Audubon California appreciates the opportunity to provide public comment on the draft Colusa Subbasin Groundwater Sustainability Plan (GSP) prepared by the Colusa Groundwater Authority (CGA) and Glenn Groundwater Authority (GGA), collectively referred to hereafter as the "Colusa GSAs." Audubon California is a statewide nonprofit organization with a mission to protect birds and the places they need. Our organization has a long history of solutions-focused work in the Central Valley in collaboration with state and federal agencies, water districts, non-profits, and landowners. Audubon is reviewing draft GSPs as a stakeholder for the environment with a particular focus on managed wetlands. We are commenting on draft GSPs to provide technical assistance to Groundwater Sustainability Agencies (GSAs) to improve their GSPs prior to the deadline to submit final GSPs to the Department of Water Resources in January 2022. Audubon would also like to identify areas of opportunity to partner with landowners and GSAs to provide groundwater and wildlife habitat benefits in the implementation of the Sustainable Groundwater Management Act (SGMA).

Over 90 percent of historic wetlands in the Central Valley have been replaced with agriculture or urban development. Disconnected from natural water sources as a consequence of surface water diversions and groundwater over-pumping, wetland landowners must utilize surface water deliveries or pump groundwater to provide flooded habitat. But managed wetlands provide outsized public trust benefits for their minor water use.

The remaining wetlands in the Central Valley are a critical component of the Pacific Flyway, supporting millions of migratory waterfowl, hundreds of thousands of shorebirds, and state listed species like the Tricolored Blackbird. Central Valley managed wetlands are part of California's commitment to national and international Pacific Flyway agreements and provide significant public trust benefits, including habitat for migratory birds, recharge of overdrafted aquifers, carbon sequestration, and recreation opportunities for birders, hunters, and disadvantaged communities.

As recognized by the Colusa GSAs, managed wetlands require specific consideration in GSPs under SGMA statute and regulations, as detailed below. GSAs are required to identify managed wetlands as beneficial users of groundwater and as land uses and property interests and should recognize this land use consistent with other active users of surface and groundwater. The overall basin water budget must

include managed wetlands as a specific water use sector and the GSP is required to consider the effects of the GSP on managed wetlands as a beneficial user or land use.

When GSPs fail to adequately consider the water needs and recharge contributions of managed wetlands, projects and management actions may ignore managed wetlands, their need for protection as public trust resources, and their potential to be part of sustainability solutions. If future actions include groundwater allocations, managed wetlands face the potential of being excluded if not recognized in the GSP, risking further loss in critical wetland acreage.

SGMA Requirements Related to Managed Wetlands

A primary requirement for GSAs during GSP development is the consideration of the interests of "all beneficial uses and users of groundwater" [Water Code Section 10723.2], which includes "[e]nvironmental users of groundwater" [Water Code Section 10723.2(e)].

Articulated into the SGMA regulations, the concept of beneficial uses and users of groundwater is first represented in CCR, Title 23, Section 354.10. Notice and Communication, which directs the GSP to "…include a summary of information relating to notification and communication by the Agency with other agencies and interested parties including the following: (a) A description of the beneficial uses and users of groundwater in the basin, including the land uses and property interests potentially affected by the use of groundwater in the basin, the types of parties representing those interests, and the nature of consultation with those parties." [emphasis added].

Furthermore, the SGMA regulations provide a definition that explicitly includes managed wetlands as a beneficial user where:

> "'Water use sector' refers to categories of water demand based on the general land uses to which the water is applied, including urban, industrial, agricultural, managed wetlands, managed recharge, and native vegetation." CCR, Title 23, Section 351(al) [emphasis added].

GSAs are then directed to include all water user sectors in the description of the GSP area and to quantify groundwater use by these sectors in the historic, current and projected budgets [emphasis added]:

> CCR §354.8. Description of Plan Area: Each Plan shall include a description of the geographic areas covered, including the following information:
>
> (a) One or more maps of the basin that depict the following, as applicable:
>
> (4) Existing land use designations and the identification of water use sector and water source type.
>
> and,
>
> CCR §354.18. Water Budget:
>
> (b) The water budget shall quantify the following, either through direct measurements or estimates based on data:
>
> (3) Outflows from the groundwater system by water use sector, including evapotranspiration, groundwater extraction, groundwater discharge to surface water sources, and subsurface groundwater outflow.

Given these explicit requirements, GSAs are required to identify and map managed wetlands and include their water needs in water budgets in the GSP.

Furthermore, each GSP is also required to describe "undesirable results" where such included:

> "Potential effects on the beneficial uses and users of groundwater, on land uses and property interests, and other potential effects that may occur or are occurring from undesirable results." CCR, Title 23, Section 354.26(b)(3) [emphasis added]

Comment Overview

In reviewing this draft GSP, we applaud the Colusa GSAs for their proactive effort to include managed wetlands throughout the GSP. As a result, our comments are limited and summarized as follows:

1. Identification of managed wetlands: Audubon appreciates that the GSA has identified and specifically included managed wetlands in maps and water budgets, specifically the three primary refuges: Sacramento National Wildlife Refuge, Delevan National Wildlife Refuge, and Colusa National Wildlife Refuge.
2. Water budget: Audubon appreciates the specific inclusion of managed wetlands into the water budgets (e.g. Table 3-11). However, the future condition water budgets should reflect CVPIA Full Level 4 water supplies being available and delivered to each of the three national wildlife refuges. The use of 2013 to represent unconstrained delivery conditions (e.g. see GSP Table 3-9, page 3-88) reflects deliveries to these refuges that are less than the CVPIA Full Level 4 mandated quantities. Annual Full Level 4 water supplies during unconstrained conditions are as follows:
    a. Sacramento NWR = 50,000 acre-feet,
    b. Delevan NWR = 30,000 acre-feet, and
    c. Colusa NWR = 25,000 acre-feet.

    During constrained conditions, these same refuges generally are provided 75% of this quantity, as stipulated in their water delivery agreements with the U.S. Bureau of Reclamation.
3. Consideration of managed wetlands: Audubon appreciates that several of the listed projects included in Table 6-2 include identified opportunities for multi-benefit projects that provide water supply and wildlife habitat benefits.

Draft Groundwater Sustainability Plan Page-by-Page Comments

Additional page-by-page comments on the Colusa GSAs' draft GSP are detailed below. We welcome any follow up questions and look forward to seeing the issues raised below addressed in the final GSP submission in January 2022.

> Figure 2-8: Suggest modifying the color scheme or naming for the category "native" to distinguish the refuges from other "native" areas as the refuges are distinctly different land uses than the traditional native upland areas, for instance, in the southwestern portion of the subbasin. Private managed wetlands and managed wetlands in U.S. Fish and Wildlife Service Management Areas that have federal easements are currently not identified in land use or jurisdictional maps.
>
> Table 2-3, page 2-11: Since the three national wildlife refuges are mandated to receive stipulated quantities (though have yet to achieve them), this table should also list the CVPIA Full Level 4 quantities of: Sacramento NWR = 50,000 acre-feet, Delevan NWR = 30,000 acre-feet, and Colusa NWR = 25,000 acre-feet. While the historic average deliveries are useful for baseline understanding, modeling of future conditions should include the full water supplies for these three refuges.

Page 3-13, line 32/33: The term "land" should be added to the end of the sentence to result in "federal wildlife land."

Table 3-9, page 3-88: The future condition water supplies for the three national wildlife refuges should reflect the CVPIA Full Level 4 water supply. Deliveries in 2013, represented as a Shasta Non-critical year, did not result in Full Level 4 deliveries to these refuges. The CVPIA Full Level 4 quantities include a portion that is labeled "Level 2" that reflects delivery of CVP project water, and a portion labeled "Incremental Level 4" (the difference between Full Level 4 and Level 2) that can come from other sources. The GSP will need to make reasonable assumptions whether the Incremental Level 2 supply will be derived from other surface water sources or from groundwater, though either is possible.

Section 3.3.3.1 Historical (Water Budget), page 3-89: Under "Agricultural Water Demand" the following sentence is included: "*For ponded land uses (rice and managed wetlands), pond depths and pond drainage are also considered to simulate demands*." Under the "Current Conditions" (Section 3.3.3.2) and "Future Conditions Scenarios" (Section 3.3.3.3) water budget discussions, this same language is missing. Did these budgets recognize managed wetlands in a similar fashion as described for the historical budget? If so, we suggest adding the same sentence to each of the other water budget descriptions for clarity.

Table 3-11, page 3-96: As a result of including the CVPIA Full Level 4 water supplies for the national wildlife refuges, the values for the various future conditions for "Sacramento River Diversions" and "Groundwater Pumping – Managed Wetlands" as well as the "Evapotranspiration – Managed Wetlands" may all change. The table should be updated accordingly.

Table 3-12, page 3-97: Similar to the prior comment, values in this table for the future conditions would be expected to change when the CVPIA Full Level 4 water supply quantities are incorporated.

Section 6.5.2.3, page 6-84 to 6-86: Several demand reduction concepts are initially outlined in this section. Audubon suggests the following be considered associated with each suggested method:

1. Allocation: Use of groundwater by managed wetlands should not be restricted without adequate replacement with surface water sources, especially the national wildlife refuges. Managed wetlands in the Colusa subbasin provide invaluable benefits to the Pacific Flyway.
2. Allocation with a market: If a market is created and managed wetlands are assigned an allocation, such parcels should be able to participate in a market to optimize the use of their allocations for achieving habitat objectives, but managed wetlands should not be required to participate in a market to secure the water they need.
3. Land repurposing: Strategic siting of where irrigated lands are retired and others are kept in production should consider the potential benefits to wildlife. Areas surrounding protected areas, such as the Sacramento, Delevan and Colusa National Wildlife Refuges, should be prioritized habitat benefits.
4. Financial incentives: Public beneficial uses such as managed wetlands should not be subject to financial conditions that lesson the public benefit otherwise achieved on the lands.

Thank you for your consideration of Audubon California's comments. If you would like to discuss this matter further, please do not hesitate to contact me at (916) 737-5707 or via email at samantha.arthur@audubon.org.

Sincerely,

Samantha Arthur

Subject: CALIFORNIA DEPARTMENT OF FISH AND WILDLIFE COMMENTS ON THE COLUSA SUBBASIN DRAFT GROUNDWATER SUSTAINABILITY PLAN

Dear Ms. Fahey and Ms. Hunter:

The California Department of Fish and Wildlife (Department) appreciates the opportunity to provide comments on the Colusa Subbasin Draft Groundwater Sustainability Plan (GSP) prepared by the Colusa Groundwater Authority Groundwater Sustainability Agency (GSA) and Glenn Groundwater Authority GSA pursuant to the Sustainable Groundwater Management Act (SGMA). The Basin is designated as high priority under SGMA and must be managed under a GSP by January 31, 2022.

The Department is writing to support ecosystem preservation and enhancement in compliance with SGMA and its implementing regulations based on Department expertise and best available information and science. As trustee agency for the State's fish and wildlife resources, the Department has jurisdiction over the conservation, protection, and management of fish, wildlife, native plants, and the habitat necessary for biologically sustainable populations of such species (Fish & Game Code §§ 711.7 and 1802).

Development and implementation of GSPs under SGMA represents a new era of California groundwater management. The Department has an interest in the sustainable management of groundwater, as many sensitive ecosystems, species, and public trust resources depend on groundwater and interconnected surface waters (ISWs), including ecosystems on Department-owned and managed lands within SGMA-regulated basins.

SGMA and its implementing regulations afford ecosystems and species specific statutory and regulatory consideration, including the following as pertinent to GSPs:

- GSPs must **consider impacts to groundwater dependent ecosystems** (GDEs) (Water Code § 10727.4(l); see also 23 CCR § 354.16(g));
- GSPs must consider the interests of all beneficial uses and users of groundwater, including environmental users of groundwater (Water Code §

DocuSign Envelope ID: A88AB118-82F0-4EF0-BA24-9A61C25D884D

10723.2) and GSPs must **identify and consider potential effects on all beneficial uses and users of groundwater** (23 CCR §§ 354.10(a), 354.26(b)(3), 354.28(b)(4), 354.34(b)(2), and 354.34(f)(3));

- GSPs must **establish sustainable management criteria that avoid undesirable results** within 20 years of the applicable statutory deadline, including **depletions of interconnected surface water that have significant and unreasonable adverse impacts on beneficial uses of the surface water** (23 CCR § 354.22 *et seq*. and Water Code §§ 10721(x)(6) and 10727.2(b)) and describe monitoring networks that can identify adverse impacts to beneficial uses of interconnected surface waters (23 CCR § 354.34(c)(6)(D)); and
- GSPs must **account for groundwater extraction for all water use sectors,** including managed wetlands, managed recharge, and native vegetation (23 CCR §§ 351(al) and 354.18(b)(3)).

Furthermore, the Public Trust Doctrine imposes a related but distinct obligation to consider how groundwater management affects public trust resources, including navigable surface waters and fisheries. Groundwater hydrologically connected to surface waters is also subject to the Public Trust Doctrine to the extent that groundwater extractions or diversions affect or may affect public trust uses. (*Environmental Law Foundation v. State Water Resources Control Board* (2018), 26 Cal. App. 5th 844; *National Audubon Society v. Superior Court* (1983), 33 Cal. 3d 419.) The GSA has "an affirmative duty to take the public trust into account in the planning and allocation of water resources, and to protect public trust uses whenever feasible." (*National Audubon Society*, *supra*, 33 Cal. 3d at 446.) Accordingly, groundwater plans should consider potential impacts to and appropriate protections for ISWs and their tributaries, and ISWs that support fisheries, including the level of groundwater contribution to those waters.

In the context of SGMA statutes and regulations, and Public Trust Doctrine considerations, groundwater planning should carefully consider and protect environmental beneficial uses and users of groundwater, including fish and wildlife and their habitats, GDEs, and ISWs.

The Department recognizes and appreciates the effort of the GSAs to characterize current and projected groundwater conditions through detailed modeling. However, the Department believes the GSP could improve its considerations of environmental users of groundwater and establish more protective management criteria. The Department is providing additional comments and recommendations in Attachment A.

If have any questions related to the Departments comments and/or recommendations on the Colusa Subbasin Draft GSP please contact Bridget Gibbons, Environmental Scientist, at bridget.gibbons@wildlife.ca.gov.

CALIFORNIA DEPARTMENT OF FISH AND WILDLIFE COMMENTS ON THE COLUSA SUBBASIN DRAFT GROUNDWATER SUSTAINABILITY PLAN

COMMENTS AND RECOMMENDATIONS

The Department's comments are as follows:

1. **Comment #1** – **Interconnected Surface Water Systems** (3.2.7 Interconnected Surface Waters; starting page 3-77): The GSP does not include sufficient detail describing the timing of depletions of interconnected surface water (ISW).
    a. Issue: Though the GSP discusses annual gains and losses from interconnected surface waters in the subbasin and summarizes net gains by water year type (Table 3-6, page 3-79), the GSP does not include sufficient detail on the timing of depletions as required by 23 CCR § 354.16(f). In order to adequately assess ISW that may be gaining or losing at different times of the year, it is preferential to present net gain/loss values by month, rather than by year. Quantifying depletions by month for each reach will facilitate evaluation of impacts or benefits to environmental beneficial users that rely on surface waters during specific portions of the year.
    b. Recommendation: The Department recommends including net gains or losses to interconnected surface waters by month, rather than by year.

2. **Comment #2** – **Groundwater Dependent Ecosystems** (3.2.8 Groundwater Dependent Ecosystems; starting page 3-82): Groundwater dependent ecosystem (GDE) identification, required by 23 CCR § 354.16(g), is based on methods that risk exclusion of ecosystems that may depend on groundwater.
    a. Issues:
        i. <u>GDE Scoring Criteria:</u> The GSP assigns a rank of '1' (less likely to be a GDE) to '4' (more likely to be a GDE) to potential GDE areas within the Natural Communities Commonly Associated with Groundwater dataset. It is unclear how the rankings are utilized throughout the remainder of the GSP to assess monitoring networks, management criteria, or potential projects. Accordingly, the ranking system has no apparent actionable groundwater management relevance.
        ii. <u>Depth to Groundwater Threshold</u>: The GSP relies on a groundwater level threshold of 30-feet below the ground surface (bgs) to screen potential GDEs within the subbasin. However, mature Valley Oak

DocuSign Envelope ID: A88AB118-82F0-4EF0-BA24-9A61C25D884D

(*Quercus lobata*) can access groundwater up to 80 feet bgs (Howard 1992, Lewis & Burgy 1964). The use of a 30-foot threshold may incorrectly result in Valley Oak communities receiving a GSP-imposed score of '1,' indicating that they are least likely to be a GDE.

iii. GDEs Near Surface Water: The GSP assesses whether potential GDE areas are located near surface waters or irrigated cropland, or both. The GSP considers potential GDE areas within 150 feet of surface waters, within 150 feet of irrigated rice paddies, and within 50 feet of other irrigated croplands to have access to surface water; and therefore, the GSP assigns these areas a score of '2' or '3,' indicating they are less likely to be groundwater dependent. The GSP states that "GDEs include vegetation and habitat that are wholly dependent on groundwater" (line 9, page 3-83); however, this narrow definition of a GDE disregards a GDE's adaptability and opportunistic approach to accessing water in which vegetation and ISW may rely on *both* surface water and groundwater across seasons and years. Furthermore, this GDE definition contradicts an earlier description of GDEs within the GSP, in which the plan states that "a GDE's dependence on groundwater refers to reliance of GDE species and/or communities on groundwater for all *or a portion of* their water needs" (line 3, page 3-82). Particularly as the GDE areas receiving scores of '2' or '3' have already been determined to be located in areas with depths to groundwater of less than 30 feet, proximity to potential surface waters is insufficient evidence to categorize them as 'less likely' to be GDEs.

iv. Data Gaps: The GSP states that there is potential for GDEs to be present in the uplands west of Orland and west of Arbuckle, but that groundwater level data is lacking in these areas and there is insufficient information "to determine their existence" (line 26, page 3-83). Rather than waiting an indeterminate amount of time to gather data to prove groundwater dependence of potential GDE areas and leaving the potential GDEs unclassified in the interim, the GSP should conservatively consider these areas to be GDEs until sufficient data is collected that proves otherwise.

v. Special Status Species: SGMA defines GDEs as ecological communities *or species* that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface [23 CCR § 351 (m)]. The GSP does not identify or discuss species that may be present within the subbasin that rely on groundwater,

DocuSign Envelope ID: A88AB118-82F0-4EF0-BA24-9A61C25D884D

groundwater dependent ecosystems, or interconnected surface waters.

b. Recommendations:
    i. GDE Scoring Criteria: The GSP should clarify how the ranking system is meaningfully used in relationship to groundwater management criteria. Specifically, the GSP should clarify what GDE areas are retained for further analysis in the plan as environmental beneficial users of groundwater and how likely GDEs may be impacted by management criteria, including identification of potential undesirable results.
    ii. Depth to Groundwater Threshold: The Department recommends the GSP update the methodology for classifying GDEs to reflect accurate maximum potential rooting depth for Valley Oak communities. For areas of Valley Oak within the subbasin, the Department recommends the GSP apply a threshold of 80 feet bgs as the maximum depth at which the potential GDE could access groundwater. The Department accepts the use of a 30-foot threshold for other potential GDE areas within the subbasin that do not contain Valley Oak.
    iii. GDEs Near Surface Water: The Department recommends that the GSP err on the side of inclusivity of potential GDEs until there is site specific evidence that the overlying ecosystem has no significant dependence on groundwater across seasons and water year types.
    iv. Data Gaps: The GSP should conservatively assume that potential GDEs located in areas with poor groundwater level data availability are groundwater dependent, until such time that data is collected that demonstrates otherwise.
    v. Special Status Species: The Department recommends the GSP include a list of special status species that may be present within the Colusa Subbasin and an assessment of each species' likely groundwater dependence. The GSP should also include a spatial assessment of special status species within the subbasin to characterize which surface waters or GDE areas provide these species habitat or forage; this level of GDE-species-relationship assessment enables GSAs to prioritize GDE monitoring and management decisions.

3. **Comment #3 – Monitoring Networks** (4.2.5.4 Representative Surface Water Depletion Monitoring Network; starting page 4-33): The GSP should include

DocuSign Envelope ID: A88AB118-82F0-4EF0-BA24-9A61C25D884D

additional details related to the plans to improve the monitoring network for GDEs and ISW within the subbasin.

a. Issue: The GSP states that the ISW representative monitoring network will also be used to monitor GDEs. The GSP does not present any information or figures to support its assertion that the ISW monitoring sites are located sufficiently near to GDEs to assess shallow groundwater levels in those areas. While the Department appreciates the GSP's acknowledgement of data gaps related to the characterization of GDEs and ISW within the subbasin and the GSP's proposed plan to install up to an additional 10 shallow monitoring wells, the GSP does not provide details on planned locations or timelines for installation of these additional monitoring locations.
b. Recommendation: The GSP should include additional detail related to the anticipated timeline for installation of additional wells to further refine ISW and GDE characterization and management. The Department recommends that the GSP assess the locations of special status species within the subbasin to determine which GDE areas likely provide priority habitat. GDE areas and ISW that support special status species or are most at risk of negative impacts due to groundwater pumping should be prioritized for monitoring to inform management actions (See Comment #2(v)).

4. **Comment #4 – Sustainable Management Criteria** (5.3.6 Depletion of Interconnected Surface Water, 5.4.6 Depletions of Interconnected Surface Water; starting pages 5-15 and 5-30): Interconnected surface water sustainable management criteria (SMC) may not protect against undesirable results for fish and wildlife beneficial uses and users.
    a. Issues:
        i. Minimum Thresholds: Minimum thresholds (MTs) for ISW are set at 10 feet below the measured historical low for each representative monitoring well. The GSP states that establishing MTs below the historic lows is necessary to provide a sufficient margin of operational flexibility during GSP implementation, and that no undesirable results were observed at the historic low; however, the GSP does not include sufficient analysis or discussion to support this claim. In 2015, the second of back-to-back critically dry water years in the Sacramento Valley which resulted in recent historical low groundwater levels, vegetated and aquatic GDEs experienced adverse impacts including stressed or dying riparian vegetation, poor instream habitat availability, and increased water temperatures (DFW 2019). It is unclear what, if any, studies or

DocuSign Envelope ID: A88AB118-82F0-4EF0-BA24-9A61C25D884D

analyses were completed to assess whether environmental users within the subbasin experienced undesirable results at the historical low groundwater levels, or what metrics the GSP would evaluate to determine the presence of an undesirable result for GDEs or ISW in the event of additional groundwater decline beyond the historic low as the MTs allow. The ISW SMC are also referenced as protective of GDE beneficial users of groundwater according to the GSP, but the supporting discussion focuses on groundwater gradients and associated depletions. No analysis is presented that characterizes whether the established MTs are sufficient to maintain water levels that have historically been shallow enough to support GDEs, or if the MTs would permit groundwater levels to fall below root zones, removing groundwater as an available water source to some GDEs. If MTs are not protective of GDE access to groundwater supplies, significant impacts to environmental beneficial users of groundwater will likely be experienced before MTs are reached. Furthermore, the GSP reports annual net values for streamflow depletion from the modeled baseline conditions, baseline conditions with climate change, and baseline conditions with climate change and project scenarios. However, the annual analysis does not provide sufficient detail on the timing of depletions to adequately assess potential impacts to environmental users (See Comment #1). The GSP compares modeled annual depletions to *total* annual flow in these river systems, and uses this annual normalization to characterize groundwater contributions to ISW as nominal. This coarse annual comparison does not take into account how groundwater contributions to river base flows are often proportionately greater in dry years or during annual low-flow seasons, or how groundwater contributions play a key role in maintaining water quality and temperatures. Properly contextualizing groundwater contributions to surface water is especially important to understanding potential impacts of groundwater depletion on surface waters and their ecosystems, particularly when the GSP states that streamflow accretion is expected to decrease by 38.3% with climate change impacts (line 9, page 6-2).

ii. Undesirable Results: The GSP requires 25% of ISW representative monitoring wells in the subbasin to fall below their MTs for 24 consecutive months before identifying an undesirable result to GDEs or ISW. While environmental users are adapted to sustain short-term lowering of groundwater levels during dry periods,

DocuSign Envelope ID: A88AB118-82F0-4EF0-BA24-9A61C25D884D

environmental users may not be able to sustain extended periods of reduced groundwater access that would result from allowing groundwater levels to fall to historic lows for 24 months. By the time an undesirable result is declared, and management actions are triggered in response to the undesirable result, environmental groundwater users will have already experienced significant stress and potentially irreversible mortality.

b. Recommendations:
    i. Minimum Thresholds: The Department recommends the GSP reselect minimum thresholds that would better protect environmental uses and users of groundwater, rather than enabling declines in groundwater levels over the implementation horizon beyond the historic low. Additional analyses of the specific impacts of the established thresholds on GDE and ISW beneficial users of groundwater should be included.
    ii. Undesirable Results: The Department recommends the GSP reconsider the 24-month duration of groundwater levels below MTs required to constitute an undesirable result, recognizing that extended durations of groundwater inaccessibility for environmental users will likely lead to adverse impacts that cannot be easily reversed when groundwater levels recover. At a minimum, the Department recommends identifying physical triggers (e.g., declining Normalized Difference Vegetation Index signals) and associated management actions (e.g., demand reduction) to enable the GSAs to identify and mitigate localized patterns of lowering groundwater or depleted ISW and associated negative impacts before the second year of MT exceedances yields more significant and undesirable impacts. These interim action triggers will help preempt irreversible losses and undesirable results for environmental users.

5. **Comment #5** – **Projects and Management Actions** (PMAs) (6.5.2.3 Long-term Demand Management Action, 6.5.2.4 Strategic Temporary Land Idling for Drought and Localized Short-Term Groundwater Management; starting page 6-84): The GSP should include additional metrics and timelines related to the implementation of demand management within the subbasin.
    a. Issue: The Department appreciates the GSP's identification of both short- and long-term demand management actions that will serve as a "backstop" to the other identified PMAs. As the other PMAs focus largely on implementing recharge projects that may be costly, rely on securing additional surface water supplies, and/or require potentially lengthy

DocuSign Envelope ID: A88AB118-82F0-4EF0-BA24-9A61C25D884D

permitting processes, demand management may be necessary in instances where a quick response to undesirable results within the subbasin is needed. Though the GSP identifies various demand management strategies, the GSP states that these management actions are in the “early conceptual stage” and as such, no timelines have been determined.

b. Recommendation: The Department recommends detailing specific timelines and metrics that would trigger the implementation of the identified demand management scenarios should recharge projects encounter delays or fail to produce the anticipated groundwater benefits to the subbasin.

CONCLUSION

In conclusion, though the draft GSP provides detailed characterization of subbasin groundwater conditions, the GSP lacks a robust analysis of potential impacts to environmental beneficial users and should establish more protective management criteria. The Department recommends that the Colusa Subbasin GSAs address the above comments before GSP submission to DWR to best prepare for the following regulatory criteria for plan evaluation:

1. The assumptions, criteria, findings, and objectives, including the sustainability goal, undesirable results, minimum thresholds, measurable objectives, and interim milestones are not reasonable and/or not supported by the best available information and best available science (23 CCR § 355.4(b)(1)). (See Comment #1, 2, 4)
2. The GSP does not identify reasonable measures and schedules to eliminate data gaps. (23 CCR § 355.4(b)(2)) (See Comment #3)
3. The interests of the beneficial uses and users of groundwater in the basin, and the land uses and property interests potentially affected by the use of groundwater in the basin, have not been considered. (23 CCR § 355.4(b)(4)) (See Comment #1, 2, 4)
4. The projects and management actions are not feasible and/or not likely to prevent undesirable results and ensure that the basin is operated within its sustainable yield. (23 CCR § 355.4(b)(5)) (See Comment #4)

From: Orland City Council

Subject: Comments on Draft Colusa Subbasin Groundwater Sustainability Plan

On behalf of the residents of the City of Orland, the Orland City Council recognizes the admirable cooperation of various water users in developing a plan, the scientific data that went into development of the plan, and the inherent assumptions necessarily undergirding the plan. In the spirit of public comment on the plan, we offer the following observations:

1. Chapter 5 states that the subbasin is currently being managed sustainably without undesirable results despite over 150 domestic wells going dry this summer alone as 2021 data is not yet included in plan development. It is notable that a key partner in the draft plan explained at the October 13th public meeting, "The current actual drought is more compelling than modeled future sustainability challenges."

2. The plan's allowance for up to 20% of domestic wells going dry may be understandable in light of the age and depths of most of the wells. However, depletion of up to 5% of groundwater storage (over 5 years) and inelastic subsidence of up to ½ foot per year were also considered acceptable in the July version of the draft plan, apparently due to an estimate that we still have 26-140 million AF (acre feet) of water in the aquifer. Consultants to the GGA suggest that 26M AF is reliably established, but the estimate of upwards of 140M AF is more of a projection. We are concerned about any reliance on the 140M AF estimate, and suggest that the subbasin should be more conservatively managed to an assumption of 26M AF.

3. We welcome the recent consultant proposal, adopted by the Board October 11th, to revise the plan with an amendment tightening the measurable objectives (MO) and minimum thresholds (MT) for inelastic subsidence, as the draft plan's original allowance for excessive subsidence would have exposed municipal services like water, wastewater and storm drainage to unacceptable risk of severe disruption.

4. City of Orland observes that the draft plan as written does not appear to adequately protect the integrity of domestic and municipal drinking water wells. With most said wells being less

than 200' deep, more than 20% would be dry by the time well depth MO were reached and almost all would be dry by the point MT were reached. It would seem that the MO and MT for well depths should be reconsidered and revised to a more conservative and protective standard.

5. Finally, we commend the GGA Board for its many projects in progress, planned and contemplated, as laid forth in Chapter 6. However, there do not yet appear to be real "triggers" that would commit the GGA to certain substantive actions when passing MO and approaching MT. We hope the GGA works with the State and consultants in coming years to develop and specify such triggers as a backstop to recharge projects in order to truly protect the precious drinking water resources on which the people of Orland and Glenn County rely.

Thank you for your consideration of our comments.

SUBJECT: Support for Groundwater Sustainability Plans and Concern about Groundwater Surface Water Interactions

---

Glenn-Colusa Irrigation District (GCID) is located in the heart of the Sacramento Valley; we are the largest and one of the oldest diverters of water from the Sacramento River. GCID diverts water from the Sacramento River through a 65-mile long irrigation canal into a complex system of nearly 500 miles of laterals. The water is delivered to more than 1,200 families who farm approximately 141,000 acres of valuable, productive agricultural land. More than $270 million of agricultural products are produced annually on Glenn-Colusa Irrigation District farms, helping to sustain an estimated 12,000 jobs in the region. GCID is also the sole source of surface water deliveries for three wildlife refuges – the Sacramento, Delevan and Colusa National Wildlife Refuges that comprise over 20,000 acres of critical wildlife habitat. Winter water supplied by GCID to thousands of acres of rice land also provides a rich oasis for migrating waterfowl.

GCID is an active member of the Colusa Groundwater Authority, the Glenn Groundwater Authority, and the Corning Subbasin Groundwater Sustainability Agency.

Support for Groundwater Sustainability Plans

GCID appreciates the opportunity to provide comment to your agency for Groundwater Sustainability Planning in the Sacramento Valley (Valley). As a member of three Groundwater Sustainability Agencies (GSAs) within the Valley, GCID staff have valued our participation in the development of two Draft Groundwater Sustainability Plans (GSPs) and support a collaborative approach to management across a shared resource. We support the adoption of the GSPs by each of the GSAs to meet the January 31, 2022, deadline and we look forward to continued participation during implementation.

Concern about Groundwater Surface Water Interactions

While we support the adoption of the GSPs, this communication serves as a formal written comment to highlight and express a particular area of concern that could lead

to the development of an incomplete decision framework and compromise the stability afforded to groundwater users in the various Sacramento Valley subbasins and more specifically to surface water users and senior water right holders which includes our District. We are writing to express deep concern regarding the lack of consideration in the GSPs about stream-aquifer interactions and impacts from unrestricted groundwater pumping.

This year in response to historically dry conditions, GCID and our fellow Sacramento River Settlement Contractors (SRSCs) took a multitude of voluntary actions significantly reducing the supply to our water users. These actions collaboratively supported watershed objectives in the face of declining storage and identified environmental concerns. While GCID and its partners were working daily for months with Central Valley Project (CVP) operators and State resource agencies to reduce surface water use and stabilize flows in the Sacramento River to help with Delta outflows and environmental needs, groundwater pumpers accessed the resource unabated impacting the stream flows we were actively working to stabilize.

As a significant contributor to groundwater recharge within the Valley, we only utilize that resource in years of shortage. We contribute every year to over 100,000 acre-feet (*Colusa GSP Draft, Appendix 3D, pg. 27*) of groundwater recharge even in Shasta critically dry years. However, we only utilize the resource when our surface water supplies are diminished by drought. Even with all of our voluntary surface water reductions in 2021, we only utilized 20,000 ac-ft of groundwater, while taking over 20,000 acres of land out of production to balance our supply and demand.

According to the Draft GSPs for Vina, Butte, Corning, and Colusa Subbasins, current year estimates of groundwater pumping, summarized in the table below, are over 1 million acre-feet per year (ac-ft/yr) in the region that surrounds our District.

Table 1, Groundwater Pumping in Subbasins in and around GCID (TAF)

	Historical	Current	Future, No Climate Change	Future, 2030 Climate Change	Future, 2070 Climate Change
Butte[a]	142.2	162.8	162.6	189.4	210.5
Vina[b]	243.5	209.2	215.8	225.9	238
Colusa[c]	502	499	499	525	559
Corning[d]	132.3	153		159.3	167.3
Totals (TAF)	***1020***	***1024***	***877.4***	***1099.6***	***1174.8***

Notes

[a]Butte Groundwater Sustainability Plan, Public Review Draft, Section 2, pg. 2-65

[b]Vina Groundwater Sustainability Plan, Public Final Draft, Section 2, pg. 82

[c]Colusa Groundwater Sustainability Plan, Final Draft Report, Section 3, pg. 3-96

[d]Corning Groundwater Sustainability Plan, Public Review Draft, Section 4, pg. 4-69

This groundwater pumping impacts groundwater storage as evidenced by declining groundwater levels and impacts surface-groundwater interactions as evidenced by decreased streamflow and more reaches becoming losing streams. These numbers

indicate a need to understand the origin of groundwater pumping and the potential impacts to the subbasins as water users pull from a shared resource. In looking at these pumping numbers, a particular concern that becomes palpable is that all the GSPs identify increased groundwater pumping which will result in groundwater storage impacts and will result in increased streamflow depletion.

After reviewing the documents, senior surface water rights holders and their operations seem to be a minor share of the use of the resource, but a significant contributor to the replenishment of the resource. We ask that as GSAs move from planning to implementation and continue to look for opportunities to leverage surface water over groundwater, you consider those members and partners with senior water rights and stable contracts that contribute to our shared aquifers and provide high quality environmental habitat. We look forward to better identifying and quantifying this benefit for the subbasins during implementation. Further, we ask that GSAs work with their County partners to consider land use planning and accountability.

Thank you for your consideration of these concerns. We urge you to consider language to address or at least acknowledge this issue in the GSPs. We look forward to working through this issue during implementation.

Re: Public Comment Letter for Colusa Subbasin Draft GSP

Dear Mary Fahey,

On behalf of the above-listed organizations, we appreciate the opportunity to comment on the Draft Groundwater Sustainability Plan (GSP) for the Colusa Subbasin being prepared under the Sustainable Groundwater Management Act (SGMA). Our organizations are deeply engaged in and committed to the successful implementation of SGMA because we understand that groundwater is critical for the resilience of California's water portfolio, particularly in light of changing climate. Under the requirements of SGMA, Groundwater Sustainability Agencies (GSAs) must consider the interests of all beneficial uses and users of groundwater, such as domestic well owners, environmental users, surface water users, federal government, California Native American tribes and disadvantaged communities (Water Code 10723.2).

As stakeholder representatives for beneficial users of groundwater, our GSP review focuses on how well disadvantaged communities, drinking water users, tribes, climate change, and the environment were addressed in the GSP. While we appreciate that some basins have consulted us directly via focus groups, workshops, and working groups, we are providing public comment letters to all GSAs as a means to engage in the development of 2022 GSPs across the state. Recognizing that GSPs are complicated and resource intensive to develop, the intention of this letter is to provide constructive stakeholder feedback that can improve the GSP prior to submission to the State.

Based on our review, we have significant concerns regarding the treatment of key beneficial users in the Draft GSP and consider the GSP to be **insufficient** under SGMA. We highlight the following findings:

1. Beneficial uses and users **are not sufficiently** considered in GSP development.
    a. Human Right to Water considerations **are not sufficiently** incorporated.
    b. Public trust resources **are not sufficiently** considered.
    c. Impacts of Minimum Thresholds, Measurable Objectives and Undesirable Results on beneficial uses and users **are not sufficiently** analyzed.
2. Climate change **is not sufficiently** considered.

3. Data gaps **are not sufficiently** identified and the GSP **does not have a plan** to eliminate them.
4. Projects and Management Actions **do not sufficiently consider** potential impacts or benefits to beneficial uses and users.

Our specific comments related to the deficiencies of the Colusa Subbasin Draft GSP along with recommendations on how to reconcile them, are provided in detail in **Attachment A.**

Please refer to the enclosed list of attachments for additional technical recommendations:

Attachment A	GSP Specific Comments
Attachment B	SGMA Tools to address DAC, drinking water, and environmental beneficial uses and users
Attachment C	Freshwater species located in the basin
Attachment D	The Nature Conservancy's "Identifying GDEs under SGMA: Best Practices for using the NC Dataset"
Attachment E	Maps of representative monitoring sites in relation to key beneficial users

Thank you for fully considering our comments as you finalize your GSP.

Attachment A

Specific Comments on the Colusa Subbasin Draft Groundwater Sustainability Plan

1. Consideration of Beneficial Uses and Users in GSP development

Consideration of beneficial uses and users in GSP development is contingent upon adequate identification and engagement of the appropriate stakeholders. The (A) identification, (B) engagement, and (C) consideration of disadvantaged communities, drinking water users, tribes,[1] groundwater dependent ecosystems, streams, wetlands, and freshwater species are essential for ensuring the GSP integrates existing state policies on the Human Right to Water and the Public Trust Doctrine.

A. Identification of Key Beneficial Uses and Users

Disadvantaged Communities, Drinking Water Users, and Tribes

The identification of Disadvantaged Communities (DACs), drinking water users, and tribes is **incomplete**. The GSP provides a map of tribal lands in the subbasin (Figure 2-5), and provides information on DACs, including identification by name and location on a map (Figure 2-6). However, the plan fails to clearly document the population of each DAC and the population dependent on groundwater as their source of drinking water in the subbasin.

While the plan provides a density map of domestic wells in the subbasin (Figure 2-7), the GSP fails to provide depth of these wells (such as minimum well depth, average well depth, or depth range) within the subbasin.

These missing elements are required for the GSAs to fully understand the specific interests and water demands of these beneficial users, and to support the consideration of beneficial users in the development of sustainable management criteria and selection of projects and management actions.

RECOMMENDATIONS

- Provide the population of each identified DAC. Identify the sources of drinking water for DAC members, including an estimate of how many people rely on groundwater (e.g., domestic wells, state small water systems, and public water systems).
- Include a map showing domestic well locations and average well depth across the subbasin (i.e., a map similar to Figure 2-7 showing average well depth per square mile).

[1] Our letter provides a review of the identification and consideration of federally recognized tribes (Data source: SGMA Data viewer) within the GSP from non-tribal members and NGOs. Based on the likely incomplete information available to our organizations for this review, we recommend that the GSA utilize the California Department of Water Resources' "Engagement with Tribal Governments" Guidance Document (https://water.ca.gov/Programs/Groundwater-Management/SGMA-Groundwater-Management/Best-Management-Practices-and-Guidance-Documents) to comprehensively address these important beneficial users in their GSP.

Interconnected Surface Waters

The identification of Interconnected Surface Waters (ISWs) is **insufficient**, due to lack of a comprehensive map of ISWs in the subbasin. Despite the lack of an ISW map, the GSP presents a thorough, comprehensive evaluation of ISWs in the subbasin as presented in Appendix 3G of the GSP (Evaluation of Depletions of Interconnected Surface Water in the Colusa Subbasin). Streamflow depletion in the Colusa Subbasin was evaluated using the C2VSimFG-Colusa model, an integrated hydrologic flow model for the subbasin. The model is described in Appendix 3D (Model Development and Calibration) and used groundwater and surface water data from 1990-2015. Appendix 3D describes the groundwater data used in the model, including spatial location of wells and screening depths. The ISW section of the GSP could be improved with the following recommendations.

RECOMMENDATIONS

- Provide a map showing all the stream reaches in the subbasin, with reaches clearly labeled as interconnected (gaining and losing) or disconnected. Consider any segments with data gaps as potential ISWs and clearly mark them as such on maps provided in the GSP.
- Discuss stream reaches in the interior of the subbasin. For example, discuss whether they were included in the groundwater model and discuss relevant depth to groundwater data. Clearly state that they are considered to be disconnected, if that is the case, and what data was utilized to support that conclusion.
- To confirm the results of the groundwater modeling analysis and support conclusions about the smaller interior stream reaches, overlay the stream reaches shown with depth-to-groundwater contour maps to illustrate groundwater depths and the groundwater gradient near the stream reaches. For the depth-to-groundwater contour maps, use the best practices presented in Attachment D. Specifically, ensure that the first step is contouring groundwater elevations, and then subtracting this layer from land surface elevations from a Digital Elevation Model (DEM) to estimate depth-to-groundwater contours across the landscape. This will provide accurate contours of depth to groundwater along streams and other land surface depressions where GDEs are commonly found.

Groundwater Dependent Ecosystems

The identification of Groundwater Dependent Ecosystems (GDEs) is **insufficient**. The GSP took initial steps to identify and map GDEs using the Natural Communities Commonly Associated with Groundwater dataset (NC dataset). However, we found that some mapped features in the NC dataset were improperly disregarded. NC dataset polygons were incorrectly removed in areas adjacent to irrigated fields or due to the presence of surface water supplies. However, this removal criteria is flawed since GDEs, in addition to groundwater, can rely on multiple water sources – including shallow groundwater receiving inputs from irrigation return flow from nearby irrigated fields – simultaneously and at different temporal/spatial scales. NC dataset polygons adjacent to irrigated land or surface water supplies can still potentially be reliant on shallow groundwater aquifers, and therefore should not be removed solely based on their proximity to irrigated fields or surface water supplies.

The GSP states (3-82): "*Average spring groundwater level data from 2014 to 2018 indicates that shallow groundwater levels (i.e., within 30 feet of ground surface) exists throughout most of the*

subbasin. A depth to water (DTW) of 30 feet based on the average DTW for 2014 to 2018 was used as one of the primary criteria in the initial screening of potential GDEs." While we recognize that the period 2014-2018 represents multiple water year types, we recommend that a longer baseline period (10 years from 2005 to 2015) be established to characterize groundwater conditions.

The GSP does not provide an inventory of the flora or fauna species present in the subbasin's GDEs, except to discuss the four most prevalent vegetation species. Furthermore, the GSP does not acknowledge endangered, threatened, or special status species in the subbasin.

RECOMMENDATIONS

- Provide a comprehensive set of maps for the subbasin's GDEs. For example, provide a map of the NC Dataset. On the map, label polygons retained, removed, or added to/from the NC dataset (include the removal reason if polygons are not considered potential GDEs, or include the data source if polygons are added). Discuss how local groundwater data was used to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer. Refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer.

- Use depth-to-groundwater data from multiple seasons and water year types (e.g., wet, dry, average, drought) to determine the range of depth to groundwater around NC dataset polygons. We recommend that a baseline period (10 years from 2005 to 2015) be established to characterize groundwater conditions over multiple water year types. Refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer.

- Provide depth-to-groundwater contour maps, noting the best practices presented in Attachment D. Specifically, ensure that the first step is contouring groundwater elevations, and then subtracting this layer from land surface elevations from a DEM to estimate depth-to-groundwater contours across the landscape.

- If insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons as "Potential GDEs" in the GSP until data gaps are reconciled in the monitoring network. It is not clear from the description in the GSP whether NC dataset polygons labeled with a 'GDE Likelihood Score' of 1 to 3 on Figure 3-36 are retained as potential GDEs.

- Include an inventory of the fauna and flora present within the subbasin's GDEs (see Attachment C of this letter for a list of freshwater species located in the Colusa Subbasin). Note any threatened or endangered species.

Native Vegetation and Managed Wetlands
Native vegetation and managed wetlands are water use sectors that are required to be included in the water budget.[2,3] The integration of these ecosystems into the water budget is **sufficient** because the GSP included the groundwater demands of native vegetation and managed wetlands in the historical, current, and projected water budgets.

B. Engaging Stakeholders

Stakeholder Engagement during GSP Development
Stakeholder engagement during GSP development is **insufficient**. SGMA's requirement for public notice and engagement of stakeholders is not fully met by the description in the Stakeholder Communication and Engagement Plan (Appendix 2E).[4]

We note the following deficiencies with the overall stakeholder engagement process:

- The opportunities for public involvement and engagement with DACs, drinking water users, tribes, and environmental stakeholders are described in very general terms. They include technical and informational workshops and meetings open to the public. No specific outreach targeted to DACs, drinking water users, tribes, or environmental stakeholders is described in the GSP.

- The plan does not include a plan for continual opportunities for engagement through the *implementation* phase of the GSP for DACs, domestic well owners, tribes, and environmental stakeholders.

RECOMMENDATIONS

- In the Stakeholder Communication and Engagement Plan, describe active and targeted outreach to engage DACs, drinking water users, tribes, and environmental stakeholders throughout the GSP development and implementation phases. Refer to Attachment B for specific recommendations on how to actively engage stakeholders during all phases of the GSP process.

- Describe efforts to consult and engage with DACs and domestic well owners within the subbasin.

[2] "'Water use sector' refers to categories of water demand based on the general land uses to which the water is applied, including urban, industrial, agricultural, managed wetlands, managed recharge, and native vegetation." [23 CCR §351(al)]
[3] "The water budget shall quantify the following, either through direct measurements or estimates based on data: (3) Outflows from the groundwater system by water use sector, including evapotranspiration, groundwater extraction, groundwater discharge to surface water sources, and subsurface groundwater outflow." [23 CCR §354.18]
[4] "A communication section of the Plan shall include a requirement that the GSP identify how it encourages the active involvement of diverse social, cultural, and economic elements of the population within the basin." [23 CCR §354.10(d)(3)]

- Utilize DWR's tribal engagement guidance to comprehensively address all tribes and tribal interests in the subbasin within the GSP.[5]
- Describe efforts to consult and engage with environmental stakeholders within the subbasin.

C. Considering Beneficial Uses and Users When Establishing Sustainable Management Criteria and Analyzing Impacts on Beneficial Uses and Users

The consideration of beneficial uses and users when establishing sustainable management criteria (SMC) is **insufficient**. The consideration of potential impacts on all beneficial users of groundwater in the basin are required when defining undesirable results and establishing minimum thresholds.[6,7,8]

Disadvantaged Communities and Drinking Water Users

For chronic lowering of groundwater levels, the minimum threshold at representative monitoring wells is calculated by finding the deeper value of: (1) 20th percentile of shallowest domestic well depths in the monitoring well's Thiessen polygon, and (2) 50% of range below the historical low groundwater elevation. The GSP states (p. 5-20): *"The GSAs chose this methodology for calculating the minimum threshold to balance the needs of multiple beneficial uses and users of the groundwater by allowing for adequate flexibility to compensate for drought periods while potentially protecting up to 80 percent of nearby domestic wells, therefore avoiding undesirable results. Additionally, anecdotal evidence provided by the GSA member stakeholders suggest that groundwater levels seen in 2015 did not result in significant and unreasonable impacts to beneficial uses and users. Although some wells in that period were dewatered, those wells were generally replaced with deeper wells. The GSAs therefore consider the historical low groundwater elevation to be protective of current and future beneficial uses and users."* Despite this analysis, the GSP does not sufficiently describe whether minimum thresholds will avoid significant and unreasonable loss of drinking water to domestic well users in those 20% not protected by the minimum threshold, and whether the undesirable results are consistent with the Human Right to Water policy.[9]

In addition, the GSP does not sufficiently describe or analyze direct or indirect impacts on DACs or tribes when defining undesirable results, nor does it describe how the groundwater levels minimum threshold will avoid significant and unreasonable impacts on beneficial users beyond 2015 and be consistent with Human Right to Water policy.

Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Sustainable-Groundwater-Management/Best-Management-Practices-and-Guidance-Documents/Files/Guidance-Doc-for-SGM-Engagement-with-Tribal-Govt_ay_19.pdf

[6] "The description of undesirable results shall include [...] potential effects on the beneficial uses and users of groundwater, on land uses and property interests, and other potential effects that may occur or are occurring from undesirable results." [23 CCR §354.26(b)(3)]

[7] "The description of minimum thresholds shall include [...] how minimum thresholds may affect the interests of beneficial uses and users of groundwater or land uses and property interests." [23 CCR §354.28(b)(4)]

[8] "The description of minimum thresholds shall include [...] how state, federal, or local standards relate to the relevant sustainability indicator. If the minimum threshold differs from other regulatory standards, the agency shall explain the nature of and the basis for the difference." [23 CCR §354.28(b)(5)]

[9] California Water Code §106.3. Available at: https://leginfo.legislature.ca.gov/faces/codes_displaySection.xhtml?lawCode=WAT&sectionNum=106.3

The GSP states (3-67): *"Groundwater quality concerns within the Colusa Subbasin include locally elevated levels of salinity, TDS, adjusted sodium absorption ratio, arsenic, boron, hexavalent chromium, iron, manganese, and nitrate."* However, for degraded water quality, salinity is the only constituent of concern (COC) for which SMC are established in the subbasin. The minimum threshold for salinity has been established for electrical conductivity (EC) as the higher of either the recommended California Secondary Maximum Contaminant Level (SMCL), or the pre-2015 historical maximum recorded EC value. The use of the latter term, with no values associated with it, is inappropriate; the Plan must provide actual historical data identifying what this minimum threshold would be. Furthermore, this value should not in any case exceed the salinity objective in the Basin Plan.

The GSP states (5-11): *"Existing regulatory programs address most water quality concerns, and the CGA and GGA will coordinate with these programs, the lead regulatory agencies, and the regulated community within the Colusa Subbasin during implementation of this GSP, including during development and implementation of projects and management actions."* However, SMC should be established for all COCs in the subbasin impacted or exacerbated by groundwater use and/or management, in addition to coordinating with water quality regulatory programs.

RECOMMENDATIONS

Chronic Lowering of Groundwater Levels

- Describe direct and indirect impacts on drinking water users, DACs, and tribes when describing undesirable results and defining minimum thresholds for chronic lowering of groundwater levels.

Degraded Water Quality

- Describe direct and indirect impacts on drinking water users, DACs, and tribes when defining undesirable results for degraded water quality. For specific guidance on how to consider these users, refer to "Guide to Protecting Water Quality Under the Sustainable Groundwater Management Act."[10]
- Evaluate the cumulative or indirect impacts of proposed minimum thresholds for degraded water quality on drinking water users, DACs, and tribes.
- For EC, provide a summary table that presents the pre-2015 historical maximums, the salinity objective from the Basin Plan, the SMCL, and the resulting minimum thresholds. Ensure that the minimum thresholds do not exceed the salinity objective in the Basin Plan.
- Set minimum thresholds and measurable objectives for all water quality constituents within the subbasin that can be impacted and/or exacerbated as a result of groundwater use or groundwater management. Ensure they align with drinking water standards.[11]

[10] Guide to Protecting Water Quality under the Sustainable Groundwater Management Act https://d3n8a8pro7vhmx.cloudfront.net/communitywatercenter/pages/293/attachments/original/1559328858/Guide_to_Protecting_Drinking_Water_Quality_Under_the_Sustainable_Groundwater_Management_Act.pdf?1559328858.

[11] "Degraded Water Quality [...] collect sufficient spatial and temporal data from each applicable principal aquifer to determine groundwater quality trends for water quality indicators, as determined by the Agency, to address known water quality issues." [23 CCR §354.34(c)(4)]

Groundwater Dependent Ecosystems and Interconnected Surface Waters

Sustainable management criteria for chronic lowering of groundwater levels provided in the GSP do not consider potential impacts to environmental beneficial users. The GSP neither describes nor analyzes direct or indirect impacts on environmental users of groundwater when defining undesirable results. This is problematic because without identifying potential impacts to GDEs, minimum thresholds may compromise, or even destroy, these environmental beneficial users. Since GDEs are present in the subbasin, they must be considered when developing SMC for chronic lowering of groundwater levels.

Sustainable management criteria for depletion of interconnected surface water are established by proxy using groundwater levels at existing monitoring wells with locations and depths considered appropriate for monitoring groundwater with potential to influence interconnected streams. Minimum thresholds were established at groundwater levels that are 10 feet deeper than the observed Fall 2015 water level. However, if minimum thresholds are set to levels lower than historic low groundwater levels and the subbasin is allowed to operate at or close to those levels over many years, there is a risk of causing catastrophic damage to ecosystems that are more adverse than what was occurring at the height of the 2012-2016 drought. This is because California ecosystems, which are adapted to our Mediterranean climate, have some drought strategies that they can utilize to deal with short-term water stress. However, if the drought conditions are prolonged, the ecosystem can collapse.

No analysis or discussion is presented to describe how the SMC will affect GDEs, or the impact of these minimum thresholds on GDEs in the subbasin. Furthermore, the GSP makes no attempt to evaluate the impacts of the proposed minimum threshold on environmental beneficial users of surface water. The GSP does not explain how the chosen minimum thresholds and measurable objectives avoid significant and unreasonable effects on surface water beneficial users in the subbasin, such as increased mortality and inability to perform key life processes (e.g., reproduction, migration).

RECOMMENDATIONS

- When defining undesirable results for chronic lowering of groundwater levels, provide specifics on what biological responses (e.g., extent of habitat, growth, recruitment rates) would best characterize a significant and unreasonable impact to GDEs. Undesirable results to environmental users occur when ‘significant and unreasonable’ effects on beneficial users are caused by one of the sustainability indicators (i.e., chronic lowering of groundwater levels, degraded water quality, or depletion of interconnected surface water). Thus, potential impacts on environmental beneficial uses and users need to be considered when defining undesirable results in the subbasin.[12] Defining undesirable results is the crucial first step before the minimum thresholds can be determined.[13]

- When establishing SMC for the subbasin, consider that the SGMA statute [Water Code §10727.4(l)] specifically calls out that GSPs shall include “impacts on groundwater dependent ecosystems”.

[12] “The description of undesirable results shall include [...] potential effects on the beneficial uses and users of groundwater, on land uses and property interests, and other potential effects that may occur or are occurring from undesirable results”. [23 CCR §354.26(b)(3)]

[13] The description of minimum thresholds shall include [...] how minimum thresholds may affect the interests of beneficial uses and users of groundwater or land uses and property interests.” [23 CCR §354.28(b)(4)]

- When defining undesirable results for depletion of interconnected surface water, include a description of potential impacts on instream habitats within ISWs when minimum thresholds in the subbasin are reached.[14] The GSP should confirm that minimum thresholds for ISWs avoid adverse impacts to environmental beneficial users of interconnected surface waters as these environmental users could be left unprotected by the GSP. These recommendations apply especially to environmental beneficial users that are already protected under pre-existing state or federal law.[6,15]

2. Climate Change

The SGMA statute identifies climate change as a significant threat to groundwater resources and one that must be examined and incorporated in the GSPs. The GSP Regulations require integration of climate change into the projected water budget to ensure that projects and management actions sufficiently account for the range of potential climate futures.[16] The effects of climate change will intensify the impacts of water stress on GDEs, making available shallow groundwater resources especially critical to their survival. Condon *et al.* (2020) shows that GDEs are more likely to succumb to water stress and rely more on groundwater during times of drought.[17] When shallow groundwater is unavailable, riparian forests can die off and key life processes (e.g., migration and spawning) for aquatic organisms, such as steelhead, can be impeded.

The integration of climate change into the projected water budget is **insufficient**. The GSP incorporates climate change into the projected water budget using DWR change factors for 2030 and 2070. However, the plan does not consider multiple climate scenarios (e.g., the 2070 extremely wet and extremely dry climate scenarios) in the projected water budget. The GSP should clearly and transparently incorporate the extremely wet and dry scenarios provided by DWR into projected water budgets or select more appropriate extreme scenarios for the subbasin. While these extreme scenarios may have a lower likelihood of occurring, their consequences could be significant and their inclusion can help identify important vulnerabilities in the subbasin's approach to groundwater management.

The GSP incorporates climate change into key inputs of (e.g., precipitation and evapotranspiration) of the projected water budget. However, imported water should also be adjusted for climate change and incorporated into the surface water flow inputs of the projected water budget. The sustainable yield is calculated based on the projected water budget with climate change incorporated. However, if the water budgets are incomplete, including the omission of extremely wet and dry scenarios and the omission of projected climate change effects on imported water inputs, then there is increased uncertainty in virtually every subsequent calculation used to plan for projects, derive measurable objectives, and set minimum thresholds. Plans that do not adequately include climate change projections may underestimate future

[14] "The minimum threshold for depletions of interconnected surface water shall be the rate or volume of surface water depletions caused by groundwater use that has adverse impacts on beneficial uses of the surface water and may lead to undesirable results." [23 CCR §354.28(c)(6)]

[15] Rohde MM, Seapy B, Rogers R, Castañeda X, editors. 2019. Critical Species LookBook: A compendium of California's threatened and endangered species for sustainable groundwater management. The Nature Conservancy, San Francisco, California. Available at: https://groundwaterresourcehub.org/public/uploads/pdfs/Critical_Species_LookBook_91819.pdf

[16] "Each Plan shall rely on the best available information and best available science to quantify the water budget for the basin in order to provide an understanding of historical and projected hydrology, water demand, water supply, land use, population, climate change, sea level rise, groundwater and surface water interaction, and subsurface groundwater flow." [23 CCR §354.18(e)]

[17] Condon et al. 2020. Evapotranspiration depletes groundwater under warming over the contiguous United States. Nature Communications. Available at: https://www.nature.com/articles/s41467-020-14688-0

impacts on vulnerable beneficial users of groundwater such as ecosystems, DACs, domestic well owners, and tribes.

RECOMMENDATIONS

- Integrate climate change, including extremely wet and dry scenarios, into all elements of the projected water budget to form the basis for development of sustainable management criteria and projects and management actions.
- Incorporate climate change into surface water flow inputs, including imported water, for the projected water budget.
- Incorporate climate change scenarios into projects and management actions.

3. Data Gaps

The consideration of beneficial users when establishing monitoring networks is **insufficient**, due to lack of specific plans to increase the Representative Monitoring Sites (RMSs) in the monitoring network that represent water quality conditions and shallow groundwater elevations around DACs, domestic wells, tribes, GDEs, and ISWs in the subbasin.

Figure 4-6 (Representative Groundwater Level Monitoring Network) shows insufficient representation of drinking water users and tribal users for groundwater elevation monitoring. Figure 4-7 (Representative Groundwater Quality Monitoring Network) shows insufficient representation of DACs and tribal users for water quality monitoring. Refer to Attachment E for maps of these monitoring sites in relation to key beneficial users of groundwater. These beneficial users may remain unprotected by the GSP without adequate monitoring and identification of data gaps in the shallow aquifer. The Plan therefore fails to meet SGMA's requirements for the monitoring network.[18]

The GSP provides some discussion of data gaps for GDEs and ISWs in Sections 4.2.4.5 (Proposed Actions to Address Data Gaps) and Section 7.1.2.1 (Expand Shallow Groundwater Level Monitoring Network), but does not provide specific plans, such as locations or a timeline, to fill the data gaps.

RECOMMENDATIONS

- Provide maps that overlay current and proposed monitoring well locations with the locations of DACs, domestic wells, tribes, GDEs, and ISWs to clearly identify potentially impacted areas.
- Increase the number of RMSs in the shallow aquifer across the subbasin as needed to adequately monitor all groundwater condition indicators across the subbasin and at appropriate depths for *all* beneficial users. Prioritize proximity to DACs, domestic wells, tribes, and GDEs when identifying new RMSs.

[18] "The monitoring network objectives shall be implemented to accomplish the following: [...] (2) Monitor impacts to the beneficial uses or users of groundwater." [23 CCR §354.34(b)(2)]

- Ensure groundwater elevation and water quality RMSs are monitoring groundwater conditions spatially and at the correct depth for *all* beneficial users - especially DACs, domestic wells, tribes, and GDEs.

- Describe biological monitoring that can be used to assess the potential for significant and unreasonable impacts to GDEs or ISWs due to groundwater conditions in the subbasin.

4. Addressing Beneficial Users in Projects and Management Actions

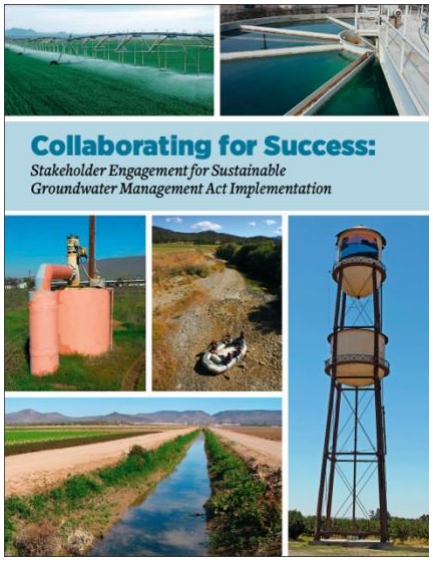
The consideration of beneficial users when developing projects and management actions is **insufficient** due to the failure to completely identify benefits or impacts of identified projects and management actions, including water quality impacts, to key beneficial users of groundwater such as GDEs, aquatic habitats, surface water users, DACs, drinking water users, and tribes. Therefore, potential project and management actions may not protect these beneficial users. Groundwater sustainability under SGMA is defined not just by sustainable yield, but by the avoidance of undesirable results for *all* beneficial users.

We commend the GSAs for including the Colusa Subbasin Multi-Benefit Groundwater Recharge project, developed in partnership with The Nature Conservancy. The GSP describes the multiple benefits of this project, including benefits to migratory shorebirds, DACs, private landowners, and groundwater conditions.

The GSP includes a domestic well mitigation program. However, the mitigation program is described as a potential project to be implemented on an as-needed basis instead of a proposed project that will be implemented within the GSP planning horizon.

RECOMMENDATIONS

- Clarify the planning horizon of the described domestic well mitigation program to ensure that it will proactively monitor and protect drinking water wells through GSP implementation. Refer to Attachment B for specific recommendations on how to implement a drinking water well mitigation program.



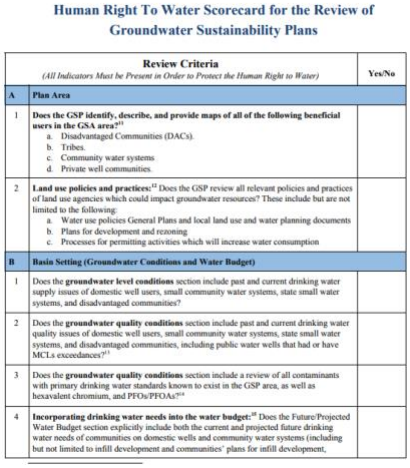
- For DACs and domestic well owners, include a discussion of whether potential impacts to water quality from projects and management actions could occur and how the GSAs plans to mitigate such impacts.

- Develop management actions that incorporate climate and water delivery uncertainties to address future water demand and prevent future undesirable results.

Attachment B

SGMA Tools to address DAC, drinking water, and environmental beneficial uses and users

Stakeholder Engagement and Outreach



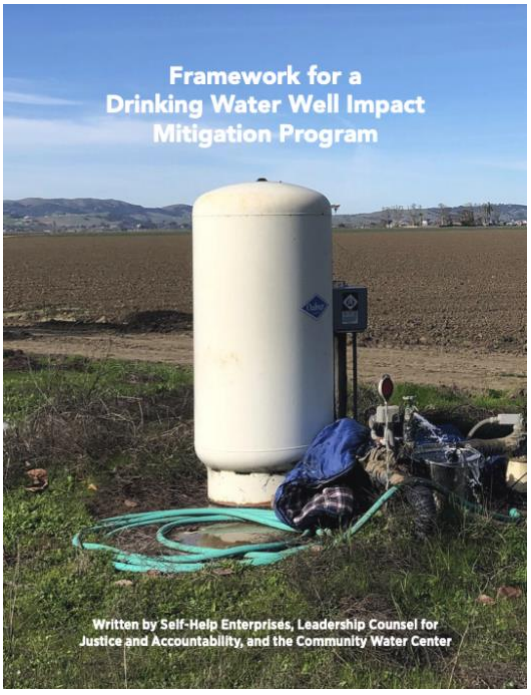
Clean Water Action, Community Water Center and Union of Concerned Scientists developed a guidance document called Collaborating for success: Stakeholder engagement for Sustainable Groundwater Management Act Implementation. It provides details on how to conduct targeted and broad outreach and engagement during Groundwater Sustainability Plan (GSP) development and implementation. Conducting a targeted outreach involves:

- Developing a robust Stakeholder Communication and Engagement plan that includes outreach at frequented locations (schools, farmers markets, religious settings, events) across the plan area to increase the involvement and participation of disadvantaged communities, drinking water users and the environmental stakeholders.

- Providing translation services during meetings and technical assistance to enable easy participation for non-English speaking stakeholders.

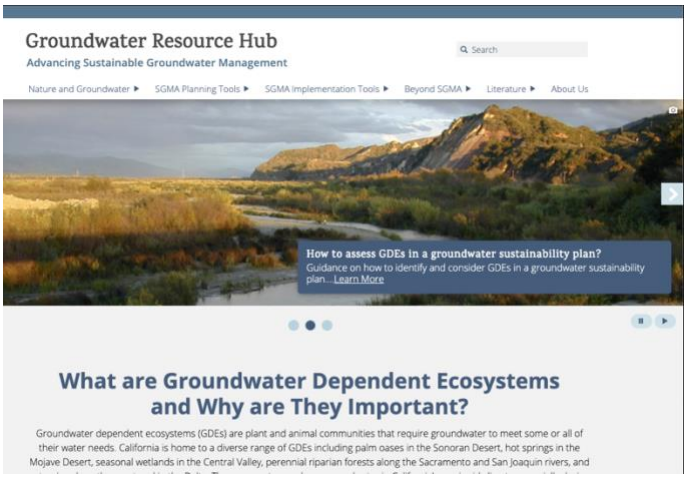
- GSP should adequately describe the process for requesting input from beneficial users and provide details on how input is incorporated into the GSP.

The Human Right to Water



Human Right To Water Scorecard for the Review of Groundwater Sustainability Plans

	Review Criteria *(All Indicators Must be Present in Order to Protect the Human Right to Water)*	Yes/No
A	**Plan Area**	
1	**Does the GSP identify, describe, and provide maps of all of the following beneficial users in the GSA area?**[43] a. Disadvantaged Communities (DACs). b. Tribes. c. Community water systems. d. Private well communities.	
2	**Land use policies and practices:**[44] Does the GSP review all relevant policies and practices of land use agencies which could impact groundwater resources? These include but are not limited to the following: a. Water use policies General Plans and local land use and water planning documents b. Plans for development and rezoning c. Processes for permitting activities which will increase water consumption	
B	**Basin Setting (Groundwater Conditions and Water Budget)**	
1	Does the **groundwater level conditions** section include past and current drinking water supply issues of domestic well users, small community water systems, state small water systems, and disadvantaged communities?	
2	Does the **groundwater quality conditions** section include past and current drinking water quality issues of domestic well users, small community water systems, state small water systems, and disadvantaged communities, including public water wells that had or have MCLs exceedances?[45]	
3	Does the **groundwater quality conditions** section include a review of all contaminants with primary drinking water standards known to exist in the GSP area, as well as hexavalent chromium, and PFOs/PFOAs?[46]	
4	**Incorporating drinking water needs into the water budget:**[48] Does the Future/Projected Water Budget section explicitly include both the current and projected future drinking water needs of communities on domestic wells and community water systems (including but not limited to infill development and communities' plans for infill development,	



The Human Right to Water Scorecard was developed by Community Water Center, Leadership Counsel for Justice and Accountability and Self Help Enterprises to aid Groundwater Sustainability Agencies (GSAs) in prioritizing drinking water needs in SGMA. The scorecard identifies elements that must exist in GSPs to adequately protect the Human Right to Drinking water.

Drinking Water Well Impact Mitigation Framework

The Drinking Water Well Impact Mitigation Framework was developed by Community Water Center, Leadership Counsel for Justice and Accountability and Self Help Enterprises to aid GSAs in the development and implementation of their GSPs. The framework provides a clear roadmap for how a GSA can best structure its data gathering, monitoring network and management actions to proactively monitor and protect drinking water wells and mitigate impacts should they occur.

Groundwater Resource Hub

The Nature Conservancy has developed a suite of tools based on best available science to help GSAs, consultants, and stakeholders efficiently incorporate nature into GSPs. These tools and resources are available online at GroundwaterResourceHub.org. The Nature Conservancy's tools and resources are intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

Rooting Depth Database

The Plant Rooting Depth Database provides information that can help assess whether groundwater-dependent vegetation are accessing groundwater. Actual rooting depths will depend on the plant species and site-specific conditions, such as soil type and

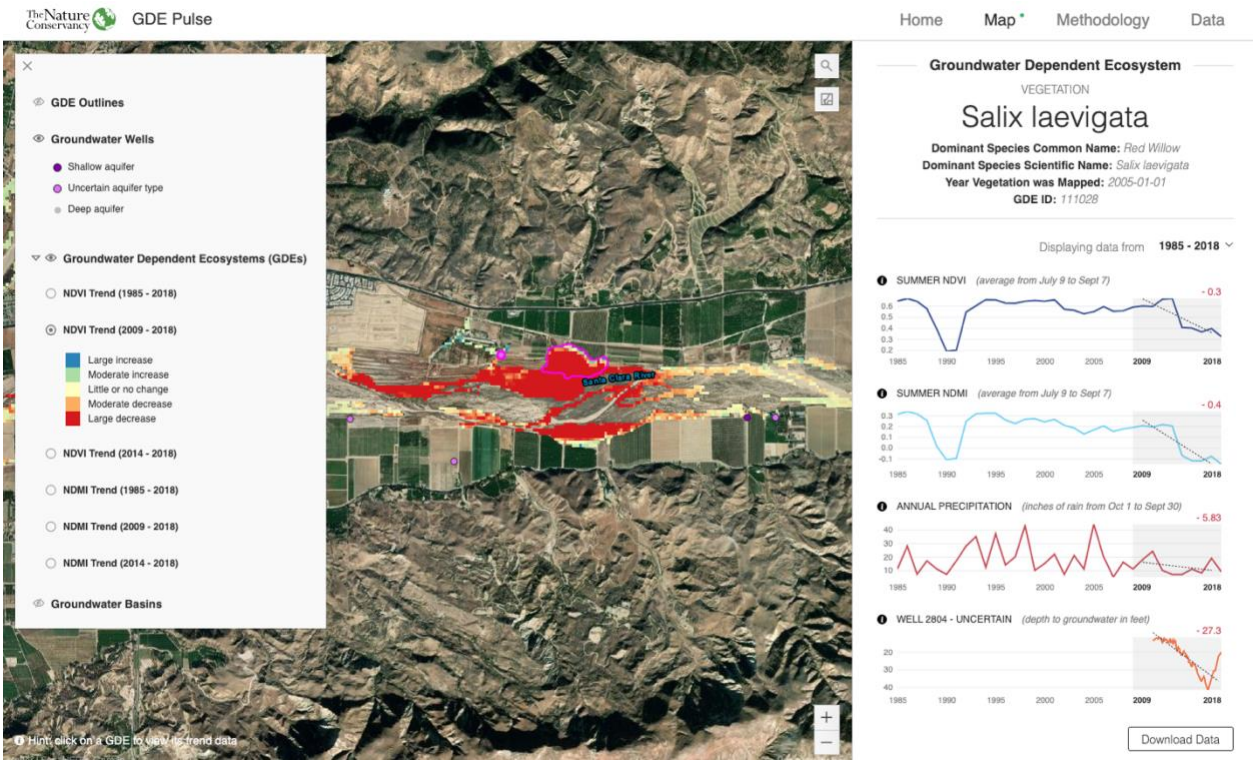
availability of other water sources. Site-specific knowledge of depth to groundwater combined with rooting depths will help provide an understanding of the potential groundwater levels are needed to sustain GDEs.

How to use the database

The maximum rooting depth information in the Plant Rooting Depth Database is useful when verifying whether vegetation in the Natural Communities Commonly Associated with Groundwater (NC Dataset) are connected to groundwater. A 30 ft depth-to-groundwater threshold, which is based on averaged global rooting depth data for phreatophytes[1], is relevant for most plants identified in the NC Dataset since most plants have a max rooting depth of less than 30 feet. However, it is important to note that deeper thresholds are necessary for other plants that have reported maximum root depths that exceed the averaged 30 feet threshold, such as valley oak (*Quercus lobata*), Euphrates poplar (*Populus euphratica*), salt cedar (*Tamarix spp.*), and shadescale (*Atriplex confertifolia*). The Nature Conservancy advises that the reported max rooting depth for these deeper-rooted plants be used. For example, a depth-to groundwater threshold of 80 feet should be used instead of the 30 ft threshold, when verifying whether valley oak polygons from the NC Dataset are connected to groundwater. It is important to re-emphasize that actual rooting depth data are limited and will depend on the plant species and site-specific conditions such as soil and aquifer types, and availability to other water sources.

The Plant Rooting Depth Database is an Excel workbook composed of four worksheets:

1. California phreatophyte rooting depth data (included in the NC Dataset)
2. Global phreatophyte rooting depth data
3. Metadata
4. References



How the database was compiled

The Plant Rooting Depth Database is a compilation of rooting depth information for the groundwater-dependent plant species identified in the NC Dataset. Rooting depth data were compiled from published scientific literature and expert opinion through a crowdsourcing campaign. As more information becomes available, the database of rooting depths will be updated. Please Contact Us if you have additional rooting depth data for California phreatophytes.

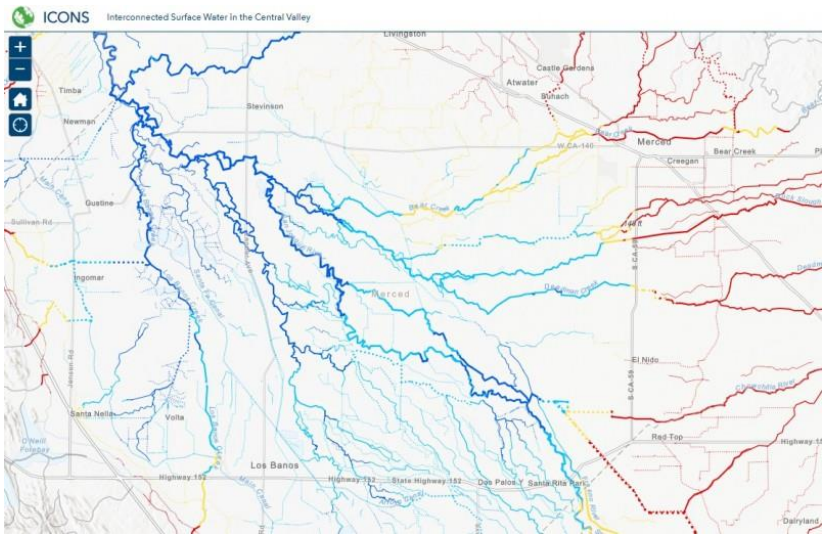
[1] Canadell, J., Jackson, R.B., Ehleringer, J.B. et al. 1996. Maximum rooting depth of vegetation types at the global scale. Oecologia 108, 583–595. https://doi.org/10.1007/BF00329030

GDE Pulse

GDE Pulse is a free online tool that allows Groundwater Sustainability Agencies to assess changes in groundwater dependent ecosystem (GDE) health using satellite, rainfall, and groundwater data. Remote sensing data from satellites has been used to monitor the health of vegetation all over the planet. GDE pulse has compiled 35 years of satellite imagery from NASA's Landsat mission for every polygon in the Natural Communities Commonly Associated with Groundwater Dataset. The following datasets are available for downloading:

Normalized Difference Vegetation Index (NDVI) is a satellite-derived index that represents the greenness of vegetation. Healthy green vegetation tends to have a higher NDVI, while dead leaves have a lower NDVI. We calculated the average NDVI during the driest part of the year (July - Sept) to estimate vegetation health when the plants are most likely dependent on groundwater.



Normalized Difference Moisture Index (NDMI) is a satellite-derived index that represents water content in vegetation. NDMI is derived from the Near-Infrared (NIR) and Short-Wave Infrared (SWIR) channels. Vegetation with adequate access to water tends to have higher NDMI, while vegetation that is water stressed tends to have lower NDMI. We calculated the average NDVI during the driest part of the year (July–September) to estimate vegetation health when the plants are most likely dependent on groundwater.

Annual Precipitation is the total precipitation for the water year (October 1st – September 30th) from the PRISM dataset. The amount of local precipitation can affect vegetation with more precipitation generally leading to higher NDVI and NDMI.

Depth to Groundwater measurements provide an indication of the groundwater levels and changes over time for the surrounding area. We used groundwater well measurements from nearby (<1km) wells to estimate the depth to groundwater below the GDE based on the average elevation of the GDE (using a digital elevation model) minus the measured groundwater surface elevation.

ICONOS Mapper

Interconnected Surface Water in the Central Valley

ICONS maps the likely presence of interconnected surface water (ISW) in the Central Valley using depth to groundwater data. Using data from 2011-2018, the ISW dataset represents the likely connection between surface water and groundwater for rivers and streams in California's Central Valley. It includes information on the mean, maximum, and minimum depth to groundwater for each stream segment over the years with available data, as well as the likely presence of ISW based on the minimum depth to groundwater. The Nature Conservancy developed this database, with guidance and input from expert academics, consultants, and state agencies.

We developed this dataset using groundwater elevation data available online from the California Department of Water Resources (DWR). DWR only provides this data for the Central Valley. For GSAs outside of the valley, who have groundwater well measurements, we recommend following our methods to determine likely ISW in your region. The Nature Conservancy's ISW dataset should be used as a first step in reviewing ISW and should be supplemented with local or more recent groundwater depth data.

Attachment C

Freshwater Species Located in the Colusa Subbasin

To assist in identifying the beneficial users of surface water necessary to assess the undesirable result "depletion of interconnected surface waters", Attachment C provides a list of freshwater species located in the Colusa Subbasin. To produce the freshwater species list, we used ArcGIS to select features within the California Freshwater Species Database version 2.0.9 within the basin boundary. This database contains information on ~4,000 vertebrates, macroinvertebrates and vascular plants that depend on fresh water for at least one stage of their life cycle. The methods used to compile the California Freshwater Species Database can be found in Howard et al. 2015[1]. The spatial database contains locality observations and/or distribution information from ~400 data sources. The database is housed in the California Department of Fish and Wildlife's BIOS[2] as well as on The Nature Conservancy's science website[3].

Scientific Name	Common Name	Legal Protected Status		
		Federal	State	Other
BIRDS				
Agelaius tricolor	Tricolored Blackbird	Bird of Conservation Concern	Special Concern	BSSC - First priority
Coccyzus americanus occidentalis	Western Yellow-billed Cuckoo	Candidate - Threatened	Endangered	
Egretta thula	Snowy Egret			
Nycticorax nycticorax	Black-crowned Night-Heron			
Pandion haliaetus	Osprey		Watch list	
Riparia riparia	Bank Swallow		Threatened	
Actitis macularius	Spotted Sandpiper			
Aechmophorus clarkii	Clark's Grebe			
Aechmophorus occidentalis	Western Grebe			
Aix sponsa	Wood Duck			
Anas acuta	Northern Pintail			
Anas americana	American Wigeon			
Anas clypeata	Northern Shoveler			
Anas crecca	Green-winged Teal			
Anas cyanoptera	Cinnamon Teal			
Anas discors	Blue-winged Teal			
Anas platyrhynchos	Mallard			
Anas strepera	Gadwall			
Anser albifrons	Greater White-fronted Goose			
Ardea alba	Great Egret			
Ardea herodias	Great Blue Heron

IDENTIFYING GDEs UNDER SGMA

Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online[1] to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)[2]. This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.

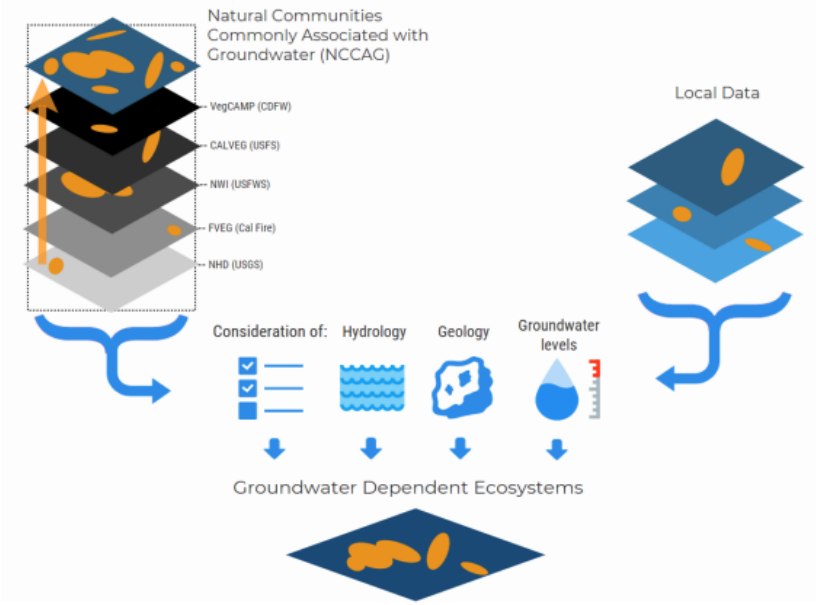

Figure 1. Considerations for GDE identification.
Source: DWR[2]

[1] NC Dataset Online Viewer: https://gis.water.ca.gov/app/NCDatasetViewer/
[2] California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf

The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48 publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California[3]. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset[4] on the Groundwater Resource Hub[5], a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer*.

[3] For more details on the mapping methods, refer to: Klausmeyer, K., J. Howard, T. Keeler-Wolf, K. Davis-Fadtke, R. Hull, A. Lyons. 2018. Mapping Indicators of Groundwater Dependent Ecosystems in California: Methods Report. San Francisco, California. Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. **(b)** Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. **Bottom: (c)** Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem's connection to groundwater. **(d)** Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California's climate. DWR's Best Management Practices document on water budgets[6] recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline[7] could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach[8] for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC's GDE guidance document[4], one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California's Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California's GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet[4] of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer[9]. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP until data gaps are reconciled in the monitoring network (see Best Practice #6).

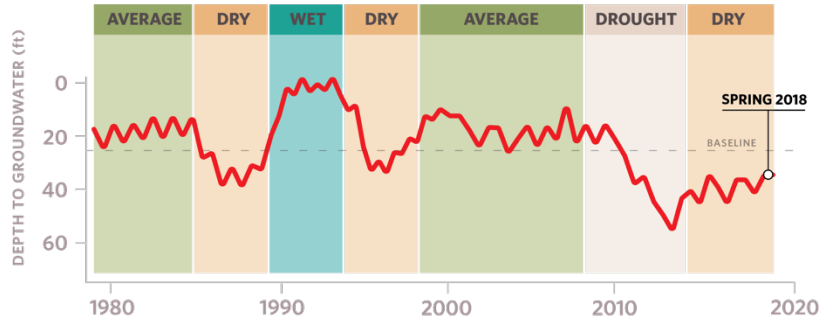

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

[6] DWR. 2016. Water Budget Best Management Practice. Available at: https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_Water_Budget_Final_2016-12-23.pdf

[7] Baseline is defined under the GSP regulations as "historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin." [23 CCR §351(e)]

[8] Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs[4]).

[9] SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals[10], which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

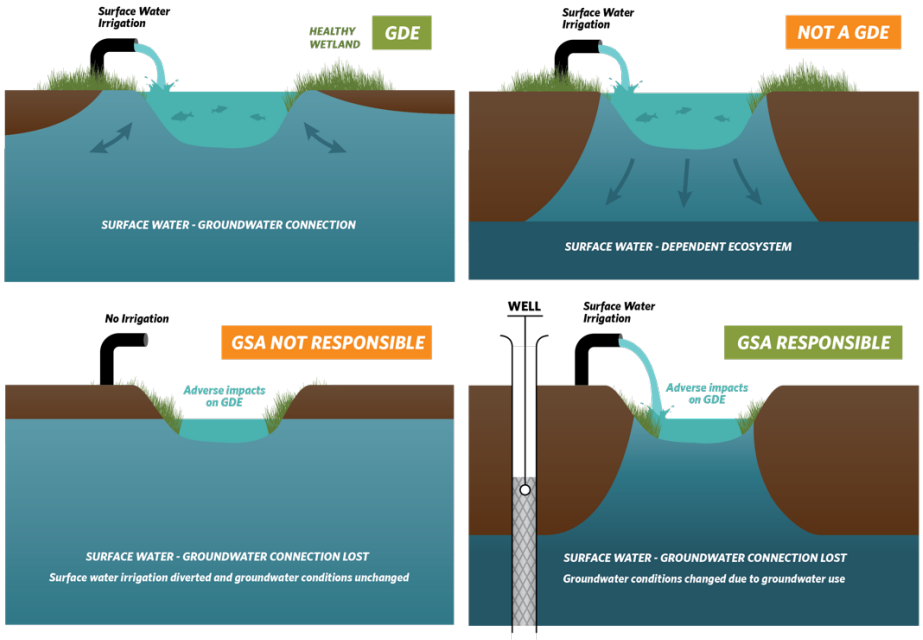

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. **(Right)** Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. **Bottom: (Left)** An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. **(Right)** Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

[10] For a list of environmental beneficial users of surface water by basin, visit: https://groundwaterresourcehub.org/gde-tools/environmental-surface-water-beneficiaries/

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.

- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.

- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

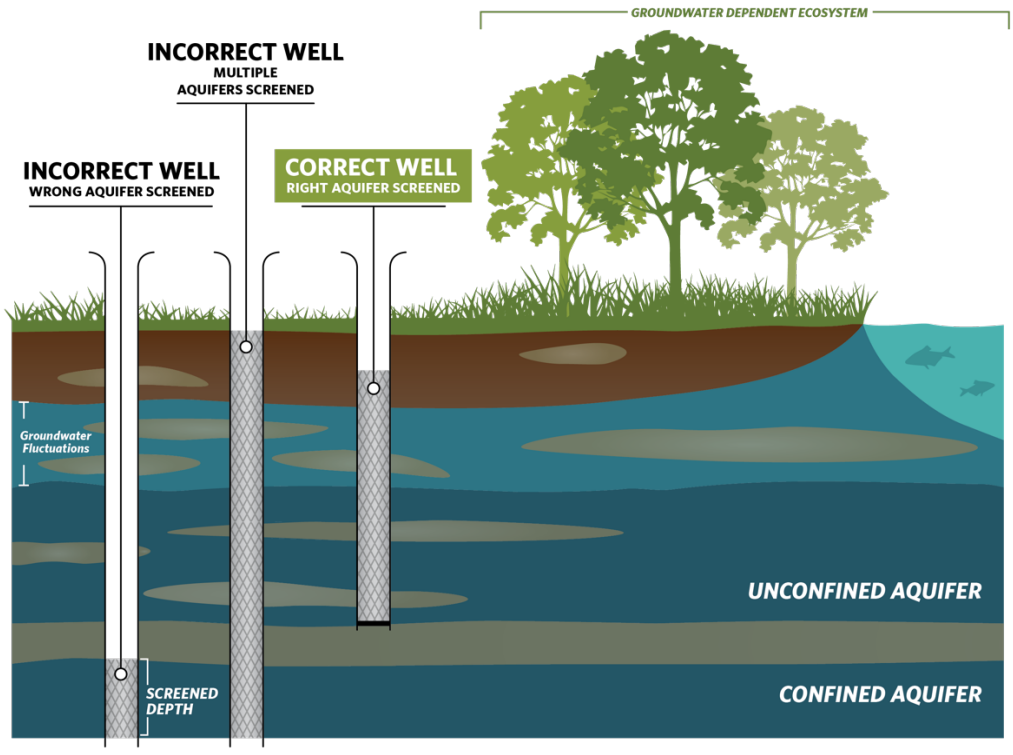

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[11] to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

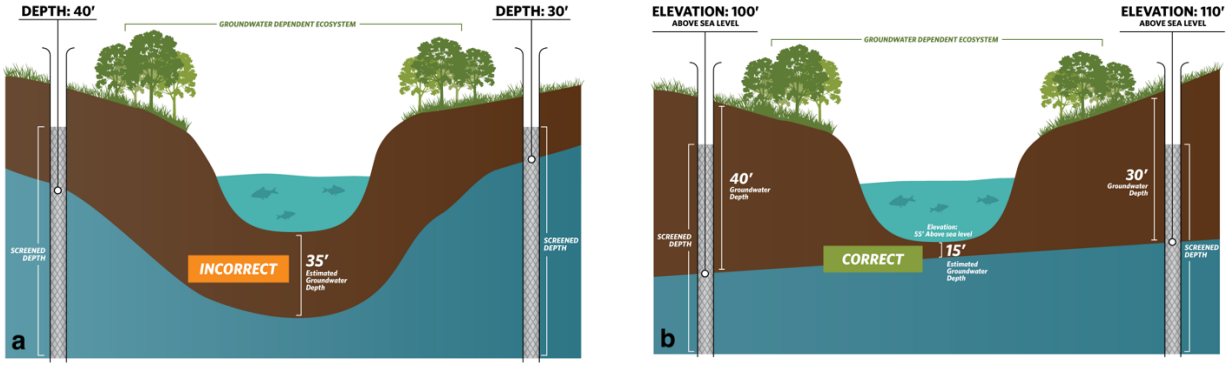

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. **(b)** Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

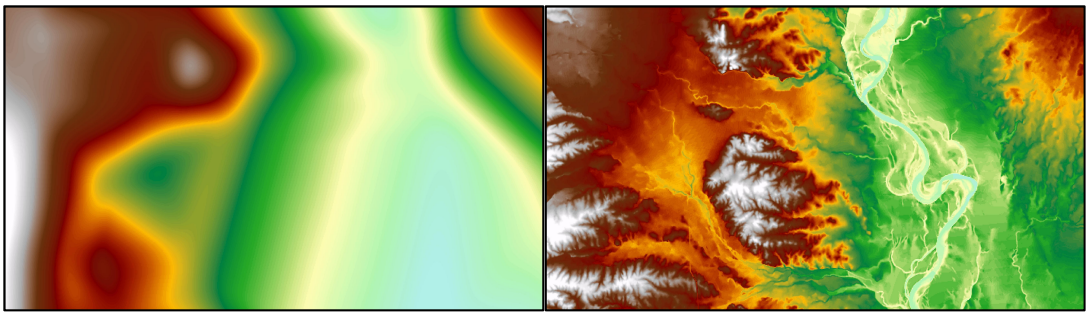

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. **(Right)** Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

[11] USGS Digital Elevation Model data products are described at: https://www.usgs.gov/core-science-systems/ngp/3dep/about-3dep-products-services and can be downloaded at: https://iewer.nationalmap.gov/basic/

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, **The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network.** Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

---

Hi Mary,

Here is the cite of the first paragraph of the Abstract for Hydrogeology of the Sutter Basin by George Curtin:

"***A mound of saline water exists in continental sediments between two fresh water rivers in the Sutter Basin of the Sacramento Valley, California. This saline water has moved from the marine sediments, at depth, upward along the Sutter Basin Fault and then through 2,000 feet of alluvium."***

I have also attached the USGS Sacramento Valley Tectonism Study published in 1987. This USGS report explains the faults surrounding the ancient Sutter Buttes volcano and the fact that the faults are still active.

As I mentioned, I am concerned about the potential for further later movement of the salt water northward towards the Butte Sink that may be cause by future groundwater substitution on east side of the Sacramento River near Colusa. As you know Colusa, Grimes, Sutter and Meridian use groundwater. The other issue that came to my mind was the potential for further deterioration due to future earthquake activity.

Perhaps – this area might be a good candidate for an Aerial mapping if the mapping could detect higher chloride levels in the groundwater?

Thanks again

Ben King

LATE CENOZOIC TECTONISM OF THE SACRAMENTO VALLEY, CALIFORNIA

By DAVID S. HARWOOD and EDWARD J. HELLEY

ABSTRACT

Structure contours drawn on top of the Cretaceous rocks in the Sacramento Valley define a large number of diversely oriented folds and faults that are expressed in topographic, hydrologic, and geologic features at the land surface. Although many of the structures in the valley have a protracted history of movement, some dating back to the late Mesozoic, a remarkable number of these structures show late Cenozoic deformation that can be accurately determined from folding and faulting of widespread, dated Pliocene and Pleistocene volcanic units. These time-stratigraphic units are used to define structural domains of essentially contemporaneous late Cenozoic deformation that was characterized by east-west compressive stress. The oldest structural domain is located in the southeastern part of the valley, where east-side-up reverse movement on the Willows fault ceased prior to deposition of continentally derived sediments of late Miocene and early Pliocene age. In the middle Pliocene to early Pleistocene, east-west compressive deformation progressed northward through the valley so that the youngest late Cenozoic deformation is recorded in east-northeast-trending folds and faults in the Battle Creek domain, at the northernmost part of the valley. The northward progression of east-west compressive deformation appears to be related to the northward eclipse of eastward subduction of the Juan de Fuca plate before the northwestward migration of the Mendocino triple junction along the continental margin west of the valley.

Much of the east-west compressive stress that affected the valley in the late Cenozoic was accommodated by east-side-up reverse movement on the steeply east-dipping, northwest-trending Willows fault and the north-trending Corning fault that splays off from the main stem of the Willows fault north of Sutter Buttes. Significant strain release also occurred on the northwest-trending fault beneath the Chico monocline and on the east-northeast-trending Red Bluff, Battle Creek, and Bear Creek faults in the past 2.0 m.y. Southeast of Sutter Buttes, the Willows fault follows the boundary between dense, magnetic, presumably ophiolitic basement to the west and Sierran basement to the east. The Chico monocline follows the same basement boundary north of Sutter Buttes, but that structure is stepped eastward from the trace of the Willows fault. It seems reasonably certain that the southeastern extension of the Willows fault and the Chico monocline fault are middle and late Cenozoic structures, respectively, that owe their existence and orientation, in part, to earlier, Mesozoic tectonic juxtapositioning of significantly different basement terranes.

INTRODUCTION

The Oroville earthquake ($M = 5.6$, August 1, 1975) added a new dimension to geologic studies of the Sacramento Valley. That event, more than any of the infrequent earthquakes that previously occurred in the area, awakened the geologic and engineering communities to the potential of active faulting in the valley and in the adjacent Sierran foothills. Because the Oroville earthquake occurred near the Lake Oroville dam (fig. 1) at a time when other large dams were being constructed along the Sierran foothills, several geologic studies, including this one, were conducted to specifically evaluate the late Cenozoic structural history of the region (Woodward-Clyde Consultants, 1977; Harwood and others, 1981; Helley and others, 1981; Helley and Harwood, 1985).

For about a half century prior to the Oroville earthquake, most geologic investigations of the Sacramento Valley (fig. 1) focused on locating natural gas in the deeper parts of the valley fill and water resources in the near-surface deposits. These investigations produced a wealth of stratigraphic and structural data that was gathered primarily from numerous gas fields scattered throughout the valley (map A, pl. 1). Several geologic syntheses resulted from these studies, but they were designed primarily to facilitate further exploration for these valuable resources and did not emphasize late Cenozoic tectonism (Bryan, 1923; Repenning, 1960; Olmsted and Davis, 1961; Safonov, 1968; Hackel, 1966; Redwine, 1972; California Department of Water Resources, 1978).

Recent developments in the concept of plate tectonics have given new emphasis and scope to regional geologic analyses by enabling integration of studies in the valley with those in the Coast Ranges to the west and the Sierra Nevada to the east (fig. 2). Within this concept, the Sacramento Valley was interpreted to be a late Mesozoic forearc basin (Dickinson, 1970; Ingersoll, 1976, 1978a, 1978b; Dickinson and Seely, 1979) that formed contemporaneously with and between the accretionary trench deposits of the Franciscan Complex to the west (Ernst, 1965, 1970; Blake and Jones, 1974; Blake and others, 1974) and an eastern magmatic arc complex, the roots of which are exposed in the Sierra Nevada (Hamilton, 1969). Although debate about the extent, geographic origin, and nature of the material accreted to the Mesozoic continental margin continues (Coney and others, 1980), the basic three-component model of an arc-trench system remains fundamental (Dickinson and Seely, 1979). Although the Sacramento Valley may be the most completely studied ancient forearc basin in the world (Ingersoll and others, 1977), the emphasis and scope of published paleogeo-

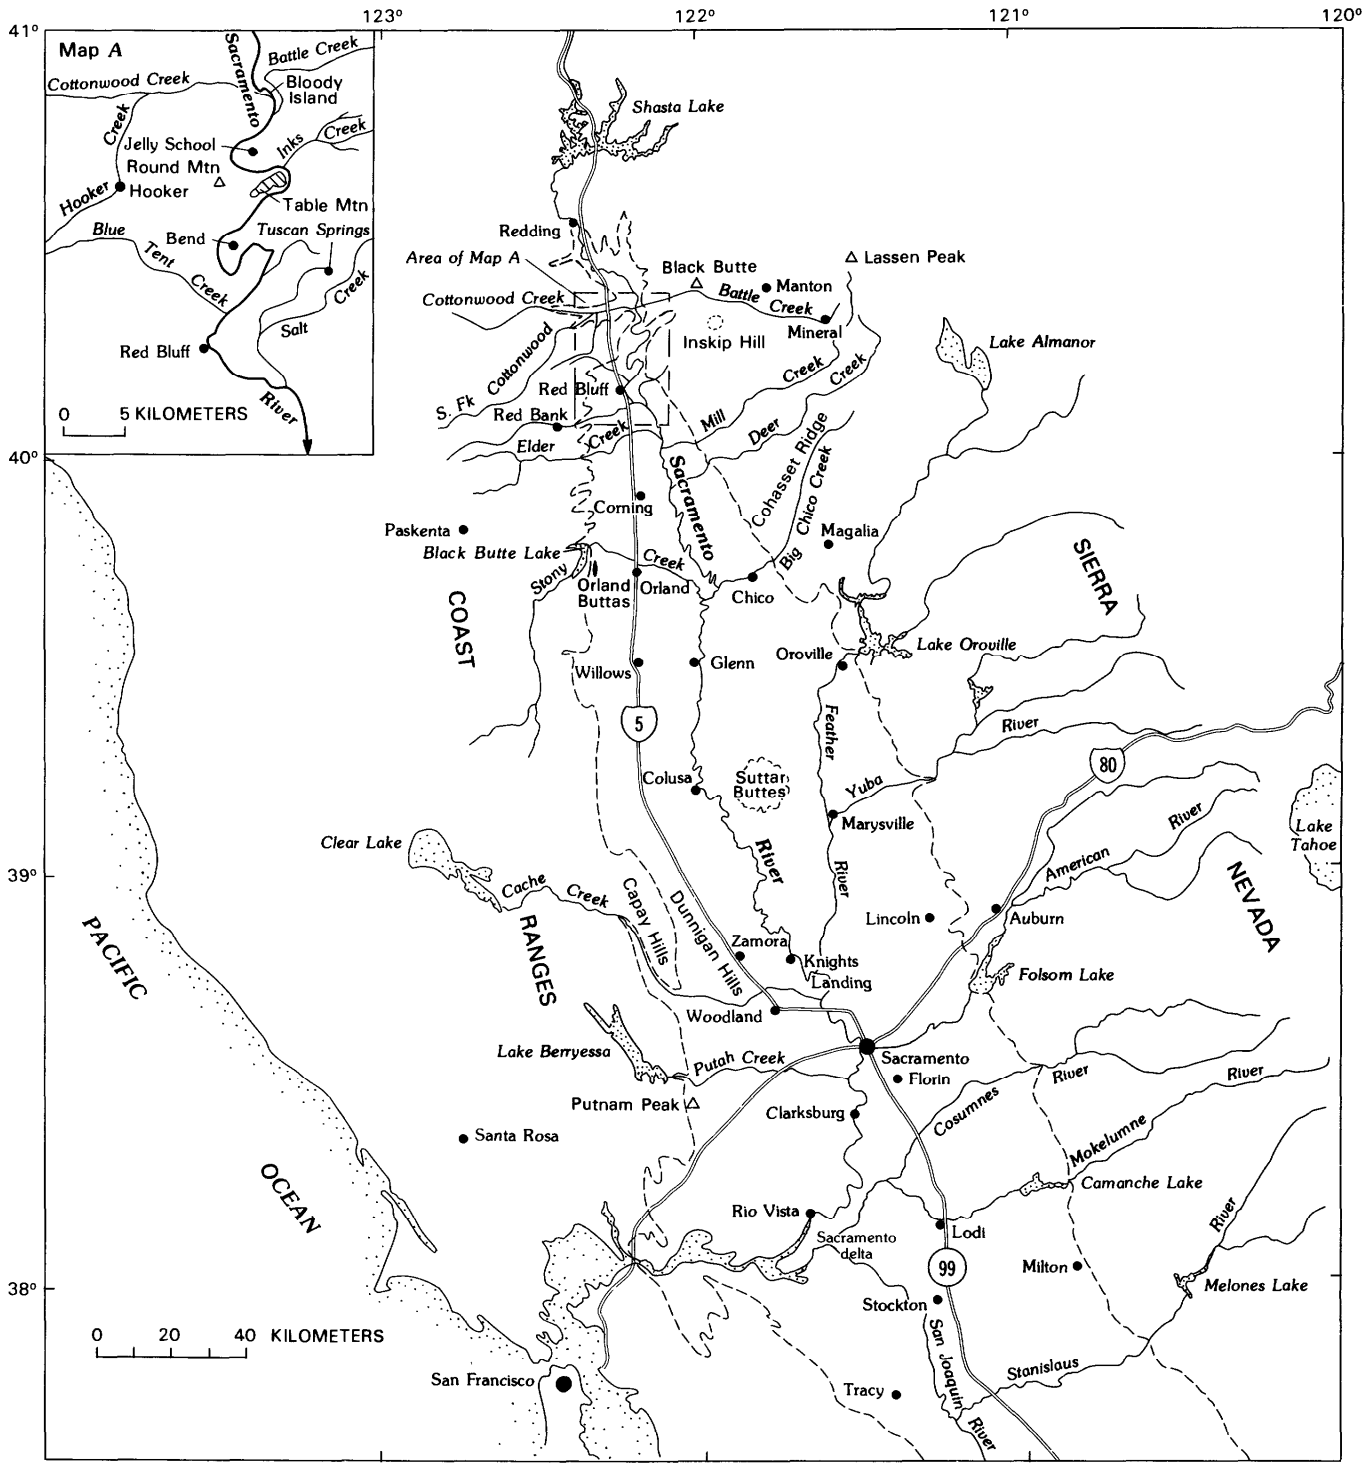

FIGURE 1.—Index map of northern California showing 500-foot topographic contour (dashed), which coincides approximately with boundary of Sacramento Valley.

graphic and paleotectonic studies generally precluded detailed analysis of late Cenozoic tectonism.

Structures discussed in this report are generally too young to provide new data for the late Mesozoic arc-trench model. In fact, a major objective of this report is to document that most of the folds and faults in the valley either formed in the late Cenozoic or are older structures that have undergone renewed deformation in the past few million years. In this respect, structures in the valley are more closely related to tectonic models of Cenozoic subduction, including subsequent lateral convergence along the San Andreas fault system and extension in the Basin and Range province to the east, than they are to the late Mesozoic tectonic models (Hamilton and Myers, 1966; Atwater, 1970; Christiansen and Lipman, 1972; Atwater and Molnar, 1973; Dickinson, 1979).

ACKNOWLEDGMENTS

The structure contour map presented in this report (pl. 1) integrates subsurface data from many summary reports of oil and gas operations published by the California Division of Oil and Gas. Credit is given to specific authors of gas field reports in the "Sources of Data" shown on plate 1, and we would like to express our appreciation to those authors, whose work contributed much of the basic data for our compilation. In addition to published reports, we analyzed well logs from a number of areas in the valley, and we acknowledge the courteous service provided by the staff of the Woodland office of the California Division of Oil and Gas.

Interpretation of the subsurface data was influenced to a great degree by exceptionally high-quality seismic-reflection profiles purchased from Seisdata Services Inc. We thank Seisdata Services Inc. for allowing us to reproduce a small segment of one of those profiles in this report.

We thank David Wagner of the California Division of Mines and Geology for sending us a preprint of his detailed map and discussion of the Capay Valley-Capay Hills area. Special thanks are given to the California Academy of Sciences for making available their collection of thin sections of basement rocks that were penetrated in wells in the Sacramento Valley.

We also acknowledge stimulating discussions with our colleagues J.A. Bartow, M.C. Blake, Jr., K.F. Fox, Jr., D.L. Jones, R.J. McLaughlin, T.H. Nilsen, A.M. Sarna-Wojcicki, and C.M. Wentworth. These discussions sharpened the focus of many points in this report, but responsibility for the analysis of subsurface structures and regional tectonism rests with Harwood, and the mapping of surficial deposits, which document the youthfulness of many structures, rests with Helley.

REGIONAL SETTING

The Sacramento Valley comprises the northern third of the Great Valley of California (fig. 2)—a broad, fertile lowland situated between mountainous terrains of the Coast Ranges to the west and the Sierra Nevada to the east. Marine sedimentary rocks, ranging in age from Late Jurassic to early Miocene, underlie the deeper parts of the Sacramento Valley. They are unconformably capped by a relatively thin cover of alluvial deposits and locally prominent volcanic rocks of early Miocene to Holocene age.

Marine sedimentary rocks exposed on the west flank of the Sacramento Valley record a nearly unbroken depositional sequence from Upper Jurassic through Upper Cretaceous (Lachenbruch, 1962; Ingersoll and others, 1977). On the east side of the valley, Upper Cretaceous sandstone and shale, described by Taft and others (1940) and Haggart and Ward (1984), rest unconformably on metamorphic and plutonic rocks of the Sierra Nevada basement and indicate a progressive eastward onlap of marine sedimentation during the late Mesozoic (Ingersoll and others, 1977). In a broad area south of Sutter Buttes, younger Upper Cretaceous sandstone and shale record a westward-prograding deltaic sequence and marine regression (Drummond and others, 1976; Garcia, 1981) during the Late Cretaceous, as the depositional basin was broadly uplifted and tilted to the south and west. Intermittent periods of uplift and subsidence, apparently caused by Paleogene subduction and possibly by lateral faulting to the west (Nilsen and Clarke, 1975; Nilsen and McKee, 1979), affected the depositional basin through the early Tertiary.

Four distinct submarine canyons developed during the uplift cycles, and they were subsequently filled with transgressive marine sequences during times of subsidence (fig. 2). Almgren (1978) has documented three ancient oscillatory tectonic-depositional cycles in the southern part of the Sacramento Valley. He concludes that the Martinez canyon was cut in the late early to middle Paleocene, the Meganos canyon was cut in early Oligocene and filled in late Oligocene and early Miocene, and the Markley canyon was cut in early Oligocene and filled in early Miocene time. Although the timing of the fourth submarine canyon is not as closely constrained by the sedimentary record as the other three, Redwine (1972) concluded that the Princeton canyon, located in the north-central part of the valley (fig. 2), was cut and filled between the late Paleocene and early Eocene, probably coincident with the formation of the Martinez canyon to the south (Almgren, 1978). Eocene marine deposits in the Princeton canyon apparently grade northward and eastward into alluvial deposits derived from the northern Sierra Nevada.

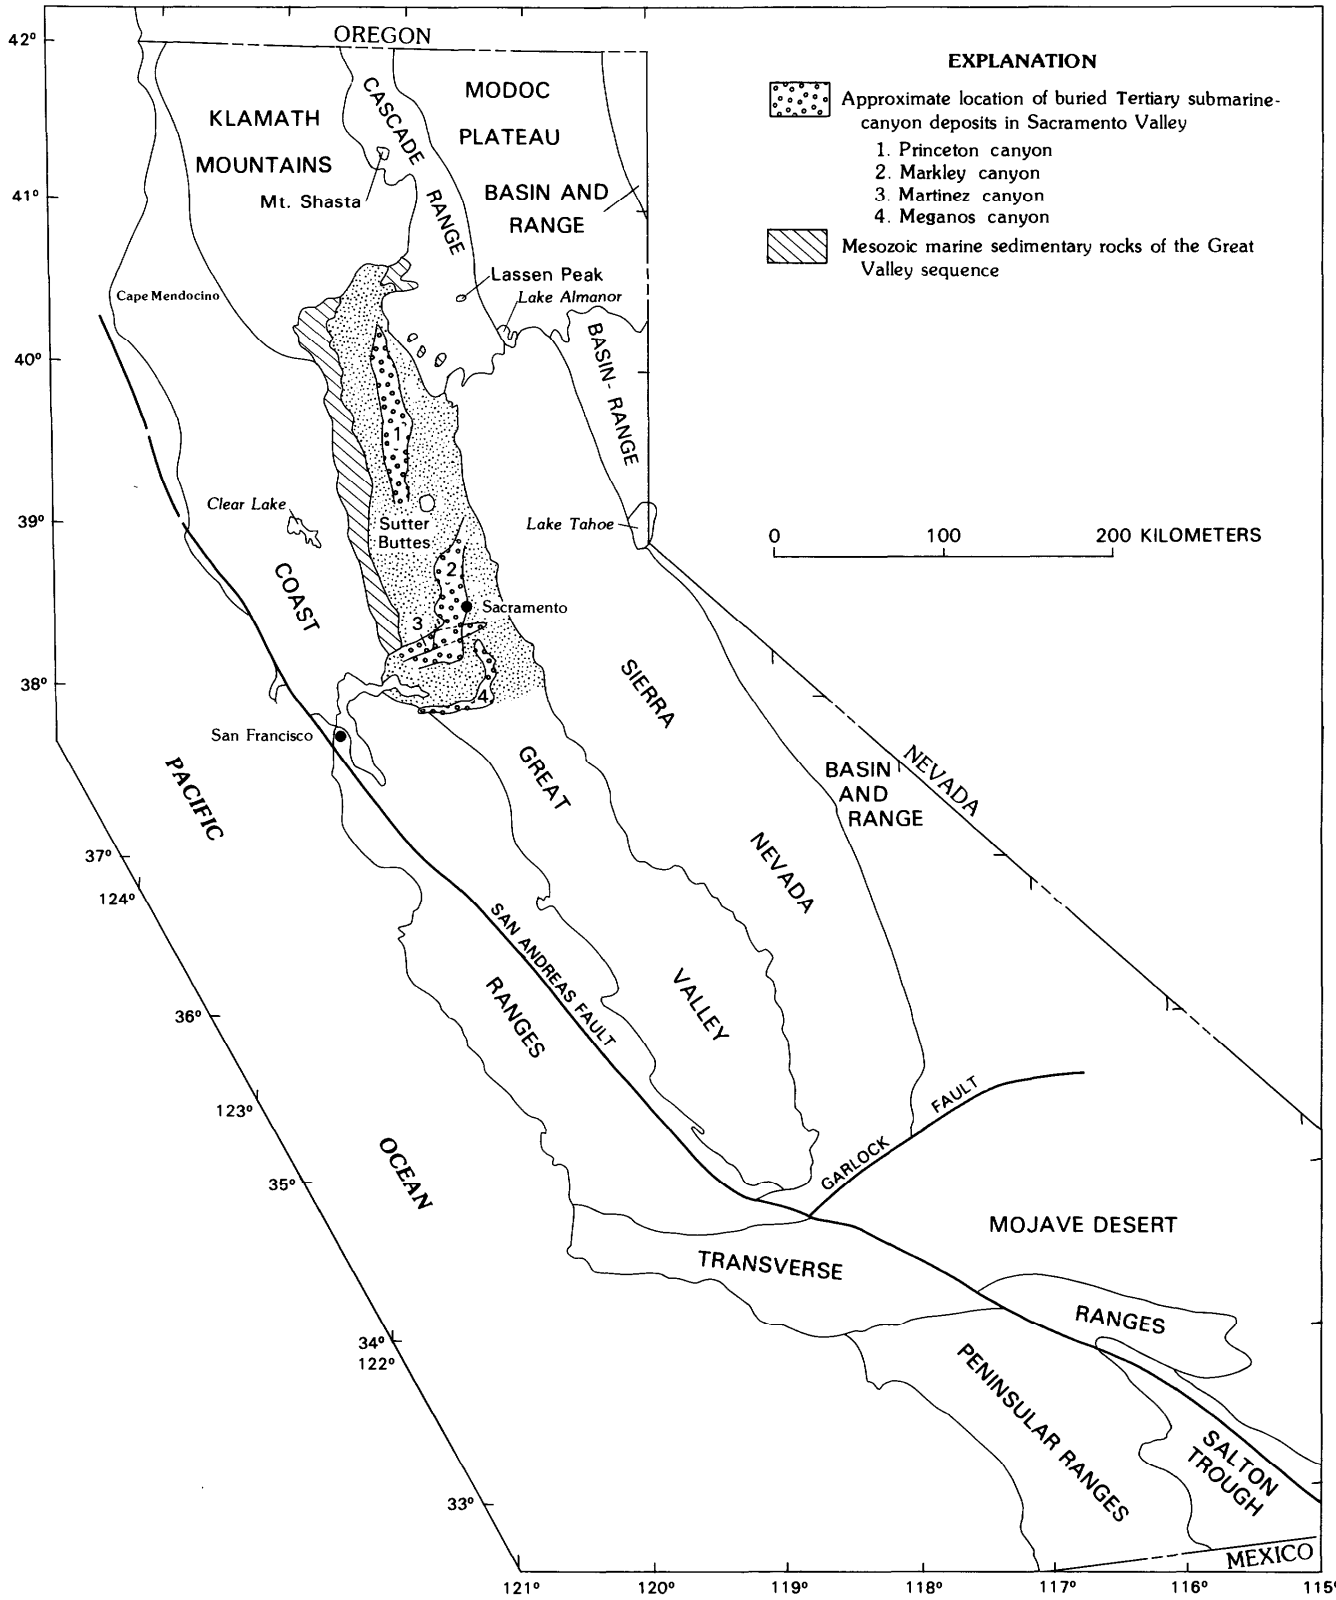

FIGURE 2.—Outline of geomorphic provinces in California and general location of buried Tertiary submarine canyon deposits in Sacramento Valley (stippled).

By the early Miocene, the northern part of the Sacramento Valley clearly was an emergent area, subjected to fluvial erosion and deposition. During this time, between 23.8 and 22.3 m.y. ago according to Dalrymple (1964), the Lovejoy Basalt was erupted from a vent or vents in the northern Sierra Nevada (Durrell, 1959) and flowed westward in a confined channel until it reached the Sacramento Valley near Oroville. Upon reaching the valley, the Lovejoy Basalt spread laterally, filling distributary alluvial channels (van den Berge, 1968) and flowed both westward, across the present axis of the valley now occupied by the Sacramento River at least to Orland Buttes, and southward at least to the vicinity of Putnam Peak (Weaver, 1949) (fig. 1), 260 km from the presumed source. Because of its distinctive characteristics, widespread distribution in both the surface and subsurface parts of the Sacramento Valley, and radiometrically determined age, the Lovejoy Basalt is an important marker unit (pl. 1) that places an age constraint on Cenozoic deformation in the valley.

After eruption of the Lovejoy Basalt, alluvial sediments of late middle Miocene to early Pliocene age accumulated in the central and southern part of the valley, capping marine sedimentary rocks deposited in the Princeton and Markley canyons (Redwine, 1972; Almgren, 1978). These alluvial deposits, however, are not present in surface exposures in the northern part of the valley, where Pliocene alluvium of the Tehama Formation in the northwest and coeval volcanic rocks of the Tuscan Formation in the northeast rest directly on the Lovejoy Basalt or on older rocks where the Lovejoy is missing.

A widespread felsic pumiceous tuff, the Nomlaki Tuff Member of the Tuscan and Tehama Formations, occurs at or near the base of the Pliocene rocks and serves as a second important time-stratigraphic marker in the valley, dated at 3.4 m.y. (Evernden and others, 1964). The Nomlaki, which was erupted from the vicinity of Lassen Peak, generally marks the beginning of volcanic activity that has occurred intermittently into historic time at the southern end of the Cascade Range (fig. 2). Pliocene and Pleistocene volcanic rocks, erupted from the Lassen area, flowed westward and interfingered with alluvial deposits of the ancestral Sacramento River system in the northern part of the valley (Anderson, 1933; Lydon, 1968; Harwood and others, 1981; Helley and others, 1981). Several of the volcanic units have been dated (Harwood and others, 1981), and they are important time indicators for the late Cenozoic depositional and tectonic evolution of the Sacramento Valley. Two informally designated volcanic units, the Rockland ash bed (referred to as the ash of Mount Maidu by Harwood and others, 1981) and the basalt of Deer Creek, dated at 0.45 and 1.09 m.y., respectively (Meyer and others, 1980; Harwood and others, 1981), are particularly significant because they bracket the age of the Red Bluff Formation. The Red Bluff forms a thin, widespread gravel pediment that unconformably caps the Pliocene rocks in the northern part of the valley. The fact that the Red Bluff Formation is faulted and folded clearly establishes the presence of late Cenozoic deformation, within the past million years, on most of the major features shown on the structure contour map (pl. 1).

A volcanic center, composed of andesitic fragmental deposits intruded by late-stage rhyolite domes, formed at Sutter Buttes in the central part of the valley between 2.4 and 1.4 m.y. ago (Williams, 1929; Williams and Curtis, 1977). This late Cenozoic volcanic center is located over a northwest-trending tectonic boundary that juxtaposes a basement of dense, magnetic, presumed oceanic crust (Cady, 1975; Griscom, 1973) on the west against metamorphic and plutonic rocks of the Sierran basement on the east. The boundary between the basement terranes is a Mesozoic tectonic feature that apparently has been reactivated by Cenozoic deformation (Harwood, 1984). Southeast of Sutter Buttes, the Willows fault approximately follows the contact between oceanic and Sierran basement terranes, and northeast of Sutter Buttes that basement boundary lies beneath the Chico monocline.

In the southeastern part of the valley, structure contours are drawn on the basement surface (pl. 1). In the rest of the valley, the datum is the top of the Cretaceous rocks. Contouring procedures are described on plate 1.

INTERPRETATION OF BASEMENT CONTOURS

The most pronounced deflection in basement contours is located beneath Sutter Buttes (pl. 1). This anomaly in basement topography was shown first by Smith (1964) and mentioned briefly by Williams and Curtis (1977, p. 6), who noted more than 395 m of local relief on the basement surface but offered no interpretation of the anomaly. Although some of the upwelling of the basement surface may be related to volcanic intrusion at Sutter Buttes, Harwood (1984) suggests that much of the basement uplift was related to east-side-up movement on the Willows fault, which passes just west and south of the Sutter Buttes.

Data from deep wells a few kilometers north of Sutter Buttes (pl. 1) indicate that the basement surface has a major deflection related to a northeast-trending fold or fault, or both. All of these possible structural configurations were investigated, and we conclude that the structure in the area is a northeast-trending fold, faulted along its southeast limb. The fault is interpreted to be a steeply dipping to vertical normal fault with southeast-side-down displacement. Both the fold and fault, however, appear to die out to the northeast.

In a zone southeast of Sutter Buttes that extends to the Stockton fault (pl. 1), variations in the slope of the base-

ment surface are shown by northwest-trending zones of broadly spaced and relatively close-spaced contours. The basement surface may dip eastward locally in those areas marked by broadly spaced contours (see Jacobsen, 1981), but well data are too sparse to locate closed contours in this area, even if they would show at the chosen contour interval of 150 m.

From Sacramento south to the Stockton fault, the slope of the basement steepens significantly west of the −1,500-m contour. This change in basement slope lies near the eastern edge of the positive gravity and magnetic anomalies in the Great Valley that Cady (1975) interpreted to represent ophiolitic oceanic crust tectonically juxtaposed against Sierran basement rocks to the east. Reports of two wells south of Sacramento, however, show "granite" and "gneiss" at −1,954 m and −2,861 m, respectively, suggesting that the interpreted suture between oceanic and Sierran basements is not marked by the topographic break in the basement surface at the −1,500-m contour. It must be emphasized, however, that these identifications of basement rocks were made some time ago by the operators who drilled the wells, and it is possible that the "granite" may be a leucocratic rock associated with ophiolitic basement, such as plagiogranite, and the "gneiss" may be any dark-colored rock, even part of the ophiolitic basement. It seems reasonably certain, in any case, that the topographic break at the −1,500-m contour is controlled in some measure by a fault, possibly the extension of the Willows fault southeast of Sutter Buttes. It is interesting, and not altogether fruitless, to speculate that the Willows fault southeast of Sutter Buttes coincides with and represents the up-section propogation of the major fault between oceanic crust and the arc-massif basement of the Sierra Nevada. If such is the case, the Willows fault southeast of the Sutter Buttes may represent a structure inherited from the upper-slope discontinuity, a region of structural weakness over the boundary between forearc-basin and arc-massif basements, identified by Karig and Sharman (1975) in modern forearc basins.

From Sutter Buttes north to Chico, a number of wells penetrate basement rocks reported as diorite, gabbro, noritic gabbro, and serpentine. Not surprisingly, this part of the Sacramento Valley is characterized by large, positive gravity and magnetic anomalies that mark the northern part of the inferred Great Valley ophiolitic basement (Cady, 1975). Some thin sections of gabbro and diorite from wells in this area, contained in a collection of thin sections of basement rocks held by the California Academy of Sciences, reveal remarkably fresh coarse- and medium-grained clinopyroxene-plagioclase rocks that show pronounced cumulate textures. These textures, previously unrecognized, provide supporting evidence for the interpretation that the source rocks of the Great Valley anomaly are oceanic crust.

South and east of Sutter Buttes, several wells penetrate rocks reported as granite, granodiorite, metavolcanic rocks, and "gneiss" typical of rocks exposed in the Sierran foothills. The outline of granitic plutonic rocks, shown on plate 1, was determined from reported basement rocks, augmented by our interpretation of residual isostatic gravity data (Roberts and others, 1981). The boundary between the Sierran basement and mafic and ultramafic rocks of probable ophiolitic basement trends about N. 45° E. from Sutter Buttes to Oroville. It is clearly marked by significant changes in the gravity and magnetic patterns of the respective areas. The basement contours do not reflect this inferred lithologic change, and the northeast-trending fault north of Sutter Buttes is contained within the mafic-ultramafic basement terrane.

Sierran crystalline rocks are exposed in several deep canyons that cut through the Pliocene volcanic rocks of the Tuscan Formation east of Chico (Harwood and others, 1981). The mafic-ultramafic basement appears to abut against Sierran basement rocks along a major basement fault beneath the Chico monocline. This tectonic juxtaposition of basement terranes was proposed first by Griscom (1973), and the basement fault he proposed from geophysical data is confirmed by stratigraphic data. The basement fault beneath the Chico monocline shows east-side-up displacement with a minimum stratigraphic throw of 367 m on the basement surface. This fault represents late Cenozoic deformation superposed on a segment of the late Mesozoic boundary between the forearc-basin and arc-massif basements, and it is thus part of the upper-slope discontinuity (Karig and Sharman, 1975).

STRUCTURAL FEATURES IN THE VALLEY FILL

Structure contours drawn on top of the Cretaceous rocks outline a large number of diversely oriented folds and faults distributed throughout the valley. Some of these structures, such as the Corning domes, the Chico monocline, and the Dunnigan Hills anticline, have topographic expression and were recognized in the early ground-water studies of the valley by Kirk Bryan (1923). Most of the other structures do not have obvious surface expression, and they were discovered during exploration and development of the numerous small gas fields in the valley (pl. 1, map A). Although detailed reports have been published for many of the gas fields, few reports have synthesized the data from these studies into detailed structural analyses of the valley as a whole. Noteworthy exceptions to this generalization exist, however, and include the early stratigraphic and structural synthesis by Safonov (1968), the detailed study of the Princeton submarine channel system by Redwine (1972), and the continuing efforts of the California Division of Mines and

Geology to compile available data from the valley into small-scale maps of the entire state (Jennings, 1977).

The extent of many of the faults, particularly the complex pattern of the Willows fault and the relations between that fault system and many folds in the northern valley, has not been reported previously. Analyses of well logs, which are the basis for most reports of individual gas fields, do not provide sufficient data to interpret unequivocally the structure of each field. If recognizable stratigraphic units in the well logs are at different elevations in adjacent wells, it is generally impossible to determine if the units are offset by folding or faulting, or both, without additional data from surface exposures or seismic-reflection profiles. Our interpretation of the structural relations in the valley is based on data from well logs, augmented by detailed mapping of the surficial deposits by Helley, and exceedingly valuable seismic-reflection data obtained from Seisdata Services Inc.

WILLOWS FAULT SYSTEM

The main stem of the Willows fault was discovered in the subsurface rocks of the northern valley when it was penetrated by the Marathon Oil Company (formerly Ohio Oil Company) "Capital Company No. 1" well during development of the Willows-Beehive Bend gas field in the late 1950's (California Division of Oil and Gas, 1960; Alkire, 1962; 1968). From the discovery well, Redwine (1972) traced the Willows fault in the subsurface southeast to Sutter Buttes and suggested that it extended northwest of the discovery well, possibly connecting with the surface fault mapped west of the Orland Buttes (Anderson and Russell, 1939; Jennings and Strand, 1960). On the basis of the distribution of Quaternary units immediately south of Orland Buttes and of two seismic profiles north of the buttes, we have extended the Willows fault into northwestern Tehama County. At Orland Buttes, Upper Cretaceous rocks, the Lovejoy Basalt, and the Tehama Formation, on the up-thrown side of the Willows fault, are juxtaposed against the Tehama Formation on the down-thrown fault block to the west.

Redwine (1972) documented displacement on a 40-km segment of the main stem of the fault from east of Willows to Sutter Buttes and concluded that it dipped 74° or steeper to the east and showed reverse, east-side-up movement that decreased upward toward the surface. He found that the Princeton submarine channel was localized by movement on the fault and that vertical separation in the discovery well varied from about 488 m on top of the Cretaceous rocks to about 477 m on the top of the Eocene Capay Formation.

The pattern of deformation on the Willows fault and its effect on the thickness and facies patterns in the Capay Formation are clearly shown in figure 3. In this approximately east-trending cross section through the Marathon "Capital Company No. 1" well (No. 3, fig. 3), the thalweg of the Princeton channel, which is occupied by marine shale of the Capay, coincides with a syncline in the underlying Upper Cretaceous rocks. The west limb of the complementary anticline in the Upper Cretaceous rocks is broken by east-side-up movement on the Willows fault. The electric logs show that west of the fault the Capay is composed of shale, and east of the fault it is dominantly sandstone that interfingers with shale eastward toward the thalweg of the channel. Folding and faulting clearly postdated the deposition of Upper Cretaceous strata and preceded the deposition of the Capay and occurred between about 60 and 53 m.y. ago. During that time there was some erosion of the Upper Cretaceous rocks, particularly along the channel thalweg. The westward increase in sandstone and a complementary decrease in thickness of the Capay toward the fault suggest that the anticlinal welt of Upper Cretaceous rocks was a shoal area during Capay deposition. Because the shale-rich Capay west of the fault is about the same thickness as the sandstone-rich Capay east of the fault, there appears to have been little, if any, deformation on the Willows fault in this area during deposition of the Capay. The section shows about 475 m of post-Capay offset and possibly small offset on the base of the Tehama, but the amount of post-Pliocene offset is difficult to determine because there is no record for the upper part of well 2 (fig. 3).

CORNING FAULT

Data from a number of sources indicate that the Willows fault is far more extensive and complex than previously thought. The first clue that the Willows fault branched into a multistrand fault system was provided by an analysis of seismicity of the northern valley and Sierran foothills after the Oroville earthquake. Marks and Lindh (1978) located a number of small-magnitude earthquakes along a zone that originated near the Marathon "Capital Company No. 1" well in the Willows-Beehive Bend gas field and extended north about 30 km, rather than following the northwest trend of the Willows fault. These epicenters are shown relative to the trace of the Willows fault in figure 4. The trend of seismic events suggests that a north-trending fault splayed off from the main stem of the Willows fault and passed west of the Corning domes (pl. 1). In the Corning gas fields, analysis of well records by the Sacramento Petroleum Association (1962) showed an anticlinal fold in the area of the Corning domes, with about 121 m of maximum closure on the base of the Tehama Formation in the north dome and a steeply dipping southeast-trending fault located at the north end of south Corning dome, but it did not identify a fault west of them.

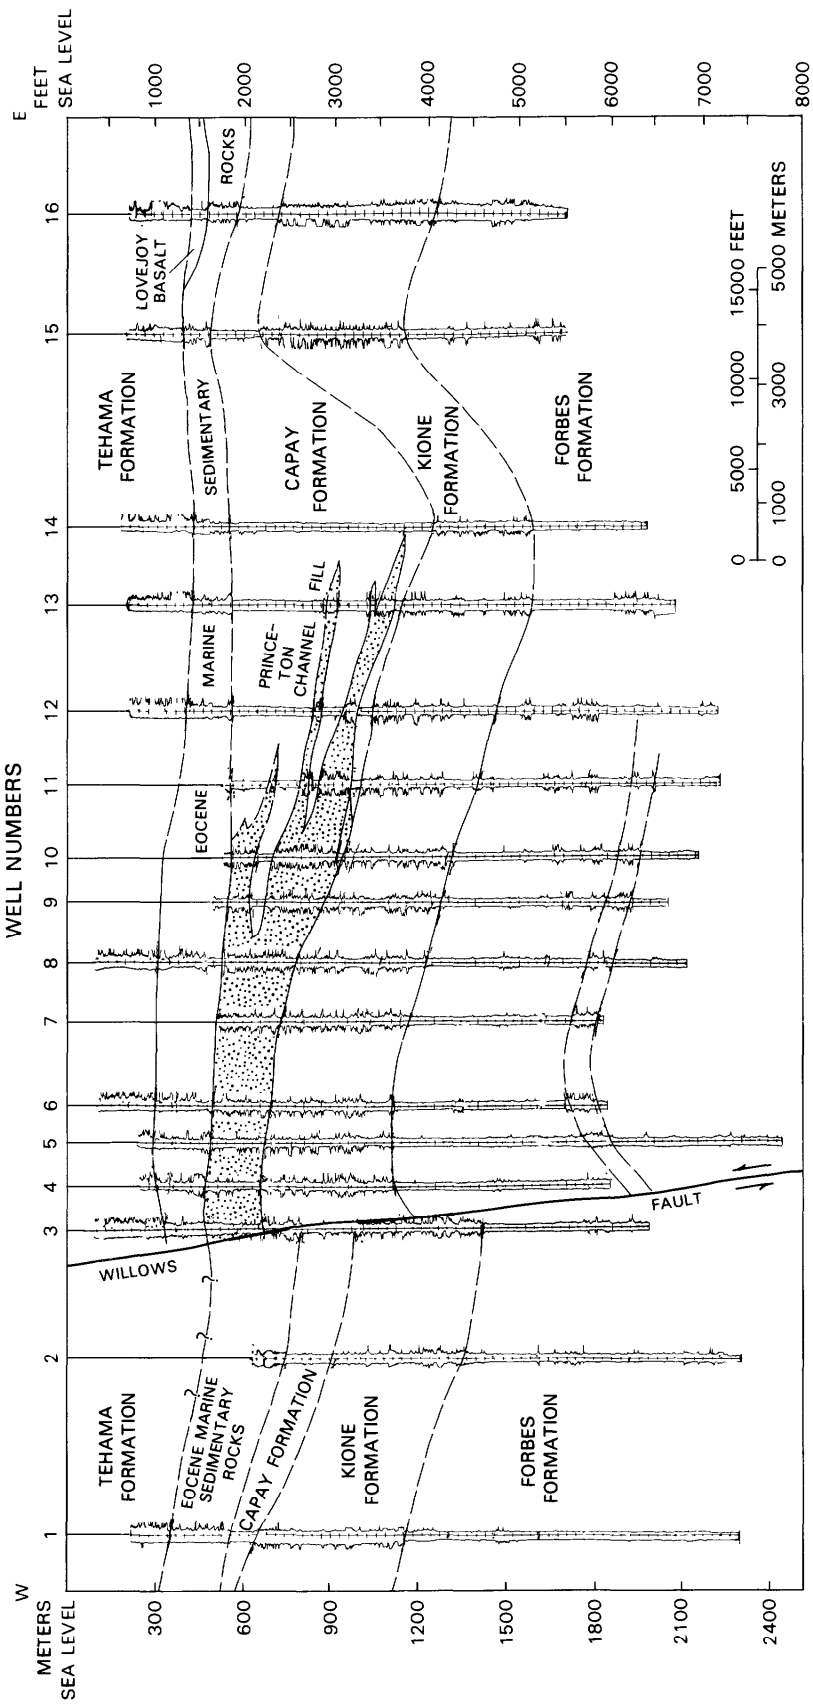

FIGURE 3.—Cross section showing electric logs and stratigraphic and structural relations across Willows-Beehive Bend gas field, Calif. Sandstone in Capay Formation indicated by stipple. Willows fault penetrated in well No. 3. Names of wells shown in appendix. Stratigraphic nomenclature used may not necessarily conform to that adopted by U.S. Geological Survey.
