FIGURE 4.—Epicenters (X) of seismic events in area of Oroville, Calif., from June 1975 to August 1976 (modified from Marks and Lindh, 1978). Note north trend of epicenters extending from Willows fault approximately along trace of Corning fault. Unlabeled heavy lines indicate other faults. Triangles show epicenters of two unusually deep (40 km) earthquakes.

Seismic-reflection profiles in the area by Seisdata Services Inc. have identified a major north-trending, steeply east-dipping reverse fault that passes west of the Corning domes and the Greenwood anticline. We call this structure the Corning fault (pl. 1), and part of one of the profiles across it is shown in figure 5. The profile clearly shows that the shallow reflecting horizons in the eastern block are arched beneath the Corning dome by east-side-up drag on the Corning fault. It is also apparent in the profile that the vertical displacement increases with depth, indicating progressive deformation through time, similar to the deformation pattern on the main stem of the Willows fault in the Willows-Beehive Bend gas field (fig. 3). Curiously, however, the amount of vertical displacement of the Upper Cretaceous and younger strata shown on the profile is relatively small compared to the offset of the basement surface suggested by the few deep wells in the area shown on figure 6.

The deepest well east of the Corning fault is the Shell Oil Company "Victor Ranch No. 4" (sec. 7, T. 23 N., R. 2 W.), which bottomed in the Venado Sandstone of Late Cretaceous (Turonian) age at an elevation of −3,713 m (fig. 6). Lithologic information from this well helps interpret the seismic-reflection profile, and its total depth provides a minimum value for the basement elevation 8 km east of the Corning fault. Although local variations in the slope of the basement surface exist, the basement generally dips about 5° SW. between the Chico monocline and the Corning fault. The intersection of the basement surface and the Corning fault ranges in elevation from about −3,900 m in the north to about −4,600 m in the south. This south-southeast plunging line of intersection appears to lie significantly above the basement surface west of the Corning fault.

West of the Corning fault, only one well, the Shell Oil Company "Vilche No. 2" (sec. 5, T. 27 N., R. 4 W.), reached basement, which was serpentinite penetrated at an elevation of −5,978 m (fig. 6). Data from this well are not sufficient to determine the dip of the basement surface west of the Corning fault, but the dip immediately west of the fault may be the same as that just east of the fault, assuming that the basement surface was not chaotically tilted prior to deposition of the Great Valley sequence. If such is the case, the −6,000-m contour can be extrapolated south of the Shell Oil Company "Vilche No. 2" well parallel to the contours east of the Corning fault, as shown on figure 6. This extrapolation gives a vertical separation of about 1,500 m on the basement surface if one assumes no offset on the Red Bluff fault (fig. 6). Because the Red Bluff fault (discussed in a following section of this report) shows down-to-the-south displacement of the valley fill, similar basement offset on the Red Bluff fault would increase the basement separation on the Corning fault. Therefore, 1,500 m of vertical offset on the basement surface across the Corning fault is considered to be a minimum value.

The reason why the basement offset does not appear on the seismic reflection profile is not known. Perhaps the energy input was not sufficient to generate reflections from the deeper basement. Alternatively, the Venado Sandstone, which thickens westward, may have masked reflections from older rocks of the Great Valley sequence and the basement surface west of the Corning fault. Whatever the reason, geologic data strongly suggest that the basement was offset at least 1,500 m on the Corning fault prior to Turonian time and that pre-Turonian rocks of the Great Valley sequence, deposited on the down-dropped block of the fault were unconformably overlapped by the Venado Sandstone. Post-Turonian displacement on the Corning fault is a few hundred meters.

The youngest deposits deformed by the Corning fault are gravels of the Pleistocene Red Bluff Formation, the age of which is between 0.45 and 1.09 m.y. (Harwood and others, 1981).

NORTHWEST EXTENSION OF WILLOWS FAULT

The location of the Willows fault system north and northwest of Orland Buttes is not clearly indicated by direct evidence in either the surface or subsurface rocks.

Wells are sparse in this area of the valley, particularly west of the probable trace of the main stem of the Willows fault. For that reason, the structure contours are very generalized and of little value in locating even major structures.

Our projection of the Willows fault into the Cold Fork, Elder Creek, and Paskenta faults (pl. 1) mapped by Jones and others (1969) is based primarily on the outcrop pattern of the Tehama Formation. North of Elder Creek, the Tehama Formation dips gently east, and the Nomlaki Tuff Member is at the base of the Tehama or is, at most, a few tens of meters above its base. South of Elder Creek, however, the Tehama dips more steeply eastward into the valley, and the Nomlaki is a few hundred meters above the base of the Tehama. This outcrop pattern of the Tehama Formation suggests that the underlying Great Valley sequence was topographically higher and projected farther east into the valley north of the Willows fault prior to deposition of the Pliocene strata. The position of the Nomlaki Tuff Member, relative to the base of the Tehama on opposite sides of the Willows fault, indicates that the Tehama filled a topographic low southwest of the fault

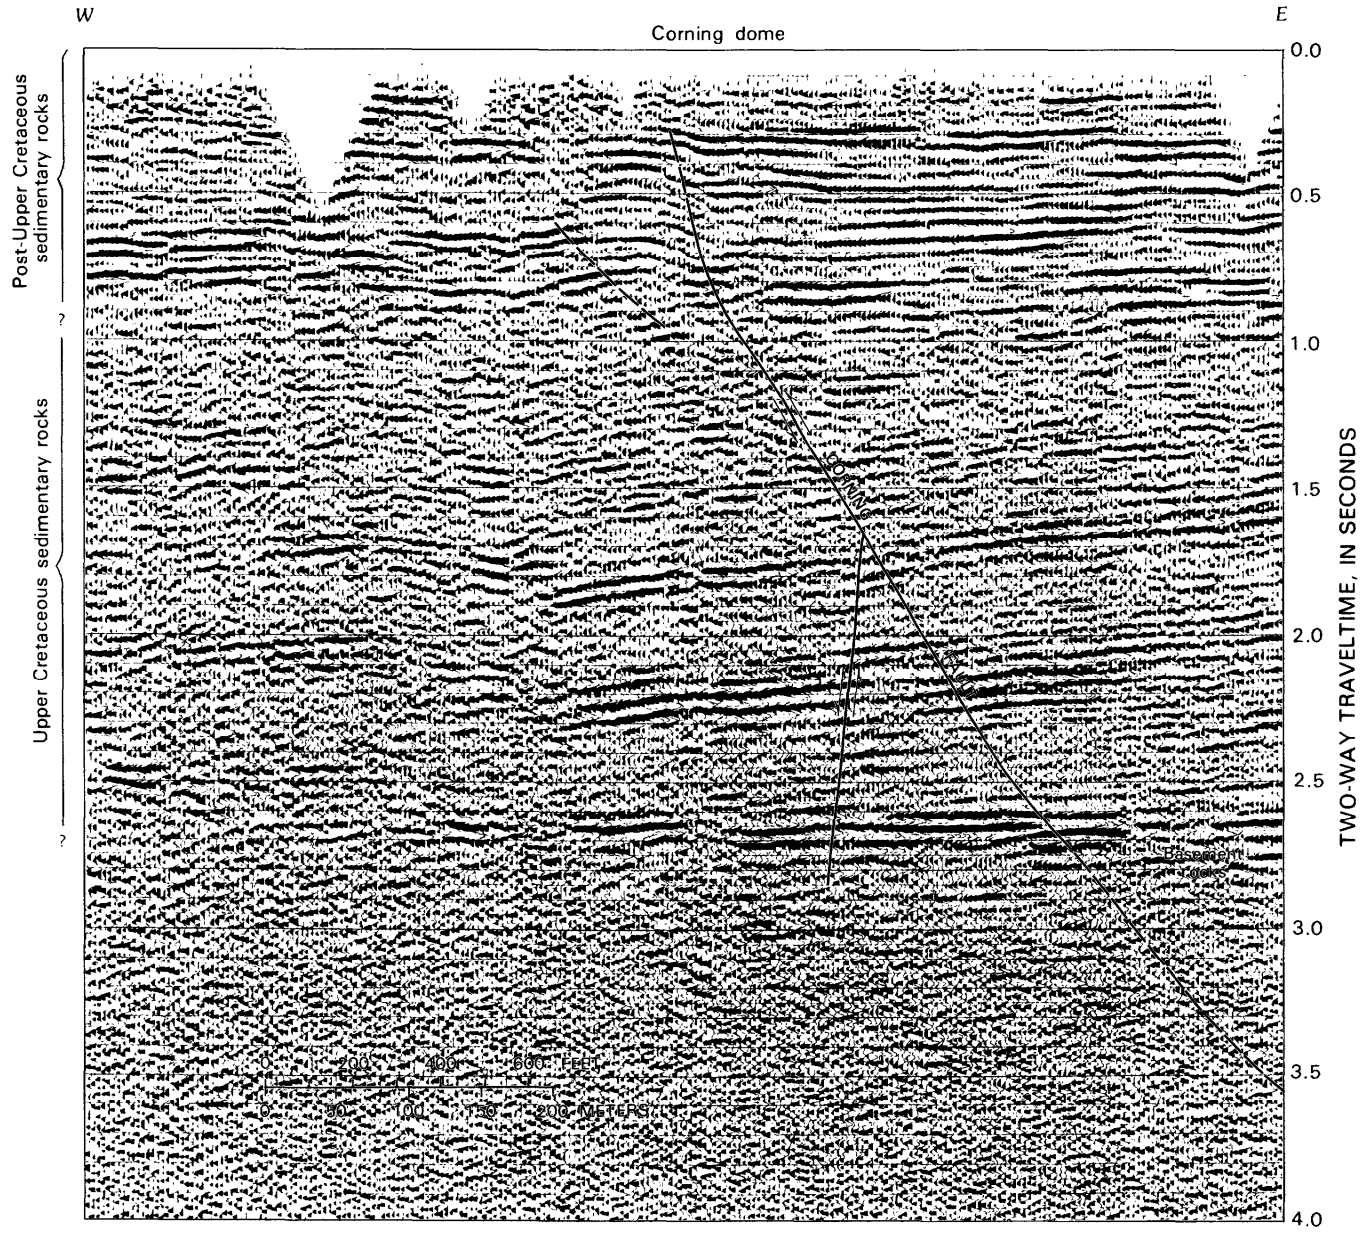

FIGURE 5.—Seismic-reflection profile, from Seisdata Services Inc., showing structural and generalized stratigraphic relations across Corning fault between Corning and Red Bluff, Calif.

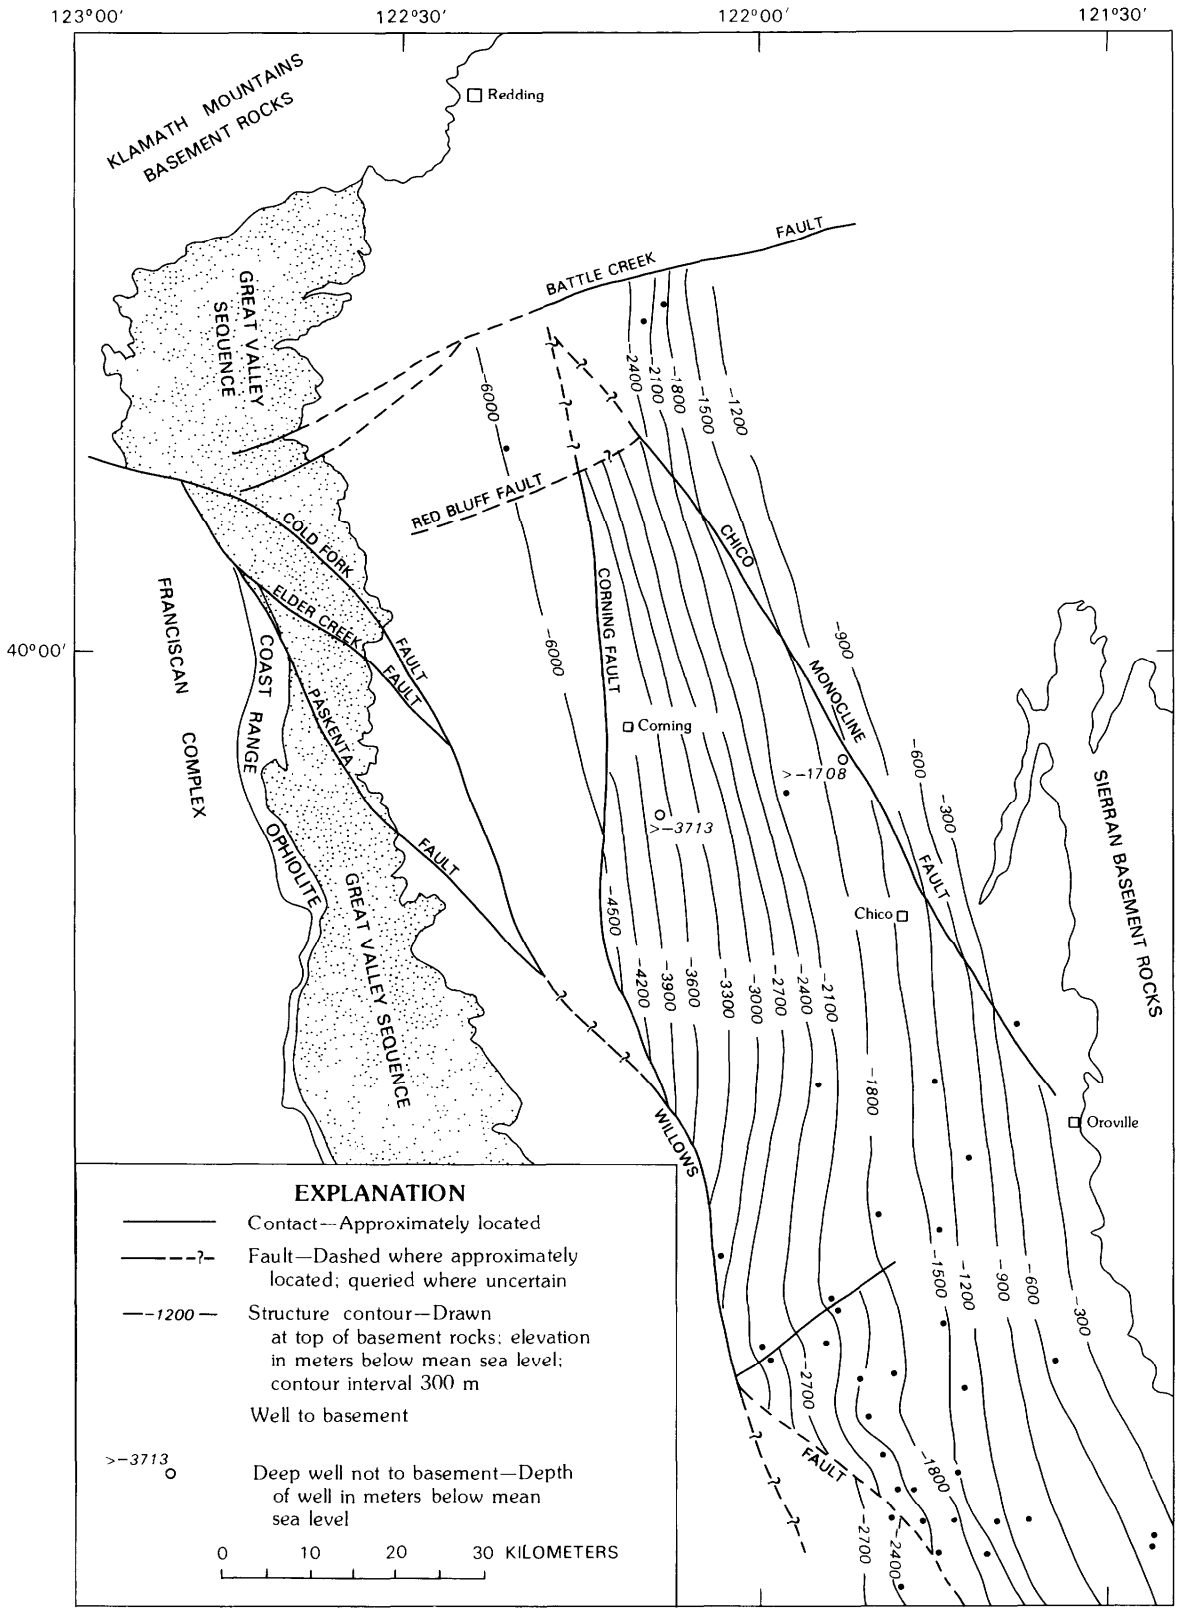

FIGURE 6.—Map of northern Sacramento Valley showing structure contours, drawn on top of basement rocks, used to estimate amount of vertical displacement of basement across Corning fault.

prior to eruption of the Nomlaki about 3.4 m.y. ago. We interpret the topographic low, reflected by the thicker basal part of the Tehama, to be the result of east-side-up movement on the Willows fault, prior to and possibly during, deposition of the lower part of the Tehama Formation. If this interpretation is correct, late Cenozoic movement on the Willows-Elder Creek fault system differs significantly, in style and amount of displacement, from the Cretaceous movement on the Elder Creek-Cold Fork-Paskenta fault system oulined by Jones and Irwin (1971).

Jones and Irwin (1971) inferred at least 96 km of left-lateral displacement of the Lower Cretaceous (Valanginian) strata along the combined Cold Fork-Elder Creek-Paskenta faults. They concluded that this deformation commenced shortly after deposition of the Valanginian strata and continued concurrently with deposition until at least the middle Late Cretaceous. Well-documented vertical displacement of Upper Cretaceous and overlying rocks on the Willows fault in the Willows-Beehive Bend gas field is not incompatible with left-lateral displacement on the Elder Creek fault system to the northwest, but it does indicate that the inferred lateral displacement was accompanied, or postdated by, a major component of east-side-up vertical movement. This vertical movement is consistent with the interpretation that the Elder Creek fault system represents tear faults in the upper plate of the Coast Range thrust (Jones and Irwin, 1971), along which the Klamath Mountains terrane moved upward and westward over the Coast Ranges province (fig. 2).

SOUTHEAST EXTENSION OF WILLOWS FAULT

Location of the Willows fault southeast of Sutter Buttes is not closely constrained by sparse well data along the eastern margin of the valley. No seismic-reflection profiles, that we are aware of, extend far enough east to cross the fault. However, wells in three widely spaced areas do extend far enough east from the deeper parts of the valley to cross the fault, and they provide the most direct evidence for the southeastern extension of the Willows fault. The first area we investigated extends southwest from near Marysville and passes through the Tisdale gas field (pl. 1, map A) just southeast of Sutter Buttes. A cross section (fig. 7) through wells in this area shows that the slope of the basement is significantly steeper east of the Willows fault (between wells 4 and 5, fig. 7), and we infer about 165 m of east-side-up displacement on the basement surface. Shale of the Eocene Capay Formation is recognizable in all of the electric logs in figure 7, and that unit shows about 100 m of displacement between wells 4 and 5. The base of continental deposits (nonmarine sedimentary rocks), which coincides generally with the base of fresh water in the valley, is difficult to identify in all the well logs of this section, but it does not appear to be offset between wells 3 and 5. The dip of the fault is not constrained in this section, and we have shown a steeply east-dipping reverse fault between wells 4 and 5, primarily because the pattern of offset in that area is so similar to that on the Willows fault to the northwest.

About 23 km southeast of the Tisdale gas field, a second line of wells extends from the Sacramento River near Knight's Landing northeastward toward Lincoln. Interest was directed initially to this line of wells because the outline of the Markley canyon, shown by Almgren (1978), is sharply deflected to the south in this area. A section through this line of wells is shown in figure 8. All of the sedimentary rocks in this part of the valley, except those in the Markley canyon, are offset up to the east between wells 3 and 4 (fig. 8). The amount of displacement appears to increase downward in the section from about 30 m at the base of the continental deposits to about 45 m in sandstone and shale sequences in the Upper Cretaceous rocks. Displacement of the basement is inferred to be about 150 m, but the depth to basement west of the Willows fault is not closely constrained by available well data. The most interesting aspect of the section is the marked asymmetry of the Markley canyon fill. Canyon development may have shifted progressively westward, to be localized immediately east of this part of the Willows fault, where the deepest part of the asymmetric canyon fill is located. This pattern of erosion and sedimentation suggests that late Oligocene and early Miocene movement on the Willows fault directly influenced the location and form of the Markley canyon.

The third line of wells we investigated extends from the Sacramento River near Clarksburg to the area east of Florin, where a series of low hills underlain by Pliocene continental deposits of the Laguna Formation rise above the surrounding Pleistocene alluvial deposits. A section through these wells is shown in figure 9. The electric log of the D. D. Feldman "Unit Plan No.1" well (sec. 8, T. 7 N., R. 6 E.); (No. 9, fig. 9) shows an obvious repeat in the Cretaceous rocks just above the basement. We interpret this repeat to represent east-side-up displacement on the Willows fault, which was intersected by the well at an elevation of −1,277 m. If this interpretation is correct, the basement surface is offset about 120 m. A similar offset is shown by Upper Cretaceous rocks.

West of the Willows fault (fig. 9), a steeply east-dipping normal fault, previously unreported, offsets the Capay Formation and older rocks down to the east about 153 m. This normal fault does not appear to offset the base of post-Eocene and younger nonmarine rocks, nor are these rocks offset by the Willows fault to the east. Offset of the basement between wells 5 and 6 (fig. 9) appears to be east side up and suggests early reverse movement on the east-dipping fault.

The location of the Willows fault southeast of Florin is

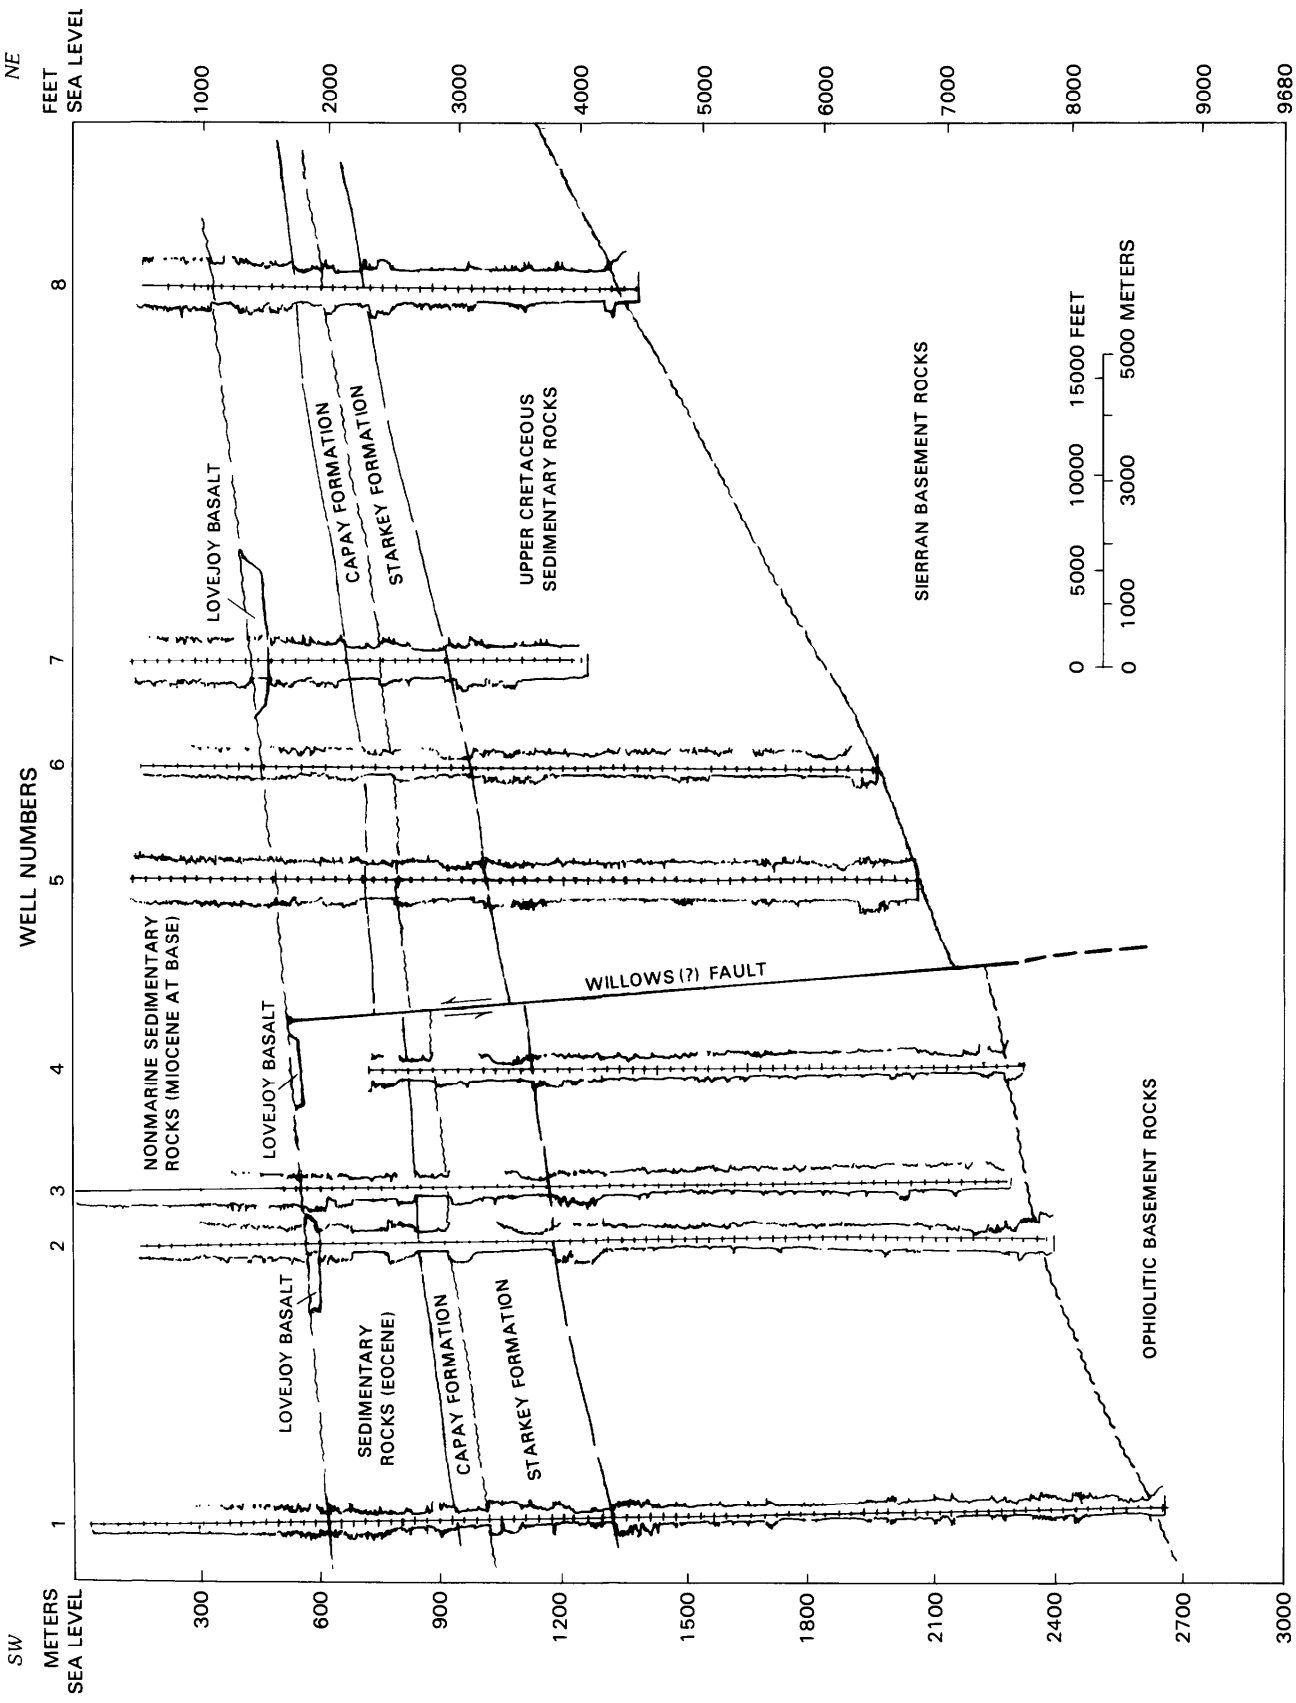

FIGURE 7.—Cross section showing electric logs and stratigraphic and structural relations across possible southeast extension of Willows fault near Tisdale gas field southeast of Sutter Buttes, Calif. Names of wells listed in appendix. Stratigraphic nomenclature used may not necessarily conform to that adopted by U.S. Geological Survey.

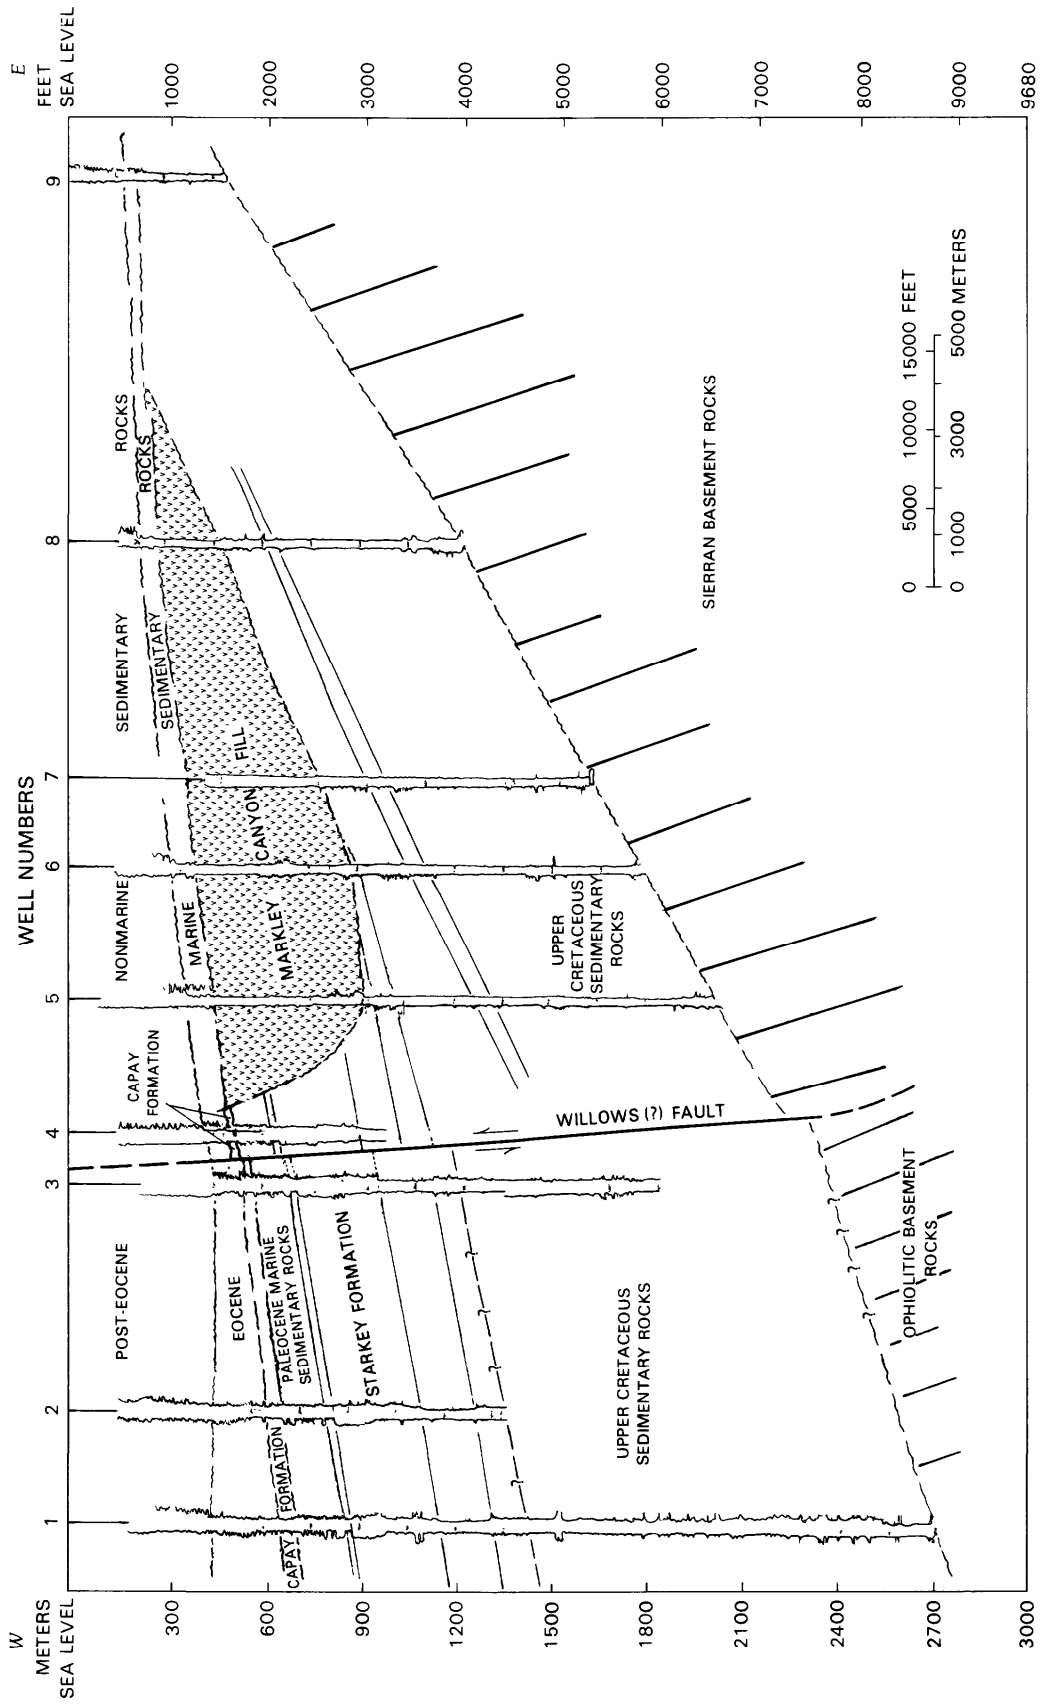

FIGURE 8.—Cross section showing electric logs and stratigraphic and structural relations across possible southeast extension of Willows fault near Catlett-Nicolaus gas fields, Calif. Names of wells listed in appendix. Note asymmetry of Markley canyon fill (patterned) and absence of offset in post-Eocene continental deposits. Stratigraphic nomenclature used may not necessarily conform to that adopted by U.S. Geological Survey.

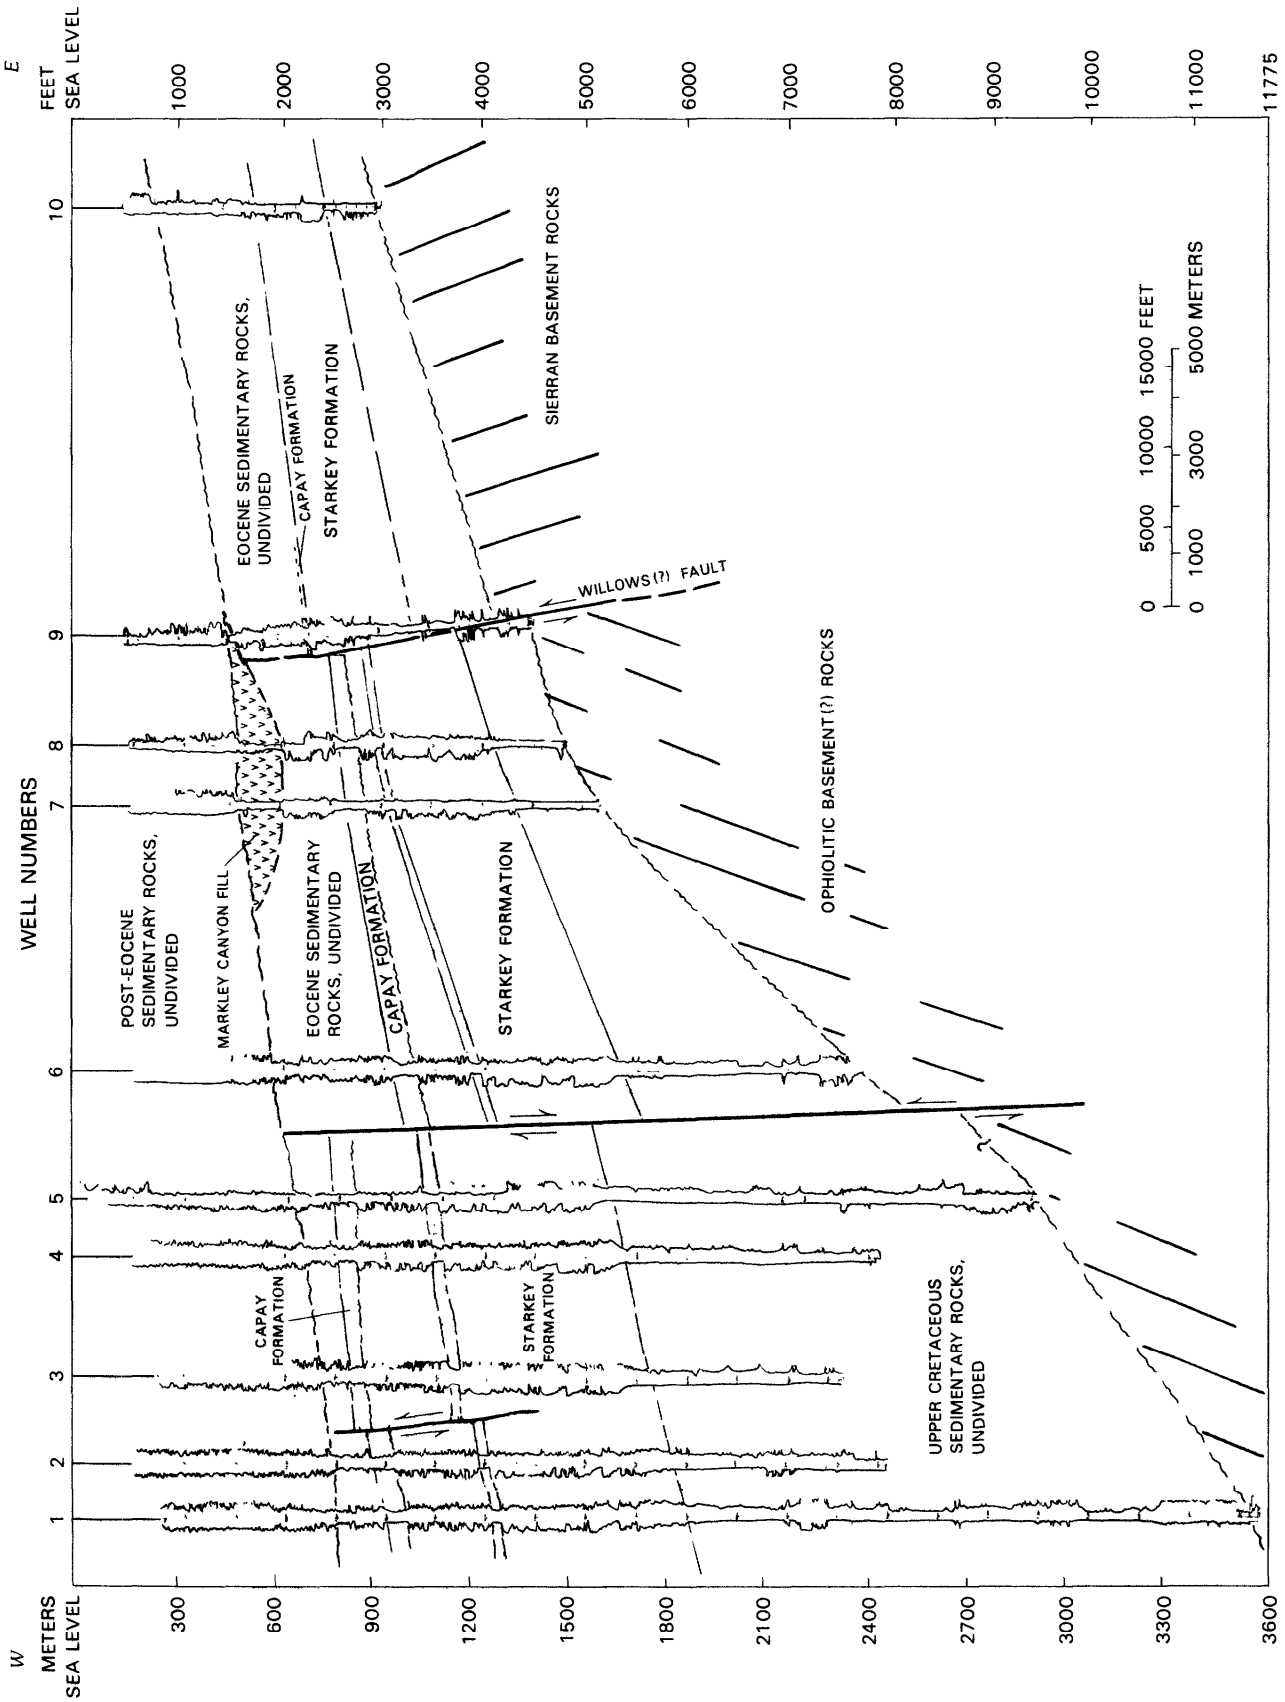

FIGURE 9.—Cross section showing electric logs and stratigraphic and structural relations across possible southeast extension of Willows fault southeast of Florin, Calif. Names of wells listed in appendix. Note repeated electric-log pattern near bottom of well 9 and apparent early east-side-up displacement of basement by unnamed fault between wells 5 and 6, followed by east-side-down offset of Cretaceous and early Tertiary rocks. Stratigraphic nomenclature used may not necessarily conform to that adopted by U.S. Geological

uncertain. A section through several wells east and west of the Lodi gas field, shown in figure 10, indicates a minor deflection in the Capay Formation between wells 6 and 7, but the underlying Cretaceous rocks and the basement surface are not significantly offset in that area. The general east-side-up flexure of the Capay between wells 6 and 7 is the type of deformation that would be expected adjacent to the Willows fault, but the absence of offset in underlying units argues against the existence of the fault. Deformation expressed as fault movement north of Lodi may be expressed as gentle warping to the south.

STRUCTURES NORTHEAST OF THE WILLOWS FAULT

The Willows fault diagonally transects the Sacramento Valley from northwest to southeast and divides the region into two late Cenozoic structural provinces. To the northeast, on the upthrown block of the Willows fault, the present axis of the Sacramento Valley is underlain by the Los Molinos and Glenn synclines (pl. 1). These narrow synclines, coupled with the Corning domes to the west and the Chico monocline to the east, have tightly controlled the course of the Sacramento River and influenced alluvial deposition during the late Quaternary. This tectonic control of alluvial deposition has profoundly influenced land use, particularly in the northeastern part of the valley, where a narrow strip of cultivated land, shown near the top of figure 11, flanks the river and lies directly over the trace of the Los Molinos syncline. South of the constricting influence of the Corning domes and the Chico monocline, late Quaternary alluvial deposits spread laterally across much of the valley over the Glenn syncline, the axial trace of which controls the present course of the Sacramento River as far south as Glenn, Calif. (pl. 1). From Glenn to Colusa, the course of the river lies along the trace of the Willows fault.

From the vicinity of Willows southeast to the Sacramento Delta, the downthrown southwest block of the Willows fault is capped by Holocene basin deposits that flooded over the broad Zamora syncline (pl. 1), burying older deposits, to rest unconformably on Upper Cretaceous rocks north of the Dunnigan Hills. The following part of the report discusses specific structural features on the northeast block of the Willows fault.

SUTTER BUTTES

Sutter Buttes (fig. 11) is a prominent set of hills composed of late Cenozoic volcanic rocks that rise about 635 m above the floor of the Sacramento Valley 15 km northwest of Marysville. According to Williams and Curtis (1977), volcanism and accompanying deformation of the surrounding sedimentary rocks occurred between 2.4 and 1.4 m.y. ago and consisted of two phases. During the early phase of magma injection, Upper Cretaceous and Tertiary rocks were arched into a dome 13 km across, broken by normal and high-angle reverse faults, and rapidly eroded so that the Tertiary rocks were stripped from the core of the dome before the explosive phase of volcanism. Explosive volcanism produced the rampart beds of tuff and tuff breccia that form the peripheral deposits of the buttes (fig. 11).

Extensive drilling for natural gas located an elongate dome in the subsurface about 10 km west of Sutter Buttes. Williams and Curtis (1977) referred to this structure as the buried Colusa buttes, but because it lacks surface expression, we refer to it as the buried Colusa dome (fig. 12). In the buried Colusa dome, several wells (fig. 12) penetrated volcanic rocks similar in composition and age to those in the Sutter Buttes. These data led Williams and Curtis (1977) to conclude that the buried Colusa dome formed solely by forceful magma injection contemporaneous with magmatism at Sutter Buttes. We suggest, however, that magmatism may have been localized by movement on the Willows fault and possibly by movement on the Mesozoic tectonic boundary between ophiolitic and Sierran basement terranes which passes beneath the eastern margin of Sutter Buttes (fig. 12).

The orientation and movement patterns of structures at Sutter Buttes and the buried Colusa dome suggest that deformation occurred in a regional east-west compressive stress field. The distribution of structural features at Sutter Buttes is distinctively asymmetrical. Beds in the Upper Cretaceous rocks on the south and southeast sides of the buttes dip steeply away from the core. Locally, they are overturned. Beds on the north and northwest sides of the buttes generally dip gently away from the core. As shown in figure 12, folds and faults are more abundant on the eastern half of the buttes and the wavelength of folds is tighter there than on the west. In addition to the small normal faults that surround the core of the dome, the eastern half of the dome is cut by a prominent set of steeply inward-dipping, arcuate high-angle reverse faults. This pattern of structural features indicates that the core of Sutter Buttes was thrust eastward as it moved upward.

The northward elongation of the buried Colusa dome strongly suggests that it too was formed in an east-west compressive stress regime. In fact, the amplitude, wavelength, and axial extent of the buried Colusa dome are remarkably similar to folds that occur just east of the Willows fault farther north (pl. 1; fig. 3). Although Redwine (1972) projected the Willows fault southeastward across the buried Colusa dome, our analysis of subsurface data suggests that a fault, possibly the Willows fault or a splay fault related to it, may lie just west of the buried Colusa dome. We conclude that the buried Colusa dome formed partly by east-side-up drag on a high-angle reverse fault along its western margin and partly by magma in-

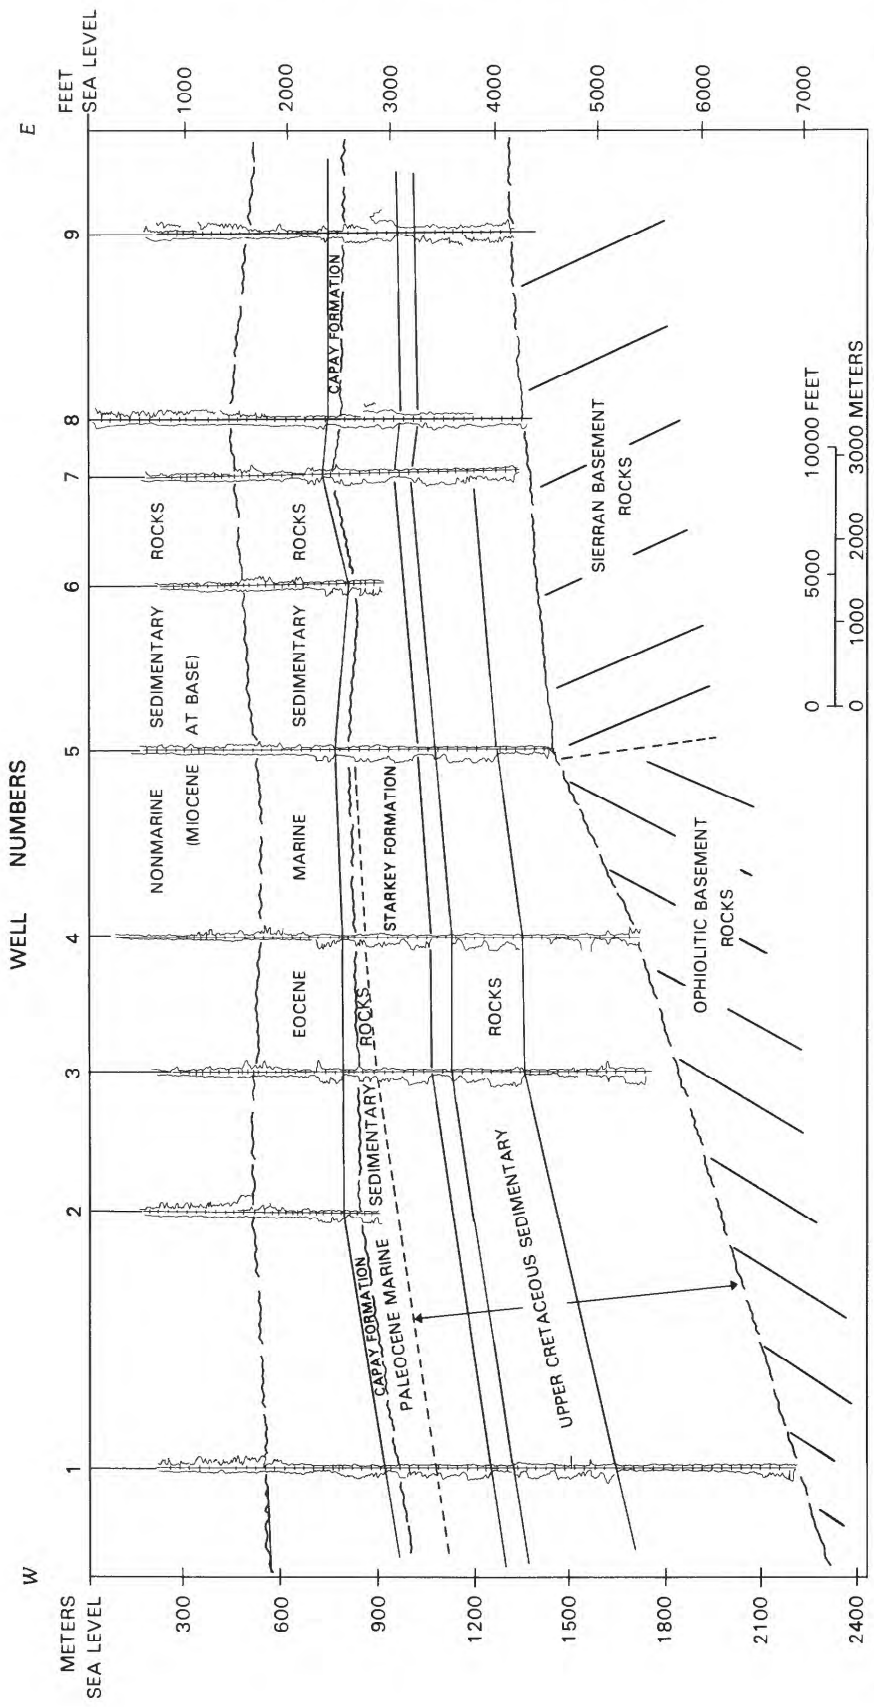

FIGURE 10.—Cross section showing electric logs and stratigraphic and structural relations across possible southeast extension of Willows fault (approximately follows trace of well 5) in area of the Lodi and Galt gas fields, Calif. Names of wells listed in appendix. Stratigraphic nomenclature used may not necessarily conform to that adopted by U.S. Geological Survey.

jection that was localized by movement on that fault.

The pattern of radial normal faults around the core of Sutter Buttes, flanked by reverse faulting to the east and west, assuming that the Willows fault was involved in the tectonism, is the type of deformation found by Withjack and Scheiner (1982) in their modelling experiments of doming in a compressive stress field. Although it is difficult to unequivocally separate magmatic doming from regional compressive deformation in the Sutter Buttes area, supporting evidence for the regional east-west compressive stress field is found in the Chico monocline about 40 km to the north.

FIGURE 11.—U.S. Air Force high-altitude oblique aerial photograph showing northern Sacramento Valley viewed to the north from vicinity of Sutter Buttes (center foreground), a late Pliocene and early Pleistocene volcanic center, approximately 16 km in diameter. Dark core of buttes composed primarily of andesite surrounded by lighter colored volcaniclastic deposits that form peripheral rampart beds of Williams and Curtis (1977). Narrow strip of cultivated land (dark) along Sacramento River (SR) between Corning domes (CD) and Chico monocline (CM) is surface expression of Los Molinos syncline (pl. 1). Oroville dam (OD) located near north end of Cleveland Hills faults where ground rupture occurred during August 1, 1975, Oroville earthquake.

CHICO MONOCLINE

The Chico monocline (fig. 13) is a northwest-trending, southwest-facing flexure that bounds the northeast side of the Sacramento Valley between Chico and Red Bluff. East of the monocline, Pliocene volcanic rocks of the Tuscan Formation dip less than 5° SW., but bedding steepens to 20° or more along the monoclinal flexure where the Tuscan dips beneath Quaternary deposits of the valley. The trace of the monocline is characterized by a complex surface pattern of anastomosing fault strands

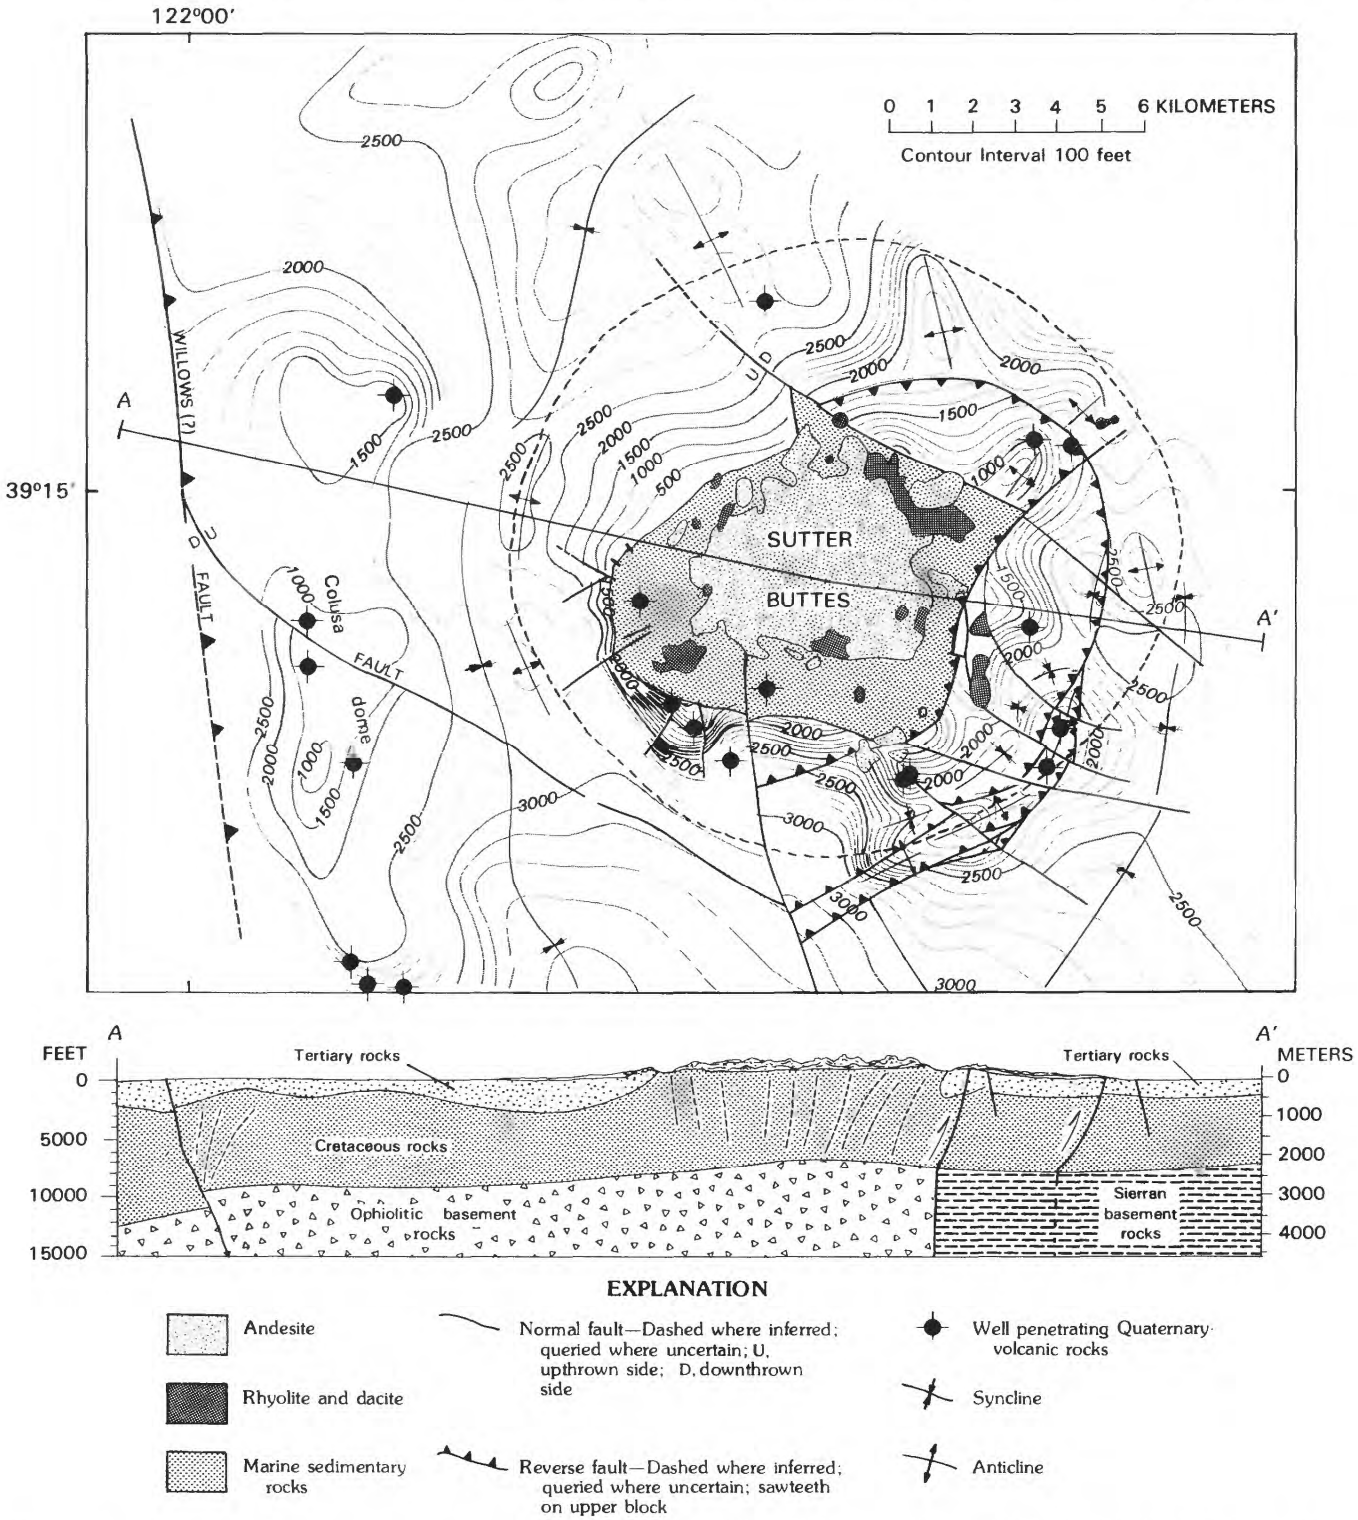

FIGURE 12.—Structure contour map of area around Sutter Buttes, modified from Williams and Curtis (1977, fig. 11) with data from Redwine (1972) and from our examination of electric logs in area of buried Colusa dome. Structure contours in feet; datum is top of the Kione sand of local usage (Williams and Curtis, 1977). Dashed circle on map marks approximate outer limit of rampart beds on valley floor; thin dashed lines on section represent schematic paths of magma injection.

FIGURE 13.—Composite of two U.S. Air Force high-altitude oblique aerial photographs showing pronounced linear trace of Chico monocline (CM, upper right to lower left), broad alluvial fan west of Chico monocline capped by Red Bluff Formation (RB, gray, uncultivated grazing land), and dissected topography of Tuscan Formation (TF) to east. DC, Deer Creek; CD, north Corning dome. Sacramento River (SR) follows trace of Los Molinos syncline (LMS) between north Corning dome and alluvial fan to east.

that show both west- and east-side-down displacements of small magnitude (Harwood and others, 1981).

Structure contours drawn on top of the Cretaceous rocks in the vicinity of the monocline indicate clearly that the Cretaceous strata are flexed and faulted by a major northwest-trending fault at depth beneath the surface trace of the monocline (pl. 1). The best control on the amount of displacement on the master fault beneath the Chico monocline comes from a line of wells that extends generally westward from the Exxon "C. C. Baccala No. 1" well (No. 4, fig. 14), which was drilled just west of the monocline about 18 km northwest of Chico. Although the Baccala well did not reach basement, it bottomed in Upper Cretaceous conglomerate at a depth of −1,700 m and provides a minimum elevation on the basement immediately west of the monocline when used in conjunction with the Pacific Western "Cana No. 1" well (No. 2, fig. 14) that reached serpentine at a depth of −2,100 m about 9 km to the west. Although no wells have been drilled east of the monocline, some control on the elevation and dip of the unconformities at the top and base of the Upper Cretaceous rocks is provided by exposures of these surfaces in several deep canyons to the east. When the trend of the basement surface at these exposures is projected westward, to pass beneath the bottom of the Baccala well, a minimum east-side-up offset of 365 m in the basement rocks is indicated on the fault beneath the monocline (fig. 14). The dip of this major fault cannot be determined directly from surface exposures or subsurface well data, but we show it as a steeply east-dipping reverse fault, because gravity and magnetic data (Griscom, 1973; Cady, 1975; Roberts and others, 1981) indicate that the relatively dense and magnetic basement beneath the northern part of valley extends eastward beneath the Sierran basement exposed east of the monocline. In the Sierran foothills southeast of Oroville, steep east dips are also commonly found in surface exposures of faults that may be the southeastward continuation of the fault beneath the monocline.

From available geophysical evidence, it appears that the fault beneath the monocline is a major tectonic boundary, with a long and complex tectonic history, along which the Sierran basement to the east was juxtaposed against highly magnetic, dense ophiolitic basement to the west (Cady, 1975; Griscom, 1973). These basement terranes were tectonically juxtaposed prior to deposition of the Upper Cretaceous strata. If this interpretation is correct, the fault beneath the Chico monocline may represent a part of the upper-slope discontinuity of Karig and Sharman (1975) that marks the boundary between basement of the late Mesozoic forearc basin to the west and that of the magmatic arc complex to the east. The Chico monocline, in that case, would be a structure inherited from the upper-slope discontinuity, possibly when that major tectonic break was reactivated by late Cenozoic subduction north of the migrating Mendocino triple junction.

The Chico monocline is clearly a late Cenozoic tectonic feature. It formed after deposition of the Ishi Tuff Member of the Tuscan Formation, about 2.6 m.y. ago and prior to the eruption of the olivine basalt of Deer Creek 1.09 m.y. ago (Harwood and others, 1981). Late Cenozoic displacement on the Chico monocline fault has been predominantly east side up, with an apparent component of left-lateral movement that may have contributed to the formation of the Salt Creek, Tuscan Springs and Sevenmile domes at the north end of the monocline and possibly influenced the northeast-trending Inks Creek fold system and Battle Creek fault zone farther northwest.

There is some indication that the Chico monocline fault may be active. The olivine basalt of Deer Creek is offset, but the amount of offset is small. Similarly, a few faults along the monocline show scarps about 1 m in height in the surface of the Tuscan Formation (Harwood and others, 1981). These observations indicate that movement has taken place on the monocline fault system within the past million years. In their study of regional seismicity after the Oroville earthquake, Marks and Lindh (1978)

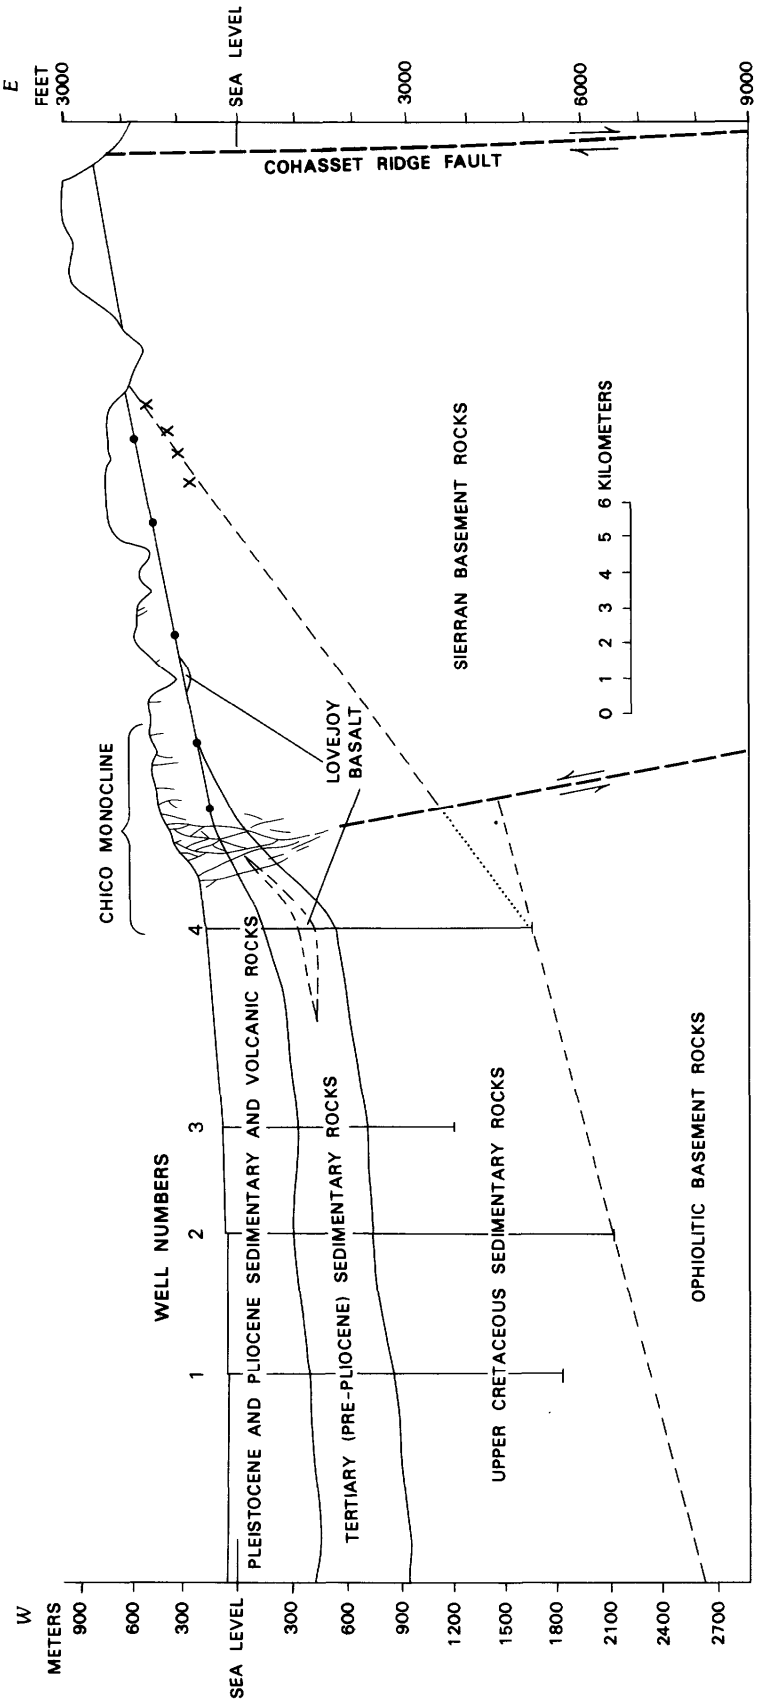

FIGURE 14.—Cross section across Chico monocline about half way between Chico and Red Bluff, Calif., showing offset of basement terranes. Names of wells listed in appendix.

identified two events west of the Oroville aftershock zone at a depth of 40 km, significantly below the main cluster of aftershocks associated with the Oroville earthquake. We interpret those deep events to have occurred on the

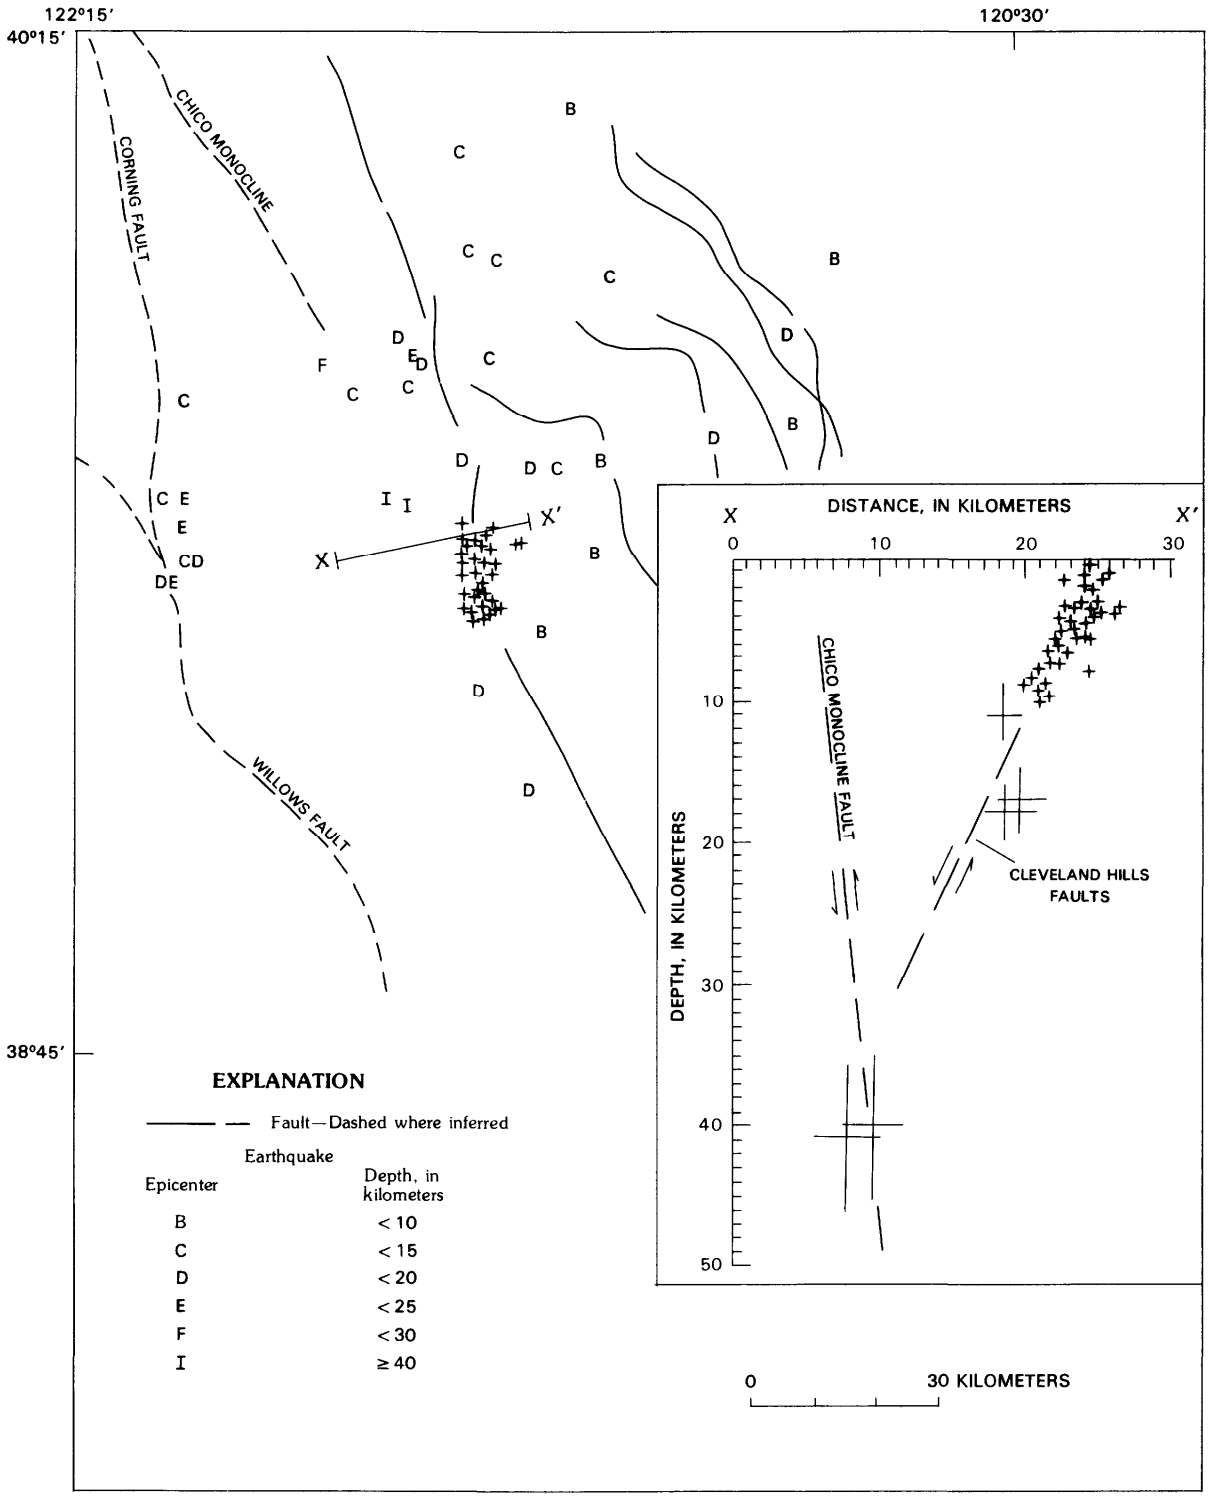

FIGURE 15.—Map and section showing locations of Oroville earthquake aftershocks (crosses on section) in relation to Cleveland Hills faults and Chico monocline (modified from Marks and Lindh, 1978). Earthquakes labeled I on map (largest crosses on section) at a depth of about 40 km are interpreted to have occurred on Chico monocline fault.

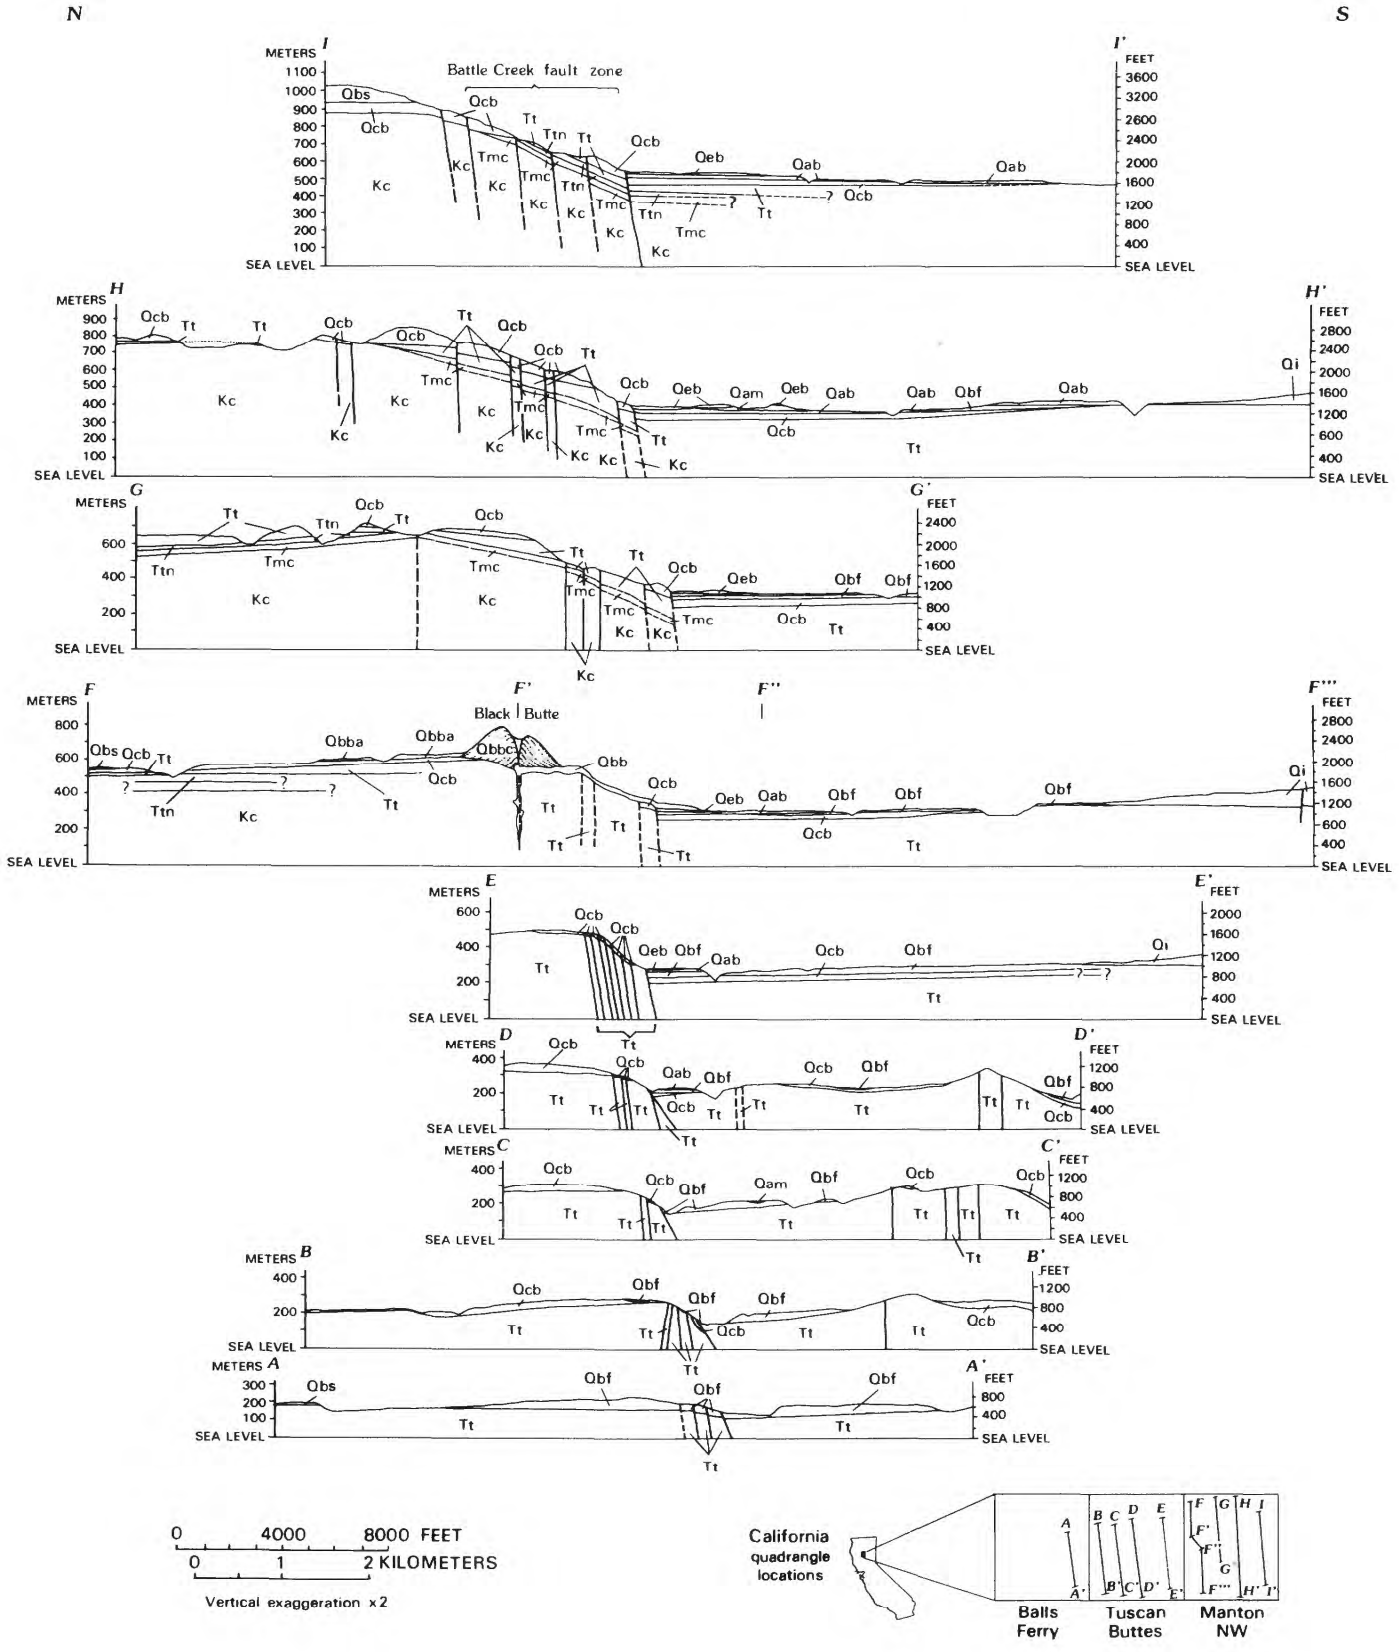
basement fault beneath the Chico monocline and not on the Cleveland Hills faults, where most of the aftershock events were located (fig.15). The steeply east-dipping normal fault, shown east of the Chico monocline on figure 15, is one of several short, north- and north-northwest-trending normal faults that extend along the northern foothills of the Sierra Nevada (pl. 1). This normal fault is probably part of the fault system on which the August 1, 1975, Oroville earthquake occurred.

BATTLE CREEK FAULT ZONE

The Battle Creek fault zone strikes east-northeast across the Sacramento Valley between Red Bluff and Redding, nearly at right angles to the trend of the Chico monocline. East of the Sacramento River, the Battle Creek fault zone is marked by a pronounced south-facing escarpment, shown in figure 16, that extends from the river northeastward toward Lassen Peak for a distance of 32 km. Fault strands within this part of the fault zone dip steeply southeast and show predominantly south-side-down, normal fault movement (Harwood and others, 1980; Helley and others, 1981). Vertical displacement on the fault zone increases from about 45 m just east of the Sacramento River to 330 m at Black Butte (fig. 1) and to about 440 m north of Manton. A small component of right-lateral strike-slip movement is suggested by fractures on some of the fault strands, but the exact amount of lateral displacement is not known.

West of the Sacramento River, the valleys of Cottonwood Creek and its south fork are probably controlled in part by the Battle Creek fault system, but modern stream activity and agricultural practices obscure any young traces of the faults east of the South Fork of Cottonwood Creek (pl. 1). At the South Fork of Cottonwood Creek and along Red Bank Creek, late Quaternary terraces show evidence of young faulting (Helley and others, 1981). To the west-southwest, the faults in the terrace deposits merge into previously mapped faults in the Red Bluff and Tehama Formations, and, on strike, they appear to merge with tear faults in the upper plate of the Coast Range thrust mapped by Bailey and Jones (1973).

FIGURE 16.—Photograph of Battle Creek fault scarp (BC) capped by basaltic cinder cone of Black Butte. View to northeast along Highway 36 and across rolling grassy plains underlain by volcanic fanglomerate correlated with the Red Bluff Formation.



The orientation and distribution of faults in the Battle Creek fault zone east of the Sacramento River are shown in figure 17. Section *A-A′* is located 2.4 km east of the Sacramento River and shows relatively little offset of the fanglomerate that caps the Tuscan Formation. As the fault zone extends eastward, offset on the various Pliocene and Pleistocene units and the height of the fault scarp increases. From near the Sacramento River east to Black Butte (sections *A-A′* through *F-F′*, fig. 17), the fault strands are closely grouped along the fault scarp, but east of Black Butte (sections *G-G′* through *I-I′*, fig. 17) the fault strands are more widely spaced. In map view, the eastern fault strands veer northwestward and appear to die out a short distance north of the escarpment (Harwood and others, 1980).

Several clusters of small-magnitude earthquakes were reported along the eastern third of the Battle Creek fault zone, generally east of Black Butte (Bolt, 1979). Since 1980 the California seismic net of the U.S. Geological Survey has recorded several small-magnitude earthquakes (J. Eaton, oral commun., 1982) that lie approximately along the Battle Creek fault zone and extend west nearly to the Sacramento River.

Coarse volcanic fanglomerate, correlated here with the Red Bluff Formation by soil stratigraphy and geomorphic surface, is offset by the Battle Creek fault zone east of the Sacramento River and dates the major movement as younger than 1.09 m.y. The Rockland ash bed (referred to as the ash of Mount Maidu by Helley and others, 1981) appears to have been partly channeled by the Battle Creek fault scarp, suggesting that the faulting occurred prior to about 0.45 m.y. ago, the age of the Rockland ash bed (Meyer and others, 1980).

INKS CREEK FOLD SYSTEM

A set of northeast-trending folds, referred to as the Inks Creek fold system by Helley and others (1981), deforms the rocks south of the Battle Creek fault zone and structurally controls the major loops in the Sacramento River at Jelly School and the nearby Table Mountain (pl. 1; figs. 1, 18). The axial trace of the major syncline in the fold set passes through Table Mountain and extends northeastward, nearly coincident with Inks Creek. The complementary anticline to the north arches the volcanic fanglomerate, which is correlated with the Red Bluff Formation, and the underlying basalt of Coleman Forebay (Helley and others, 1981), exposing strata of the uppermost part of the Tuscan Formation northeast of Jelly

School. Axial surfaces of the folds are vertical, and fold axes plunge 20°–35° SW. Axial traces of the folds change strike to the northeast so that the anticlinal trace merges with the trend of the Battle Creek fault zone and apparently dies out along the fault to the east-northeast.

West of the Sacramento River, the Inks Creek fold system is expressed as a broad area of uplift known as the Hooker dome (fig. 18). This structure, which has profoundly influenced drainage patterns in the area, particularly along Hooker Creek and Blue Tent Creek (fig. 18), is underlain by the Tehama Formation capped by a few scattered erosional remnants of the Red Bluff Formation.

The Inks Creek fold system is clearly reflected in the structure contours drawn on top of the Cretaceous rocks, which show a closure of about 485 m over the anticline (pl. 1). Although only a few wells in this area reach basement, the elevation of the basement in two wells drilled on the anticline of the Inks Creek fold system is higher than the total depth of some wells to the west that bottomed in Upper Cretaceous rocks. These data indicate that the basement was deformed, along with the cover rocks, during formation of the Inks Creek fold system. They also strongly suggest that the folds shown by the structure contours on plate 1 involve the basement of the valley rather than deformation on a decollement or a series of detachment thrusts in the cover rocks.

The fact that the anticlinal trace of the Inks Creek fold system merges with the Battle Creek fault zone suggests a genetic relation between these major structures. If this interpretation is correct, evidence for the age of the Inks Creek fold system provides data for the age of movement on the Battle Creek fault zone. At Round Mountain, about 3 km southwest of Jelly School, the Rockland ash bed rests unconformably on the eroded western contact of the Red Bluff Formation at an elevation of 160 m. We assume that the ash was deposited in an ancestral channel of the Sacramento River, which apparently formed a large westward bend at that time extending from Bloody Island on the north to the vicinity of Bend on the south (fig. 18). Uplift and erosion of the Red Bluff Formation, which was deposited between 0.45 and 1.09 m.y. ago, had begun

prior to deposition of the ash. In contrast to the occurrence of the ash at Round Mountain, alluvial deposits of the lower part of the Riverbank Formation are found at an elevation of 120 m in this region, and they flank the present sinuous course of the Sacramento River through the structurally controlled loops of the river at Jelly School and Table Mountain. Clearly, the Sacramento River was forced into its tortuous course around the Inks Creek fold system by early Riverbank time. We conclude, therefore, that the Inks Creek fold system and at least some of the displacement on the Battle Creek fault zone developed in the timespan between 0.45 m.y., the age of the ash, and about 0.4 m.y. ago, the age of the lower part of the Riverbank Formation (Marchand and Allwardt, 1981).

SALT CREEK, TUSCAN SPRINGS, AND SEVENMILE DOMES

Small areas of Upper Cretaceous marine rocks are exposed beneath the Pliocene Tuscan Formation in Salt Creek, at Tuscan Springs, and in Sevenmile Creek between the north end of the Chico monocline and the Inks Creek fold system (pl. 1). In each area, beds in the Tuscan dip outward, away from the Upper Cretaceous rocks, and define three small domes, shown on plate 1 as the Salt Creek, Tuscan Springs, and Sevenmile domes.

The long axes of the domes trend north-northeast and plunge 15°–25° NE. and SW. Cold sulfurous springs are present in the Salt Creek and Tuscan Springs domes, and olivine basalt rests unconformably on steeply northwest-dipping Upper Cretaceous rocks in the core of Sevenmile dome. The olivine basalt was extruded from a north-trending fissure after the Tuscan Formation was domed and erosion had exposed the Upper Cretaceous rocks.

The age of the olivine basalt is unknown, but it probably is a few tens of thousands of years old, at most, and is roughly coeval with similar basalt flows and cinder cones found at Inskip Hill (pl. 1) and Black Butte along the Battle Creek fault zone. The domes probably formed during the same phase of late Quaternary deformation about 0.4–0.45 m.y. ago that produced the Inks Creek fold system and the Battle Creek fault zone, and they are thus younger than the Chico monocline.

RED BLUFF FAULT

The Red Bluff fault is a subsurface structure that extends southwest of Red Bluff for at least 25 km. West of Red Bluff, there is no surface feature associated unequivocally with the fault, and its location on plate 1 is taken from Jennings' (1977) geologic map of California. Apparently Jennings included the fault on that map on the basis of seismic-reflection data obtained from private industry (Oliver and Griscom, 1980). We have not seen that data or any other seismic profiles that might cross the fault. Griscom (1973) inferred the existence of a major northeast-trending fault in the area from magnetic data.

East of Red Bluff, structure contours on top of the Cretaceous rocks outline a major anticline, the broad crest of which lies beneath the Salt Creek, Tuscan Springs, and Sevenmile domes. The axial trace of this anticline roughly coincides with the east-northeast projection of the Red Bluff fault, but there is no indication that the Tuscan Formation is faulted at the surface along the N. 70° E. trend. The southeast limb of the anticline may be faulted at depth, but surface and subsurface data are too sparse to either prove or refute that structural possibility. Between Tuscan Springs and the Humble "Cone Ranch No. 1" well (sec. 20, T. 27 N., R. 2 W.) to the south, the top of the Cretaceous sequence drops about 1,433 m over a distance of less than 8 km. The lower elevation is due to warping and faulting on the Chico monocline fault, as well as to folding and possible faulting along the northeast projection of the Red Bluff fault.

From our reinterpretation of a north-south section along the Sacramento River near Red Bluff given by Redwine (1972, section *F-F'*), the base of the Tehama Formation could be offset, down to the south, by as much as 141 m across the Red Bluff fault just east of Red Bluff. Because of the lack of northeast-trending surface faulting in the Tuscan to the east, however, it seems unlikely that all of that differential elevation is due to fault displacement; much of it may be related to folding over a fault at depth.

FAULTS SOUTH OF INSKIP HILL

The northwest-trending arcuate faults that are shown south of Inskip Hill (pl. 1) are a gross simplification of the faults and fractures found in that area. In detail, the Tuscan Formation is laced with a dense network of short anastomosing faults along which thin lines of shrubs and trees grow (fig. 19). The amount of offset on a single fault is small, generally a few meters or less, and there appears to be no significant cumulative offset in the Tuscan Formation across the fractured area.

The arcuate pattern of faults is concave toward the area of Mineral, to the east, where Wilson (1961) identified a major volcanic center that he called Mount Maidu. It seems reasonably certain that the fracture pattern is related to volcanic-tectonic activity in the Lassen area, but whether it is associated with Mount Maidu or some other volcanic center is uncertain.

STRUCTURES SOUTHWEST OF THE WILLOWS FAULT

With the exception of the buried Colusa dome, the subsurface structure of the valley southeast of the Willows fault to the Sacramento Delta is dominated by the Zamora

syncline. South of buried Colusa dome, the Zamora syncline is asymmetrical and has a broad, gently west-dipping east limb that extends to the Sierran foothills and a steeply dipping west limb that is warped by southeast-plunging folds. North of the buried Colusa dome, the axial trace of the Zamora syncline intersects the Willows fault, and the top of the Upper Cretaceous rocks defines a generally east-dipping homocline.The following sections discuss structural features west of the axial trace of the Zamora syncline.

CAPAY VALLEY-CAPAY HILLS AREA

Cache Creek drains east from Clear Lake and enters the Sacramento Valley west of Woodland, through the tectonically controlled depression of Capay Valley. On the west, Capay Valley is flanked by the eastern slope of the Coast Ranges that contain a remnant of Eocene marine sandstone and shale of the Capay Formation (Redwine, 1972) resting unconformably on Upper Cretaceous marine rocks (Kirby, 1943a). Beds in the Capay and underlying rocks dip 25°-55° E. The Capay Hills, previously known as the Rumsey Hills (Kirby, 1943b), lie immediately east of Capay Valley and are underlain by the same Upper Cretaceous rocks exposed to the west. Here, however, the Cretaceous rocks lie in the core of a faulted southeast-plunging anticline, shown by structure contours on plate 1. They are unconformably overlain by nonmarine sandstone and shale of the Pliocene Tehama Formation. The Eocene Capay Formation is not present in the Capay Hills or in the Capay Valley, where scattered subsurface and surface data indicate that the Tehama rests unconformably on Upper Cretaceous rocks.

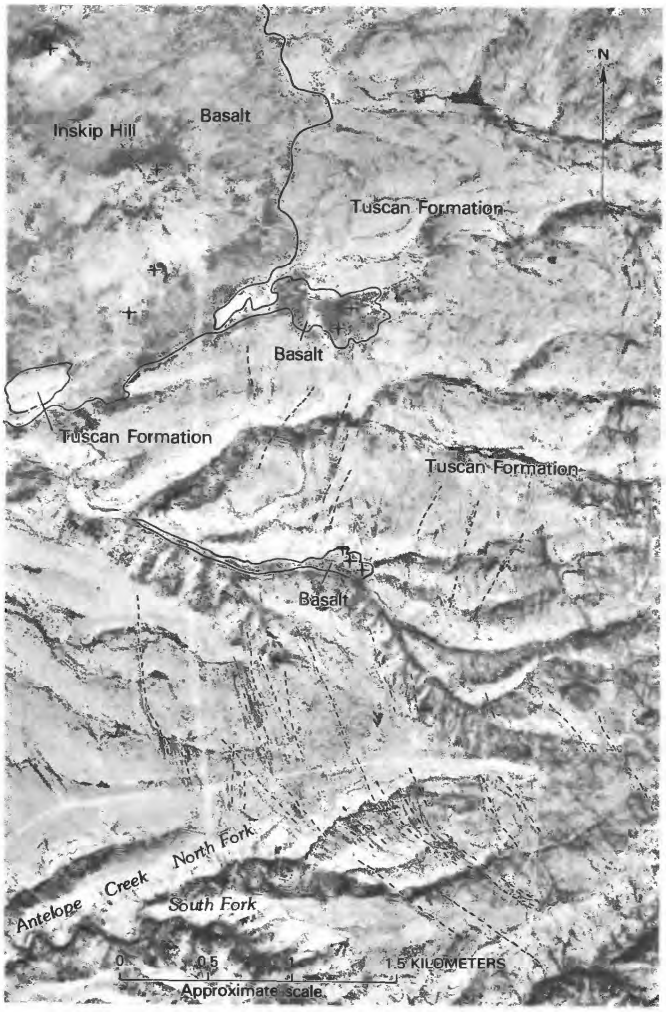

FIGURE 19.—Low-altitude vertical aerial photograph (U.S. Geological Survey) showing arcuate fault pattern (dashes) and cinder cones (crosses) south of Inskip Hill. Gray incised plains are underlain by the Tuscan Formation; thin dark lines are concentrations of brush and trees growing along fault traces.

On the floor of Capay Valley, the Tehama and older rocks have been eroded, and old stream channels have been filled with a variety of Quaternary alluvial deposits. Alluvial deposits of the upper part of the Modesto Formation indicate that Cache Creek entered the Sacramento Valley through a channel cut in the Tehama Formation near the west boundary of Capay Valley in late Wisconsin time. During the past 12,000 years the course of Cache Creek has shifted eastward so that the creek now exits Capay Valley through a sharp gorge cut into the relatively resistant Upper Cretaceous rocks at the southern end of Capay Hills. The shift in the course of Cache Creek and the surface and subsurface data that show faulting in the Tehama Formation provide strong evidence for late Cenozoic tectonism in Capay Valley.

Along the west flank of the Capay Hills, Kirby (1943b) mapped a northwest-trending, east-dipping thrust, the Sweitzer fault, and a lower ancilliary thrust, the Eisner fault; both faults place Upper Cretaceous rocks in contact with the Tehama. Wagner and Saucedo (1984) have reinterpreted the Sweitzer and Eisner faults as west-dipping normal faults. Their interpretation of the Sweitzer fault is supported by subsurface data at the south end of Capay Hills, where the contact between the Forbes and Guinda Formations of Kirby (1943a) is downfaulted about 50 m on the west (fig. 20, wells 3 and 4). Compared to other faults in the area, the Sweitzer fault appears to have played a relatively minor part in the structural evolution of the Capay Valley and Capay Hills.

West of the Sweitzer fault, the contact between the Forbes and Guinda Formations was reported at an elevation of about 219 m beneath the Capay Valley (fig. 20, well 2). That contact is displaced about 610 m up to the west along the northwest-trending, steeply east-dipping East Valley fault (fig. 20). Along the west margin of Capay Valley, the contact between Upper Cretaceous rocks and the Tehama Formation is down faulted about

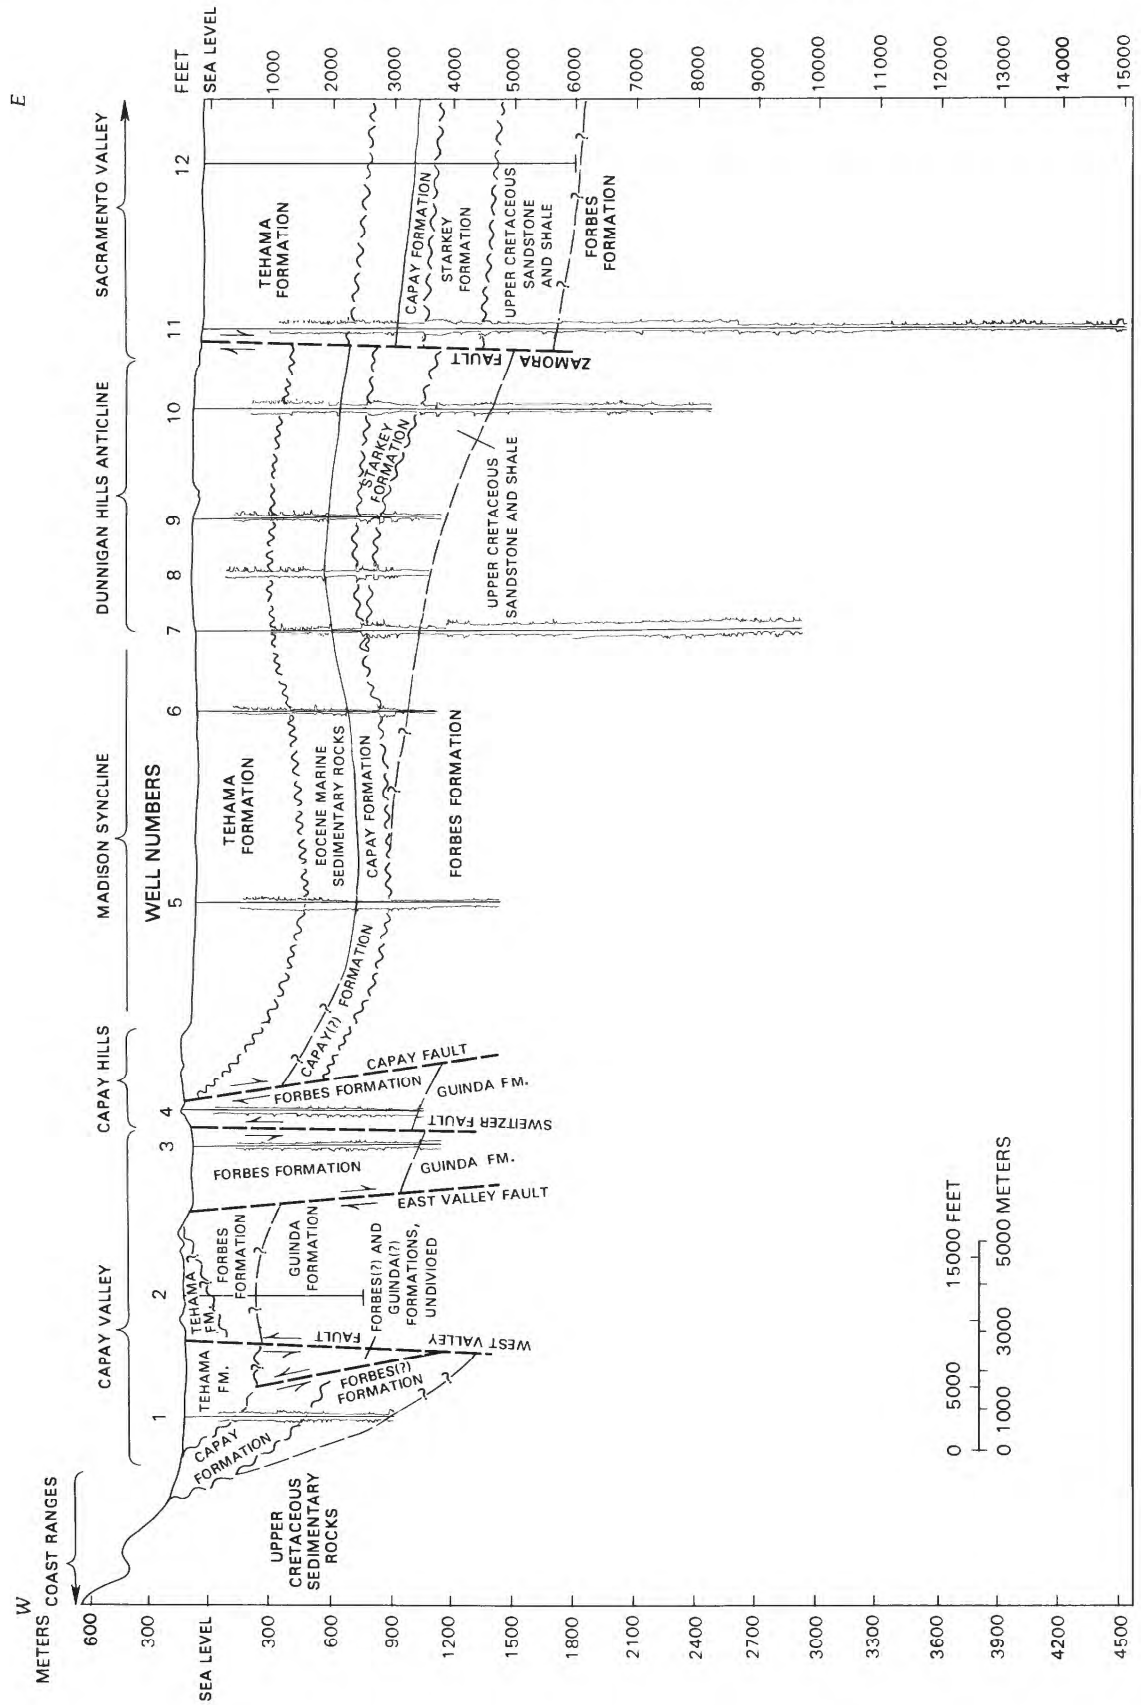

FIGURE 20.—Cross section showing electric logs and stratigraphic and structural relations in Capay Valley, Capay Hills, and Dunnigan Hills. Names of wells listed in appendix. Stratigraphic nomenclature used may not necessarily conform to that adopted by U.S. Geological Survey.

150 m to the west by the near-vertical West Valley fault (fig. 20). At the south end of Capay Valley, Upper Cretaceous rocks are thrust over the Eocene Capay Formation along a thrust or high-angle reverse fault that is exposed to the south along the east flank of the Coast Ranges (pl. 1). The location of this thrust or high-angle reverse fault is unknown east of the West Valley fault.

East of Capay Hills, the Capay Formation unconformably overlies east-dipping Upper Cretaceous rocks beneath the Madison syncline and the Dunnigan Hills anticline (pl. 1; fig. 20). The Capay Formation and overlying Eocene marine rocks are not exposed in the Capay Hills where the Pliocene Tehama Formation rests unconformably on Upper Cretaceous rocks. Because the Capay Formation is present west of Capay Valley, however, we assume that the Capay Formation once extended over the area of the Capay Hills but that it was eroded from the area after west-side-up movement on the Capay fault (fig. 20) and the other high-angle reverse faults to the west under Capay Valley. In this interpretation, the minimum displacement on the Capay fault would be about 700 m. Major west-side-up reverse movement occurred on the Capay fault, the East Valley fault, and the unnamed thrust or high-angle reverse fault to the west in post-Eocene time and before deposition of the Tehama Formation, which contains the 3.4-m.y. old Putah Tuff Member near its base (Sarna-Wojcicki, 1976). West-side-down movement occurred on the West Valley fault subsequent to deposition of the Tehama Formation, and east-side-down, post-Tehama displacement also may have occurred on the East Valley fault and the Capay fault.

DUNNIGAN HILLS ANTICLINE AND THE ZAMORA FAULT

Near Woodland, Bryan (1923) recognized accordant summit elevations capped by Red Bluff gravel on a series of northwest-trending dissected uplands that he called the Hungry Hollow Hills, but which are now known as the Dunnigan Hills. The northeast flank of the upland is bounded by a linear escarpment that Bryan called the Hungry Hollow fault, but which is referred to here as the Zamora fault (pl. 1; fig. 20). He recognized down-to-the-east displacement of at least 121 m at the north end of the fault scarp and offset of about 60 m near Cache Creek to the south (Bryan, 1923, p. 79).

Bryan's early work, combined with the topographic relief in the area, made the Dunnigan Hills a prime target for early seismic-reflection studies that resulted in the discovery of the Dunnigan Hills gas field in 1946 (Rofe, 1962). The gas-producing structure is a doubly plunging, northwest-trending anticline along which various Upper Cretaceous sandstone beds are unconformably capped by the Eocene Capay Formation (fig. 20). This major structure has topographic relief. Red Bluff gravel wraps around the northwest-plunging nose of the fold and occurs in scattered patches along the east flank, on the crest line, and at the southeast-plunging nose of the fold. Oat Creek (pl. 1) and Bird Creek to the southeast (not shown on pl. 1) are antecedent to the fold and change from southeast to northeast courses approximately at its axial trace.

Data from a recent well drilled near Zamora by the U.S. Geological Survey provide new information on the amount of late Cenozoic deformation in the area. A conspicuous volcanic ash bed, penetrated at a depth of −137 m (Page and Bertoldi, 1983), has been correlated tentatively by mineralogy and chemical composition of the glass with the Rockland ash bed by C. E. Meyer and A. M. Sarna-Wojcicki (oral commun., 1982). Because the ash occurs directly above Red Bluff gravels elsewhere in the valley (Harwood and others, 1981; Helley and others, 1981), it is assumed that the ash overlies the Red Bluff in the Zamora well and that there is a minimum of 220 m of vertical displacement of the Red Bluff Formation. This vertical separation is the result of folding on the Dunnigan Hills anticline and displacement on the Zamora fault (fig. 20).

MIDLAND FAULT

The Midland fault is a major subsurface structure that was discovered in the Sacramento Delta during development of the Rio Vista gas field between 1936 and 1943 (Frame, 1944). Through data from extensive drilling, the fault was extended about 25 km north of the Rio Vista field to the Maine Prairie gas field (Arleth, 1968). North of that field, the location of the Midland fault is uncertain. Redwine (1972) proposed that the Sweitzer fault, mapped by Kirby (1943b) in the Capay Hills, was the northwest continuation of the Midland fault. Although Jennings (1977) showed the Midland-Sweitzer fault connection, suitably queried, on his geologic map of California, that interpretation is no longer considered correct (C. Jennings, oral commun., 1981). The location of the Midland fault south of the Rio Vista gas field is uncertain.

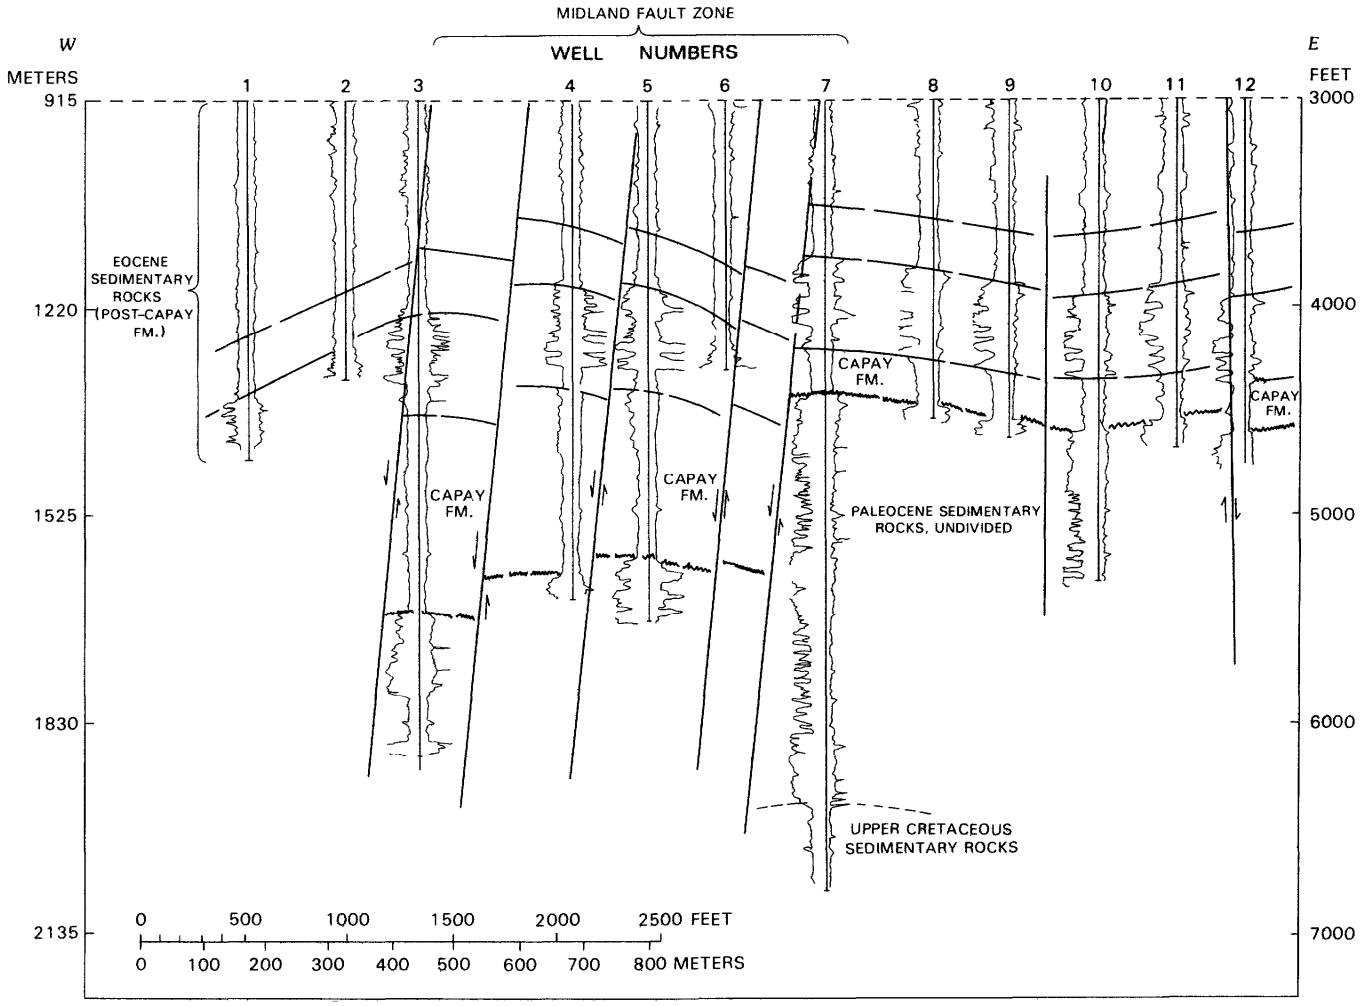
In the Rio Vista gas field, the Midland fault is actually a north-trending, steeply west-dipping to vertical fault zone that offsets Paleocene and Eocene rocks down to the west in a series of fault blocks as shown in figure 21. Early in the development of the Rio Vista gas field, it became apparent that movement on the Midland fault had controlled local patterns of Tertiary sedimentation. Frame (1944) noted that the Capay Formation was significantly thicker west of the Midland fault, and he suggested that maximum movement occurred on the fault during or at the close of Capay deposition. Although the Capay Formation shows the greatest amount of syntectonic thickening across the fault, all of the Paleocene and Eocene units show some differential thickening west of the fault (Bur-

roughs and others, 1968). In his detailed analysis of depositional and tectonic cycles in the southern Sacramento Valley, Almgren (1978) demonstrated approximately 610 m of episodic movement on the fault between the early Paleocene and early Oligocene. There is no indication that early Oligocene or younger deposits are offset by the Midland fault; therefore, it appears that the Midland fault was an active structural feature on the early Tertiary continental margin but that it has not been active in the late Cenozoic.

By combining data presented by Burroughs and others (1968) and Almgren (1978), it is possible to calculate approximate displacement rates on the Midland fault during the early Tertiary. Calculation of the displacement rates, shown in figure 22, assumes that displacement occurred on a single fault strand during the time deduced for various units by Almgren (1978) and that initial offset began in the Paleocene. Between 60 and 53 m.y. ago the slip rate was 3.8 cm/1,000 yr. The rate increased to a maximum of 7.2 cm/1,000 yr between 53 and 50 m.y., and it decreased significantly to 0.75 cm/1,000 yr between 49 and 42 m.y.

THORNTON ANTICLINE

The Thornton anticline, or the Thornton arch of Silcox (1968), is an east- to southeast-trending, west-plunging fold that is transected in part by closely spaced northwest-trending faults that generally show west-side-down displacements of less than 20 m. The fold extends from the east-central part of the Sacramento Delta to the vicinity of Lodi and provides structural control for several gas fields along its trace. Silcox (1968) provides the most detailed information on the structural development of the



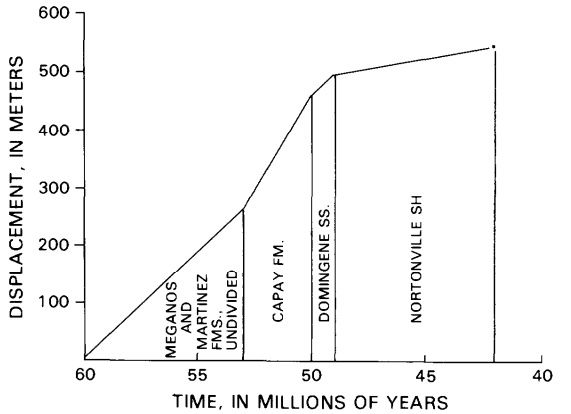


FIGURE 21.—Cross section showing electric logs and stratigraphic and structural relations across Midland fault zone in Rio Vista gas field (modified from Burroughs and others, 1968). Note significant thickening of the Eocene Capay Formation west of easternmost strand of Midland fault zone. Names of wells given by Burroughs and others (1968).

Thornton anticline in his description of the Thornton and Walnut Grove gas fields.

According to Silcox (1968) initial development of the Thornton anticline occurred prior to deposition of the basal Eocene rocks and may have been contemporaneous with Paleocene displacement on the Midland fault to the west. Maximum flexure of the structure apparently occurred in the late Eocene when lower and middle Eocene rocks were eroded and subsequently buried unconformably beneath deposits of the Markley submarine canyon. Miocene continental rocks, which were deposited unconformably on Markley canyon fill, do not show any significant folding over the Thornton anticline, nor are they offset by the northwest-trending faults that cut earlier deposits along the fold. Therefore, the structures are pre-Miocene.

STOCKTON FAULT

The Stockton fault is a northeast-trending, southeast-dipping subsurface fault that extends across the southern part of the Sacramento Valley between Tracy (south of pl. 1) on the west and the vicinity of Milton on the east. The fault lies north of a cross-valley, northeast-trending structural high in the basement, known as the Stockton arch, that apparently was discovered during some of the earliest seismic-reflection profiling done in the valley in the mid-1930's. Wells drilled near the Stockton fault during that time found only minor amounts of gas, and the relations between displacement on the Stockton fault and folding in the Upper Cretaceous marine rocks were not determined until development of the Lathrop gas field during the late 1940's. Teitsworth (1968), in his analysis of the Lathrop gas field, presents the most detailed study of the complex tectonic history of the Stockton fault. His work coupled with our analysis of wells to basement north of the Stockton fault, and Bartow's (1983) analysis of wells south of the fault provide the data for this discussion.

UNIT	DIFFERENTIAL THICKNESS (m)	POSTFORMATION OFFSET (m)	TOTAL OFFSET (m)	TIME (m.y. ago)	RATE (cm/10³ yr)
Nortonville Sh	15	38	53	(49-42)	0.75
Domingene Ss.	26	23	49	(50-49)	4.9
Capay Fm.	215	0	215	(53-50)	7.2
Meganos and Martinez Fms., undivided	260	5	265	(60-53)	3.8

FIGURE 22.—Graph showing amounts and rates of offset on Midland fault zone, assuming all displacement occurred on a single fault strand and that displacement began in the Paleocene. Amount of offset and syntectonic thickening of units taken from figure 21 (modified from Burroughs and others, 1968).

Near the city of Stockton, the −3,000-m basement contour is offset about 5 km in a left-lateral sense and depressed about 300 m down to the south, but the vertical component of movement is not closely controlled in that area. Eastward, near the −2,500-m contour, the basement surface is offset left-laterally about 6 km and depressed nearly 500 m south of the fault. The vertical component of displacement there is reasonably well controlled by wells north and south of the fault. Both the left-lateral and vertical components of displacement decrease eastward along the Stockton fault and appear to die out completely between the −500-m and 0 basement contours. No trace of the Stockton fault has been mapped in the exposed metamorphic rocks of the Sierran foothills between the north end of Gopher Ridge and the Mokelumne River (pl. 1) (Wagner and others, 1981).

Teitsworth's (1968) study of the Lathrop gas field (pl. 1, map A), which is located about 9 km southeast of Stockton, corroborates our analysis of the basement offset on the Stockton fault and adds valuable data about the amount and timing of deformation recorded in the Upper Cretaceous rocks. Teitsworth concluded that the Upper Cretaceous rocks were thicker south of the Stockton fault, indicating south-side-down vertical movement during early phases of deposition, and that they were subsequently offset about 3 km left-laterally during Late Cretaceous time. Deposition of Upper Cretaceous marine shale followed earlier strike-slip displacement on the Stockton fault, and these marine shale units also show left-lateral displacement. Following deposition and strike-slip displacement of the uppermost Upper Cretaceous unit in the area, but prior to deposition of Miocene continental strata that unconformably cap the Upper Cretaceous section, the Stockton fault experienced about 1,000 m of reverse, south-side-up movement (Teitsworth, 1968). During this period of reverse movement, west- and west-northwest-trending anticlines formed in the Upper Cretaceous rocks south of the fault, providing closure that trapped the gas in the Lathrop and East Stockton gas fields (pl. 1, map A). The trend of these folds and the northwest-trending anticlines in the Roberts Island and McDonald Island gas fields (pl. 1, map A) north of the Stockton fault indicate northeast-southwest compression in the area during the period of reverse movement on the Stockton fault. Teitsworth (1968) concluded that reverse

movement probably occurred after the middle Eocene but before deposition of Miocene continental deposits. However, he shows a west-northwest-trending fold in contours drawn on the base of the Miocene rocks south of the Stockton fault, from which we conclude that the northeast-southwest compressive stress operated in the area into the middle Tertiary.

FAULTS IN THE SIERRAN FOOTHILLS

Clark (1960) combined data from a number of sources with his own field observations to produce the first regional structural synthesis of the Sierran foothills. He defined the Foothill fault system as a group of northwest-trending, steeply east-dipping to vertical faults that tectonically separate distinctive belts of Paleozoic and Mesozoic rocks for more than 320 km along strike in the western foothills of the Sierra Nevada. He recognized that the component faults in the system were actually complex fault zones marked by multiple fault strands and intensely sheared, cataclastic, and crumpled rocks, which were associated geographically, in many areas, with major bodies of sheared serpentinite. On the basis of limited paleontologic and radiometric data, he concluded that the major tectonic activity of the Foothill fault system occurred in the Late Jurassic.

Although displacement of Tertiary volcanic units was recognized locally along segments of the Foothill fault system after Clark's study (Bateman and Warhaftig, 1966), few investigations were made into the late Cenozoic deformational history of the fault system before the Oroville earthquake. That seismic event produced ground rupture on the Cleveland Hills faults (Clark and others, 1976) and opened the question of potential late Cenozoic deformation within the whole Foothill fault system.

In their earthquake evaluation studies of the Auburn Dam area, Woodward-Clyde Consultants (1977) made a regional analysis of potential late Cenozoic deformation along many linear features related to the Foothill fault system, and they trenched those linear features that had direct bearing on their Auburn Dam study. That study provided most of the data for our analysis of those strands of the fault system in the border zone between the Sierran foothills and the Sacramento Valley.

COHASSET RIDGE FAULT

Cohasset Ridge is a prominent south- to southwest-trending interfluve located northeast of Chico, between the major drainages of Big Chico Creek and Deer Creek. The ridge is capped by at least two essentially contemporaneous olivine basalt flows that appear to have originated in the Butte Mountain area (about 12 km east of pl. 1), on the southwest slope of a Pliocene volcano named Mount Yana by Lydon (1968). The olivine basalts flowed southwestward in channels eroded in the underlying Tuscan Formation, but subsequent erosion has inverted the topography so that the basalt now stands as the highest unit on the ridge. The olivine basalt of Cohasset Ridge represents the final phase of volcanism that reached the Sacramento Valley from Mount Yana. The upper basalt flow has been dated at 2.41 m.y. (Harwood and others, 1981).

East of Brushy Mountain (pl. 1), the olivine basalt of Cohasset Ridge is abruptly truncated on the east by a steeply east-dipping fault that strikes about N. 40° W., roughly parallel to the Chico monocline fault. Aune (cited in Woodward-Clyde Consultants, 1977) first recognized this fault, which he called the Cohasset Ridge fault, and concluded that the eastern equivalents of the olivine basalt of Cohasset Ridge were downfaulted to the east about 30 m along the normal fault. The Cohasset Ridge fault can be traced north of Deer Creek through an intensely fractured zone in the Tuscan Formation to the vicinity of Mill Creek, where it becomes obscured by a complex pattern of west- and northwest-trending arcuate faults (pl. 1; fig. 19). Although the area south of Deer Creek is heavily forested and the slopes are covered by a veneer of colluvium, the trace of the Cohasset Ridge fault is defined by a prominent topographic linear feature, observed by Rich and Steele (1974), that extends nearly to Magalia, where it apparently is intersected by the Magalia fault.

The Cohasset Ridge fault is a northwest-trending, steeply east-dipping fault that has experienced at least 30 m of east-side-down normal movement in the past 2.41 m.y.

MAGALIA FAULT

About 9 km north of Magalia, (pl. 1), the Cohasset Ridge fault is intersected by the N. 20° W.-trending Magalia fault. Extensive mine workings, which followed Tertiary auriferous gravel deposits at the base of the Tertiary volcanic sequence in the area, provide detailed data on the nature and local extent of the Magalia fault (Gassaway, 1899; Logan, 1930; Woodward-Clyde Consultants, 1977).

Although the Magalia fault is shown as a single fault on the map, detailed mine maps indicate that the fault is actually a complex fault zone consisting of numerous fault strands that have different orientations and amounts of displacement. In the Dix mine at the north end of the mining district, the gold-bearing gravels are offset 28 m down to the east. Southeastward along the trace of the Magalia fault at the Black Diamond mine, the gravel deposits are offset 68 m down to the east. Farther southeast at the Magalia mine, the channel deposits are offset down to the west from 2 to 11 m along three reverse

faults that trend N. 60° W. and dip 58° NE.

From the mining records it appears that the various fault strands in the Magalia fault zone have experienced episodic and different movement through the Tertiary, with both normal east-side-down and reverse east-side-up displacement recorded. The relative ages of this disparate movement pattern along the Magalia fault are unknown, but the youngest movement appears to post-date movement on the Cohasset Ridge fault.

CLEVELAND HILLS FAULTS

The Cleveland Hills faults coincide with surface ruptures that occurred during the Oroville earthquake. During that seismic event, the ground surface failed in a 3.8-km long en echelon pattern of north- and north-northwest-trending normal faults that showed at least 55 mm of horizontal separation across the surface ruptures and as much as 180 mm of west-side-down vertical separation (Clark and others, 1976). Aftershocks of the Oroville earthquake defined a zone of seismic activity, assumed to coincide with the controlling fault, that dipped about 60° W. and trended nearly due north (fig. 15; also Bufe and others, 1976).

Trenches, dug across the zone of surface rupture by the California Department of Water Resources and logged by Akers and McQuilkin (1975), showed a gouge zone about 2 m wide in the bedrock below the surface ruptures that was flanked by 2-4 m of intensely fractured rock transitional into the country rock of foliated greenstone. The gouge zone contains anastomosing shear zones of deformed gouge that provide evidence of repeated earlier faulting along the zone of the ground failure. Earlier deformation in the area is also indicated by 30-60 m of apparent west-side-down offset of an erosion surface of probable Pleistocene age across the Cleveland Hills faults (Aune, 1975).

About 5.7 km northwest of the Cleveland Hills faults (pl. 1), Creely (1965) mapped a north-trending, steeply east-dipping fault that offset the base of Pleistocene or older gravel deposits about 2 m down to the west. Clark and others (1976) reported a second fault in the area that showed minor east-side-down offset of the gravel deposit.

FAULTS SOUTHEAST OF OROVILLE

In their earthquake evaluation of the Auburn Dam area, Woodward-Clyde Consultants (1977) identified a number of prominent linear features in the Sierran foothills southeast of the Cleveland Hills faults. With the exception of the northeast- and north-trending Highway 49 and Hancock Creek lineament zones (pl. 1), the linear features they investigated have northwest trends that coincide closely with the projected trace of the Chico monocline fault. The linear features were trenched extensively and logged in detail (Woodward-Clyde Consultants, 1977), and trench data were integrated with surficial geologic investigations in each area. Evidence of movement in the past 10 m.y. (Woodward-Clyde Consultants' definition of the "late Cenozoic") was detected in the trenches across the northwest-trending linear features, which are shown on plate 1 as the Swains Ravine, Spenceville, and Maidu fault zones and the Dewitt fault.

Deformation in the bedrock exposed in the trenches is remarkably similar to that shown in trenches across the Cleveland Hills faults. In most areas, bedrock beneath the surface lineaments contained one or more zones of slickensided clay-rich gouge a few meters wide or less. The gouge commonly contained anastomosing shear zones composed of polydeformed gouge and thin clay seams that indicated multiple phases of deformation. Rock adjacent to the gouge zones commonly was highly fractured, bleached, or manganese-stained and injected by thin quartz veins. In some trenches, a paleosol rested unconformably on bedrock and was offset locally along the faults marked by the gouge zones. That evidence led Woodward-Clyde Consultants (1977) to conclude that at least some of the faulting had occurred in the past 100,000 years. Based on the evidence presented by Woodward-Clyde Consultants (1977) and our observations in many of the trenches that they excavated during that study, we agree with their conclusions.

REGIONAL STRUCTURAL ANALYSIS

STRUCTURAL DOMAINS IN THE SACRAMENTO VALLEY

As we have shown in preceding sections of this report, late Cenozoic structural features in the valley have diverse orientations and displacement histories. In spite of this diversity, large areas of the valley are characterized by coeval structures that appear to have formed in a similar stress regime. To analyze the late Cenozoic structural evolution of the Sacramento Valley, we have grouped coeval structures that have similar displacement patterns into structural domains (fig. 23).

Delineating the various structural domains obviously depends on correctly identifying and correlating late Cenozoic deposits throughout the valley. Many of the late Cenozoic alluvial deposits are similar in outcrop characteristics, but fortunately they contain or are bracketed by distinctive tephra beds or volcanic flows that allow widespread correlation of alluvial units and provide absolute age control for the alluvial and tectonic histories of the region. In this regard, we have used the following time-stratigraphic units to define the late Cenozoic structural domains of the valley:

Unit	*Age/Age range (m.y.)*	*Reference*
Rockland ash bed	0.4-0.45	Sarna-Wojcicki and others (1985); Meyer and others (1980)
Red Bluff Formation	0.5-1.0	Harwood and others (1981)
Olivine basalt of Deer Creek	1.09	Harwood and others (1981)
Ishi Tuff Member of the Tuscan Formation	2.6	Harwood and others (1981; unpublished data, 1985)
Volcanic rocks of Sutter Buttes	1.4-2.4	Williams and Curtis (1977)

With the exception of the Dunnigan Hills, the structural domains shown in figure 23 become progressively younger northward through the valley. Late Cenozoic deformation in the Dunnigan Hills domain apparently overlapped that in the Corning domain, but the respective styles of deformation and the inferred stress regimes discussed in a later section differ significantly. This point emphasizes the fact that the structural domains include tectonic features that are homogeneous in time and style of deformation as far as we can determine. To a certain extent, the ages of the structural domains reflect the distribution of the time-stratigraphic units used to identify the major late Cenozoic deformation in a domain. It may be possible to subdivide some domains as more information on the distribution of the younger time-stratigraphic units becomes available. Furthermore, it is important to note that ascribing an age to the late Cenozoic deformation in a domain does not imply that all deformation necessarily began or ended within that time. Many late Cenozoic structural features in the valley formed over earlier structures in the upper Mesozoic or Tertiary rocks, and thus they owe their existence, in part, to tectonic heredity. In some areas, historic low-magnitude earthquakes can be identified with specific structural features such as the Battle Creek fault zone (Bolt, 1979) and Corning fault (Marks and Lindh, 1978), indicating that strain is currently being released on these structures.

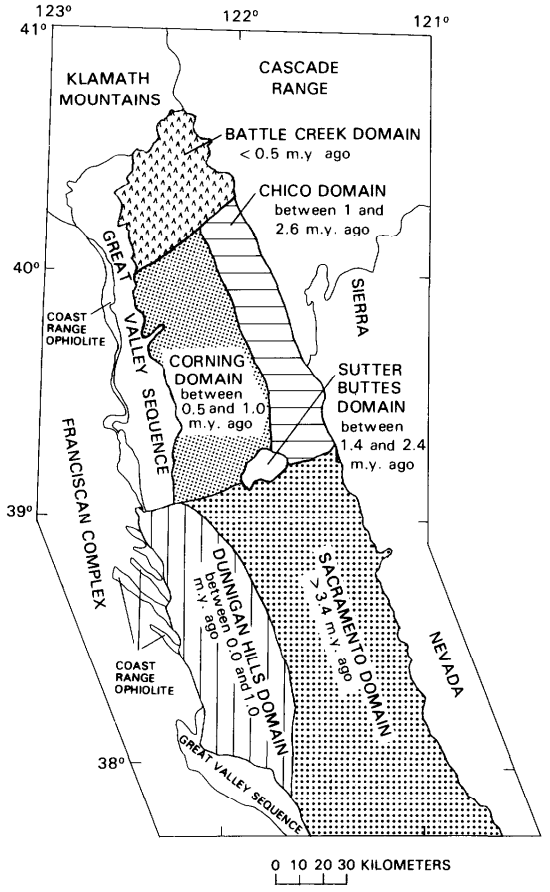

FIGURE 23.—Structural domains in Sacramento Valley. Numbers under domain names give duration or age of deformation that produced late Cenozoic structures in that domain.

SACRAMENTO DOMAIN

The Sacramento domain includes the Stockton fault, the Midland fault, the Thornton anticline, and the possible southeast extension of the Willows fault and other unnamed northwest-trending faults southeast of Sutter Buttes. None of these structures appear to offset or deform late Cenozoic alluvial deposits that are younger than the Nomlaki Tuff Member (figs. 7-10; Silcox, 1968; Teitsworth, 1968).

The minimum age of deformation is difficult to determine. If the Markley submarine canyon was localized, in part, by movement on the southeast extension of the Willows fault, as suggested by figures 8 and 9, then major deformation occurred in the domain in the middle Tertiary and could be as young as early Miocene, which is the upper age of the Markley canyon fill (Almgren, 1978). However, the Pliocene Laguna Formation, which contains the Nomlaki Tuff Member near its base just east of Marysville (Bussaca, 1982), does not appear to be offset in this domain; therefore, we conclude that deformation is older than 3.4 m.y. Upper Cretaceous rocks indicate syndepositional offset on the Stockton fault (Teitsworth, 1968) so the maximum age of deformation is Late Cretaceous.

The Willows fault north of Sutter Buttes (fig. 3) and the faults in Capay Valley (fig. 20) also show protracted deformation, ranging in age from Late Cretaceous to the middle Tertiary, that undoubtedly was contemporaneous with deformation in the Sacramento domain.

SUTTER BUTTES DOMAIN

The complex pattern of folds and faults at Sutter Buttes and the buried Colusa dome was interpreted by Williams

(1929) and Williams and Curtis (1977) to have formed by forceful intrusion of magma between 2.4 and 1.4 m.y. ago. Harwood (1984; this report) suggested that magmatism was localized at Sutter Buttes and the buried Colusa dome by movement on the Willows fault and possibly on the Mesozoic tectonic boundary between oceanic and Sierran basement terranes beneath Sutter Buttes. In this interpretation, deformation in the Sutter Buttes domain occurred through the combined effects of forceful intrusion of magma and east-west compression in a regional stress field.

Deformation in the Sutter Buttes domain may have overlapped in time with deformation in the Chico domain. However, the style of tectonism at Sutter Buttes is unique, and the area must be considered as a separate domain in a regional analysis.

Although Williams and Curtis (1977) suggested that Sutter Buttes formed in roughly half a million years, based on volume and morphology of volcanic deposits, their K/Ar ages for the volcanic complex range from about 1.4 to 2.4 m.y., and we have used that age range as the age of the structural domain.

CHICO DOMAIN

The Chico monocline is the dominant structure in the Chico domain (fig. 23). The monoclinal flexure and the controlling fault at depth (fig. 14) formed after the eruption of the Ishi Tuff Member of the Tuscan Formation, about 2.6 m.y. ago (Harwood, unpub. data, 1984), but before the eruption of the olivine basalt of Deer Creek, about 1.0 m.y. ago (Harwood and others, 1981). Formation of the monocline resulted directly from uplift of the northern Sierra Nevada and rupture along the controlling fault beneath the monocline. On the basis of geophysical evidence (Griscom, 1973; Cady, 1975), it seems reasonably certain that the controlling fault was a major late Mesozoic structure, separating oceanic from magmatic-arc crustal blocks, that was reactivated in the late Cenozoic.

Late Cenozoic tectonic uplift markedly increased erosion in streams antecedent to the monocline from Deer Creek northwest to Salt Creek just east of Red Bluff. Due to their tectonically steepened gradients, these streams deposited coarse, bouldery alluvial fanglomerate composed of volcanic material derived from the Tuscan Formation, extending from the monoclinal arch westward into the valley. The olivine basalt of Deer Creek filled the ancestral channel of Deer Creek east of the monocline and cascaded over the coarse fanglomerate, forming westward-overturned folds at the base of the flow west of the monoclinal flexure.

In Salt Creek and along nearby Hogback Road just east of Red Bluff, the fanglomerate (unit QTog of Harwood and others, 1981) rests unconformably on a partially stripped soil that developed on the Tuscan Formation. The soil indicates a significant period of nondeposition and weathering prior to flexing of the monocline and prior to rapid deposition of the alluvial fanglomerate. A period of erosion also followed deposition of the fanglomerate. The Red Bluff Formation was deposited unconformably on both the Tuscan and fanglomerate in Salt Creek. These stratigraphic relations, coupled with the fact that the Ishi Tuff Member is flexed, eroded, and unconformably overlain by the olivine basalt of Deer Creek along the monocline, establish deformation in the Chico domain between 1.0 and 2.6 m.y. This is clearly before deformation in the Corning domain to the west, where the Red Bluff is significantly folded and faulted.

The orientation of the horizontal compressive stress vector is not closely constrained in the Chico domain. Slickensides on some faults along the monocline flexure have a rake of 35° NW., suggesting some left-lateral oblique slip on the northwest-trending fault system. Whether the slickensides developed at the time the monocline formed or subsequently is unknown, but if they do record strain released during flexing of the monocline, the principal horizontal stress may have been oriented approximately east-west.

CORNING DOMAIN

West of the Chico monocline in an area extending to the Willows fault, late Cenozoic structures range in orientation from northwest to approximately north. The main stem of the Willows fault and the fault along the flank of South Corning dome nearly parallel the trend of the Chico monocline. On the other hand, the Corning fault, the Corning domes, and the Los Molinos and Glenn synclines trend more northerly than the monocline and converge on that structure near Red Bluff. All of these structures, within the Corning domain (fig. 23), deform the Red Bluff Formation and thus postdate the flexing of the Chico monocline. However, the subparallel orientation of structures in the Corning domain northeast of the Willows fault and of those in the Chico domain suggests that all may have formed in a common stress field.

The maximum horizontal compressive stress probably was oriented approximately east-west, normal to the trace of the Corning domes. The Corning fault might represent one shear diagonal of the strain ellipse, and the northwest-trending faults would indicate the other shear diagonal. In this model, strain release would have migrated westward with time, beginning along the Chico monocline and later moving to the Corning domes and Corning fault. Clearly, some offset may have occurred on the Corning fault and the northwest part of the Willows fault during formation of the monocline, and the small amount of offset in the olivine basalt of Deer Creek over the monocline may have occurred during the upwarping of the Red Bluff

Formation over the Corning domes.

The area of the Corning domain southwest of Sutter Buttes and the Willows fault is largely capped by Holocene basin deposits that lap westward onto Upper Cretaceous rocks along the western margin of the valley. These deposits could obscure many structures that might be recorded in the Red Bluff Formation in that area, indicating that the downthrown side of the Willows fault has been a structural basin throughout most of the late Quaternary.

DUNNIGAN HILLS DOMAIN

The Dunnigan Hills domain (fig. 23) includes the Zamora fault, the Dunnigan Hills anticline, the Madison syncline, and the tectonically complex area of Capay Valley and the Capay Hills. The Red Bluff Formation is folded by the Dunnigan Hills anticline and offset by the Zamora fault along the east margin of the Dunnigan Hills (fig. 20). Therefore, the late Cenozoic structures in that area are at least as young as the folds and faults in the vicinity of Corning domes, and they could be younger. Because there is no clear evidence for the minimum age of structures in the domain, we assume that late Cenozoic deformation ranges from 1.0 m.y. to the present.

Although the late Cenozoic deformation may overlap in time with that in the Corning and Battle Creek domains, the orientation and movement pattern of structures are significantly different. The northwest-trending axial surface of the Dunnigan Hills anticline and normal displacement on the northwest-trending Zamora fault suggest that these structures may have formed in a stress field in which the maximum horizontal compressive stress was oriented approximately north-south and the least horizontal compressive stress (maximum extension) was oriented approximately east-west. Because this is the present orientation of the stress field associated with the San Andreas fault in this area (Zoback and Zoback, 1980), late Cenozoic structures in the Dunnigan Hills domain may be related to right-slip wrench tectonism associated with movement on the San Andreas fault system (Allen, 1981).

BATTLE CREEK DOMAIN

The Battle Creek domain (fig. 23) is the youngest structural domain and occurs at the northern end of the valley. It is characterized by northeast-trending folds and faults oriented nearly perpendicular to the north- and northwest-trending structures of other domains to the south.

Late Cenozoic displacement on the northeast-trending, steeply south-dipping faults is invariably down to the south, with a suggestion of minor right-lateral slip on the Battle Creek fault system (Helley and others, 1981). The amount of horizontal separation on the Battle Creek fault is unknown, but it probably is on the order of a few tens of meters to a few hundred meters at the most. The Bear Creek and Red Bluff faults are not exposed well enough to establish or refute the occurrence of late Cenozoic horizontal slip on those structures. The amount of vertical displacement increases eastward along the Battle Creek fault zone, with about half of the vertical separation of units caused by broad anticlinal folding and half by fault displacement (fig. 17). Vertical separation of late Cenozoic units on the Bear Creek and Red Bluff faults is also accomplished partly by folding.

These observations, plus the fact that the Inks Creek fold system appears to be genetically related to folding and faulting on the Battle Creek fault zone, indicate that the structures in the Battle Creek domain formed either by northwest-southeast horizontal compressive stress or by right-lateral shear stress. Strain was released initially by folding, followed by rupture and predominantly normal fault displacement. Initial movement on the Battle Creek fault zone postdated deposition of fanglomerate, which is correlated with the Red Bluff Formation, and the fault scarp restricted movement of the proximal ash-flow part of the Rockland ash bed. Deformation younger than 0.45 m.y. is indicated by distribution of the early Riverbank-age alluvial deposits north of the Battle Creek fault zone and in the tectonically controlled loops of the Sacramento River around the Inks Creek fold system. The late Cenozoic structures in the Battle Creek domain formed in the past half million years.

Little surface evidence is available to document deformation before the late Cenozoic in the Battle Creek domain. A detailed analysis of paleomagnetic directions and lithofacies in the Upper Cretaceous marine rocks and Eocene continental rocks, which locally overlie the Cretaceous rocks, might provide data to resolve this question, but we did not pursue these studies. In the light of recent paleomagnetic studies (Simpson and Cox, 1980; Beck and Plumley, 1980; Magill and Cox, 1981), which suggest a two-phase, clockwise rotation of the Oregon Coast Ranges and possibly of the Klamath Mountains in Eocene and post-Oligocene times, we believe the Battle Creek domain may be a zone of decoupling between the Klamath Mountains and Oregon Coast Ranges provinces to the north and the Sacramento Valley-Sierra Nevada provinces to the south.

VALLEY STRUCTURES RELATED TO REGIONAL STRESS PATTERNS

With the exception of structures in the Dunnigan Hills domain and recent movement on the Cleveland Hills faults, late Cenozoic folds and faults in the Sacramento Valley appear to have formed in an east-west compressive stress regime. The north- and northwest-trending

Willows, Corning, and Chico monocline faults dip steeply east and show reverse displacements. The east-northeast-trending Red Bluff, Battle Creek, and Bear Creek faults dip steeply south and have normal offsets. The axial traces of many folds are parallel to the trends of adjacent faults, and the folding appears to be related to drag on those faults. The amount of lateral displacement on faults in the valley is difficult to determine, but the rake of slickensides and the orientation of ancilliary fractures suggest minor left-lateral movement on the northwest-trending Chico monocline fault and minor right-lateral slip on the east-northeast-trending Battle Creek fault zone. These kinematic patterns are consistent with a regional stress field in which the maximum horizontal component of compressive stress is oriented about N. 75° E. (Harwood, 1984).

The late Cenozoic kinematic pattern and inferred east-west compressive stress regime in the Sacramento Valley appear to be anomalous with respect to contemporary tectonism in adjacent regions. In the California Coast Ranges to the west and in the northern Basin and Range province to the east, north-trending faults generally show normal and right-lateral displacements, east-trending faults show reverse and left-lateral movement, and northwest- and northeast-trending faults show dominantly right-lateral and left-lateral displacement, respectively (Zoback and Zoback, 1980; Hill, 1982). From these kinematic patterns, as well as earthquake focal-plane solutions, and in-situ stress measurements, Zoback and Zoback (1980) and Hill (1982) inferred that the maximum horizontal compressive stress was oriented approximately north-south and the least horizontal compressive stress (maximum extension) was oriented approximately east-west. Hill (1982) related the contemporary stress patterns to movement between the North American and Pacific plates and visualized the western part of the North American plate as a continuous broad zone of deformation following the model first proposed by Atwater (1970).

East-west compressive deformation in the Sacramento Valley suggests that the late Cenozoic stress field was not homogeneous between the continental margin and the northern Basin and Range province. Instead, the Sacramento Valley apparently acted as an independent block where relatively small-scale compressive strain was periodically released in response to large-scale right-lateral transform tectonism in the San Andreas fault zone to the west and major east-west crustal extension in the northern Basin and Range province to the east.

Furthermore, the well-dated deformation patterns in the Sacramento Valley indicate that the compressive strain was not released randomly but, rather, that the late Cenozoic structural features formed in a sequential pattern that is progressively younger to the north. Northward progression of the compressive deformation implies a northward-migrating stress regime or a migrating energy source sufficient to initiate deformation in a regional compressive stress field. The interaction of lithospheric plates along the continental margin appears to provide a reasonable mechanism for generating the sequential compressive strain release observed in the valley.

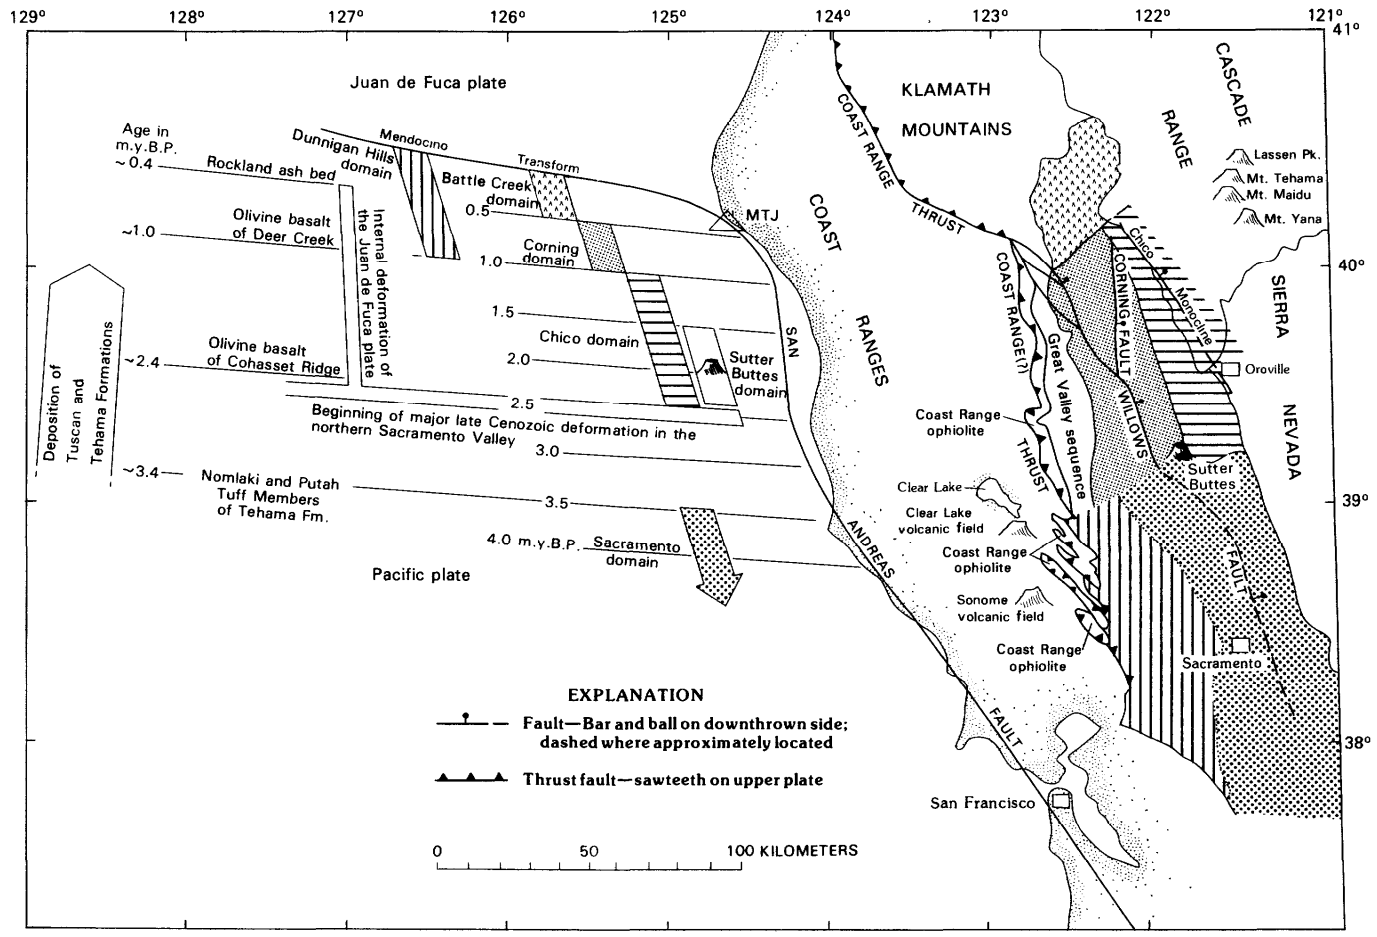
Successive positions of the Mendocino transform, extrapolated backward in time to 4.0 m.y. at a rate of 5.5 cm/yr (Atwater and Molnar, 1973), are shown relative to the late Cenozoic structural domains in the Sacramento Valley in figure 24. Each domain is characterized by a particular set of late Cenozoic structural features that formed during a definite period of time. The time of deformation in the structural domains is linked to respective positions of the Mendocino transform by corresponding patterns on figure 24. Compressive deformation in the Sacramento domain occurred prior to eruption of the Nomlaki and Putah Tuff Members of the Tehama Formation about 3.4 m.y. ago, but we are unable to correlate movement on specific structures in that domain with relative plate motions shown by successive positions of the Mendocino transform. Beginning with magmatism and deformation in the Sutter Buttes domain about 2.4 m.y. ago, however, reasonable correlation exists between the position of the Mendocino transform and progressive east-west compressive deformation in the Sacramento Valley. This correlation clearly reflects the availability of geologic information that dates deformation in the northern part of the valley, but it may also reflect a greater degree of tectonism in the valley over the past 2.4 m.y. that was related to increased tectonism ahead of the advancing Mendocino triple junction (fig. 24).

According to Silver (1971), an episode of major bending and fracturing occurred in the Juan de Fuca plate (fig. 24) between 2.5 and 0.5 m.y. ago. This deformation apparently increased the north-south compressive stress ahead of the advancing Mendocino triple junction and caused underthrusting of oceanic crust in the Juan de Fuca plate beneath the Mendocino transform. Dickinson and Snyder (1979a) suggested that this type of instability at the Mendocino triple junction would increase the east-west extensional stress in the vicinity of the triple junction and possibly cause eastward migration of right-slip strain release along the San Andreas fault zone. Internal deformation of the Juan de Fuca plate also may have changed the rate and relative motion of the subducted part of that plate relative to the North American plate sufficiently to initiate magmatism at Sutter Buttes and at the Pliocene volcanic centers of Mount Yana and Mount Maidu (fig. 24) (Lydon, 1968) about 2.4 m.y. ago. Subsequent relative movement of the North American plate southwestward from its position above the subducted Juan de Fuca slab, over the eastern projection of the Mendocino transform and onto the area of the slab

window of Dickinson and Snyder (1979b), may have initiated progressive deformation in the Sacramento Valley north of the Sutter Buttes domain.

According to Dickinson and Snyder (1979b), an expanding, triangular-shaped region, which they called the slab window, has developed east of the lengthening San Andreas transform since the rise-trench encounter about 20 m.y. ago. As the slab window expanded, upwelling asthenosphere came into contact with the base of the North American crust producing an expanding region of Neogene extensional tectonism. The northern boundary of the slab window, which is the eastern projection of the Mendocino transform, migrated northward as a consequence of the northward migration of the Mendocino triple junction and relative motion between the North American and Juan de Fuca plates. Successive positions of the northern boundary of the slab window beneath the Sacramento Valley for the past 2.5 m.y. are shown in figure 25.

About 2.5 m.y. ago, the northern boundary of the slab window was located approximately at the latitude of Sutter Buttes (fig. 25*A*). As the North American plate moved southwestward relative to the Juan de Fuca plate, the base of the valley crust near Sutter Buttes moved off the subducted ocean crust of the Juan de Fuca plate and encountered asthenophere in the slab window. This change in thermal regimes at the base of the valley crust possibly reactivated the Willows fault and the ancient tectonic boundary between ophiolitic basement rocks and the Sierran basement rocks, allowing magma to rise and differentiate below Sutter Buttes and the buried Colusa dome. Subsequent southwestward relative movement of the North American plate exposed an increasing area of the Sacramento Valley and northern Sierra Nevada crustal blocks to the higher thermal regime of the slab window. Basaltic volcanism erupted in the Tahoe-Almanor graben (fig. 25*A*) north of Lake Tahoe soon after magmatism began at Sutter Buttes (Dalrymple, 1964). Ac-



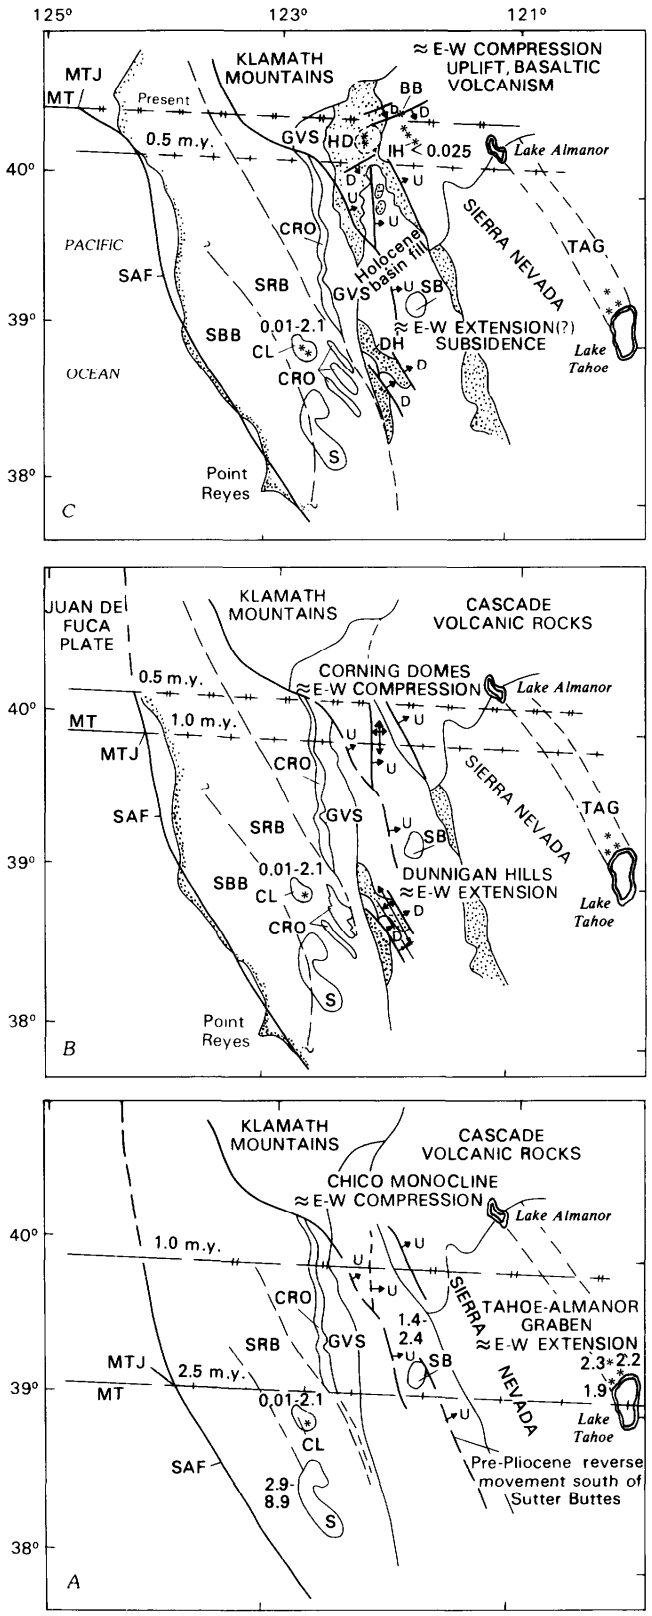


FIGURE 24.—Map of northwestern California relating late Cenozoic structural features and structural domains (patterned) to inferred position of the Mendocino triple junction (MTJ) during time structures formed. celerated uplift of the Sierra Nevada, which began about 3.0 m.y. ago in the central part of the range (Huber, 1981; Slemmons and others, 1979), eventually caused rupture between 2.5 and 1.0 m.y. ago along the Mesozoic fault that separates valley and Sierran blocks beneath the Chico monocline. Volcanism at Clear Lake (fig. 25), which began about 2.1 m.y. ago (Donnelly-Nolan and others, 1981), lagged behind passage of the northern boundary of the slab window and has continued nearly to the present.

Between 1.0 and 0.5 m.y. ago (fig. 25*B*), exposure of the base of the valley crust to the slab window may have reactivated the basement fault in the vicinity of the Corning domes, resulting in east-west compressional tectonism. Wrench tectonism and related east-west extension apparently started to affect the southwestern part of the valley after creating a zone of high shear strain in the Santa Rosa block (Fox, 1983), located in the eastern part of the Coast Ranges province. This is the earliest evidence of east-west extensional tectonism found in the valley and suggests a delay time of about 2.5 m.y. between passage of the slab-window boundary and production of recognizable extensional structures.

In the past 0.5 m.y., the northern boundary of the slab window has passed beneath about half of the Battle Creek domain (figs. 24, 25*C*). The morphology of the valley in the Battle Creek domain, therefore, may reflect recent,

and possibly on-going, structural changes in the deeper parts of the valley fill and basement caused in part by changes in the thermal regime beneath the thick valley crust. This hypothesis was investigated by Helley and Jaworowski (1983), who used the distribution of the Red Bluff pediment as a surface indicator of deeper valley structures. The elevation of the floor rises abruptly north of Red Bluff, and the dissected uplands expose the Pliocene Tehama Formation that is unconformably capped by remnants of the Red Bluff Formation. Drainage patterns reflect local structures, such as Hooker dome (fig. 18), and major creeks locally follow the dominant northeast structural trends. The gradient of the Sacramento River steepens significantly across the Battle Creek domain, and its incised meanders are structurally controlled. Many of these geomorphic features are preserved, in somewhat more subdued form, around Corning domes and elsewhere in the valley south of Red Bluff (Helley and Jaworowski, 1985).

The northeast-trending Inks Creek fold system and the folding associated with the Battle Creek and Red Bluff faults suggest a northwest-southeast compressive stress system. If such is the case, however, normal displacement on the Bear Creek, Battle Creek, and Red Bluff faults are anomalous. The structural features in the Battle Creek domain may reflect a stress regime in which the maximum horizontal compressive stress (east-west) and the least horizontal compressive stress (north-south) vectors are more nearly equal. This inferred change in the stress pattern may be caused by oblique subduction of the Juan de Fuca plate and the possible buttressing effect of the Klamath Mountains on deformation in the northernmost part of the Sacramento Valley.

CONCLUSIONS

Kinematic patterns of late Cenozoic structural features in the Sacramento Valley differ significantly from those in the Coast Ranges province to the west and the northern Basin and Range province to the east. Certainly for the past 2.5 m.y., and probably much longer, deformation in the valley has occurred in a regional stress field in which the maximum horizontal component of compressive stress was oriented approximately east-west and the minimum component of compressive stress (maximum extension) was oriented approximately north-south. Within this stress regime, strain has been released primarily by reverse movement on north- and northwest-trending high-angle faults and associated folding in the sedimentary rocks of the valley fill. This style of deformation contrasts sharply with the pattern of northwest-trending en echelon folds and pull-apart basins, and east-west oriented thrust faults associated with large-scale right-lateral displacements on the San Andreas fault system (Blake and others, 1978; Graham, 1978; Harding, 1976; McLaughlin, 1981; Page, 1981) and the pattern of pervasive normal faulting, widespread volcanism, and large-scale east-west extension in the Basin and Range province (Christiansen and Lipman, 1972; Lipman and others, 1972; Zoback and others, 1981). During the late Cenozoic, the Sacramento Valley appears to have acted as an independent block on which relatively small-scale compressive deformation was imposed by eastward-directed subduction that was followed by large-scale transform tectonism along the continental margin and major east-west crustal extension in the Basin and Range. Early Tertiary deformation on the Willows fault and in the area of Capay Valley may be related to eastward tectonic wedging of the Franciscan Complex described by Wentworth and others (1984).

Tectonic heredity appears to have played a significant role in late Cenozoic deformation in the Sacramento Valley. Many of the faults that break or drape the upper Cenozoic deposits are located over pre-existing structures within and at the boundaries of basement blocks that were tectonically juxtaposed and broken during the Mesozoic and early Tertiary. The tectonic boundary between ophiolitic and Sierran basement rocks apparently has been reactivated beneath the Chico monocline and the possible southeast extension of the Willows fault. The Corning fault occurs over a Mesozoic fault within the ophiolitic basement terrane.

Within the past 2.5 m.y., at least, late Cenozoic east-west compressive deformation has progressed northward so that structures observed in the Battle Creek domain are a million years younger than those around Sutter Buttes. The northward progress of late Cenozoic deformation correlates with extrapolated positions of the Mendocino transform. Deformation may have been initiated by thermal changes in the valley basement as the North American plate moved relatively southwestward off the subducted oceanic crust of the Juan de Fuca plate and over asthenosphere in the slab window proposed by Dickinson and Snyder (1979b). During this sequential deformation, the relative magnitude of the horizontal compressive stress vectors appears to have changed. The kinematic pattern of structures south of Red Bluff suggests that east-west compression was dominant ($S_{maxEW} >> S_{minNS}$) and resulted in high-angle reverse faulting. However, the horizontal compressive stresses appear to have been more nearly equal ($S_{maxEW} \cong S_{minNS}$) in the Battle Creek domain causing northeast-trending folds and normal displacements on east-northeast-trending faults.

Northwest-trending folds and normal displacement on the Zamora fault suggest that east-west extension may have affected the southwestern part of the valley during the past million years, when east-west compressive deformation was occurring in the Corning domain. Focal-plane solutions constrained by geologic data in the Clear

Lake area indicate that the maximum compressive stress in the Coast Ranges is presently oriented approximately north-south (Bufe and others, 1981). These data, coupled with the observation that right-lateral tectonism is more intense in the Coast Ranges adjacent to the Dunnigan Hills domain than it is to the west or north (Fox, 1983), suggest that late Cenozoic deformation in the Dunnigan Hills domain was related to wrench tectonism on the San Andreas fault system. If such is the case, the beginning of right-lateral wrench tectonism in the valley appears to have lagged behind the northward migration of the Mendocino triple junction by about 2.5 m.y. A similar delay was noted between the migration of the triple junction and the build-up of maximum heat flow in the Coast Ranges by Lachenbruch and Sass (1980).

The well-dated and diverse deformation patterns in the Sacramento Valley indicate that late Cenozoic tectonism evolved through the region in response to major crustal movements outside the valley's physiographic boundaries. East-west compressive tectonism may have been imposed on the valley by eastward subduction of the Juan de Fuca plate, and consequent tectonic wedging of the Franciscan Complex coupled with a major component of westward stress due to east-west extension in the Basin and Range province.

CONVERSION FACTORS

Factors for converting inch-pound units to the International System (SI) of units are given below:

Multiply	*By*	*To obtain*
acres	0.004047	km^2 (square kilometers)
acre-ft (acre-feet)	0.001233	hm^3 (cubic hectometers)
ft (feet)	0.3048	m (meters)
mi (miles)	1.609	km (kilometers)
mi^2 (square miles)	2.590	km^2 (square kilometers)

Degrees Fahrenheit are converted to degrees Celsius by using the formula: °C=(°F-32)/1.8

Additional abbreviations:

µg/L	(micrograms per liter)
mm	(millimeters)
mg/L	(milligrams per liter)
(mg/L)/yr	(milligrams per liter per year)

National Geodetic Vertical Datum of 1929 (NGVD of 1929). A geodetic datum derived from a general adjustment of the first-order level nets of both the United States and Canada, formerly called mean sea level. NGVD of 1929 is sometimes referred to as sea level in this report.

CENTRAL VALLEY OF CALIFORNIA RASA PROJECT

GEOCHEMISTRY OF GROUND WATER IN THE SACRAMENTO VALLEY, CALIFORNIA

By LAURENCE C. HULL

ABSTRACT

A geochemical investigation was done to evaluate temporal changes in water quality and to determine the processes that control water chemistry in shallow ground water of the Sacramento Valley, California. A total of 671 chemical analyses from 651 wells were used to study the processes controlling water chemistry. Temporal variations in dissolved-solids and nitrate concentrations were studied in 140 and 62 wells, respectively, having multiple observations with time.

The Sacramento Valley can be divided into six hydrochemical facies having distinctive chemical compositions. Waters from the Tuscan volcanic rocks and Victor Plain facies, along the eastern margin, have lower concentrations of dissolved solids and higher concentrations of silica than the waters from other areas of the Sacramento Valley. Ground waters in the basin hydrochemical facies (Butte Basin and Sutter Basin) along the valley axis are higher in iron, manganese, arsenic, and potassium. West side facies, the north alluvial fans and south alluvial fans, are low in silica. The south alluvial fans facies is higher in dissolved solids and has very high boron concentrations.

Significant increases have occurred in dissolved-solids and nitrate concentrations since the mid-1950's. Dissolved solids increased in five of the six hydrochemical facies, with rates ranging from 0.95 milligrams per liter per year in the Tuscan volcanic rocks facies to 4.75 milligrams per liter per year in the south alluvial fans facies. Nitrate-nitrogen did not significantly increase in the Tuscan volcanic rocks, Butte Basin, or Sutter Basin hydrochemical facies. Rates of increase of 0.036, 0.036, and 0.099 milligrams per liter per year occurred in the Victor Plain, south alluvial fans, and north alluvial fans, respectively.

Two processes control over 50 percent of the spatial variation in ground-water chemistry. Thirty-six percent of the variation in the data is explained by the effects of recharge water chemistry on the chemistry of ground water. Low dissolved solids and high silica from east-side recharge produces fairly uniform conditions in east-side ground waters. Recharge from the northwest is intermediate in dissolved solids and silica. Southwest recharge is high in dissolved solids, boron, and fluoride. High boron concentrations in the ground water originate in thermal springs in the Coast Ranges. A second important process consists of reactions occurring in the fine-grained sediments of the flood basin in the central part of the Sacramento Valley. Reducing conditions here produce higher concentrations of manganese, iron, and arsenic. Nitrate concentrations are low, probably reflecting denitrification reactions.

Precipitation and dissolution of aluminosilicates appear to control the relation between silica and aluminum in parts of the valley. Silica and aluminum in ground waters of the Sutter Basin hydrochemical facies show parallel behavior and have a ratio of 3 to 1. In the Tuscan volcanic rocks facies silica and aluminum are inversely related and are controlled by the solubility of halloysite. The clay minerals halloysite and illite were identified in the sediments. The clay mineral predicted to be the most stable in equilibrium with valley ground water is montmorillonite. Halloysite represents an intermediate step in the weathering of primary minerals to more stable secondary phases.

INTRODUCTION

GEOGRAPHY

The Sacramento Valley comprises the northern third of the Central Valley of California in the north-central part of the State (fig. 1). It is a sedimentary basin bounded by mountains to the east (Sierra Nevada), northeast (Cascade Range), and west (Coast Ranges). To the south, the valley merges with the delta of the Sacramento and San Joaquin Rivers. The area lies between 38°30′ and 40°15′ N. latitude, and 121°15′ and 122°30′ W. longitude. The valley covers about 4,400 square miles, is 150 miles in length from Red Bluff to the delta, and ranges in width from about 8 miles at Red Bluff to about 50 miles near the southern end. The topography consists of generally flat plains, with low dissected hills near the margins. The elevation of the valley at the southern end is near sea level, increasing northward and reaching 300 feet above sea level near Red Bluff. The relatively flat topography of the valley is interrupted near the center, where a volcanic neck of late Tertiary age, Sutter Buttes, rises 2,100 feet above the valley floor.

The Sacramento River enters the valley from the north and flows along the entire length of the valley before entering the delta region to the south. The Feather River is the only other principal stream that flows through the valley. The Sacramento and Feather Rivers are fed by tributaries draining the surrounding mountain areas. From the Sierra Nevada come the American, Bear, Yuba, and Feather Rivers. The Cascade Range is drained primarily by Big Chico, Butte, Mill, and Deer Creeks in the area adjacent to the Sacramento Valley. The streams entering the valley from the west rise in the Coast Ranges and are much smaller than the streams from the east. Thomes, Stony, Cache, and Putah Creeks are the only sizable streams entering

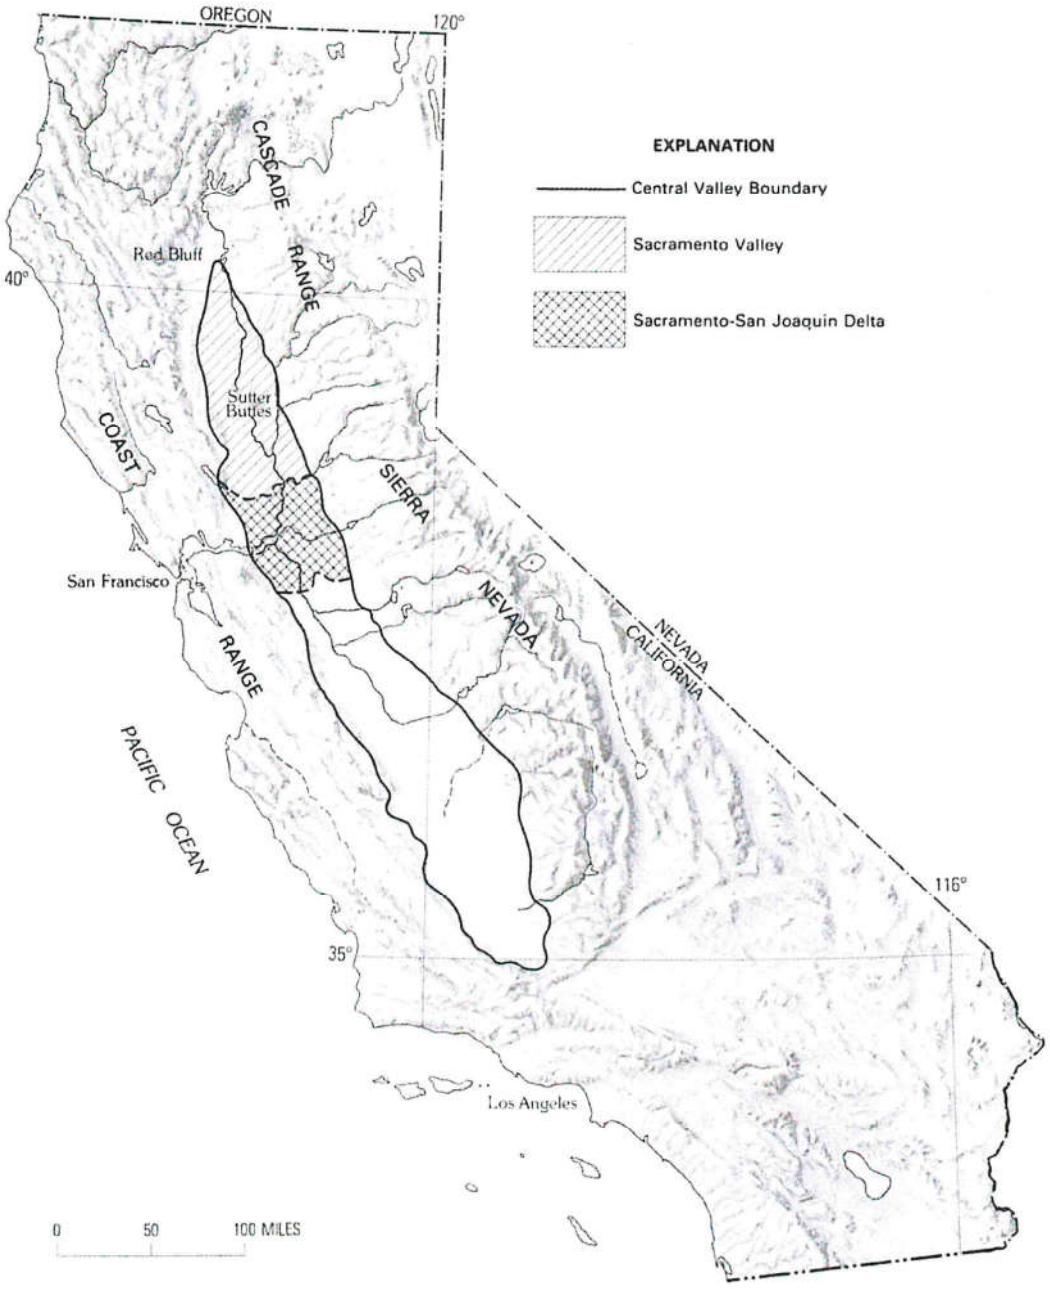

FIGURE 1.—Location map showing Sacramento Valley of California.

the west side of the valley. (See pl. 1*B* for stream locations.)

Little precipitation falls in the valley during the summer growing season, and irrigation is necessary to support extensive agricultural development. Early irrigated farming began in the mid-1800's as the gold miners moving to California created a demand for foodstuffs. Development of irrigation was slow, however, until the drought of 1864 stimulated the construction of new irrigation projects. During both world wars, heavy demand for agricultural products spurred periods of rapid development. Ground water has always lagged behind surface water as a source of irrigation water, amounting to only about 10 percent of the total use in the late 1910's. Since the late 1950's, however, the use of ground water has been increasing, and in 1970,

it accounted for about 40 percent of all irrigation water used in the Sacramento Valley.

PURPOSE AND SCOPE

The U.S. Geological Survey began a series of hydrologic investigations—the regional aquifer systems analysis (RASA) program—to aid effective management of the Nation's ground-water resources by providing information on the hydrology and geochemistry of regional aquifer systems (Bennett, 1979). The Central Valley aquifer project, covering the Central Valley of California, is one of 29 such projects throughout the country and was started because of the long history of ground-water development and the importance of the area's agricultural production to the national economy (Bertoldi, 1979). Specific water-quality information needed for effective management in the future includes (1) the general inorganic chemical character of water from aquifers currently in use, (2) delineation of areas where degradation is occurring and where degradation may occur in the future, (3) the changes that have occurred in ground-water quality with time, and (4) the processes that control ground-water chemistry. This report evaluates temporal changes and geochemical processes as they influence the chemical quality of shallow ground water in the Sacramento Valley, the northern third of California's Central Valley. A companion report (Fogelman, 1983) deals with spatial variations in the chemical character of ground water and the delineation of areas of potential water-quality problems for this same study region.

DATA COMPILATION

Collection of additional water-quality samples was unnecessary because of the extensive data base of the U.S. Geological Survey and California Department of Water Resources. Chemical analyses from 653 wells throughout the Sacramento Valley sampled by the Geological Survey between 1974 and 1976 were already in the Survey's water-quality file (Fogelman, 1975, 1976; Fogelman and Rockwell, 1977). From the unpublished files of the California Department of Water Resources, an additional 2,136 analyses from 281 wells were added to the water-quality file. During the summer of 1979, 63 additional samples were collected by the Geological Survey in Yolo County to extend coverage into an area where high boron concentrations suggested a need for water-quality evaluation. All wells from which chemical analyses were used in this study have driller's logs on file with the California Department of Water Resources. Thus, reasonably reliable information is available about depths and perforated intervals for these wells. Some of the samples represented multiple observations over time from single wells, and these were used for the temporal studies. Samples for the period 1974–79 were examined, and complete analyses with less than 5 percent error in the electrical balance between cations and anions were used to study the spatial variation in the valley. These latter data consisted of 671 analyses from 651 wells.

Manipulation of data files and the statistical analyses used in this report were accomplished using the Statistical Analysis System (SAS)[1] programs on the U.S. Geological Survey's Reston computer system.

WELL-NUMBERING SYSTEM

Wells are identified according to their location in the rectangular system used for the subdivision of public lands. The identification consists of the township number, north or south; the range number, east or west; and the section number. A section is further divided into sixteen 40-acre tracts lettered consecutively (except I and O), beginning with A in the northeast corner of the section and progressing in a sinusoidal manner to R in the southeast corner. Within the 40-acre tract, wells are sequentially numbered in the order they are inventoried. The final letter refers to the base line and meridian relative to which the townships and ranges are numbered. For the Sacramento Valley, this is the Mount Diablo base line and meridian (M). Figure 2 shows how the well number 11N/02E–23N01M is derived.

ACKNOWLEDGMENTS

The California Department of Water Resources has cooperated with the U.S. Geological Survey in past studies during which much of the data analyzed in this report were collected. The Department also provided additional unpublished chemical-quality data from their files. The author would like to thank J. R. Slack of the Geological Survey for his helpful suggestions on trend analysis. The cooperation of the residents of the Central Valley who have permitted the Geological Survey to collect water samples from their wells is also appreciated.

DESCRIPTION OF THE STUDY AREA

GEOLOGY AND GEOMORPHOLOGY

The Geology and geomorphology of the Sacramento Valley have been covered in detail by Olmsted and Davis (1961), the California Division of Mines and Geol-

[1]Use of trade names does not imply endorsement and is used for information only.

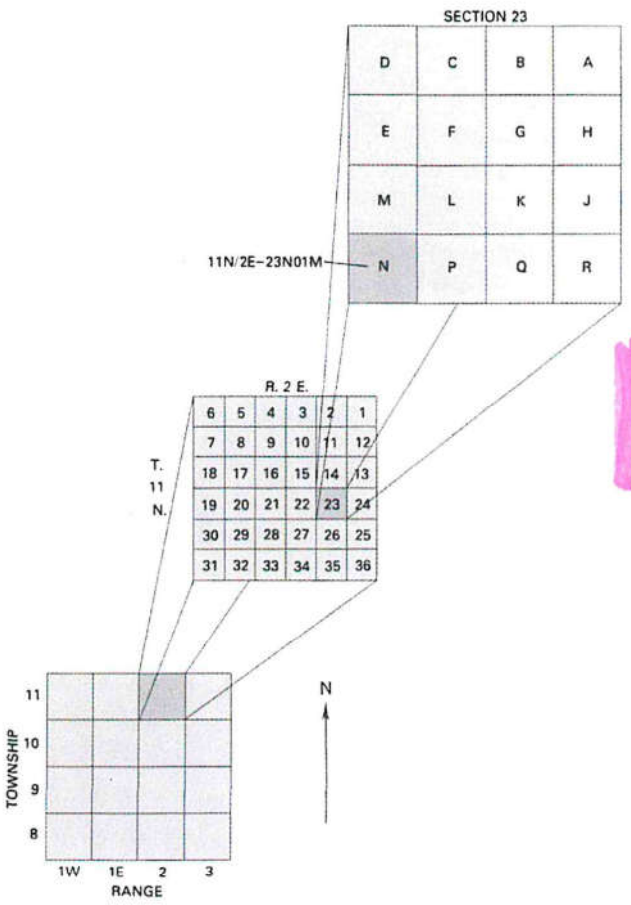

FIGURE 2.—Well-numbering system.

ogy (1966), and the California Department of Water Resources (1978a). Detailed maps and complete descriptions of the geology can be found in these publications. In this section, the geology and geomorphology are only briefly reviewed, with particular attention given to water-bearing characteristics and importance for water quality.

GEOLOGIC SYNOPSIS

The Sacramento Valley is an elongated structural trough trending to the northwest through central California. The trough is filled with a thick accumulation of sediments, perhaps as much as 50,000 feet in the deepest parts. Deposition has been occurring since early in the Cretaceous Period, with the bulk of the deposition occurring in a marine environment. A maximum of only 3,000 feet of continental deposits has been laid down as a veneer over the marine sediments. During early Tertiary time, the Cretaceous sediments west of the valley were folded and uplifted, forming the Coast Ranges and isolating the Sacramento Valley from the ocean to the west.

Early- and middle-Tertiary sedimentation was primarily confined to the southern and eastern parts of the valley, with only those sediments adjacent to the Sierra Nevada being continental deposits. During late Tertiary time, continental deposits were laid down throughout the valley, and deposition continued into Quaternary time. These continental deposits include the Tehama, Tuscan, Laguna, and Mehrten Formations and form some of the most important aquifers in the valley. Also, near the end of the Tertiary Period, andesitic lava was extruded through the older marine sediments to form Sutter Buttes, a prominent volcanic neck in the middle of the Sacramento Valley.

During Pleistocene time, continental deposition continued throughout the valley. Alluvial fans and plains developed from sediments eroded from the Sierra Nevada to the east and the Coast Ranges to the west. Continued action of rivers flowing through the valley produced alluvial channel deposits and natural levees along the axis of the valley and produced flood basins adjacent to the rivers.

GEOMORPHIC UNITS

The Sacramento Valley is generally characterized by alluvial plains and fans bounded by rugged mountains. The geomorphic units described by Olmsted and Davis (1961) are (1) Sierra Nevada, (2) Coast Ranges, (3) Cascade Range, (4) low hills and dissected uplands, (5) alluvial plains and fans, (6) flood basins, (7) stream channels and natural levees, and (8) Sutter Buttes. In this section, the location and extent of the geomorphic units are described, and the geologic formations composing each unit discussed. Attention will be given to the lithology, mineralogy, and water-bearing characteristics of the geologic units where information is avaliable. The location of the geomorphic units are illustrated on plate 1*A*.

(1) *Sierra Nevada.* The Sacramento Valley is bounded on the east by the mountainous Sierra Nevada, a massive block of the Earth's crust that has been uplifted and tilted westward. The block extends under the sediments of the valley and underlies the eastern part at depth. The Sierra Nevada is composed of intrusive igneous rocks, metamorphosed volcanic rocks, and Paleozoic sedimentary rocks. The intrusive rocks are mainly granodiorite and quartz diorite with andesitic and rhyolitic extrusive rocks. In addition to the feldspars, quartz, and biotite of the igneous rocks, a wide variety of other minerals is present. These include cal-

cite, magnesite, barite, serpentine, metal sulfides, and others. The massive rocks of the Sierra Nevada contain little water, with the little that is available occurring in joints and fractures. The water quality of streams draining the Sierra Nevada is generally very good.

(2) *Coast Ranges.* The Coast Ranges, adjacent to the west of the valley, consist of Cretaceous marine sedimentary rocks folded and uplifted into ridges trending northwest-southeast, parallel to the valley. The Cretaceous rocks dip eastward and underlie much of the Sacramento Valley at depth. Also present in the Coast Ranges is the Franciscan Complex, which consists of highly metamorphosed marine sedimentary rocks of late Mesozoic age. The major rock type is this geologic unit is greywacke, interbedded with shales and minor limestone units. The primary minerals of the sedimentary rocks are plagioclase and quartz. Many lithic fragments present contain chert, chlorite, and mica. Ultramafic minerals have been metamorphosed to serpentine and magnesite. The marine sedimentary rocks are mostly consolidated and contain little water. Some units retain connate saline water, and streams draining the Coast Ranges may be contaminated by saline springs.

(3) *Cascade Range.* Between Oroville and Red Bluff, the northeastern part of the Sacramento Valley is bounded by the Cascade Range geomorphic unit. Adjacent to the valley, this unit is composed of the gently southwestward dipping Tuscan Formation of Pliocene age. On the surface, the Tuscan Formation is extensively eroded, and southwestward flowing streams have incised deep canyons. Beneath the valley, the Tuscan extends westward under younger valley sediments as far as the Sacramento River, and there the Tuscan interfingers with the Tehama Formation. The Tuscan is composed of volcanic breccia, coarse- to fine-grained tuffs, and volcanic sands, all of primarily andesitic composition. The most abundant mineral in the black sands found in wells drilled into this unit is plagioclase, and accessory quartz and pyroxenes. Volcanic glass is also abundant from the mudflow and tuff deposits. The Tuscan is an important aquifer in the northeastern part of the valley, and it contains fresh water at all depths.

(4a) *Low hills and dissected uplands, east side.* The dissected alluvial uplands leading up to the Sierra Nevada on the east side of the valley are composed of Tertiary and lower Quaternary sediments. This gently rolling terrain merges with the foothills of the Sierra Nevada to the east and the low alluvial plains to the west. The oldest rocks here are of the Eocene Ione Formation, overlain by the Oligocene, Miocene, and Pliocene volcanic deposits of the Valley Springs and Mehrten Formations. These units extend westward to the trough of the valley, but they are generally too deep to be tapped as aquifers except in the foothills area. Overlying the volcanic sediments are upper Tertiary and Quarternary continental deposits eroded from the Sierra Nevada. The older Tertiary volcanic sediments are composites of volcanic sands, ash and mudflows, and tuff layers of rhyolitic and andesitic composition. Particular minerals noted in these units include biotite, hornblende, orthoclase, plagioclase, and quartz. The Ione Formation contains kaolinitic clay layers. The younger deposits, the Laguna Formation and Fair Oaks Formation of Shlemon (1967), are sand, gravel, and silt deposits intercalated by clay layers. The Quaternary deposits are poorly sorted, and wells finished in these units produce only moderate quantities of water.

(4b) *Low hills and dissected uplands, northeast.* The low hills on the northeast margin of the valley consist of reworked sediments eroded from the underlying Tuscan Formation. The hills show the characteristic form of alluvial fans but are deeply trenched by the streams draining the Cascade Range. These fanglomerate deposits, as they are called, are mainly cemented sands, gravels, and silts, and have a mineral composition similar to that of the Tuscan Formation from which they are derived. The fanglomerate is also an important source of water in this area.

(4c) *Low hills and dissected uplands, west side.* The low hills on the west side of the valley are composed of the Tehama Formation of Pliocene age. These deposits extend from Red Bluff on the north almost as far south as Fairfield. The Tehama is made up of poorly sorted fluviatile sediments, primarily beds of sandy silt and silty clay with some lenses of crossbedded sands and gravels. Many of the coarser layers are cemented by calcium carbonate that reduces their permeability. The Tehama extends eastward to about the middle of the valley and is generally within 150 to 200 feet of land surface. Tectonic activity since deposition has folded the Tehama into a number of structures such as the Dunnigan Hills, Corning Ridge, and Plainfield Ridge along the valley margin. Sediments originated in the Coast Ranges and are rich in plagioclase and magnesium silicates, such as chlorite and serpentine. The Tehama is an important potential aquifer, although currently most water is the area is being pumped from more permeable alluvial fan deposits nearer the surface.

(5a) *Alluvial plains and fans, east side.* The alluvial plain on the east side of the valley is referred to as the Victor Plain by Olmsted and Davis (1961). The Victor Formation[2] of Olmsted and Davis (1961), which

[2]Recent work of Marchand and Allwardt (1981, p. 207) virtually eliminates the use of the Victor Formation for the northeastern part of the San Joaquin Valley. However, because no similar recent work has been done in the Sacramento Valley, the Victor Formation as defined and mapped by Olmsted and Davis (1961, p. 93) is used in this report.

ranges in thickness from 50 to 100 feet, covers the surface throughout the area and overlies the Laguna Formation, a Pleistocene continental deposit. The plain extends from the northern San Joaquin Valley to north of Chico, where it pinches out between the fanglomerate of the Cascade Range and the Sacramento River flood plain. The Victor Formation is composed of alluvial sediments carried down from the Sierra Nevada and contains numerous channel deposits. The sediments become generally finer grained towards the west with bluish- and greenish-gray clays indicating reducing deposition environments near the center of the valley. Opposite the Sierra Nevada, the material contains extensively weathered feldspars, quartz, mica, biotite, and layers of arkosic sandstones. Opposite the Cascade Range, the Victor Formation is composed of reworked volcanic detritus from the Tuscan Formation. Water is generally available throughout the Victor Formation, though many high-capacity irrigation wells also tap the underlying Laguna Formation.

(5b) *Alluvial plains and fans, west side.* The low alluvial fans on the west side of the valley have been laid down by streams draining the Coast Ranges. The fans are aggrading and have poorly developed soil horizons. The northernmost fan is that of Stony Creek, which extends from the valley margin to the Sacramento River. South of this fan, a series of small fans built up by ephemeral streams extends only a short distance away from the Coast Ranges. Cache Creek and Putah Creek, south of the Dunnigan Hills, also have developed rather large fans which coalesce to form Putah Plain. The lithology of these fans is varied but generally is coarse-grained and poorly sorted. The mineralogy reflects the source areas in the Coast Ranges. The alluvial fans are generally good aquifers, especially where old stream channel deposits are penetrated.

(6) *Flood basins.* Low areas adjacent to the Sacramento River were subject to frequent flooding before extensive construction of levees in modern times. In these basins, fine-grained sediments have settled out of flood waters to form poorly permeable deposits. Deposits between 50 and 170 feet thick of yellow clay, indicating oxidizing conditions, overlie blue clays reflecting reducing conditions at depth. Few wells are drilled in these areas, and the only water generally available is in tongues of sand and gravel from old channel deposits.

In Sutter Basin, ground water contains high chloride concentrations and is unsuitable for irrigation purposes. The origin of this high chloride water is thought to be from Cretaceous marine sedimentary rocks brought closer to the surface by faulting associated with the formation of Sutter Buttes.

(7) *Stream channels and natural levees.* Along the major rivers and streams throughout the valley, Holocene alluvial deposits form flood plains and natural levees. The levees slope gently away from the channels and merge into the surrounding flood basin deposits. The deposits are generally coarse grained and poorly sorted. The varied mineralogy reflects the many sources from which these sediments are derived. Wells drilled in these deposits are hydraulically connected to the adjacent rivers and can produce large quantities of water.

(8) *Sutter Buttes.* Sutter Buttes, a volcanic neck of late Tertiary age, rises abruptly 2,100 feet above the surrounding plains. The core of the buttes is andesite, surrounded by alluvial fans created from the erosion of the igneous rocks. The deposits are poorly sorted and contain tuff, volcanic breccia, and sands. Some Cretaceous marine sedimentary rocks exposed at the buttes were forced upwards by the rising lava. The volcanic rocks yield little water, but the adjoining alluvium produces moderate amounts.

HYDROGEOLOGY

The direction of ground-water movement can be determined from the configuration of the water table where ground water occurs in saturated sediments and is not confined. Ground-water movement is influenced by gravity, and so is downhill as determined by the altitude of the water table. Plate 1*B* is a map showing lines of equal altitude of the water table for the Sacramento Valley in the spring of 1975. Although extensive changes occurred in some areas during the drought of 1976 and 1977, the 1975 map reflects the general conditions throughout the valley as they existed when most of the water-quality samples were collected during the mid-1970's.

In the north part of the valley, ground waters flow to the south and away from the valley walls. The Sacramento River is a gaining stream north of Colusa and is a major ground-water discharge zone in the north part of the valley. Stony Creek alluvial fan is a particularly important area for recharge. South of Colusa, the Sacramento River becomes a losing stream, contributing water to the adjacent sediments. In the west-central part of the valley, between Colusa and Woodland, recharge from the west infiltrates the valley sediments and moves toward pumping depressions east of the Dunnigan Hills. In the east-central part of the valley, from Oroville to Marysville, the Feather, Yuba, and Bear Rivers recharge the ground water near the valley margin. Once on the valley floor, the Feather River becomes a gaining stream east of Sutter Buttes, but below Marysville it begins to lose water to pumping depressions to the east and west. A large pumping depression in the southeast draws water from the Ameri-

can and Sacramento Rivers in the vicinity of Sacramento. In the southwest, much ground-water recharge occurs in the Cache and Putah Creek alluvial fans. This water moves eastward toward pumping depressions near Woodland and Davis. Some recharge from Cache Creek flows around the end of the Dunnigan Hills to pumping depressions north of Woodland.

The water table in the Sacramento Valley is generally close to the surface, and in only a few places is it more than 80 feet below the surface. Depth to water in the flood basins and alluvium along the Sacramento and Feather Rivers ranges from 10 to 20 feet. This very shallow water table extends eastward to include much of the western part of the Victor Plain. In the alluvial fans along the west side of the valley, the depth to water is between 10 and 40 feet. Lowering of water levels in pumping depressions north of Woodland and south of Davis, however, has increased the depth to water in those places. Along the southeast margin of the valley, the depth to water increases from less than 10 feet, near the flood basins, to more than 80 feet in the foothills. In the fanglomerate of the Cascade Range around Chico, the depth to water is generally 10 to 40 feet.

The valley boundary illustrated on plate 1*B* is the approximate boundary of the principal alluvial aquifers currently used in the Sacramento Valley. There is no single definition of the Sacramento Valley, and different boundaries are drawn for different purposes. The boundary shown is approximately that used in a ground-water-flow model of the Sacramento Valley (California Department of Water Resources, 1978a, Appendix A). However, the definition of the Sacramento Valley ground-water basin by the State of California encompasses a much larger area. The boundary is a reference shape to show continuity among illustrations.

On the east side of the valley, the margin coincides with the contact between the alluvium of the low hills and dissected uplands geomorphic province, and the older rocks of the Sierra Nevada and Cascade Range provinces. On the west side, the division is at the contact between the younger alluvium of the alluvial fans and plains, and the older alluvium of the low hills and dissected uplands geomorphic province. This allows delineation of the Dunnigan Hills, and excludes a large, undeveloped and sparsely populated area to the northwest of the valley.

Some wells outside the principal alluvial aquifers were included in the data analysis, as the boundary of those aquifers is somewhat arbitrary. Because these wells lie in recharge zones, their characteristics are important to an understanding of ground-water chemistry in the rest of the valley, even though they are outside the area of the principal alluvial aquifers.

HYDROCHEMICAL FACIES

The concept of hydrochemical facies as described by Back (1966) is used to designate zones or areas in which ground waters share unique chemical characteristics. The differences between facies reflect different controls on water chemistry from the lithology and mineralogy of, flow patterns in, and sources of recharge to an aquifer. The prefix "hydro" is used as a modifier of "chemical" to emphasize the interdependence of chemistry and hydrology. The ground water in the Sacramento Valley shows a great diversity in chemical compositions. By dividing the valley into hydrochemical facies, the differences can be better related to differences in the sedimentary matrix holding the water and the sources of ground-water recharge.

CRITERIA AND PROCEDURE FOR DIVISION

While hydrochemical facies have commonly been defined in terms of water types (as determined by the predominance of ions in terms of equivalents per million; Back, 1966), the definition of hydrochemical facies can be based on any unique chemical signature. For the Sacramento Valley, this division was accomplished using differences in the concentrations of some of the dissolved chemical constituents.

An initial division of the valley was attempted by studying maps showing the geomorphic units, the water table, and the distribution of individual chemical constituents. Outlines of these areas were drawn up to the nearest quarter township, and a tentative hydrochemical facies was determined for each well. This initial division broke the valley into three areas extending northwest-southeast, parallel to the axes of the valley—along the west side, the east side, and in the central basins. Each of these areas was divided into a northern and southern part resulting in six tentative divisions.

After this initial division, these six areas were tested to determine if they could be successfully differentiated on the basis of their chemistries. Linear discriminant function analysis (Davis, 1973; Drake and Harmon, 1973) was used for this purpose. In linear discriminant function analysis, a linear combination of variables is used to distinguish between previously defined groups. After the function is defined, it can be used to classify new samples of unknown origin into one of the original groups.

To determine which chemical constituents would be the best to use in the discriminant analysis, the amount of variation in the major chemical species associated with the differences between hydrochemical facies was determined. The results of this analysis of variance are shown in table 1. The first five species in this table

TABLE 1.—*Variation in chemical constituents explained by variations between hydrochemical facies*

Constituent	Percent variation explained
Silica	62.7
Boron	48.5
Sodium	44.7
Bicarbonate	39.4
Nitrate	36.8
Chloride	30.1
Magnesium	27.2
Calcium	15.1
Sulfate	9.6

were picked for the analysis. Because chloride is closely associated with sodium in the valley, it was passed over and magnesium added to give a total of six chemical constituents to use in the discriminant analysis.

Of the 671 chemical analyses available, only 340 had measurements for all the species and could therefore be used in the analysis. Most of the reduction in sample size was due to the much smaller number (358) of silica analyses. However, because silica showed by far the greatest amount of variation between the tentative hydrochemical facies, it was decided to use silica at the cost of reducing the number of samples that could be classified using the discriminant function. Samples, which lack measurements of all six of the chemical species used, were subsequently classified on the basis of nearby wells.

About one-fifth of the eligible samples were used to define the discriminant functions for the six hydrochemical facies. Using these functions, the remaining eligible samples were classified using the chemistry, and this classification was compared to the prior classification from the map data. Misclassified observations were of two types. Type 1 misclassifications were scattered throughout other facies and showed no pattern nor were particularly close to the boundary between two areas. Type 2 misclassifications were clustered in an adjacent hydrochemical facies near the boundary. In the latter case, the boundaries were redrawn and the chemical analyses reclassified.

The discriminant functions were recalculated several times with adjustments in boundaries between each calculation. The final analysis showed that 76 percent of the samples could be correctly classified by hydrochemical unit using the six chemical species. Thirteen percent of the samples were misclassified into the adjacent northern or southern portion in the same part of the valley, indicating an association between west side, east side, and basin pairs. On the basis of the classification of wells in a quarter township, each quarter township was assigned to its final hydrochemical facies. Other wells missing some of the chemical species used for the classification were classified by their quarter township location.

The discriminant analysis showed that enough chemical variation existed among the six hydrochemical facies to consider them chemically distinct. The final boundaries of the hydrochemical facies are shown on plate 1*B*. On the east side of the valley, one of the facies lies opposite the Cascade Range, and one opposite the Sierra Nevada. The flood basins along the axis of the valley are divided into two more facies, one in Butte Basin and including Sutter Buttes, the second in the Colusa, Sutter, and American Basins. The final two hydrochemical facies are opposite the Coast Ranges and are divided north and south near Colusa. In the next section, the chemical characteristics of the six hydrochemical facies are presented and compared, and differences in chemistry are discussed.

DESCRIPTIONS OF HYDROCHEMICAL FACIES

Table 2 shows the geometric mean, minimum, and maximum of chemical concentrations for each of the hydrochemical facies. To determine if the average concentrations of chemical species in the hydrochemical facies are significantly different, the differences between geometric means were tested using a t test. The results of these comparisons are illustrated quantitatively in the same table.

TUSCAN VOLCANIC ROCKS

The Tuscan volcanic rocks hydrochemical facies is along the northeastern margin of the Sacramento Valley (pl. 1*B*) adjacent to the Cascade Range. The geologic formations in this area are the Tuscan Formation and more recent alluvial sediments derived from erosion of the Tuscan. Recharge is from the Cascade Range geomorphic province, and ground water is either discharged to the Sacramento River or moves into Butte Basin south of Chico. The Tuscan and its derivatives contain andesitic sands and extensive tuff deposits. Volcanic glass and plagioclase are abundant in these sediments.

The chemistry of ground water in the area reflects the low concentrations of dissolved solids carried by recharge from the Cascade Range, having low mean concentrations of magnesium, sodium, bicarbonate, sulfate, and chloride. Silica concentrations are high due to solution of volcanic glass, and the facies has the highest average nitrate-nitrogen concentration of the six. The maximum boron concentration is rather high, although the mean concentration is only moderate. Boron in excess of 1.0 mg/L occurs in only three wells, all to the east of the Sacramento River northeast of Red Bluff.

TABLE 2.—*Geometric mean, minimum, and maximum of chemical concentrations for each of the hydrochemical facies, Sacramento Valley*

[Figure above line refers to geometric mean; figures below line refer to minimum-maximum range. H, high; L, low; VH, very high; VL, very low. NOTE.—These comparisons are relative to the other hydrochemical facies and do not necessarily describe the absolute values. Labels were assigned only where the difference between two geometric means tested significant at the 95 percent level]

The source of the high boron water is Tuscan Spring, located along Salt Creek in Tehama County in section 32 of township 28 N., range 2 W. (Waring, 1965).

VICTOR PLAIN

The Victor Plain hydrochemical facies is along the east and southeast margin of the valley, and extends westward to near the Feather and Sacramento Rivers. Recharge is primarily from the Sierra Nevada to the east, although pumping depressions southeast of Marysville and north of Sacramento induce recharge from the rivers. North of Marysville, water is discharged into the Feather River or passed into Butte Basin. South of Marysville, most of the ground-water discharge seems to be by pumping. Along the valley margin, the aquifers are volcanic sands with associated tuffaceous deposits. In the central and western parts of this facies, the volcanic units dip under the Victor Formation composed of alluvium from the Sierra Nevada.

The Victor Plain facies has a low average dissolved-solids content reflecting recharge from the Sierra Nevada. Concentrations of calcium, magnesium, bicarbonate, boron, and sulfate are all low in this area. Silica

is high, reflecting the volcanic material present in the sediments.

BUTTE BASIN

The Butte Basin hydrochemical facies roughly coincides with the Butte flood basin east of the Sacramento River. The basin extends from Chico on the north to Yuba City on the south and lies between the Feather and Sacramento Rivers. Sutter Buttes is included in this facies as too few chemical analyses were available from this area to justify a separate facies. The basin receives recharge from the Tuscan volcanic rocks facies and from Victor Plain to the east. A small amount of recharge also occurs in the vicinity of Sutter Buttes. Ground water leaves the Butte Basin facies to enter the Sacramento River and to enter the Sutter Basin facies east of Sutter Buttes. In the flood basins the sediments are fine grained and reducing.

Ground water in the Butte Basin facies has a somewhat higher average dissolved-solids concentration than the two eastern margin facies possibly reflecting longer subsurface residence times or a change in sediment lithology. Chloride and boron are the only two species that have low average concentrations in this facies. The high silica concentrations may be a result of recharge from the Tuscan volcanic rocks facies and from volcanic material around Sutter Buttes. High arsenic concentrations imply deposition in a reducing environment (Garrels and Christ, 1965). This facies has the highest average potassium concentration, which may reflect the longer residence times or a change in mineralogy of the sediments.

Information on the variation in water chemistry with depth was obtained from a U.S. Geological Survey test well drilled in section 32 of township 19 N., range 1 W. Three piezometer tubes were installed at different depths and isolated by cement packers. Data on the shallow water at the site are available from a previous study (Fogelman, 1976).

Analyses from the three piezometers and from the shallow water are shown in table 3. The percent composition of the major ionic species in terms of milliequivalents per liter are provided in figure 3. Between 80 and 595 feet, a decrease in magnesium is balanced by an increase in sodium, with calcium remaining about the same. There is a slight increase in the percent of chloride in the ground water over this same interval, but the net change in anion composition is very small. Below 595 feet, however, calcium and magnesium decrease, both in percent composition and concentration, and sodium increases. Chloride also increases, becoming the dominant anion by a depth of 968 feet. Even at 1,333 feet, however, the dissolved-solids concentration of the water is only moderate, at 526 mg/L, and the boron concentration remains low.

SUTTER BASIN

The Sutter Basin hydrochemical facies is between the Sacramento and Feather Rivers south of Sutter Buttes. This facies extends west of the Sacramento River near Colusa to include part of Colusa Basin and includes some of the American Basin east of the Feather River. Recharge comes from Sutter Buttes, from the Butte Basin hydrochemical facies east of Sutter Buttes, and from both the Sacramento and Feather Rivers. Sediments in the flood basins are generally fine grained and reducing at depth.

The Sutter Basin facies is tied with the south alluvial fans facies for the highest average dissolved-solids concentration. This facies is also high in sodium, chloride, bicarbonate, potassium, and boron. The effects of reducing conditions are evident in the relatively higher concentrations of iron, manganese, and arsenic in this area, all of which are more soluble in reducing environments (Garrels and Christ, 1965). The very low average nitrate concentration in this facies is also indicative of reducing conditions, where nitrate can be removed by denitrification reactions.

The origin of the high dissolved-solids water is thought to be connate marine water moving upward along fault zones created when Sutter Buttes was emplaced (Curtin, 1971). Throughout much of the southern part of Sutter Basin, water of very high salinity (specific conductance greater than 3,000 micromhos) is located within 400 feet of the surface.

TABLE 3.—*Chemical composition of water from wells of various depths, section 32 of township 19 N., range 1 W.*

Sample No. (fig. 3)	Site identification	Depth of well (feet)	Calcium (mg/L)	Magnesium (mg/L)	Sodium (mg/L)	Bicarbonate (mg/L)	Sulfate (mg/L)	Chloride (mg/L)	Nitrate-N (mg/L)	Boron (mg/L)	Dissolved solids (mg/L)

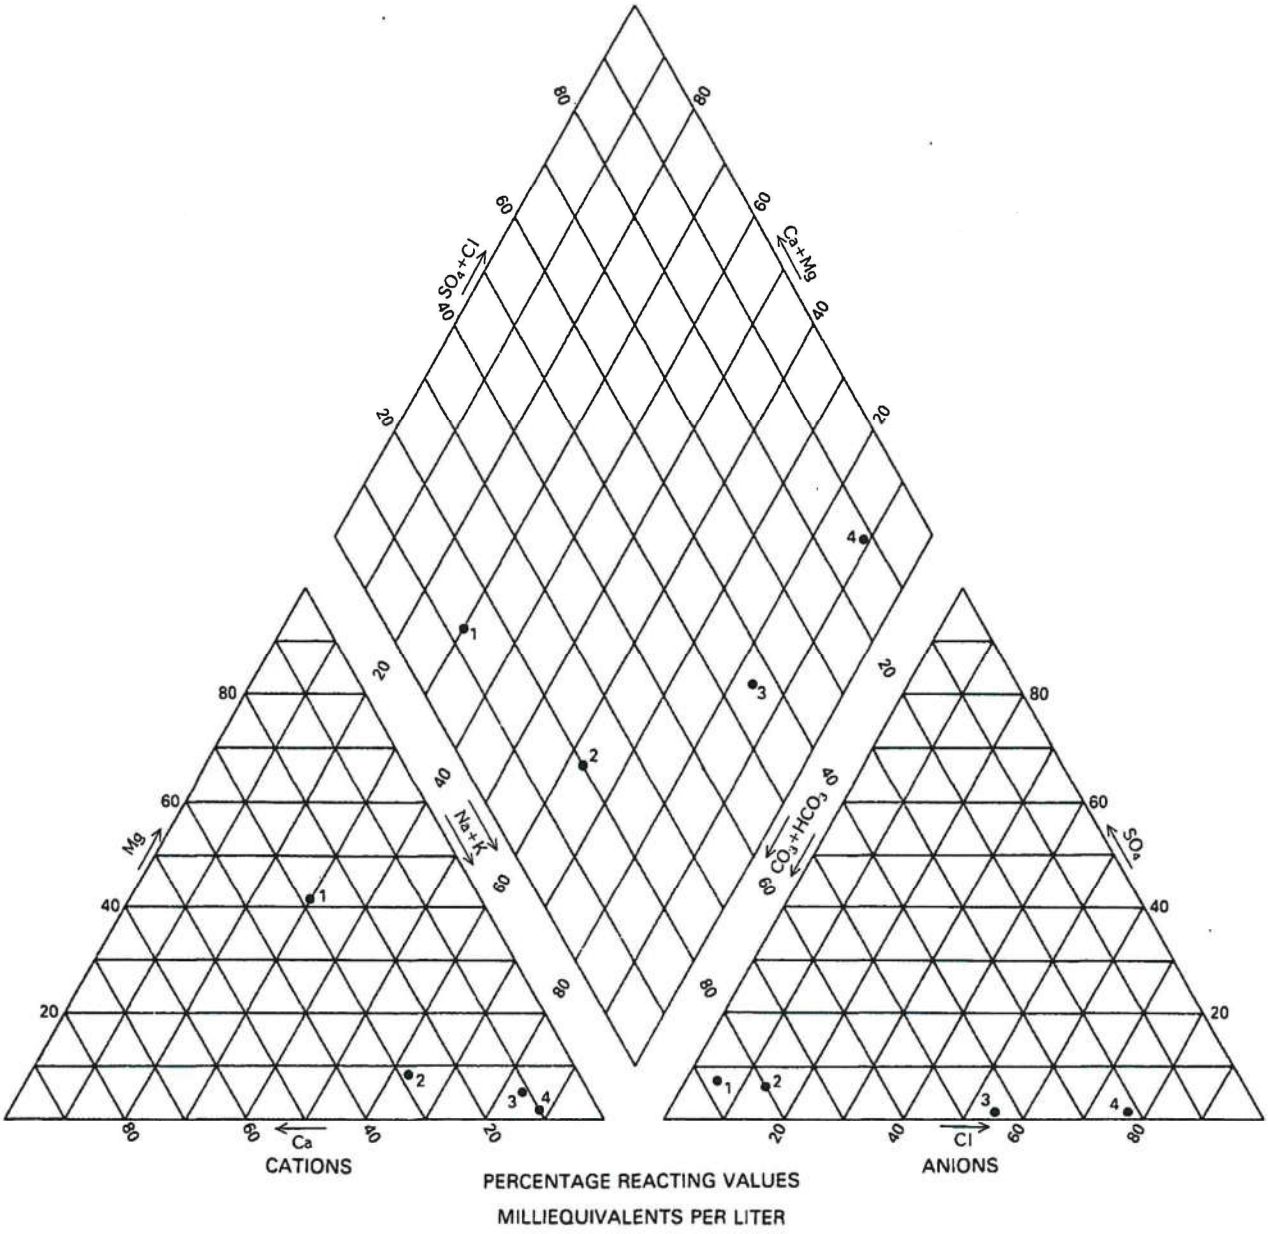

FIGURE 3.—Major-ion composition of water from wells of various depths in section 32 of township 19 N., range 1 W. Numbers refer to sample numbers in table 3.

NORTH ALLUVIAL FANS

The north alluvial fans hydrochemical facies is along the northwestern margin of the valley. Ground water occurs primarily in alluvial fan deposits and is recharged by streams draining the Coast Ranges. The alluvial fan of Stony Creek is a major source of recharge in this area, with flow radiating away from the fan to the north, east, and south. Ground-water flow in this facies is generally east and south. Most of the water is discharged to the Sacramento River along the eastern margin of the facies, although some moves into Colusa Basin along the southern boundary. Sediments in the alluvial fans are primarily derived from Mesozoic marine rocks of the Coast Ranges with sediments derived from Franciscan metamorphic rocks carried down by some of the larger streams.

The average dissolved-solids concentration in the north alluvial fans facies is moderate, and most of the chemical-constituent averages fall between those of the

other facies. Calcium is the only species with a high average concentration in this facies; this is from the waters of Stony Creek, which are high in calcium. Silica is much lower in waters on the west side of the valley, and this is shown by the low average silica concentration.

SOUTH ALLUVIAL FANS

Located along the southwestern margin of the valley in alluvial fans adjacent to the Coast Ranges, the south alluvial fans hydrochemical facies extends from Putah Creek north to township 15 N. Recharge from the Coast Ranges is provided by numerous ephemeral streams north of township 10 N., and by Cache and Putah Creeks in townships south of 11 N. Recharge from Cache Creek moves around the end of the Dunnigan Hills to pumping depressions north of Woodland. Some recharge is also drawn from the Sacramento River to these same pumping depressions.

The south alluvial fans hydrochemical facies is distinguished by having high average concentrations for many of the chemical species measured. Dissolved solids, calcium, magnesium, sodium, chloride, and fluoride all have high average concentrations here. Boron and bicarbonate concentrations in this facies average very high. With little volcanic material to provide silica, its average concentration is low, as in the north alluvial fans.

Boron and chloride concentrations in the ground water of this facies average the highest in the valley, and boron concentrations as high as 8.1 mg/L have been measured in township 11 N., range 2 E. The source of the chloride and boron has been attributed to the streams draining the Coast Ranges (Bertoldi, 1976). Information obtained from a deep test well drilled by the U.S. Geological Survey in section 34 of township 12 N., range 1 E., indicated another possible source. The test well 12N/01E–34Q was drilled to a total depth of 2,400 feet and piezometers tubes installed at 942 feet, 1,396 feet, and 2,120 feet. No sample was obtained from the 942-foot depth, but analyses from the two deeper piezometers are shown in table 4. At a depth of 2,120 feet, water containing 12 mg/L boron and 660 mg/L chloride was encountered. Piezometric heads in the test well indicate upward movement of water, which may be contaminating the shallow water.

The source of boron and chloride in the streams draining the Coast Ranges is warm saline springs, a number of which occur in the Clear Lake area. Partial chemical analyses from these springs are also shown in table 4. Boron concentrations are as high as 310 mg/L in these springs. To determine the source of the high boron concentrations in the ground water in township 11 N., range 2 E., the percent composition in milliequivalents per liter of the wells in this township were plotted along with the deep well water and the warm spring water (fig. 4). The Wilbur Oil Test is a wildcat oil well that produces cold water also high in boron and chloride.

TABLE 4.—*Data for wells and springs plotted in figures 4 and 5*

From figure 4 there is no clear indication of whether the water in the wells (sample Nos. 3–9) is derived from the thermal springs (sample Nos. 11–14) or from deep ground water in the area (sample No. 1). Two of the thermal springs, Wilbur Oil Test well and the deep well, are very high in percent sodium. Two of the thermal springs show an increase in percent magnesium, but the percent calcium remains very low.

The deep ground water and the Wilbur Oil Test well have a much higher percentage of chloride than the thermal springs, which are enriched in carbon dioxide from metamorphism at depth (Barnes and others, 1973). As no clear trends emerged in the plot of the percent compositions in milliequivalents per liter, a second plot of chloride versus boron concentrations was made (fig. 5). The dashed diagonal line in figure 5 represents the dilution of Wilbur Springs water with water containing no boron or chloride. The thermal springs all plot very close to this line, having both high chloride and boron concentrations. The shallow wells in township 11 N., range 2 E., all plot very close to the the line representing dilution of Wilbur Springs water, as does the average composition of Cache Creek. Wilbur Oil Test well and the deep wells in the valley plot to the right of the dilution line, which indicates more chloride relative to boron in these waters. From figure 5 the source of the high chloride and boron concentrations is confirmed as water from the thermal springs in the Coast Ranges carried into the valley by streams, such as Cache Creek. Distinct differences between the cold waters,

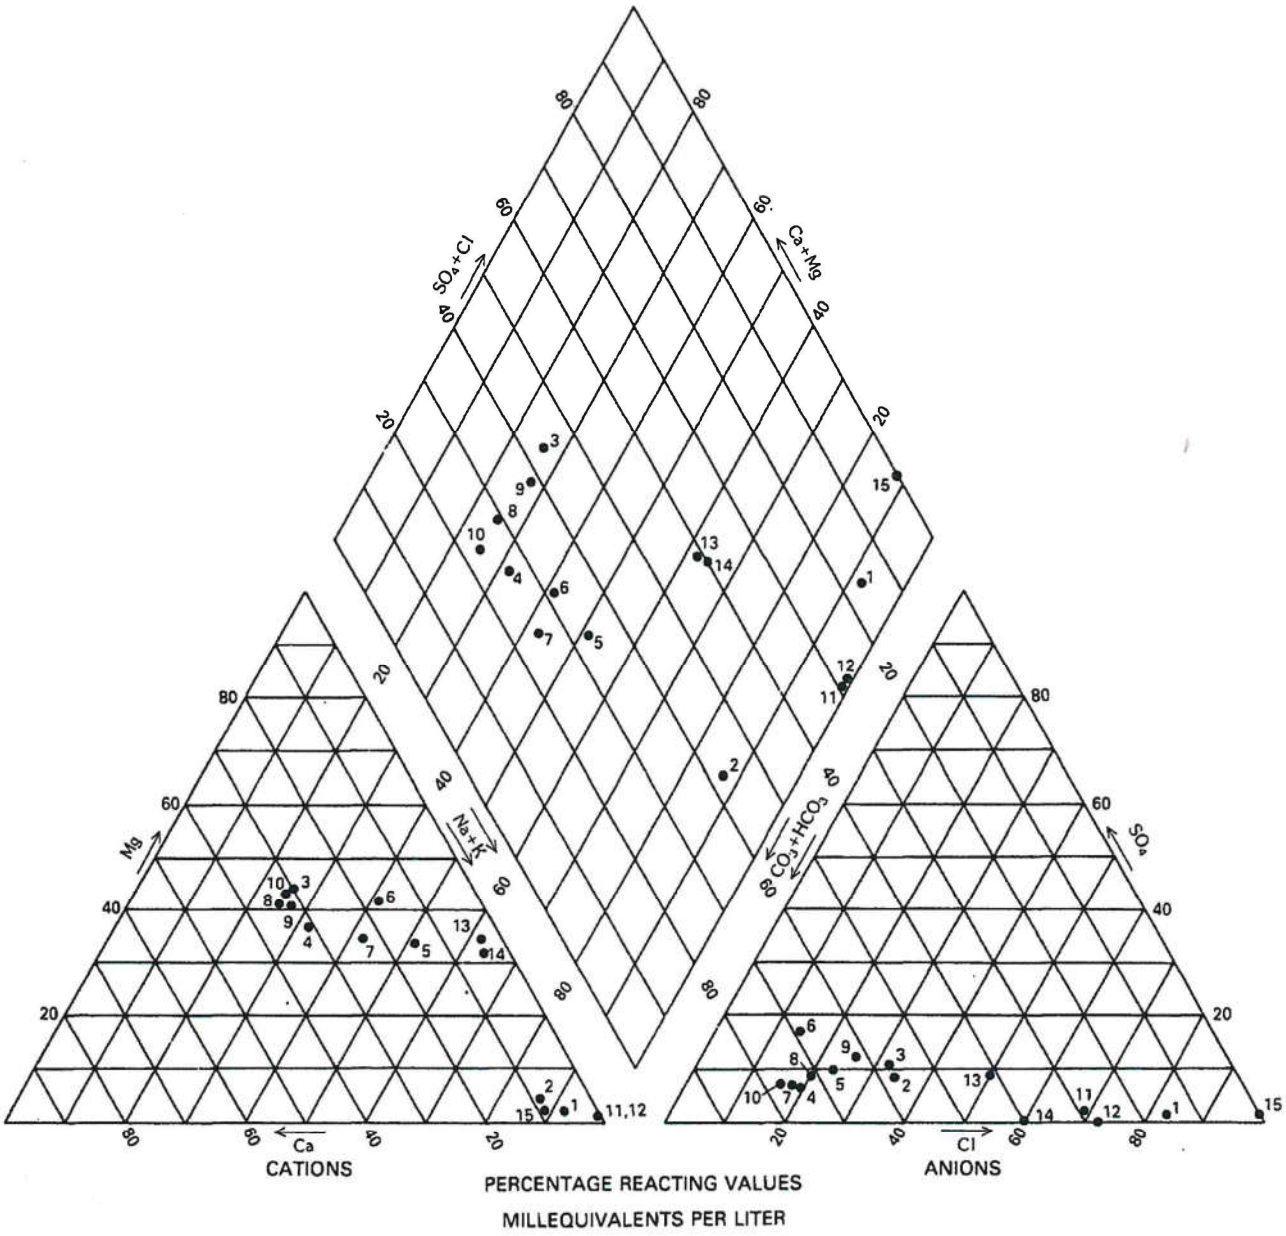

FIGURE 4.—Major-ion composition of water from springs in the Clear Lake area and from wells in a high boron area northwest of Woodland. Numbers refer to sample numbers in table 4.

such as Wilbur Oil Test and well 12N/01E–34Q01, and the thermal waters can be found in the boron-to-chloride ratio and the percent of bicarbonate ion in the waters. The hot waters probably receive inputs of carbon dioxide and boron from a gas phase produced during metamorphism of the marine sediments at depth. Cold waters are not enriched in volatile components and therefore have lower boron-to-chloride ratios and lower percent bicarbonate contents. The shallow wells in township 11 N., range 2 E., have the higher boron-to-chloride ratios indicative of a thermal water source.

TEMPORAL CHANGES

Ground-water-quality degradation may be occurring in the Sacramento Valley because of increasing development accompanied by more intensive agriculture and denser habitation. Such effects have been noted in the

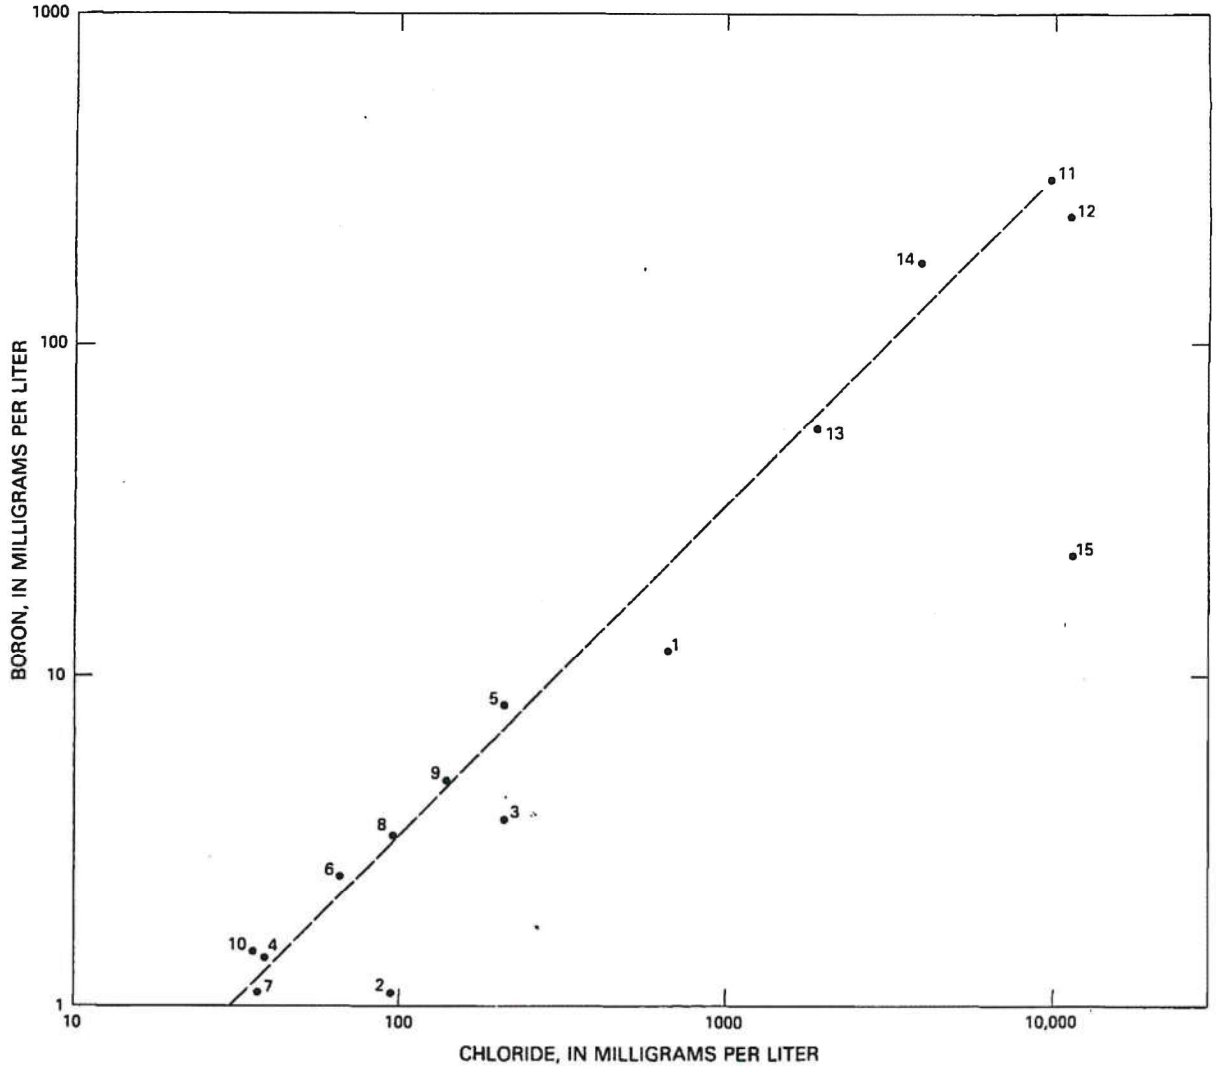

FIGURE 5.—Plot of chloride versus boron for springs in the Clear Lake area and for wells in a high boron area northwest of Woodland. Numbers refer to sample numbers in table 4. Dashed line indicates dilution of Wilbur Springs water with water containing no boron or chloride.

San Joaquin Valley (Kern County Water Agency, 1979), in San Bernardino County (Klein and Bradford, 1979), and in the Colorado River Basin (El-Ashry, 1980). Much of the problem is related to infiltrating irrigation water that (1) has been concentrated by evapotranspiration, (2) has dissolved salts added as fertilizers and soil conditioners, and (3) has leached natural salts from the unsaturated zone. Additional degradation can occur from nonagricultural activities, such as the disposal of sewage and industrial wastes.

In this section, water-quality data from the Sacramento Valley are examined for linear trends with time. Data in each of the hydrochemical facies are combined to derive an average trend for each of the areas. Individual wells are also examined for temporal changes to show more localized variations. The locations of wells used to study the temporal changes are plotted on a map of the valley, and those wells showing significant changes are labeled with symbols indicating the direction of change (pl. 2).

Two variables are used in this study, dissolved-solids and nitrate concentrations. Dissolved solids measures the total amount of dissolved chemicals in a water, and it gives a general indication of overall water quality. Nitrate is derived from a number of potential pollution sources, such as fertilizers and sewage. Increases in nitrate would indicate specific influences of man's activities. These two variables will give a fairly com-

prehensive evaluation of any temporal changes that may be occurring.

METHODS OF DATA ANALYSIS

To determine the average changes occurring in a hydrochemical facies, some technique was needed so that wells with different average dissolved-solids or nitrate concentrations could be compared. This was accomplished by standardizing the data for each well to have a mean of zero and a standard deviation of one. Data from all the wells for each year could then be averaged with equal weight being given to each well. This data manipulation procedure produced a data set with one observation per year for the period of record in each hydrochemical facies. The yearly observations represented the average for all the wells for which data were available in each hydrochemical facies.

Trends in the chemistry of the facies were then studied using a linear regression of the standardized and averaged dissolved-solids or nitrate concentrations versus time. One of the fundamental assumptions of regression analysis is that the observations are independently distributed. For sequences of data collected over time, this requirement is sometimes violated because the data are autocorrelated. Because of memory effects in natural processes, measurements taken at one time may be correlated to measurements taken at previous times.

To test the extent to which the dissolved solids and nitrate data suffered from autocorrelation problems, lag one serial correlations were calculated, and cumulative frequency histograms of these autocorrelations compiled. Matalas, Slack, and Wallis (1975) have generated a series of empirical cumulative frequency histograms for data sequences having a range of serial correlations. By comparing the cumulative frequency histograms for dissolved solids and nitrate in the Sacramento Valley to these empirical histograms, the probable population autocorrelations were determined to be about 0.3 for dissolved solids and between 0.3 and 0.5 for nitrate.

Serial correlations of this magnitude indicate a tendency for subsequent values to be positively correlated to previous values. As a result, the trends determined from the regression analyses may not be as strong as indicated. Positive autocorrelations of this magnitude, however, will not significantly affect the conclusions of the temporal study.

The equations describing the average temporal changes for the hydrochemical facies were transformed back to concentrations by destandardizing the regression equations. For each hydrochemical facies, the average of the means and standard deviations of the individual wells was calculated. By multiplying the regression equations by these average standard deviations and adding the average means, equations were obtained that give the average trend in a facies in terms of concentrations. This equation describes what might be observed in a typical well in each facies, and no individual well can be expected to show the same relation.

The equations produced by this analysis are not predictive equations, but merely reflect the average rate of change over the period of record, from about 1955 to 1977. An example of the problems that can arise if they are used as predictive equations is demonstrated by considering what happens if some of the equations are used to estimate past concentrations. The equation describing the average changes in nitrate-nitrogen concentrations for the Victor Plain hydrochemical facies indicates negative concentrations in the ground water prior to 1939. This is a physical impossibility and arises because the equation was used for a purpose for which it was not intended. While predictions of future concentrations of dissolved solids and nitrate-nitrogen may not produce negative results, the values obtained could be just as meaningless.

In addition to testing for average trends throughout a hydrochemical facies, individual wells were examined for temporal variations. Where a significant trend was noted for an individual well, the equation was recorded and the well's location plotted on a map of the valley with a symbol indicating the direction of the trend (pl. 2).

Few wells in the valley have multiple observations over time. To minimize the effects of random fluctuations, only wells with seven or more observations for dissolved solids and six or more observations for nitrate were used. There was no attempt to assure a random distribution of wells throughout the valley, and all wells in the valley or along the margins having a sufficient number of observations were used. Time is measured as the year minus 1900. For example, for the year 1975, time is equal to 1975–1900 or 75.

DISSOLVED SOLIDS

Dissolved solids is a measure of the total amount of dissolved chemicals in water. An increase in any of the individual constituents will be reflected by an increase in the dissolved solids. While not many historical dissolved-solids measurements are available, many specific-conductance measurements have been made. Specific conductance is proportional to the quantity and valence of ionized chemicals in a water. Because almost all the major dissolved chemical constituents in a water are ionized, dissolved solids and specific conductance are closely related.

It was felt that dissolved solids would have more meaning for most users of this report; therefore, specific conductivities were transformed to dissolved-solids concentrations. The relation between dissolved solids and specific conductance will depend on the specific ionized species present and the amount of uncharged species, mainly silica, present in the water. For this reason, separate equations were derived for different parts of the valley. These areas do not exactly coincide with the hydrochemical facies as they were finally defined, but the division follows the same basic pattern. Thus, the effects of different water chemistries on the relation between dissolved solids and conductance were taken into account during the transformation.

Equations that describe the relation between dissolved solids and specific conductance were derived from a linear regression on data from about 650 wells having measurements of both dissolved solids and conductance. A linear equation with both slope and intercept terms was used rather than a ratio. The intercept terms of all the linear equations were significantly different from zero, which indicates that the linear equations better fit the data than ratios.

Because the calculation of dissolved solids from conductance is a simple linear transformation, the calculation in no way affects the presence of trends in the data. All dissolved-solids values for a well were estimated from conductance measurements even if some measured dissolved-solids concentrations were available. This prevented any changes that might be induced by using dissolved-solids data from different sources.

Locations of wells examined for trends in dissolved solids are shown on plate 2A. The changes for each hydrochemical facies are discussed in the next section and coefficients for the equations describing the average temporal changes are given in table 5. Coefficients for individual wells are summarized in table 6.

HYDROCHEMICAL FACIES

Dissolved solids in the Tuscan volcanic rocks hydrochemical facies show an average annual increase of 0.95 mg/L. The trend line accounts for 31 percent of the variation in the standardized dissolved-solids data averaged over all wells by year. A plot of the trend line is shown in figure 6. Temporal variations are significant in five of the 19 wells for which historical data are available (table 6). Two of these wells show rising trends and three show decreasing trends.

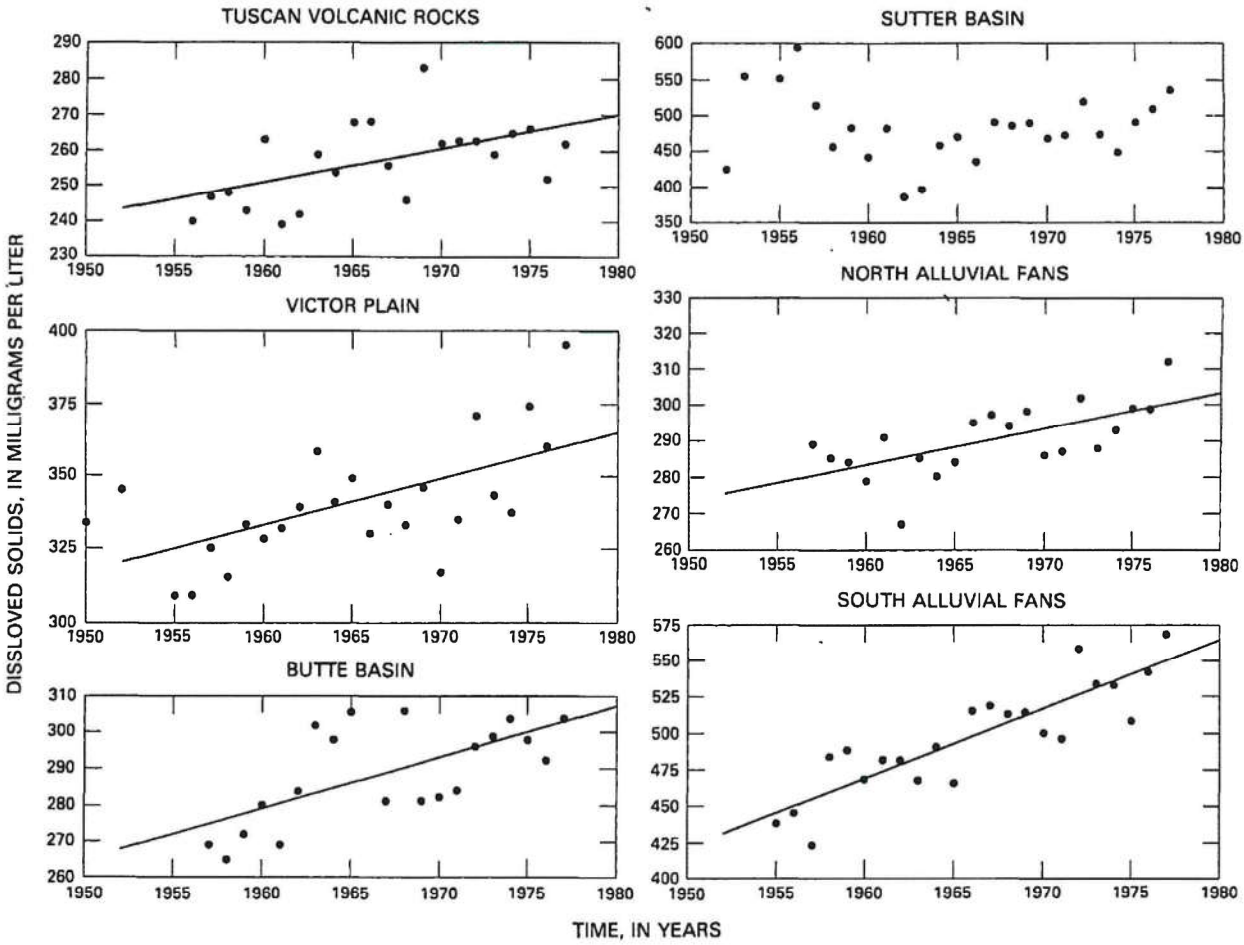

FIGURE 6.—Average yearly dissolved-solids concentrations versus time for the six hydrochemical facies in the Sacramento Valley. The coefficients and significance tests for the trend lines are given in table 5. If no line is shown, then the slope of the trend line is not significantly different from zero at the 90 percent confidence level. The technique by which the average yearly dissolved-solids values were derived is explained in the text.

The average yearly increase in dissolved solids for the Victor Plain facies is 1.61 mg/L. The trend line, which explains 38 percent of the variation in the standardized data, is shown in figure 6. Only two of the 20 wells studied in this facies showed significant changes, one of which showed an increase, and the other a decrease with time.

For Butte Basin, a temporal trend having a slope of 1.37 (mg/L)/yr explains 41 percent of the variation in the averaged data. In this facies also, two wells showed significant trends. One well demonstrated an increase and the other a decrease in dissolved solids with time.

Sutter Basin is the only hydrochemical facies to show no significant temporal change in average dissolved-solids concentration. Two of the 10 wells did show significant trends, but in opposite directions.

An increase in the average dissolved-solids concentration of the north alluvial fans facies of 1.02 (mg/L)/yr explains 43 percent of the variation in the yearly average data. A plot of the trend line is shown in figure 6. Of 62 wells that have seven or more observations in this area, 15 show significant upward trends, and none decrease.

Seventy-six percent of the variation in the average yearly dissolved-solids data are explained by a linear trend in the south alluvial fans facies. The slope is very steep 4.75 (mg/L)/yr and indicates a very rapid increase in dissolved solids (fig. 6). Of the 18 wells examined in this facies, 8 had significant increases in dissolved solids. There were no wells that showed decreases.

NITRATE

A certain amount of nitrate is present in precipitation, and chemical reactions in the soil zone may add to this amount. Thus, even under natural conditions, a finite amount of nitrate will exist in ground water. An estimate of natural nitrate concentrations in the Sacramento Valley can be made from data gathered during the period 1912–13 (Bryan, 1923). The median nitrate-nitrogen concentration in these 43 samples is 0.67 mg/L. The highest nitrate-nitrogen concentration measured was 14 mg/L, which suggests some wells were polluted as long as 70 years ago. From the frequency histogram of the 1912–13 nitrate data (fig. 7), it is estimated that under natural conditions, no more than about 3 mg/L nitrate-nitrogen would be expected in the ground water.

By the period 1974–78, the median nitrate-nitrogen concentration had more than doubled to 1.6 mg/L. The maximum observed nitrate-nitrogen concentration also increased, with two wells containing 27 mg/L and one well 61 mg/L. These increases likely reflect the influences of man's activities, and the extent of temporal changes was, therefore, investigated to determine the magnitude of the problem.

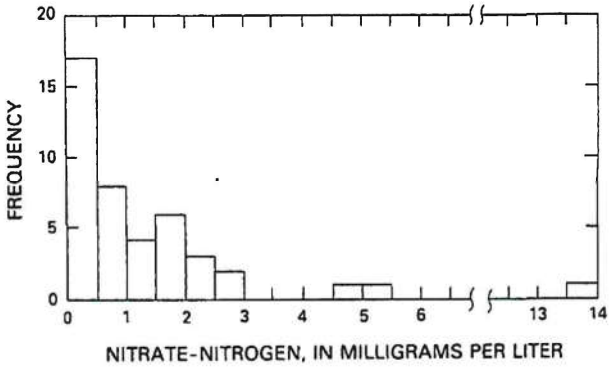

FIGURE 7.—Frequency histogram of dissolved nitrate-nitrogen concentrations in wells, 1912–13. Data from Bryan (1923).

Locations of wells examined for trends in nitrate are shown on plate 2*B*. The changes for each hydrochemical facies are discussed further and coefficients for the equations describing the average temporal changes are given in table 7. Coefficients for individual wells are summarized in table 8.

HYDROCHEMICAL FACIES

No significant average trend was found for the Tuscan volcanic rocks hydrochemical facies. However, two of the five wells examined did show significant upward trends in nitrate concentrations.

A linear trend with a slope of 0.036 (mg/L)/yr explains 63 percent of the temporal variation in the average yearly nitrate-nitrogen concentrations in the Victor Plain facies. A plot of this trend line is shown in figure 8. Of 13 wells in this area that had 6 or more observations, 5 showed significiant upward trends. None of the wells showed a significant decrease.

Neither Butte nor Sutter Basin had a significant average trend in nitrate. Also, there were no individual wells in either that showed any significant changes. However, with only three wells in Butte Basin and two in Sutter Basin having six or more observations, there are too few samples for the results of the test to be conclusive.

The nitrate-nitrogen concentrations in the north alluvial fans hydrochemical facies show a distinct upwards

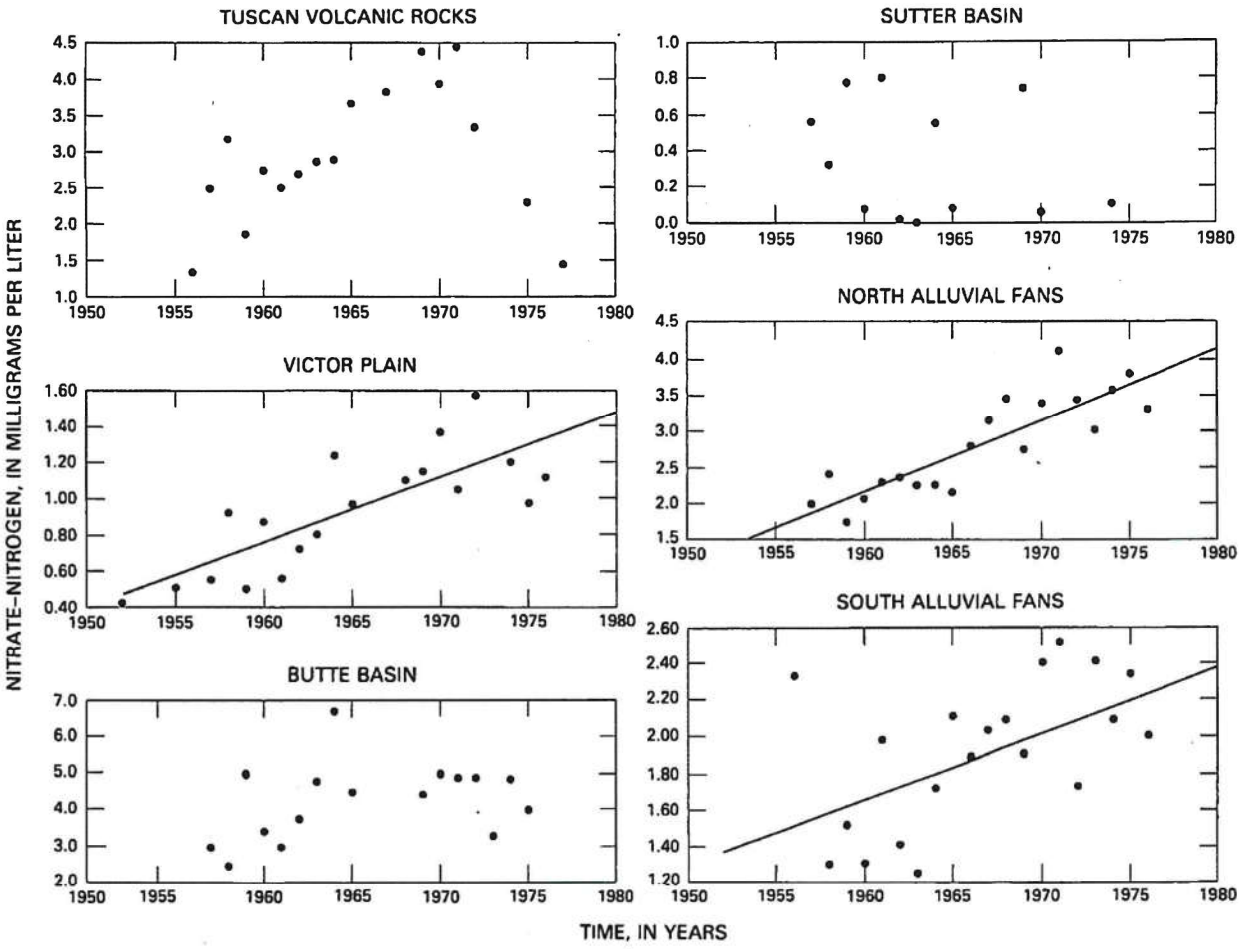

FIGURE 8.—Average yearly nitrate-nitrogen concentrations versus time for the six hydrochemical facies in the Sacramento Valley. The coefficients and significance tests for the trend lines are given in table 7. If no line is shown, then the slope of the trend line is not significantly different from zero at the 90 percent confidence level. The technique by which the average yearly nitrate-nitrogen values were derived is explained in the text.

trend with a slope of 0.099 (mg/L)/yr. Seven of the 26 wells in this facies showed significant upwards trends. The plot of the trend in figure 8 shows that the average concentration of nitrate-nitrogen in this facies has exceeded 3.0 mg/L, the maximum expected under natural conditions.

For the south alluvial fans hydrochemical facies, a linear trend having a slope of 0.036 (mg/L)/yr explains 30 percent of the temporal variation in the average annual nitrate-nitrogen concentrations. Thirteen wells had six or more observations over time, and 5 of them show significant temporal changes. Four have upwards trends, and 1 a downwards trend.

HYPOTHESIS TESTING

Because trends in the data for the individual wells were tested at the 90 percent confidence level, there is a 10 percent chance that no significant trend exists in the valley. The significant slopes that were observed could result from normally distributed random fluctuations about a true true slope of zero. If this were the case, 5 percent of the wells could show a significant increase, and 5 percent a significant decrease, although no real trend existed. If more than 5 percent of the dissolved-solids or nitrate wells show significant trends in the same direction, then it can be concluded that there has been a significant change for that species.

Of 140 wells in the Sacramento Valley tested for trends in dissolved solids, 28 (20 percent) showed an increase and 7 (5 percent) showed a decrease with time. Under the null hypothesis that no change in dissolved solids is occurring at the 90 percent confidence level, it would be expected that by random variation, 7 of the wells would show a significant decrease and 7 would

show a significant increase. For dissolved solids, the number of wells showing increases exceeds the number expected by random variation, and the increase in dissolved solids is significant.

Of 62 wells tested for trends in nitrate, 18 (29 percent) showed increases, but only 1 (2 percent) showed a decrease with time. Under the null hypothesis of no change, 3 can be expected to increase and 3 to decrease by random variation at the 90 percent confidence level. Because 29 percent of the wells showed significant increases in nitrate, the null hypothesis can be rejected, which indicates significant increases in nitrate are occurring in the Sacramento Valley.

PROCESSES CONTROLLING GROUND-WATER CHEMISTRY

Differences in the chemical composition of ground water among the six hydrochemical facies in the Sacramento Valley indicate that either different processes control the water chemistry in different areas, or that there are spatial variations in the same process. In this section, the major controlling processes are delineated from the chemical data using principal components analysis. Factor scores are than calculated for each well that reflect the magnitude of each component in that well. By studying the spatial trends in the factor scores using trend surface analysis, the areal variations in processes can be determined. Contour maps of these surfaces show the spatial distributions of the more important processes controlling ground-water chemistry.

METHODS OF DATA ANALYSIS

PRINCIPAL COMPONENTS ANALYSIS

Principal components analysis (Rummel, 1970; Davis, 1973) is used to separate the variance of a data matrix into common and unique components. Variables, in this case dissolved chemical species, that are controlled by the same process will share a common variance structure. Principal components analysis will group the variables on the basis of this shared variation and will calculate a correlation between variables and components. These components represent independent sources of variation in a data matrix and can be interpreted in terms of controlling processes using knowledge of geochemical principles.

From the correlations, or loadings as they are termed, between variables and components, factor scores can be calculated for each well that measure the intensity of a component in that well. These factor scores are a composite of all the chemical species that load on a component and summarize similar behavior in a number of different species. Where several of the chemical species are controlled by the same process, this transformation to factor scores reduces the number of variables needed to account for the significant variation in the data. The factor scores can be further analyzed as any other numerical variable.

TREND SURFACE ANALYSIS

Trend surface analysis (Davis, 1973) is a technique for separating variation in geographically distributed data into regional and local parts. Either of these parts might be the goal of a particular study. For the distribution of processes in the Sacramento Valley, however, the regional variation is of interest. A trend surface is delineated by a polynomial equation that predicts the magnitude of some variable in terms of the geographic coordinates of a set of observations. The criteria for fitting the polynomial is to minimize the squared deviations about the surface. In this study, the trend surface represents the spatial variation in processes controlling ground-water chemistry. By contouring the surface, maps can be prepared that show the spatial variation in the magnitude of the process.

PROCESSES AND THEIR SPATIAL VARIATION

For the Sacramento Valley, 15 variables (table 9) were included in the principal components analysis. A major assumption of components analysis is that the data are normally distributed. This requirement was reasonably well met by using logarithmic transformations of the chemical concentrations. Four principal components explained 73 percent of the total variation in the data and accounted for all the significant common variation (that is, only these four components had eigenvalues greater than one). The four individual components explained 36, 17, 11, and 9 percent of the total variation. Because neither the third nor fourth component yielded clear interpretations that could be attributed to processes, only the first two components are presented. These two components, however, explain

TABLE 9.—*Chemical variables included in the principal components analysis of the Sacramento Valley*

Dissolved solids	Potassium	Silica	Nitrate
Calcium	Manganese	Bicarbonate	Phosphate
Magnesium	Arsenic	Sulfate	Fluoride
Sodium	Boron	Chloride

Arsenic		.62	.38
Percent variation explained	36	17	
Cumulative percent variation explained	36	53	

over 50 percent of the variation in the chemical data from the Sacramento Valley.

Table 10 shows the results of the principal components analysis. On component one, dissolved solids, calcium, magnesium, sodium, bicarbonate, chloride, sulfate, boron, and fluoride all have positive loadings. Silica is the only species to have a significant negative loading on this component. The inverse loadings of dissolved solids and silica indicate that low silica concentrations tend to be found in conjunction with high dissolved-solids concentrations, and vice versa. The positive loadings of all the major chemical species on this factor indicate a source high in calcium, magnesium, sodium, bicarbonate, chloride, and sulfate. This source is also high in fluoride and boron, and low in silica.

The trend surface map of this component (fig. 9) shows a distinct linear trend across the valley, which accounts for 36 percent of the spatial variation in component one. Low values of component one along the eastern margin and in the northern end of the valley indicate low dissolved-solids and high silica concentrations. In the southwestern corner, high concentrations of dissolved species and boron are indicated. This distribution in the ground water is very similar to the distribution of water chemistry in surface streams draining into the valley. Table 11 shows the average concentrations of dissolved species in streams entering the valley from certain areas. East side streams are low in dissolved solids, and contain twice as much silica as streams from the southwestern margin. The silica in east side streams is likely from the weathering of volcanic detritus in the Sierra Nevada and Cascade Range. High dissolved-solids concentrations in the southwest originate in thermal springs in the Coast Ranges.

The first principal component represents the effects of the chemistry of recharge to the valley on the chemistry of the ground water. This process is active along both margins of the valley and produces fairly uniform chemical compositions along the eastern side. Along the western margin, changes in surface-water chemistry from north to south induce changes in ground-water chemistry. The effects of recharge chemistry are the single most important control on ground-water chemistry, accounting for over one-third of the total variation in the chemical data.

The second principal component (table 10) explains 17 percent of the variation in the chemical data, and contains positive loadings of silica, potassium, phosphate, manganese, and arsenic. Nitrate and fluoride have negative loadings on this component. The trend surface for component two (fig. 10) explains 38 percent of the spatial variation in this component. The pattern indicates high factor scores in the center of the valley with low values along the margins. The occurrence of high factor scores in wells in the flood basins suggests that the fine-grained sediments and reducing conditions in the basins are an important control on water chemistry.

Measurements of dissolved oxygen in the ground water in the south alluvial fans facies (table 12) show an average of 3.8 mg/L of dissolved oxygen. Although no data are available for other parts of the valley, it is reasonable to assume that the coarse-grained sediments along the valley margins would contain some dissolved oxygen. In the flood basins, where sediments are water saturated and fine grained, reducing conditions probably exist. The increase in manganese and arsenic, and decrease in nitrate, support an oxidation-reduction effect. The solubility of manganese and arsenic increases in reducing conditions, and nitrate could be removed by denitrification.

Longer residence times in the fine-grained sediments of the flood basins and weathering of volcanic detritus from Sutter Buttes could supply the higher silica and potassium concentrations indicated by component two. The inverse relation between phosphate and fluoride probably reflects spatial differences in their sources rather than equilibrium with a mineral phase, such as apatite. Phosphate, introduced along with nitrate, would not be removed by reduction reactions and would persist in the ground water. Fluoride is probably derived from thermal springs in the hills surrounding the valley and lacks a source in the central basins.

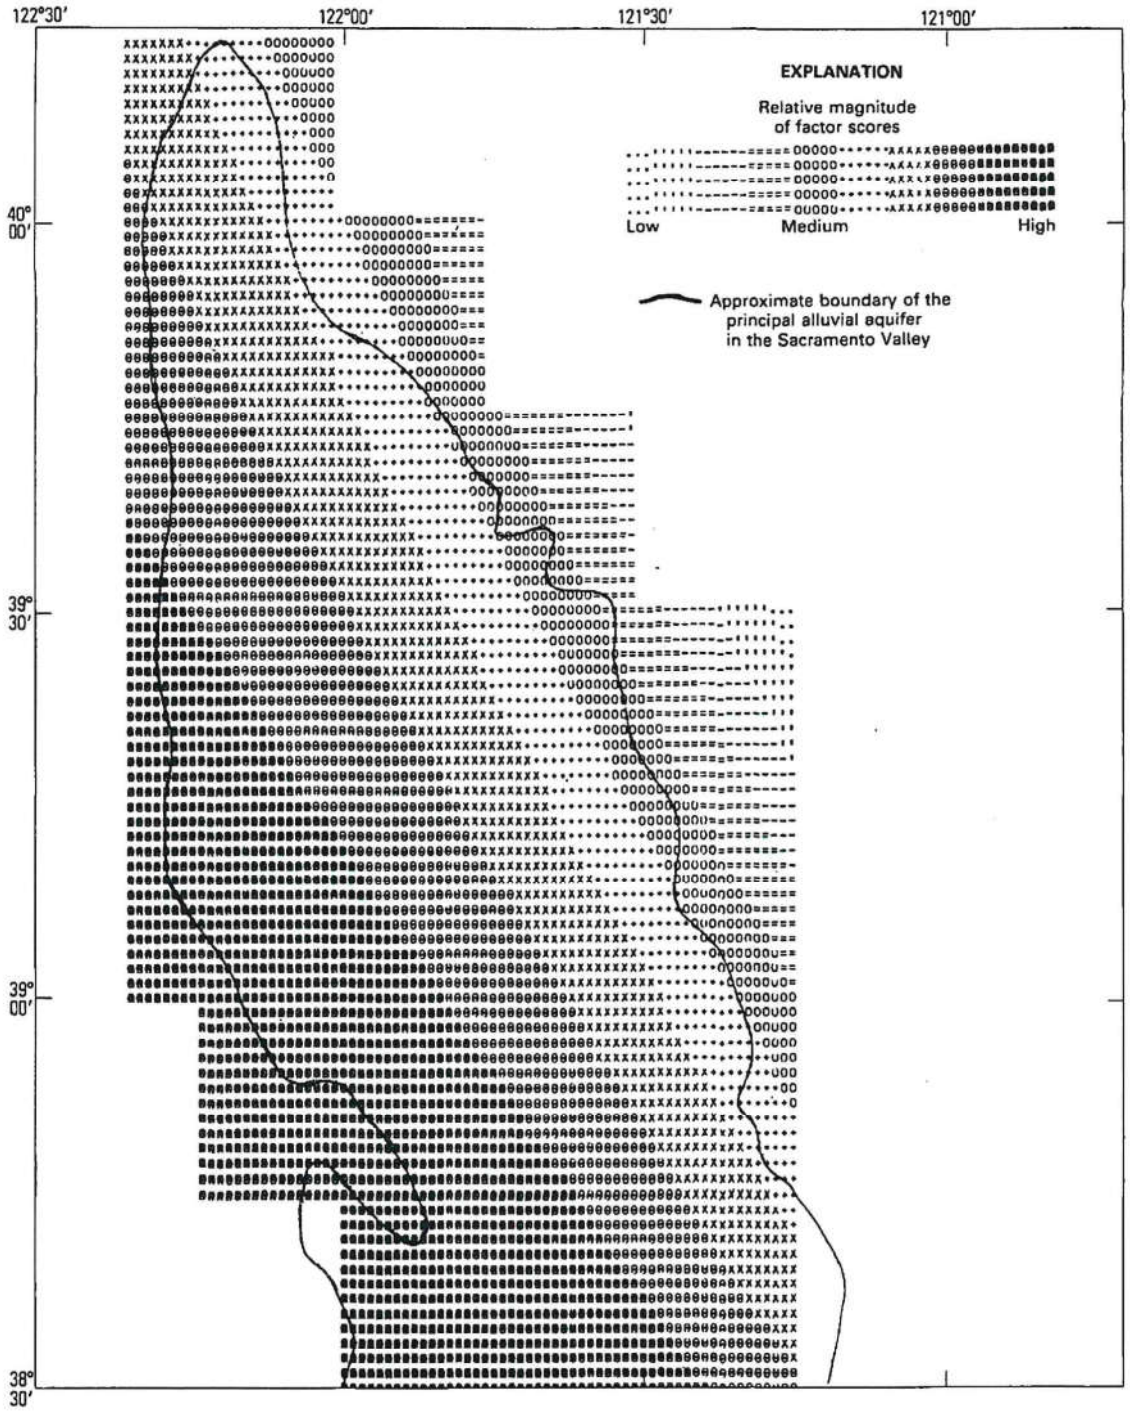

FIGURE 9.—Trend surface of factor scores for component one.

Principal components analysis shows that two components account for over 50 percent of the variation in the chemical data from the Sacramento Valley. While other processes will affect water chemistry, they seem to be either more localized or much less important than the two discussed. Recharge from the valley margins

TABLE 11.—*Average chemical compositions of surface water entering the Sacramento Valley*

Species (mg/L)	East side	Northern west side	Southern west side
Dissolved solids	85	215	592
Calcium	11	36	53
Magnesium	4.7	12	40
Sodium	6.3	13	101
Bicarbonate	55	164	314
Chloride	5.4	16	150
Sulfate	7.0	28	82
Boron	.10	.07	.51
Fluoride	.08	.08	.4
Silica	22	14	11

EXPLANATION OF LOCALITIES

East side: Antelope Creek, Mill Creek, Big Chico Creek, Butte Creek, Feather River, Yuba River, Bear River, and American River.

Northern west side: Red Bank Creek, Elder Creek, Thomes Creek, and Stony Creek.

Southern west side: Stone Corral Creek, Lurline Creek, Freshwater Creek, Salt Creek (west of Williams), Cortina Creek, Sand Creek, Oat Creek, Cache Creek, and Putah Creek.

is the most important control on ground-water chemistry, with reactions in the flood basin sediments also being important.

MINERAL STABILITY RELATIONS

Sediments deposited in the Sacramento Valley have been derived from erosion of the surrounding mountains. These mountains contain igneous and metamorphic rocks which were formed at higher temperatures and (or) pressures than are found at shallow depths in the valley sediments. Because the environment of deposition is radically different from that of formation, these minerals are generally not in equilibrium with their surroundings. As a result, the minerals react with the ground water, which dissolves the unstable primary minerals and forms secondary minerals that are more stable. Reaction rates may be very slow, so the process is gradual and can take tens of millions of years or longer. During this diagenesis, phases, such as pyroxenes, feldspars, micas, and volcanic glass, weather to more stable phases, such as clay minerals and iron hydroxides.

Water chemistry will be affected by water-rock interactions, and the three parts of the system (primary minerals, aqueous solution, and secondary minerals) are interdependent. Using thermodynamic calculations, the mineral phases that will be stable in equilibrium with solutions of various compositions can be predicted. It cannot be justifiably presumed, however, that the mineral assemblage and the ground-water chemistry are in thermodynamic equilibrium, particularly where aluminosilicate minerals are involved. Water chemistry may reflect incomplete reactions or partial equilibrium with metastable phases.

In this section, the relations between water chemistry and aquifer mineralogy are examined. Mineralogy is presented from two U.S. Geological Survey test wells. Mineral saturation indices are examined to determine any likely phases that may be controlling water chemistry. Finally, stability and metastability fields of mineral phases are compared to measured water chemistry to determine what secondary minerals will be most stable in contact with Sacramento Valley ground water.

MINERALOGY OF SEDIMENTS

Sidewall samples were collected from various depths in two test wells drilled by the U.S. Geological Survey during 1979. Data from two wells do not provide a comprehensive evaluation of sediment mineralogy, but they do provide a partial guide to what minerals may be present. Not all the samples have been analyzed as of the time of this writing and additional mineralogic data will be published in the future as basic data reports.

WELL 12N/01E–34Q

The mineralogy of sidewall samples from well 12N/01E–34Q was determined by optical microscope identification of the 0.5- to 0.125-mm size fraction. Table 13 shows the percent compositions of minerals, in this size range, for five samples collected from 323 feet to 897 feet. Data from an additional sample at 1,845 feet is also given. Feldspars compose an average of about two-thirds of the mineral grains, with about one-fifth being quartz and one-tenth being rock fragments. In all the shallower samples, the percent plagioclase having an anorthite content greater than 34 percent is smaller in the fine fraction than in the medium. The sample from 1,845 feet has an unusually small amount of anorthite-rich plagioclase in the medium fraction. The albitic plagioclase component increases between medium and fine fractions in all but one sample. The smaller size fractions, which are chemically more reactive, are dominated by albitic plagioclase.

Lithic fragments from a gravel at 1,856 feet, having a distinct greenish hue, were examined by X-ray diffraction. The sample near this depth was unusually rich in heavy lithic fragments (table 13). X-ray analysis of these fragments indicates that the composition is quartz, plagioclase, and chlorite (Ivan Barnes, U.S. Geological Survey, personal commun., 1979). The mineralogy of the sediments determined by optical methods may not reflect the complete mineralogy, especially where some minerals are contained in rock fragments which are not differentiated mineralogically. Mineral phases identified in samples from this well are shown in table 14.

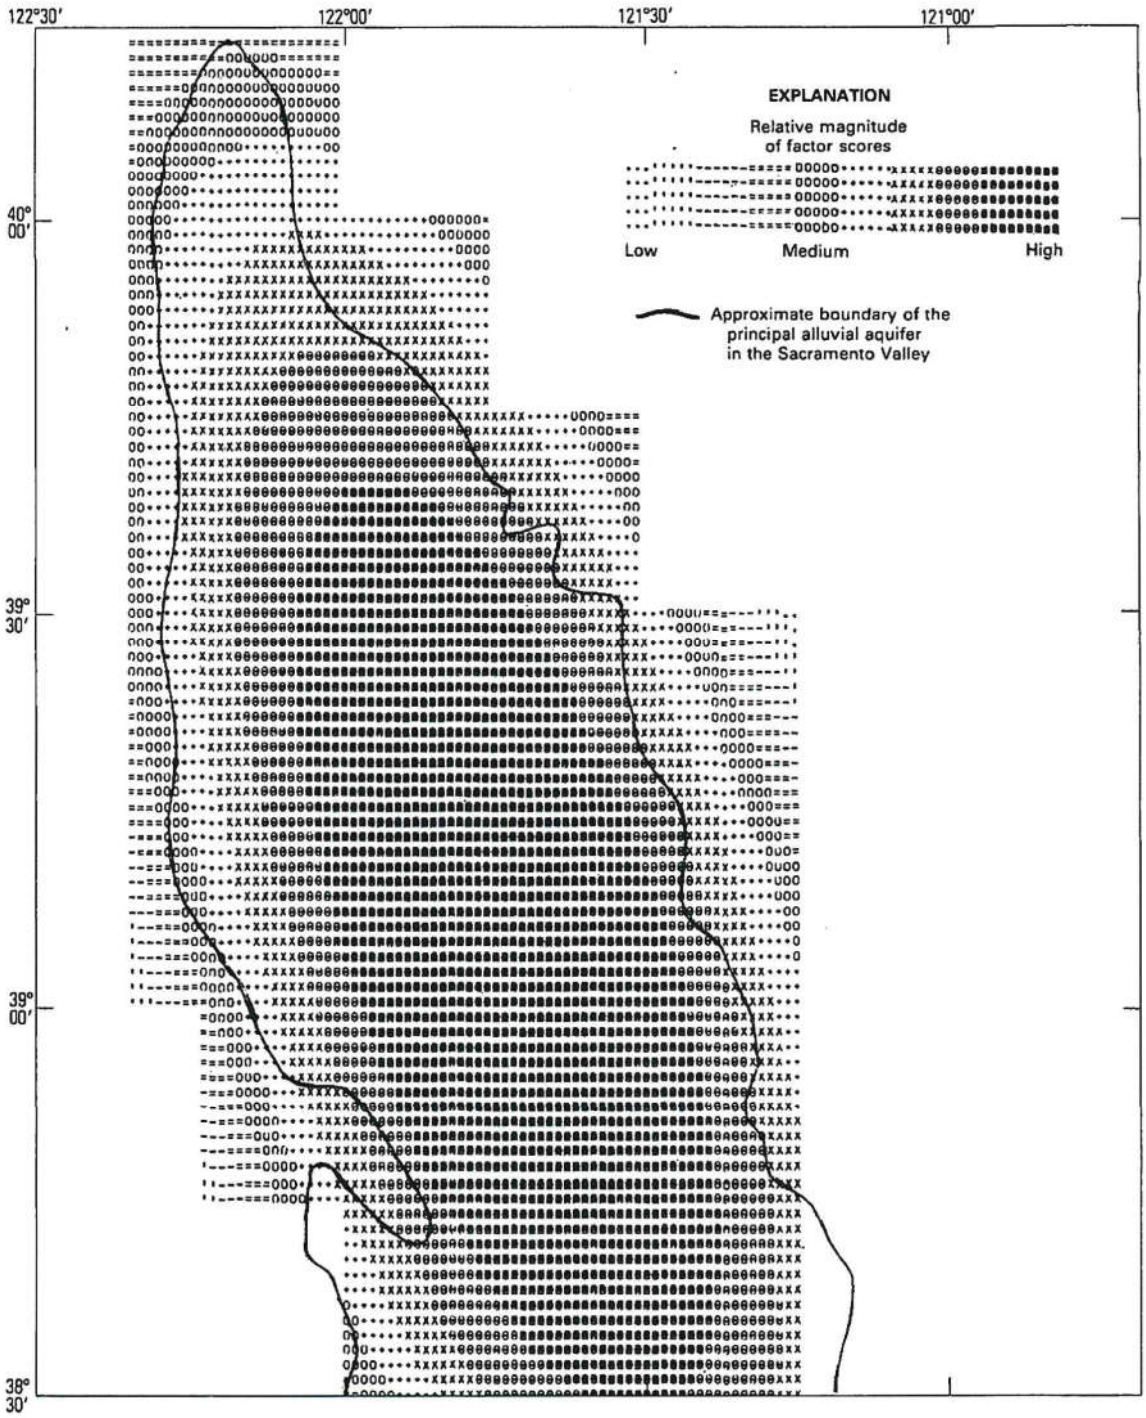

FIGURE 10.—Trend surface of factor scores for component two.

WELL 19N/01W–32G

The mineralogy of a number of fine-grained layers was determined by X-ray diffraction analysis of sidewall samples from well 19N/01W–32G. The results of the analyses are shown in table 15. Below a depth of about 562 feet, a large component of X-ray amorphous material is present in the sediments. Whether this is primary volcanic glass or an intermediate weathering

product, such as an amorphous aluminosilicate (Paces, 1978) was not investigated. The two clay minerals present in quantity are halloysite and illite. The presence of halloysite rather than kaolinite was determined using transmission electron microscopy. Figure 11 shows an electron micrograph of sediments from the 407-foot depth. The tubular structures at the center and top of the figure are halloysite, with poorly formed flakes of illite also visible. The dark, blocky particles are fine-grained quartz and plagioclase.

Optical examination of sand-size grains shows that the mineralogy is consistent with an andesitic sand. The major mineral is plagioclase, which is zoned and shows etching. Some pyroxenes are present and are clear to light green. Many of the grains are stained by ferric hydroxides.

SATURATION INDICES

According to the law of mass action, when an aqueous solution is in equilibrium with a mineral, the ion-activity product for that mineral will equal the thermodynamic equilibrium constant. The degree of saturation of a water can be represented by the saturation index (*SI*), which is the logarithm of the quotient of the ion-activity product (*IAP*) divided by the equilibrium constant (*K*):

$$SI = \text{Log}\,\frac{IAP}{K}, \tag{1}$$

where

SI=saturation index
IAP=ion-activity product, and
K=thermodynamic equilibrium constant.

The saturation index has a value of zero when the solution is in equilibrium with a solid phase. A positive saturation index indicates supersaturation and a negative index undersaturation with respect to some mineral. Minerals that are present in an aquifer and have negative saturation indices can dissolve. Minerals that have positive saturation indices may precipitate from solution, although whether this actually occurs depends on additional factors. By examining the saturation indices of water samples collected from the Sacramento Valley, some idea can be obtained about which minerals may be influencing ground-water chemistry.

TABLE 13.—*Mineralogic compositions of sidewall samples from U.S. Geological Survey test well 12N/01E–34Q*

c—coarse >0.5 mm.

TABLE 14.—*Minerals identified in sidewall samples from U.S. Geological Survey test well 12N/01E–34Q, in alphabetical order*

Actinolite-tremolite (series)[1]	Glaucophane
Amphiboles	Graphite
Analcite	Hematite (some specular)
Apatite	Hercynite
Augite-ferroaugite (series)[1]	Hornblende (green, brown, and oxy-varieties)
Basic glass	Hypersthene
Biotite	Lawsonite
Bronzite-ferrohypersthene (series)[1]	Marcasite
Chlorite	Pigeonite
Chromite	Plagioclase (series)[1]
Chrysotile	Potash feldspar (undifferentiated)
Clinozoisite	Pumpellyite
Cordierite	Richterite (part of series)[1]
Cummingtonite	Riebeckite
Diopside-hedenbergite (series)[1]	Serpentine (?)
Enstatite-bronzite (series)[1]	Sideromelane
Epidote	Sphene (titanite)
Fluorite	Spinel
Garnet (red)	Staurolite
Glauconite	Zircon
	Zoisite

[1]"Series" means several varieties within the series were found.

Saturation indices were calculated for 271 water analyses selected from those published by Fogelman (1975, 1976) and Fogelman and Rockwell (1977). Of the 271, 153 had aluminum analyses and 183 had iron analyses. Temperature, pH, and alkalinity were determined in the field. Samples for cation determinations were passed through a 0.1-micrometer filter and acidified with concentrated nitric acid. Some controversy exists as to the validity of aluminum and iron data gathered in this manner; however, the possible error introduced is generally small (Kennedy and others, 1974; Barnes, 1975). Some of the supersaturation in the aluminosilicate and iron minerals may be due to particulate iron and aluminum passing through the filter. Saturation indices were calculated using WATEQF (Plummer, and others, 1978).

Table 16 shows the mean, minimum, and maximum saturation indices for selected mineral phases along with log equilibrium constants at 20°C, the average temperature of ground waters in the Sacramento Valley. Although many minerals, such as the feldspars and montmorillonite, show variations in chemical composition, saturation indices were calculated for ideal mineral phases. Therefore, stability calculations for these minerals only approximate actual conditions, but they do provide useful indicators of the types of reactions that may be occurring.

1,193	5–15	5–10	Major	5–10	1–5	Tr minor.
1,390	5–10	2–5	Major	2–5	2–5	ND.

Most waters are close to saturation with respect to silicaglass, as might be expected from the volcanic detritus in the sediments. All samples were supersaturated with respect to amorphous ferric hydroxide, which may reflect the variability in solubility with particle size or particulate iron passing through the 0.1-micrometer filter during sampling. The waters tend to be at saturation with respect to gibbsite and slightly below saturation with respect to amorphous aluminum hydroxide.

Ground water is fairly close to saturation with respect to the carbonate minerals, calcite, dolomite, and magnesite. No carbonate minerals were recorded in sediments from either of the wells examined for mineralogy. Apparently, the formation of secondary carbonate minerals is of limited extent despite a number of samples indicating supersaturation with respect to calcite.

Potassium and sodium feldspars, which are abundant in the sediments, average close to saturation in Sacramento Valley ground water. Dissolution of these phases probably contributes to water chemistry where ground water is undersaturated with respect to these feldspars. All water samples are undersaturated with respect to anorthite, which is less abundant in the sediments. Halloysite is the only clay mineral with which the ground water is not supersaturated. Any of the other clay minerals could potentially form from most of the waters. When stability fields are considered, however, only one phase will be the most stable. These phase relations can be illustrated using activity diagrams.

ACTIVITY DIAGRAMS

Activity diagrams can be used to illustrate the phase relations among primary and secondary minerals and to predict the most stable secondary phases as a function of water chemistry. Such diagrams have been used by Feth, Roberson, and Polzer (1964), Tardy (1971) and White (1979) to depict weathering reactions in ground

FIGURE 11.—Electron micrograph of sediments from the 407-foot depth of well 19N/01W–32G. (Photograph by Technology of Materials, Santa Barbara, Calif.)

waters. The technique for calculating such diagrams is given in Garrels and Christ (1965), and Helgeson, Brown, and Leeper (1969) give numerous examples of such diagrams. A slightly different type of diagram, though basically similar, was presented by Kittrick (1969), and it depicts equilibrium between solid phases and an aqueous solution.

As an example of the calculation of the equilibrium boundary between two phases, the calculation of the phase boundary between illite and montmorillonite is given below. Formulas for these minerals are taken from WATEQF (Plummer, and others, 1978). For the reaction illite ⇆ montmorillonite, the chemical equation is written

TABLE 16.—*Mean, minimum, and maximum saturation indices in Sacramento Valley ground water for selected mineral phases*

Phase[1]	n	[2]Log K at 20 °C	Saturation index		
			Mean	Minimum	Maximum
Silica glass	271	-3.07	-0.14	-0.58	0.16

[1]Chemical formulas for these phases are as written in WATEQF (Plummer and others, 1978.)

[2]Data from the latest version of WATEQF.

[3]The log equilibrium constant at 25°C is used because no enthalpy is given in WATEQF.

$$(K_{0.6}Mg_{0.25}Al_{2.3}Si_{3.5}O_{10}(OH)_2)+2.48H_4SiO_4 +0.52Fe^{+3}+0.45Mg^{+2} \leftrightarrows 3.13H_2O+0.6K^{+1}+1.86H^{+1} +1.56(H_{0.42}Mg_{0.46}Fe_{0.34}Al_{1.47}Si_{3.82}O_{10}(OH)_2). \quad (2)$$

At the phase boundary, the ion-activity product for this reaction will equal the equilibrium constant (K):

$$\frac{[K^{+1}]^{0.6}[H^{+1}]^{1.86}}{[H_4SiO_4]^{2.48}[Fe^{+3}]^{0.52}[Mg^{+2}]^{0.45}}=K. \quad (3)$$

Brackets denote free ion activities, which are concentrations corrected for the nonideality of aqueous solutions. Rewriting in terms of log activities gives the equation:

$$0.61 \log [K^{+1}]/[H^{+1}]-0.52 \log [Fe^{+3}]/[H^{+1}]^3 -0.45 \log [Mg^{+2}]/[H^{+1}]^2-2.48 \log [H_4SiO_4]=\log K. \quad (4)$$

To plot this line on a two-dimensional graph, the equation must be reduced to two variables. The assumptions that may be considered when plotting phase diagrams include (1) controlling the concentration of a component by equilibrium with a solid phase, (2) conserving a component in solid phases during phase transformations, and (3) assigning a specified concentration for a species in solution, commonly the average for that species in the study area.

In all plots below, it is assumed that the logarithm of the activity quotient of free ferric iron to hydrogen cubed (log $[Fe^{+3}]/[H^{+1}]^3$) is controlled by the solubility of amorphous ferric hydroxide at 4.885 (Plummer and others, 1978). The average for the log activity ratio of potassium to hydrogen (log $[K^{+1}]/[H^{+1}]$) in the valley is 2.75, and ratio of magnesium to hydrogen squared (log $[Mg^{+2}]/[H^{+1}]^2$) is 11.25. The average log activity of silica in ground waters is -3.21. The use of these averages where a concentration must be assumed in the calculation of a phase transformation does not significantly affect the depicted relations between data points and phase boundaries in the following activity diagrams.

For the equilibrium between illite and montmorillonite, log $[Fe^{3}]/[H^{+1}]^3$ is assumed to be controlled by the solubility of ferric hydroxide, and log $[H_4SiO_4]$ is assigned a value of -3.21. Replacing these quantities in equation 4 gives the following equation for the phase boundary between illite and montmorillonite:

$$\log [K^{+1}]/[H^{+1}]=0.122+0.743 \log [Mg^{+2}]/[H^{+1}]^2. \quad (5)$$

Two types of diagrams are presented here to illustrate phase relations in the system MgO-K_2O-Fe_2O_3-Al_2O_3-SiO_2-H_2O. The diagrams depart, to some extent, from the traditional presentation in that metastable phases are included. Recent work by Paces (1973, 1978) and Busenberg (1978) indicates that during the weathering of feldspars, the initial solids formed are amorphous to poorly crystalline aluminosilicates which may be reversible with respect to the aqueous solution. Subsequent crystallization results in the formation of a metastable aluminosilicate commonly called halloysite. Eventually, the thermodynamically most stable mineral will form. This pathway between primary and secondary minerals generally follows Ostwald's Rule (Darken and Gurry, 1953), which states that when a system is proceeding from a less to a more stable state, the final most stable state is not necessarily reached directly but may be attained through a series of intermediate states. Neither halloysite nor illite are stable with respect to montmorillonite or kaolinite, yet they are present in the sediments. Activity diagrams showing metastable states indicate the intermediate steps, as well as the final secondary minerals that are expected to form.

All minerals included in the following diagrams are from WATEQF and have formulas and log equilibrium constants from that program. Because no information is available on the chemistry of clay minerals from the Sacramento Valley, particularly illite and montmorillonite, no better substitute is available. This use of surro-

gate minerals will introduce some uncertainty in the exact locations of phase boundaries in the diagrams. Considering the uncertainty in the knowledge of thermodynamic data on montmorillonites and illites, it is doubtful if full knowledge of mineral chemistry would improve the situation. The montmorillonite used in all the diagrams is Aberdeen montmorillonite (Kittrick, 1971) with modifications by Truesdell and Jones (1974).

Figure 12 shows the stability fields of minerals as a function of $pH-\frac{1}{3}pAl^{+3}$ and $p[H_4SiO_4]$, where p stands for -log as in $pH=-\log [H^{+1}]$, and $pAl^{+3}=-\log [Al^{+3}]$. This diagram depicts the formation of secondary minerals from an aqueous solution. The solution, in this case, is assumed to have the average ion activity ratios and silica activity observed in the Sacramento Valley. No solid phase will form from solutions with low aluminum to hydrogen ratios and low silica concentrations (bottom right corner of figure 12). At higher aluminum to hydrogen ratios, the stable solid phase changes from gibbsite to kaolinite to montmorillonite with increasing silica. Halloysite and amorphous aluminum hydroxide phase boundaries are dashed to emphasize that they are both metastable phases. A solution in equilibrium with halloysite will be supersaturated with respect to montmorillonite or kaolinite. All samples from the valley plot in the montmorillonite stability field. Only 10 percent of the samples are supersaturated with respect to halloysite.

Regression analysis was used to determine if any significant linear relation exists between aluminum and silica. Each hydrochemical facies was treated separately to preserve as much detail as possible. Only two of the regression equations were significant, those for the Tuscan volcanic rocks and the Sutter Basin facies.

The equation for the Tuscan volcanic rocks facies is

$$pH-\tfrac{1}{3}pAl^{+3}=2.10+0.39p\,[H_4SiO_4] \qquad (6)$$

with r^2 equal to 0.26 and coefficients and their 90 percent confidence limits of

$$2.10 \pm 0.83$$

and

$$0.39 \pm 0.27.$$

Rewriting the equation in terms of log activities gives

$$0.33 \log [Al^{+3}]/[H^{+1}]^3=2.10-0.39 \log [H_4SiO_4]. \qquad (7)$$

The inverse relation between the aluminum to hydrogen ratio and silica is indicative of control by a mineral phase. As silica increases in solution, $\log [Al^{+3}]/[H^{+1}]^3$ decreases to compensate.

The slope is close to and not significantly different from 0.33. Assuming that it is 0.33 and rearranging gives

$$\frac{[Al^{+3}][H_4SiO_4]}{[H^{+1}]^3}=10^{6.31}. \qquad (8)$$

The solution of halloysite or kaolinite is given by the equation:

$$\tfrac{1}{2}Al_2Si_2O_5(OH)_4+3H^{+1} \leftrightarrows \tfrac{1}{2}H_2O+Al^{+3}+H_4SiO_4. \qquad (9)$$

The ion activity product is

$$\frac{[Al^{+3}][H_4SiO_4]}{[H^{+1}]^3}=K. \qquad (10)$$

For halloysite log K equals 6.83 and for kaolinite, 4.76. The close agreement between the ion activity product of halloysite in ground water from the Tuscan volcanic rocks facies with the equilibrium constant is strong evidence that halloysite is controlling the aluminum and silica concentrations in ground water.

The Sutter Basin hydrochemical facies also showed a significant relation between $pH-\frac{1}{3}pAl^{+3}$ and $p[H_4SiO_4]$.

$$pH-\tfrac{1}{3}pAl^{+3}=6.13-0.92p[H_4SiO_4] \qquad (11)$$

with r^2 equal to 0.27 and coefficients and their 90 percent confidence limits of

$$6.13 \pm 2.91$$

and

$$0.92 \pm 0.91.$$

Rewriting the equation in terms of log activities gives

$$0.33 \log [Al^{+3}]/[H^{+1}]^3=6.13+0.92 \log [H_4SiO_4]. \qquad (12)$$

The positive slope is indicative of solution control of water chemistry, with both aluminum and silica increasing as some mineral phase is attacked by hydrogen ion. The slope is close to and not significantly different from one. This gives an aluminum to silica ratio in the dissolving phase of 1 to 3. The most likely minerals are, therefore, potassium and sodium feldspars, which have an aluminum to silica ratio of 1 to 3. This aluminum to silica ratio, along with the etched surfaces of feldspar grains observed under the microscope, may reflect stoichiometric dissolution of feldspars as found by Holdren and Berner (1979) and Berner and Holdren (1979).

Figure 13 shows the phase stability fields for minerals in terms of the log activity ratios of magnesium to

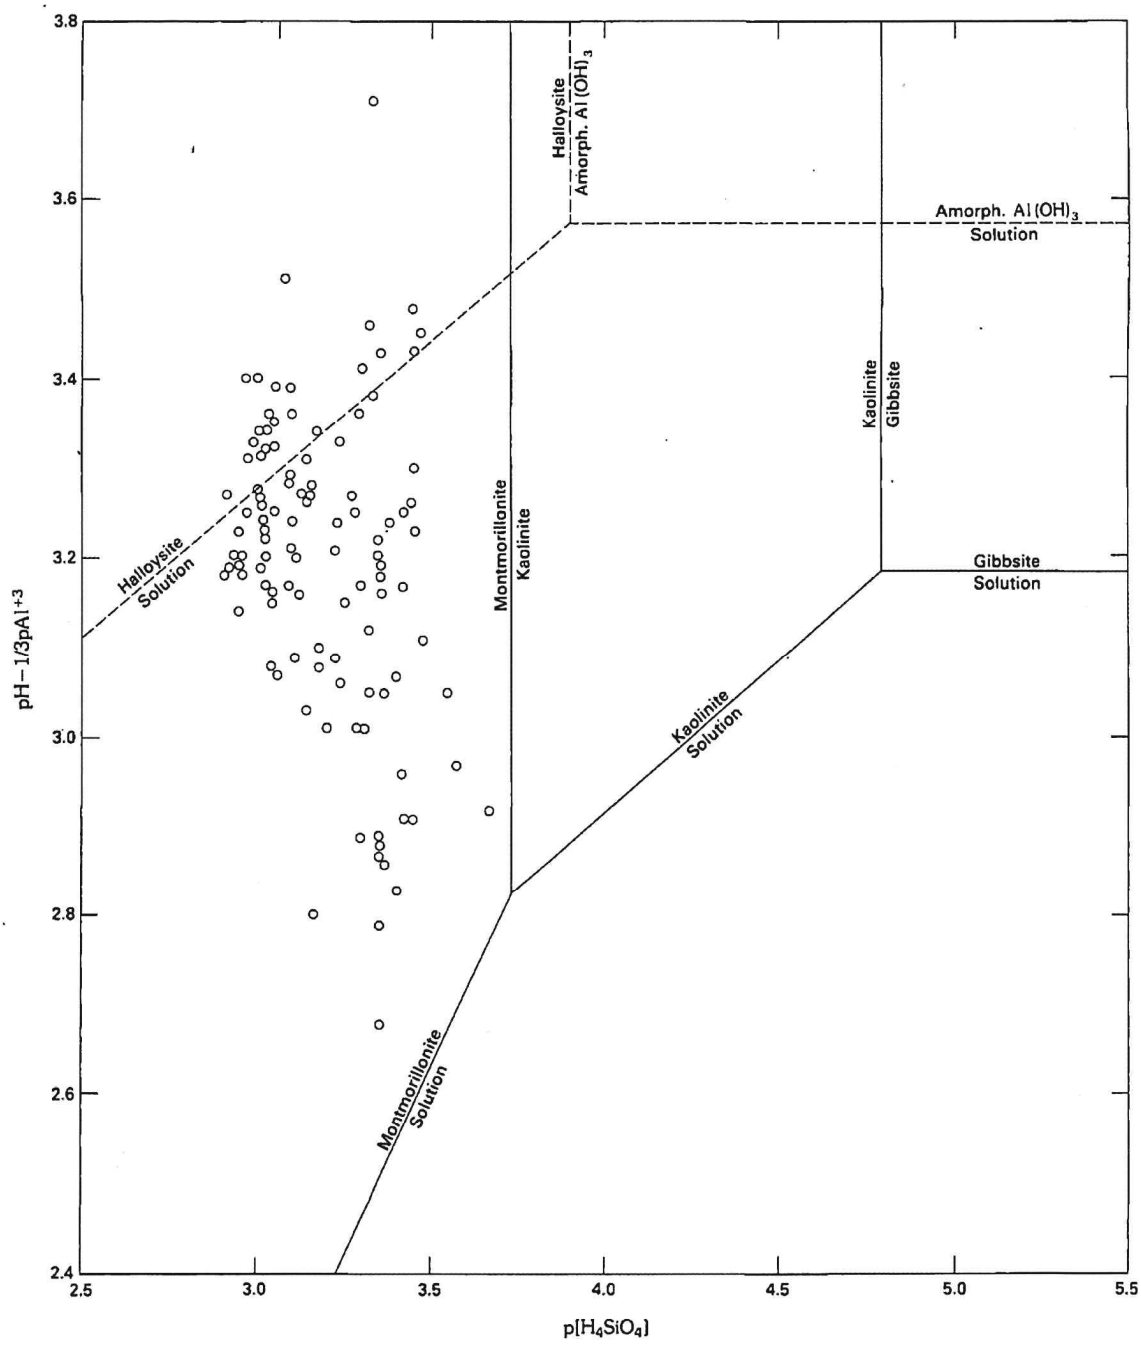

FIGURE 12.—Phase relations among minerals and aqueous solution in terms of pH-⅓pAl^{+3} and p[H_4SiO_4] at 20°C. (NOTE.—The aqueous solution is assumed to have the following ion activity ratios: log [Fe^{+3}]/[H^{+1}]^3 =4.885, log [K^{+1}]/[H^{+1}]=2.75, and log [Mg^{+2}]/[H^{+1}]^2=11.25.)

hydrogen squared and potassium to hydrogen. Aluminum is assumed to be strictly conserved in solid phases during phase transformations. Assumptions about iron and silica activities are as described at the beginning of this section on activity diagrams.

Figure 13 is actually two diagrams superimposed, so that illite, a metastable phase, can be shown. Illite is unstable with respect to montmorillonite or adularia if the three phases are considered simultaneously. The solid lines represent phase relations among the minerals

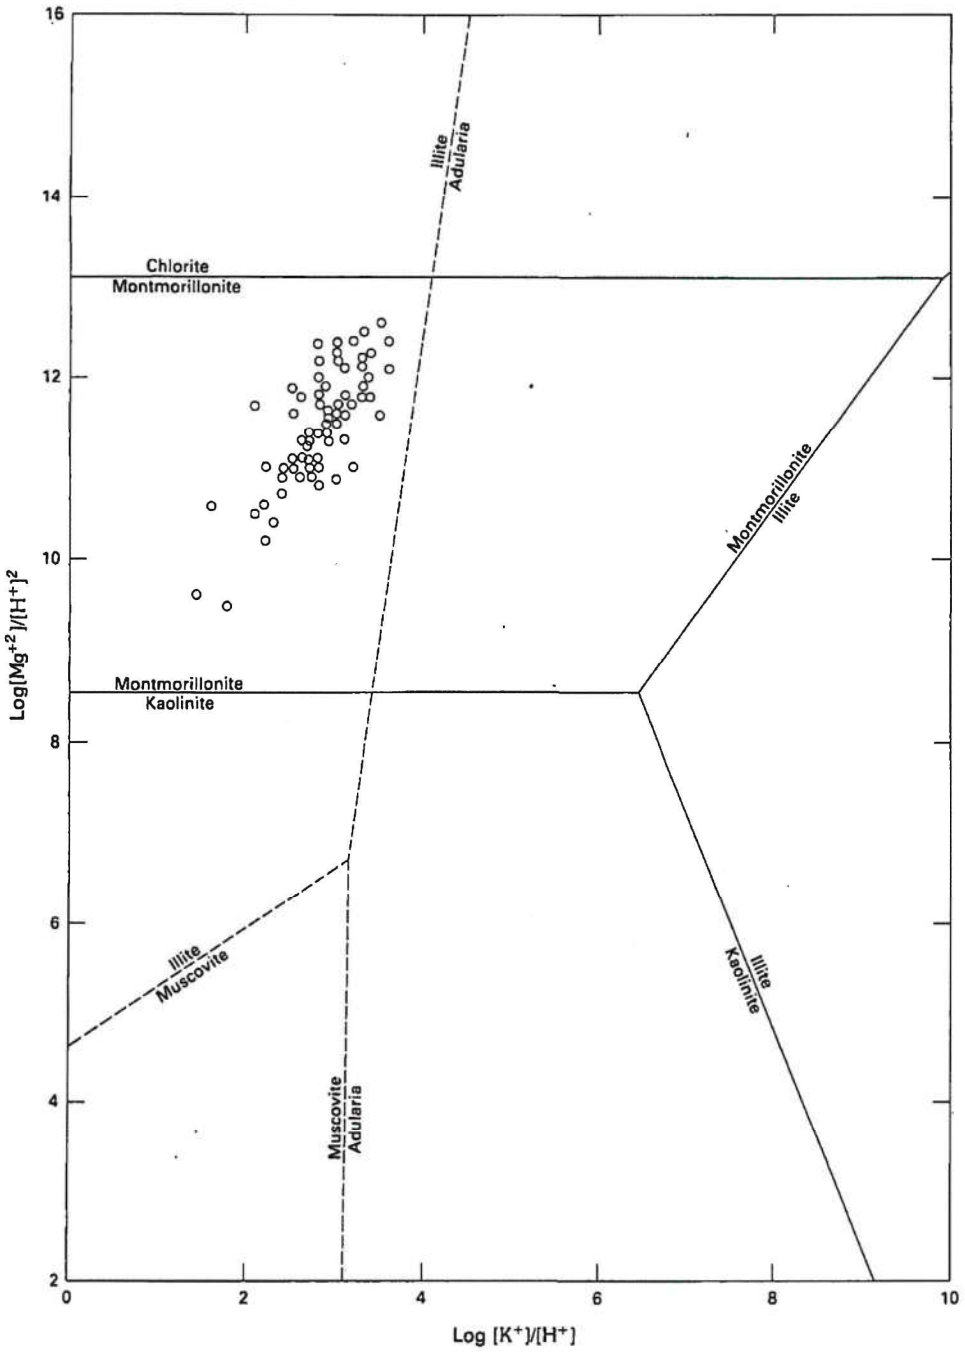

FIGURE 13.—Phase relations among minerals and coexisting aqueous solution in terms of log $[Mg^{+2}]/[H^{+1}]^2$ and log $[K^{+1}]/[H^{+1}]$ at 20°C. (NOTE.—Phase relations among chlorite, montmorillonite, illite, and kaolinite are shown by solid lines, and among illite, adularia, and muscovite by dashed lines. The aqueous solution is assumed to have the following activities of dissolved species: log $[Fe^{+3}]/[H^{+1}]^3$=4.885, log $[H_4SiO_4]$=-3.21.)

chlorite, montmorillonite, illite, and kaolinite. Among these minerals, montmorillonite is the most stable phase in equilibrium with ground water in the valley. The dashed lines represent phase relations among adularia, muscovite, and illite. Of these three minerals, illite is the most stable in contact with Sacramento Valley ground waters.

Illite is highly resistant to weathering (Berner, 1971),

and most of the illite found in samples from well 19N/01W-32G is probably detrital. Some of the illite may have formed from the weathering of primary minerals. Illite has been reported to form from orthoclase (Stumm and Morgan, 1970) and from muscovite (Berner, 1971).

Log activities from ground water in the Sacramento Valley plot in the stability field of a montmorillonite having the formula and stability of Aberdeen montmorillonite. Differences in activity ratios of ions in solution will probably produce montmorillonites of somewhat different composition in the Sacramento Valley, but some form of montmorillonite will be the most stable phase. Metastable phases either form as intermediate steps during the diagenesis of primary minerals (halloysite) or persist due to resistance to weathering (illite).

SUMMARY AND CONCLUSIONS

Shallow sediments in the Sacramento Valley were laid down as alluvial deposits in a freshwater environment. These sediments, from which ground-water samples were collected, have always been in contact with freshwater. Sediments along the valley margins are coarse grained, poorly sorted, and oxidized. In the central part of the valley, flood-basin deposits are finer grained and reduced. Most of the streams entering the valley are losing streams, at least over part of their courses, and much of the ground-water recharge is from this source.

The chemistry of ground water in the valley is greatly influenced by the chemistry of this recharge from the valley margins. Approximately one-third of the variation in ground-water chemistry can be attributed to this effect. The reducing conditions and finer grained sediments in the midvalley flood basins also influence ground-water chemistry. These processes have distinct spatial patterns that produce spatial variations in the chemical character of ground water in different areas.

Six areas, or hydrochemical facies, were delineated on the basis of geology, hydrology, and distinctions in chemical composition of ground water. Two of the facies lie along the eastern margin and receive recharge from the Cascade Range and Sierra Nevada. These waters are low in dissolved solids and high in silica. Two facies are located in the midvalley flood basins, and reducing conditions there produce higher concentrations of iron, manganese, and arsenic in the ground water. While the relative concentrations of these species are higher in the flood basins than in the rest of the valley, the absolute concentrations remain fairly low. Upwelling of saline water from underlying marine sediments contributes to high dissolved-solids concentrations in ground water in the southern parts of the flood basins.

Water along the west side of the valley is low in silica, and the water grades from moderate dissolved-solids levels in the north to high dissolved-solids levels in the south. Ground water in the southwest of the valley is also high in boron. The source of the high boron and dissolved-solids concentrations is thermal springs in the Coast Ranges. Two facies were delineated along the western margin to separate the waters having moderate and high dissolved solids. Because of the heterogeneity of ground-water chemistry in the valley, division into areas having more uniform chemical compositions provides additional detail in any investigation of water chemistry.

Dissolved-solids and nitrate concentrations were examined for linear trends with time for each of the hydrochemical facies. Significant increases in both were observed in parts of the valley. On the east side of the valley, the Tuscan volcanic rocks facies showed a significant increase in dissolved solids of 0.95 (mg/L)/yr but no significant change in nitrate concentrations. The Victor Plain facies showed significant increases in both dissolved solids [1.6 (mg/L)/yr] and nitrate-nitrogen [0.036 (mg/L)/yr]. Neither Butte Basin nor Sutter Basin hydrochemical facies, in the midvalley flood basins, showed a significant trend in nitrate with time. There were very few wells with multiple nitrate measurements, however, and the lack of significant changes may be due to the small sample size. Dissolved-solids concentrations in Butte Basin have been increasing at an average rate of 1.37 (mg/L)/yr, but are unchanged in Sutter Basin.

Both the north and south alluvial fans facies, adjacent to the Coast Ranges, show significant upward trends in dissolved solids and nitrate. The south alluvial fans facies has the greatest rate of increase for dissolved solids [4.75 (mg/L)/yr] of all the facies, and the north alluvial fans facies has the greatest rate of increase for nitrate-nitrogen [0.099 (mg/L)/yr]. The midvalley basins have fine-grained poorly permeable soils that protect the ground water from contamination. Infiltration rates are slow, and reducing conditions permit the removal of nitrate by denitrification reactions. Along the valley margins, however, significant increases in dissolved solids and nitrates have occurred since the mid-1950's.

Alkali feldspars and halloysite appear to be the most significant aluminosilicate minerals affecting water chemistry. Where waters are undersaturated, dissolution of feldspars takes place, bringing the water to near saturation with respect to adularia and albite. There is a general parallel increase in aluminum and silica reflecting the solution of aluminosilicates by ground water. In Sutter Basin, the relation between log $[Al^{+3}]/[H^{+1}]^3$ and log $[H_4SiO_4]$ indicates an increase in both aluminum and silica at a ratio 1 to 3. In the Tuscan

volcanic rocks facies, the relation between log $[Al^{+3}]/[H^{+1}]^3$ and log $[H_4SiO_4]$ is inverse. Rearranging the regression equation yields the same equation as for equilibrium between halloysite and an aqueous solution. The regression constant is very close to the equilibrium constant for halloysite, which supports the theory of solubility control by halloysite. Illite and halloysite were identified in sediments from the Sacramento Valley. Neither of these clay minerals is stable in the ground-water environment. The most stable clay minerals in equilibrium ground water of the valley is montmorillonite. Halloysite occurs as a mestastable intermediate step in the weathering of primary minerals to stable secondary minerals.

ADDRESS ALL COMMUNICATIONS TO THE SECRETARY

HONORABLE EARL WARREN, *Governor, and*
Members of the Legislature of
the State of California

GENTLEMEN: I have the honor to transmit herewith Bulletin No. 6 of the State Water Resources Board, entitled "Sutter-Yuba Counties Investigation," as authorized by Chapter 1514, Statutes of 1945, as amended.

Under provisions of the cited statute, an agreement dated October 7, 1947, was entered into between the State Water Resources Board, the Counties of Sutter and Yuba, and the Department of Public Works acting through the agency of the State Engineer. The agreement provided for

> ". . . investigation and report on the underground water supply of the valley floor in the Counties of Sutter and Yuba, including quality, replenishment and utilization thereof, and, if possible, a method or methods of solving the problems involved . . .",

and authorized funds to meet the costs of the investigation for one year. A supplemental agreement executed by the same parties on December 3, 1948, authorized funds to complete the investigation and report.

The Sutter-Yuba Counties Investigation was conducted and Bulletin No. 6 was prepared by the Division of Water Resources of the Department of Public Works, under the direction of the State Water Resources Board. Funds to meet the cost of investigation and report were provided as follows: State of California (State Water Resources Board), $20,000; County of Sutter, $10,000; and County of Yuba, $10,000. Additional funds provided by the Legislature have been expended by the State Water Resources Board in connection with the current State-Wide Water Resources Investigation, certain results of which were used in connection with the Sutter-Yuba Counties Investigation.

Bulletin No. 6 contains an inventory of the underground and surface water resources of the valley floor in the Counties of Sutter and Yuba, estimates of present and probable ultimate water utilization, estimates of present and probable ultimate supplemental water requirements, and preliminary plans and cost estimates for water development works.

Very truly yours,

C. A. Griffith
Chairman

ACKNOWLEDGMENT

Valuable assistance and data used in the investigation were contributed by agencies of the Federal Government, cities, counties, public districts, and by private companies and individuals. This cooperation is gratefully acknowledged.

Special mention is also made of the helpful cooperation of the Boards of Supervisors of the Counties of Sutter and Yuba, the Sutter County Water Council, the Yuba County Water Development Association, the Yuba County Farm Advisor, the California Water Service Company, and the Pacific Gas and Electric Company.

CHAPTER I

INTRODUCTION

In common with many other parts of California, the area under this investigation has recently experienced an increase in water utilization, and as a result is confronted with a need for more complete conservation of its water resources. An accelerated increase in ground water use in recent years, combined with progressive lowering of pumping levels and deterioration in quality of water at a number of wells, has brought about local concern regarding the adequacy of the ground water resources of Sutter and Yuba Counties.

AUTHORIZATION FOR INVESTIGATION

In consideration of the adverse ground water situation in Sutter and Yuba Counties, members of the Sutter County Water Council and the Yuba County Water Development Committee appeared before the State Water Resources Board at Sacramento on August 1, 1947, and proposed a state-county cooperative survey of ground water supplies of valley floor lands of the two counties. The Board referred the request to the State Engineer for preliminary examination and report on the need for such an investigation, and an estimate of its scope, duration, and cost.

The State Water Resources Board on September 5, 1947, approved a recommendation by the State Engineer, based on findings of the preliminary examination, for a two-year cooperative investigation, and authorized negotiation of an agreement with local agencies. The agreement, between the State Water Resources Board, the Counties of Sutter and Yuba, and the State Department of Public Works acting through the agency of the State Engineer, was executed on October 7, 1947. It provided that the work under the agreement "shall consist of investigation and report on the underground water supply of the valley floor lands in the Counties of Sutter and Yuba, including quality, replenishment and utilization thereof, and, if possible, a method or methods of solving the problems involved." This agreement authorized the provision of funds to meet the costs of investigation for one year. A supplemental agreement executed by the same parties on December 3, 1948, authorized funds to complete the investigation and report.

Funds to meet the costs of the investigation and report to the extent of $40,000 were provided as follows: State of California (State Water Resources Board), $20,000; County of Sutter, $10,000; and County of Yuba, $10,000. Additional funds have been expended in investigation of the Sutter-Yuba Area by the State Water Resources Board in connection with the current State-wide Water Resources Investigation, certain results of which have been used in connection with the Sutter-Yuba Counties Investigation.

Copies of the two agreements between the State Water Resources Board, the Counties of Sutter and Yuba, and the Department of Public Works, are included in Appendix A.

RELATED INVESTIGATIONS AND REPORTS

The following reports of prior investigations, containing information pertinent to evaluation of ground water problems in Sutter and Yuba Counties, were reviewed in connection with the current investigation:

"Soil Survey of the Marysville Area, California, 1909," by A. T. Strahorn, W. W. Mackie, L. C. Holmes, H. L. Westover, and Cornelius Van Duyne. Bureau of Soils, United States Department of Agriculture. October 25, 1911.

"Geology and Ground Water Resources of the Sacramento Valley, California," by Kirk Bryan. United States Geological Survey, Water-Supply Paper 495. 1923.

"Preliminary Report on the Proposed Sutter Irrigation District," by Milo B. Williams, Consulting Engineer. Typewritten. March 12, 1931.

"Report on Ground Water Conditions in the Proposed Sutter Irrigation District," by S. T. Harding, Consulting Engineer. Unpublished. November, 1931.

"Sacramento River Basin," Bulletin No. 26, Division of Water Resources, California State Department of Public Works. 1931.

"Memorandum on Ground Water Conditions in Area of Proposed Sutter Irrigation District During 1932," by S. T. Harding, Consulting Engineer. Unpublished. February, 1933.

"Sacramento Valley Water Investigations — Agricultural Aspects," Bureau of Agricultural Economics, United States Department of Agriculture. Mimeographed. March, 1944.

"Salt-Balance Conditions of Reclamation District No. 1500 in Sutter Basin for the Year Ending December 31, 1947," by L. V. Wilcox. Mimeographed. April, 1948.

"Water Resources of California," Bulletin No. 1, California State Water Resources Board. 1951.

The Division of Water Resources is presently conducting surveys and studies for the State-wide Water Resources Investigation, authorized by Chapter 1541, Statutes of 1947. This investigation, under direction of the State Water Resources Board, has as its objective the formulation of The California Water Plan for full conservation, control, and utilization of the State's water resources to meet present and future water needs for all beneficial purposes and uses in all parts of the State insofar as practicable. Surveys and studies are also being conducted by the Division of Water Resources for the Survey of Mountainous Areas, authorized by Chapter 30, Statutes of 1947. This investigation, which is coordinated with the state-wide investi-

gation, has as its primary objective the determination of probable ultimate water requirements of certain counties of the Sierra Nevada, and the formulation of plans for projects which will meet those requirements. Results of both of the foregoing investigations will have direct bearing on solutions to the water problems of the Sutter-Yuba Area, particularly with regard to plans to meet supplemental water requirements of the area under ultimate conditions of cultural development.

SCOPE OF INVESTIGATION AND REPORT

It has been stated that under provisions of the authorizing agreements the general objectives of the Sutter-Yuba Counties Investigation included investigation and study of the underground water supply of valley floor lands in the investigational area, including quality, replenishment and utilization thereof, and, if possible, a method or methods of solving the water problems involved. In attaining these objectives it was necessary that the scope of the investigation include full consideration of surface as well as ground water supplies, and that it involve determination of present and ultimate water utilization and supplemental water requirements.

Field work in the investigational area, and office studies, as authorized by the initial and supplemental cooperative agreements, commenced in October, 1947, and continued into 1952.

In the course of the investigation, available precipitation and stream flow records were collected and compiled in order to evaluate water supplies available to the investigational area. Five new stream gaging stations were installed and maintained to supplement the available hydrographic data. These stations were on Pleasant Grove Creek at Lincoln Road, Auburn Ravine at Highway 99E, Coon Creek at Highway 99E, Dry Creek near Waldo, and South Honcut Creek at La Porte Road.

In order to determine ground water storage capacity and yield, geologic features of the ground water basin underlying the investigational area were investigated and reported on by the Ground Water Branch of the United States Geological Survey, under terms of a cooperative agreement with the Department of Public Works. This survey included the collection and study of about 700 well logs throughout the area. The report of the Geological Survey is included as Appendix B.

The effects of draft on and replenishment of the ground water basin were determined by measurements of static ground water levels made at about 850 wells during each spring and fall of the period of investigation. These wells were chosen to form a comprehensive measuring grid over the entire area. In addition, measurements to determine monthly fluctuations of water levels were made at approximately 90 control wells.

Present land use in the investigational area was determined by a complete survey of all culture on valley floor lands. This survey was conducted in 1948, and checked in 1949 to determine changes. The total area surveyed was about 327,000 acres. The cultural survey data were used in conjunction with available data on unit water use to determine total present water utilization in the investigational area.

In order to determine future water utilization, all valley floor lands were classified with regard to their suitability for irrigated agriculture. This involved collection, field checking, and re-evaluation of land classification data from the United States Bureau of Reclamation, supplemented by data from field surveys conducted by the Division of Water Resources.

Current irrigation practices in the investigational area were surveyed in order to determine unit application of water to important crops on lands of various soil types. During the 1948 irrigation season records of application of water were collected at 35 plots, and during the following season at 21 plots. The data collected included records of pump discharge, acreage served, crops irrigated, number and period of irrigations, and amount of water applied.

Studies were made of the mineral quality of surface and ground waters, in order to evaluate their suitability for irrigation use, and to determine the cause of degradation in their mineral quality during recent years. Data used in these studies included some 200 partial and 38 complete mineral analyses of ground water from wells. In addition, a large number of analyses of surface water supplies, covering the period since 1943, were collected and studied.

Field reconnaissance surveys, including geologic examinations, were made to locate and evaluate possible dam and reservoir sites for conservation of surface runoff. Reconnaissance surveys were also made of possible routes for conveyance of water to areas of use.

Results of the Sutter-Yuba Counties Investigation are presented in this report in the four ensuing chapters. Chapter II, "Water Supply," contains evaluations of precipitation, surface and subsurface inflow and outflow, and imports of water. It also includes results of investigation and study of the ground water basin, and contains data regarding mineral quality of surface and ground waters. Chapter III, "Water Utilization and Supplemental Requirements," includes data and estimates of present and probable ultimate land use and water utilization, and contains estimates of present and probable ultimate supplemental water requirements. It also includes available data on demands for water with respect to rates, times, and places of delivery. Chapter IV, "Plans for Water Development," describes preliminary plans for conservation and utilization of available water supplies to meet supplemental water requirements, including operation and yield studies, design considerations and criteria, and

cost estimates. Chapter V, "Conclusions and Recommendations," includes conclusions and recommendations resulting from the investigation and studies.

AREA UNDER INVESTIGATION

The area under investigation comprises those portions of the valley floor of Sutter and Yuba Counties which are in whole or in part served by ground water, and has been designated the "Sutter-Yuba Area." It includes the portions of Sutter County situated east of Feather River, Sutter By-pass, and a north-south line through the center of Sutter Buttes. It includes the portion of Yuba County lying on the Sacramento Valley floor from Feather River on the west to a line marking the approximate limit of the ground water service area near the base of the foothills on the east.

The Sutter-Yuba Area is situated on the east side of the central portion of the Sacramento Valley, and its southern boundary is about 10 miles north of the City of Sacramento. The area extends north and south for a distance of about 39 miles, varying in width from about 6 to about 19 miles. Its location is indicated on Plate 1, "Location of Sutter-Yuba Area," and the area is shown in greater detail on Plate 2, entitled "Hydrologic Zones and Organized Water Agencies, 1952."

In order to facilitate reference to its several parts, the Sutter-Yuba Area was divided into four principal zones, based on geographical considerations and on respective types of water service and sources of water supply. These were designated "West Side Zone," "Northeast Zone," "East Central Zone," and "South Side Zone," and are shown on Plate 2. The West Side Zone embraces the area between the Butte-Sutter county line and Nicolaus, and west of Feather River. The Northeast Zone consists of lands between Honcut Creek and Yuba River, and east of Feather River. Similarly, the East Central Zone consists of lands between the Yuba and Bear Rivers, and east of Feather River. The South Side Zone comprises those lands lying between Bear River and the Sutter-Sacramento county line, and east of the Feather and Sacramento Rivers. As shown on Plate 2, the West Side Zone was further subdivided into the area generally devoted to orchards and served by ground water, herein designated the "Peach Bowl," and the remainder of the zone which is largely served by surface water.

Drainage Basin

The eastern portion of the Sutter-Yuba Area comprises a gently rolling plain, which merges into nearly flat land over a large part of the central and western portions. The general ground surface slopes gently from east to west. Included valley floor lands lie below an elevation of about 100 feet. The Sutter Buttes, located in the northwest corner of the area, rise to 2,132 feet above sea level.

All watersheds on the west slope of the Sierra Nevada that head between Donner and Fredonyer Passes are tributary to the Sutter-Yuba Area. Their combined drainage areas total about 5,600 square miles. In order of importance, the principal tributary stream systems are those of the Feather, Yuba, and Bear Rivers. Minor tributary streams include Honcut, Dry, Coon, and Pleasant Grove Creeks, and Markham and Auburn Ravines. The extent of the various drainage basins is shown in the following tabulation:

Drainage basin	*Area, in square miles*
Feather River, above Oroville gaging station	3,611
Yuba River, above Smartville gaging station	1,194
Bear River, above gaging station near Wheatland	294
Minor streams, above valley floor, from Wyman Ravine to Pleasant Grove Creek	500
TOTAL	5,600

The tributary watersheds are in a zone of relatively heavy precipitation, and their aggregate mean seasonal natural runoff during the 53-year period from 1894-95 to 1946-47 is estimated to have approximated 1,360 acre-feet per square mile.

The Feather River traverses and roughly bisects the Sutter-Yuba Area from north to south, and joins the Sacramento River near Verona. The Yuba and Bear Rivers are tributary to the Feather within this reach, as are Honcut Creek and Nigger Jack Slough. Reeds, Hutchinson, and Dry Creeks, drain the East Central Zone and are tributary to Bear River within the area. Coon and Pleasant Grove Creeks and Markham and Auburn Ravines drain into Sacramento River near Verona by way of the Cross Canal. Gilsizer Slough, which flows more or less parallel to the Feather River through the West Side Zone and into Sutter By-pass, and Nigger Jack Slough are important as natural surface drains. Wadsworth Canal and its tributaries, together with other minor channels, drain the portion of the West Side Zone outside the Peach Bowl, discharging into Sutter By-pass.

Climate

The climate of the Sutter-Yuba Area is characterized by dry summers with high daytime temperatures and warm nights, and wet winters with moderate temperatures. More than 80 percent of the precipitation occurs during the five-month period from November to March, inclusive. The growing season is long, the 40-year recorded average for Marysville, centrally located in the area, being 273 days between killing frosts. Temperatures at Marysville have ranged from 16° F. to 118° F., and the monthly average for the period from 1871 to 1948 ranges from 46.9° F. in January to 79.3° F. in July.

Geology

The geologic formations of the Sutter-Yuba Area include pre-Cretaceous metamorphic and igneous rocks

of the Sierra Nevada block, which extends beneath the valley fill, overlain principally by Tertiary sedimentary formations derived from these and other rocks which are exposed in the Sierra Nevada to the east. The sedimentary rocks are of both marine and continental origin and are frequently interbedded with tuff-breccias. Volcanic rocks are also represented in the area in and about the Sutter Buttes, which are erosional remnants of an extinct Pliocene volcano. Only the sedimentary rocks can be considered as being water-bearing to any appreciable degree. The principal aquifers are composed of continental sediments of Pleistocene and Recent age. These consist of as much as 100 feet of Pleistocene sands and gravels overlain by up to 125 feet of Recent alluvial fan, flood plain, and stream channel deposits.

Soils

Soils of the Sutter-Yuba Area vary in their chemical and physical properties in accordance with differences in parent material, drainage, and age or degree of development since their deposition. The soils may be divided into two broad groups: (1) those derived from recent alluvial depositions, and (2) those derived from old alluvial fans or terraces. The first group may be further divided into stream bottom soils and basin soils.

Stream bottom soils occupy the flood plains immediately adjacent to stream channels generally throughout the area. They consist of unmodified to slightly modified alluvial deposits. These soils are highly productive and suited to a wide variety of crops, and have the highest agricultural value.

Basin soils of the Sutter-Yuba Area occupy large flat basin-like areas in the southwest portion of the West Side Zone and western portion of the South Side Zone. These basin soils are derived largely from fine-grained depositions by flood flows, and have developed under poor drainage conditions. Those areas of basin soils that have been drained and protected by levees from flooding are suitable for production of rice and other shallow-rooted crops.

Soils that have developed from old alluvial fans or terraces occupy most of the remainder of the Sutter-Yuba Area. These soils have undergone considerable physical and chemical change since their deposition and are entirely underlain by hardpan. They are restricted in their agricultural use by the depth of soil over the hardpan, and are only suited to the production of shallow-rooted crops.

Present Development

Development of the eastern portion of the Sacramento Valley has centered in the Sutter-Yuba Area since the first settlements early in the Nineteenth Century. Marysville became an important transportation center during the Gold Rush period, being the head of river traffic to the mining areas. The Counties of Sutter and Yuba embrace a rich agricultural region, and both irrigation and dry farming are of major importance.

The 1950 federal census showed that the population of Sutter County was 26,140, and that of Yuba County 24,240. The principal urban centers, Marysville and Yuba City, are situated only about two miles apart, near the confluence of the Yuba and Feather Rivers, and account for some 31 percent of the total population of the two counties. The 1950 census enumerated 7,856 persons in Yuba City, while 7,777 were counted in Marysville. Wheatland and Live Oak are the largest of a number of small communities, and the rural population is distributed generally throughout the area.

Agricultural development in the Sutter-Yuba Area is said to have begun with the growing of grain about 1845 near the site of Captain John A. Sutter's Hock Farm, south of Yuba City. Early agriculture on the valley floor was stimulated by the influx of settlers during and after the gold rush, but for many years was largely restricted to the growing of dry-farmed grain crops and stock raising. By 1865, a large portion of the area was given over to the production of wheat. Irrigation developed slowly, but it is probable that the first lands on the east side of the Sacramento Valley to receive irrigation water were near the confluence of Honcut Creek and Feather River. Diminishing profits from grain farming, together with the development of more satisfactory pumping plants, gave impetus to the increase in irrigated acreage after 1910. The transition from dry farming to irrigated cropping has continued to this time.

A survey conducted in 1949 as a part of the current investigation showed that irrigated lands in the Sutter-Yuba Area totaled about 149,000 acres, while approximately 140,000 acres were dry-farmed or fallow. Principal irrigated crops, in order of acreage devoted to each crop, were deciduous orchard consisting largely of peaches, and rice, permanent pasture, beans, and alfalfa. Principal dry-farmed crops were barley and wheat.

Industry in the Sutter-Yuba Area is supported largely by agricultural production. About 100 plants are operated during the harvest seasons to can and dehydrate fruits and vegetables, and to dry fruits, nuts, rice, and seed crops. Packing houses for packing fresh fruits and melons, and cold storage and refrigeration plants, have also been established. Several lumber reprocessing and molding plants near Marysville produce finished lumber and by-products. Sand and gravel works supply local demand for aggregates, while concrete pipe, generally used in irrigation distribution systems, is manufactured locally. A large gold dredging field is situated near the edge of the valley floor at Hammonton, south of Yuba River. Electric energy is available from nearby hydroelectric installations.

Water service agencies in the Sutter-Yuba Area are described in Chapter III. However, many public agencies have been organized in the area to deal with the problems of land reclamation and drainage. The provisions of California reclamation district laws have been used extensively to effect the unwatering of low lands and their protection from overflow. Active reclamation districts in the area and data concerning them are listed in the following tabulation:

Reclamation district	*Year organized*	*County*	*Gross area of district, in acres*
No. 10	1913	Yuba	11,300
No. 777	1907	Sutter	12,500
No. 784 (Plumas Lake)	1908	Yuba	19,600
No. 803 (Rideout)	1909	Sutter	2,000
No. 817	1910	Yuba	3,120
No. 823 (Marcuse)	1911	Sutter	2,800
No. 1000 (Natomas)	1911	Sutter, Sacramento	55,100
No. 1001 (Natomas)	1911	Sutter, Placer	31,200
No. 2054	1921	Sutter, Butte	12,900
No. 2056	1921	Sutter, Butte	9,100
No. 2066 (Abbott Lake)	1924	Sutter	600

Portions of Sutter and Yuba Counties are within the boundaries of the Sacramento and San Joaquin Drainage District, which comprises practically all swamp and overflow lands of both the Sacramento and San Joaquin Valleys. This large district was formed in 1911. Two levee districts in Sutter County, organized during the period of early agricultural development, built levees to protect eastern Sutter Basin lands from floods and overflow of Feather River. These districts, Sutter County Levee District No. 1, organized in 1873, and Sutter County Levee District No. 2, organized in 1879, contain 44,000 and 17,500 acres, respectively. The Sutter By-pass, and levees of the Feather and Yuba Rivers, are parts of the Sacramento River Flood Control Project. The function of Sutter By-pass is to receive and convey excess flood waters of Sacramento River and Butte Basin through Sutter Basin.

Areas included within the boundaries of the foregoing agencies, together with water service agencies in the Sutter-Yuba Area, are shown on Plate 2.

CHAPTER II

WATER SUPPLY

The sources of water supply of the Sutter-Yuba Area are direct precipitation on overlying lands, tributary surface and subsurface inflow, and imports by surface canals of water for irrigation. The water supply of the area is considered and evaluated in this chapter under the general headings "Precipitation," "Runoff," "Imported and Exported Water," "Underground Hydrology," and "Quality of Water."

The following terms are used as defined in connection with the discussion of water supply in this report:

Annual—This refers to the 12-month period from January 1st of a given year through December 31st of the same year, sometimes termed the "calendar year."

Seasonal—This refers to any 12-month period other than the calendar year.

Precipitation Season—This refers to the 12-month period from July 1st of a given year through June 30th of the following year.

Runoff Season—This refers to the 12-month period from October 1st of a given year through September 30th of the following year.

Investigational Seasons—This is used in reference to the two runoff seasons of 1947-48 and 1948-49, during which most of the field work on the Sutter-Yuba Counties Investigation was performed.

Mean Period—This is used in reference to periods chosen to represent conditions of water supply and climate over a long period of years.

Base Period—This is used in reference to periods chosen for detailed hydrologic analysis because prevailing conditions of water supply and climate were approximately equivalent to mean conditions, and because adequate data for such hydrologic analysis were available.

In studies for the current State-wide Water Resources Investigation it was determined that the 50 years from 1897-98 to 1946-47, inclusive, constituted the most satisfactory period for estimating mean seasonal precipitation generally throughout California. Similarly, the 53-year period from 1894-95 to 1946-47, inclusive, was selected for determining mean seasonal runoff. In studies for the Sutter-Yuba Area, conditions during these periods were considered representative of mean conditions of water supply and climate.

Studies were made to select a base period for hydrologic analysis of the Sutter-Yuba Area during which conditions of water supply and climate would approximate mean conditions, and for which adequate data on inflow, outflow, and ground water levels would be available. It was determined that the nine-year period from 1939-40 to 1947-48, inclusive, was the most satisfactory in this respect. Conditions during this chosen base period so closely approached conditions prevailing during the mean period that they were considered to be equivalent. For this reason, determined relationships between base period water supply and present and probable ultimate water utilization were assumed to be equivalent to corresponding relationships which might be expected under mean conditions of water supply and climate.

PRECIPITATION

The Sutter-Yuba Area lies within the southern fringe of storms which periodically sweep inland from the North Pacific during winter months. Although the rainfall resulting from these storms is moderate on the average, direct precipitation provides a substantial portion of the water supply of the area.

Precipitation Stations and Records

Fifteen precipitation stations in or adjacent to the Sutter-Yuba Area have unbroken records of 10 years duration or longer. These stations are fairly well distributed areally and their records were sufficient to provide an adequate pattern of precipitation. All of the records of precipitation have been published in bulletins of the United States Weather Bureau, with exception of the record obtained by the Sutter Basin Corporation for the station at Robbins. The Robbins record is included as Appendix C to this report. Locations of the precipitation stations are shown on Plate 3, "Lines of Equal Mean Seasonal Precipitation," with map reference numbers corresponding to those utilized in State Water Resources Board Bulletin No. 1, "Water Resources of California." The stations and map reference numbers are listed in Table 1, together with elevations of the stations, periods and sources of record, and mean, maximum, and minimum seasonal precipitation. In those instances where it was necessary, precipitation records were extended to cover the 50-year mean period by comparison with records of nearby stations having records covering this period.

Precipitation Characteristics

Because of the uniformity of the general precipitation pattern in the Sutter-Yuba Area, as indicated on Plate 3, and the central location of Marysville, precipitation at Marysville was considered to be fairly representative of rainfall over the area. A record of precipitation at Marysville was available from a United States Weather Bureau station maintained since

1871-72. Recorded seasonal precipitation at this station is presented in Table 2 and shown on Plate 4, "Recorded Seasonal Precipitation at Marysville, 1871-72 Through 1950-51."

Precipitation in the Sutter-Yuba Area consists almost entirely of rainfall and snowfall is rare. It increases generally from west to east, as is shown on Plate 3, except on the Sutter Buttes where a sharp rise in elevation probably results in relatively heavy precipitation. Mean seasonal depth of precipitation ranges from about 18 inches along the western boundary of the area to about 23 inches at its extreme easterly limit. At Nicolaus in the southern portion of the area mean seasonal precipitation is about 18 inches, whereas at Biggs, about eight miles north of the area, it is approximately 21 inches.

Precipitation varies over wide limits from season to season, ranging from less than 40 percent of the seasonal mean to nearly 200 percent. Maximum seasonal precipitation at Marysville occurred in 1889-90 when 38.91 inches of rain were recorded. In 1884-85, the minimum season at this station, precipitation was only 8.15 inches. Long-term trends in precipitation in the Sutter-Yuba Area are indicated on Plate 5, "Accumulated Departure From Mean Seasonal Precipitation at Marysville."

More than 80 percent of the seasonal precipitation in the Sutter-Yuba Area occurs during the five months from November through March on the average, and the summers are dry. Mean monthly distribution of precipitation as recorded at Marysville is presented in Table 3.

			TOTALS	20.68	100.0

Quantity of Precipitation

The mean seasonal quantity of precipitation in the Sutter-Yuba Area was estimated by plotting recorded or estimated mean seasonal depth of precipitation at stations in or near the area on a map. Lines of equal mean seasonal precipitation, or isohyets, were then drawn, as are shown on Plate 3. By planimetering the areas between these isohyets, the weighted mean seasonal depth and total quantity of precipitation were estimated.

In order to determine seasonal depth and quantity of precipitation during the base period and investigational seasons, the foregoing estimates for the mean period were adjusted on the basis of recorded precipitation at Marysville. The results of the estimates are presented in Table 4, which also shows the precipitation index for the base period and each of the investigational seasons. The term "precipitation index" refers to the ratio of the amount of precipitation during a given season to the mean seasonal amount, and is expressed as a percentage.

TABLE 4

ESTIMATED WEIGHTED SEASONAL DEPTH AND TOTAL QUANTITY OF PRECIPITATION ON SUTTER-YUBA AREA

Season	Precipitation index	Precipitation	
		Depth, in inches	Quantity, in acre-feet
1947-48	89	18.2	529,000
1948-49	76	15.4	448,000
Average for 9-year base period, 1939-40 through 1947-48	107	21.8	635,000
Mean for 50-year period, 1897-98 through 1946-47	100	20.3	592,000

RUNOFF

Runoff from the highly productive watersheds of the Sierra Nevada constitutes the most important source of water supply available to the Sutter-Yuba Area. The Feather River, which traverses the area from north to south, is the principal tributary of the Sacramento River. The Feather River system, including the Yuba and Bear Rivers which join the Feather within the area, is largely unregulated and undeveloped and is a potential source of water to meet future requirements not only in the Sutter-Yuba Area but in water-deficient areas in other parts of California.

Stream Gaging Stations and Records

Available records of runoff of the principal streams of the Sutter-Yuba Area were sufficient in number, length, and reliability for purposes of required hydrographic studies. With respect to certain of the smaller streams, however, records of runoff were nonexistent or confined principally to measurements made during the investigational seasons. By comparison with records of nearby stations on major streams, adequate estimates were made of runoff of these smaller streams.

Table 5 lists those stream gaging stations pertinent to the hydrography of the Sutter-Yuba Area, together with their map reference numbers, drainage areas above stations where significant, and periods and sources of records. These stations are also shown on Plate 3. The map reference numbers for the first 11 stations listed correspond to those used in State Water Resources Board Bulletin No. 1, "Water Resources of California." New map reference numbers were assigned to the remaining stations listed. The last five stations listed in Table 5 were installed, operated, and maintained as a part of the Sutter-Yuba Counties Investigation. Most of the runoff records listed in Table 5 have been published by the United States Geological Survey in its Water-Supply Papers or by the Division of Water Resources in its Reports of Sacramento-San Joaquin Water Supervision. The following records have not been published elsewhere and are included in Appendix D to this report:

Coon Creek at Highway 99E—November, 1947–December, 1948
Auburn Ravine at Highway 99E—November, 1947–December, 1948
Dry Creek near Waldo—November, 1947–May, 1949
South Honcut Creek at La Porte Road—November, 1947–December, 1948

Runoff Characteristics

An excellent continuous record of flow of the Feather River at or near Oroville is available for the period since January, 1902, when a stream gaging station was established at Oroville by the United States Geological Survey. The station was moved five miles upstream in October, 1934, but without appreciable effect on characteristics of the record. Although this record does not provide an exact measure of flow of the Feather River into the Sutter-Yuba Area, it is the most important record of the Feather River system, and does reflect characteristics of tributary mountain runoff to the Sutter-Yuba Area.

Flow of the Feather River to the valley floor is impaired by operation of Lake Almanor and several smaller upstream reservoirs, and by operation of hydroelectric power plants. An estimate of the natural runoff of the Feather River at Oroville, as it would be if unaltered by upstream diversion, storage, importation, and exportation, is included in State Water Resources Board Bulletin No. 1, "Water Resources of California." This estimate, together with recorded seasonal runoff of the Feather River at or near Oroville, is presented in Table 6. The

estimate of natural flow is also shown graphically on Plate 6, "Estimated Seasonal Natural Runoff of Feather River at Oroville."

Estimates of natural flow of streams of the Feather River system indicate that average seasonal runoff during the nine-year base period approximated the seasonal mean during the 53-year period. For the Feather, Yuba, and Bear Rivers these estimates were obtained from State Water Resources Board Bulletin No. 1. Natural flow of minor streams, including those tributary to the Sutter-Yuba Area but not in the Feather River system, were estimated during the current investigation. The estimates of natural flow are presented in Table 7, together with runoff indices for the combined natural flow of the Feather River system. The term "runoff index" refers to the ratio of the amount of runoff during a given season to the mean seasonal amount, and is expressed as a percentage.

Discharge of streams of the Sierra Nevada which are tributary to the Sutter-Yuba Area varies between wide limits from season to season, and within the season. This is indicated by flow of the Feather River at

or near Oroville, where the maximum recorded seasonal runoff occurred in 1906-07 and amounted to more than 9,300,000 acre-feet. The minimum seasonal runoff recorded at this station occurred in 1923-24 and was less than 1,200,000 acre-feet. Maximum recorded instantaneous discharge was 230,000 second-feet on March 19, 1907, and the estimated minimum discharge was about 300 second-feet on November 9, 1931. Estimated mean monthly distribution of natural flow of the Feather River at Oroville is presented in Table 8.

TABLE 8

ESTIMATED MEAN MONTHLY DISTRIBUTION OF NATURAL FLOW OF FEATHER RIVER AT OROVILLE

Month	Runoff, in acre-feet	Percent of seasonal total
October	101,000	2.2
November	188,000	4.1
December	290,000	6.3
January	423,000	9.2

August	101,000	2.2
September	78,000	1.7
TOTALS	4,596,000	100.0

Quantity of Runoff

Available records of stream flow, including those obtained from measurements made in connection with the investigation, were sufficient to permit fairly reliable determination of surface inflow to and surface outflow from the Sutter-Yuba Area during the nine-year base period and during the two seasons of the investigation.

Surface inflow to the Sutter-Yuba Area from the Feather and Bear Rivers was directly measured at the stations near Gridley and near Wheatland, respectively. Inflow from Yuba River was determined by recorded flow at Smartville until the season of 1940-41, after which season that station was discontinued and inflow was determined as the combined flow of Yuba River at Narrows Dam and Deer Creek near Smartville. For seasons when records of inflow from South Honcut Creek at La Porte Road and French Dry Creek near Browns Valley were not available, inflow was estimated by correlation with the combined flow of Yuba River at Narrows Dam and Deer Creek near Smartville. Inflow to the area from Dry Creek near Waldo, Coon Creek at Highway 99E, Auburn Ravine at Highway 99E, and Pleasant Grove Creek at Lincoln Road, was estimated for seasons when records were not available by correlation with the flow of Bear River near Wheatland. Inflow to the area through the Sutter

* Partially estimated.
† Estimated.

Butte Canal was estimated by adjusting measured diversions from Feather River on the basis of acreages of crops served each season within and outside the area. Inflow to the area from Snake Slough at Sanders Road during seasons of no record was estimated by correlation with flow in the Sutter Butte Canal. Inflow from minor unmeasured drainage areas was estimated by correlation with the flow of Bear River near Wheatland.

Surface outflow from the Sutter-Yuba Area in Feather River and the Wadsworth Canal was directly measured during the nine-year base period and during the investigational seasons at the stations at Nicolaus and near Sutter, respectively. Estimates of the net amount of outflow as drainage to the Sutter By-pass were based on partial records of pumping to and from the by-pass at pumping plants operated by the Division of Water Resources. Outflow from the Cross Canal was estimated by correlation with measured runoff of streams tributary to the canal, corrected for measured pumping diversions from the canal.

Measured and estimated seasonal surface inflow to and outflow from the Sutter-Yuba Area during the base period and during 1948-49 are presented in Table 9.

IMPORTED AND EXPORTED WATER

Water is imported to the Sutter-Yuba Area through the Sutter Butte Canal system for irrigation of lands in that portion of the West Side Zone outside of the Peach Bowl. This water is diverted from the Feather River at a point about 14 miles upstream from the north boundary of the area, and is conveyed in unlined canals through a service area situated along the right bank of the Feather River both inside and outside the Sutter-Yuba Area. The estimated amount of the import was 160,000 acre-feet during the 1948-49 season, and the estimated seasonal average during the base period was 147,000 acre-feet. These estimates are shown in Table 9. For purposes of current studies the Sutter Butte Canal import was considered to be a part of surface inflow to the Sutter-Yuba Area.

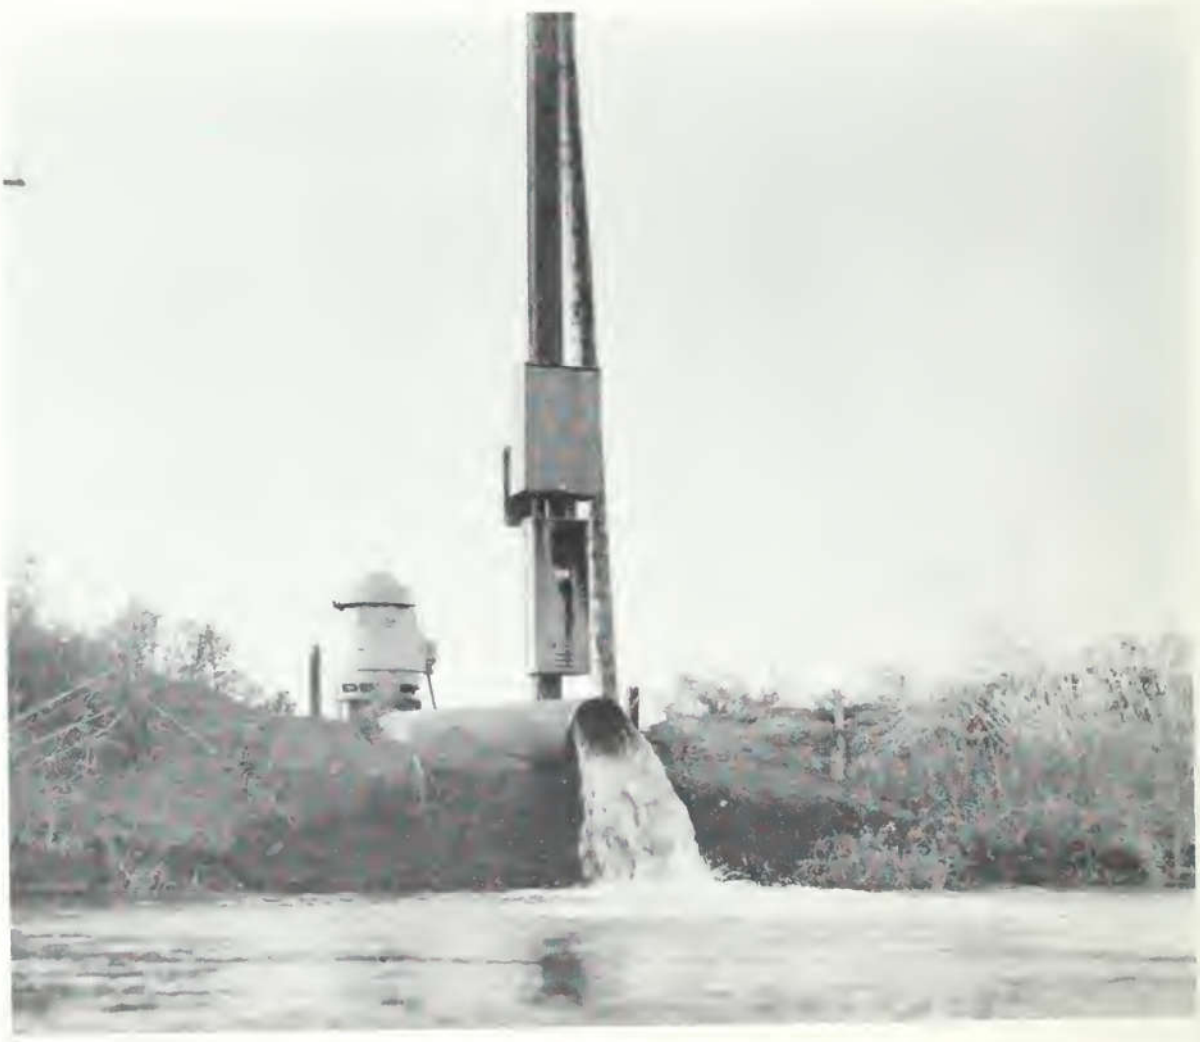
So far as was determined during the investigation, there is no record of export of water from the Sutter-Yuba Area.

UNDERGROUND HYDROLOGY

The Sutter-Yuba Area overlies a portion of the ground water basin of the Sacramento Valley, and water pumped from storage in the basin presently serves nearly two-thirds of the lands irrigated in the area. Percolation of rainfall, stream flow, and drainage from adjacent hills, and of the unconsumed portion of applied irrigation water, is the most important source of ground water replenishment.

The term "free ground water," as used in this report, generally refers to a body of ground water not overlain by impervious materials and moving under control of the water table slope. "Confined ground water" refers to a body of ground water overlain by material sufficiently impervious to sever free hydraulic connection with overlying water, and moving under pressure caused by the difference in head between intake and discharge areas of the confined water body. In areas of free ground water, the ground water basin provides regulatory storage to smooth out fluctuations in available water supplies, and changes in ground water storage are indicated by changes in ground water levels.

Data and information collected during the Sutter-Yuba Counties Investigation indicated that free ground water exists in present zones of pumping, although there may be some temporary or partial confinement in certain depth zones. Study of historic fluctuation of the water table in the Sutter-Yuba Area, under varying conditions of draft and replenishment, permitted a determination of changes in ground water storage in the basin, and its safe yield of water under stated conditions. Underground hydrology is discussed in this section under the following headings: "Ground Water Geology," "Specific Yield and Ground Water Storage Capacity," "Ground Water Levels," "Change in Ground Water Storage," "Subsurface Inflow and Outflow," "Yield of Wells," "High Water Table Areas," and "Safe Ground Water Yield."



Ground Water Geology

Geologic features of the ground water basin underlying the Sutter-Yuba Area were investigated by the Ground Water Branch of the United States Geological Survey, under terms of an agreement between that agency and the State Department of Public Works. Appendix B comprises a detailed report by the Geological Survey on ground water storage capacity, within given pumping lifts, and on geologic features of the Sutter-Yuba Area, with a general geologic map, four geologic cross-sections, and a map showing ground water storage units, prepared under the direction of Joseph F. Poland, District Geologist, by G. H. Davis and F. H. Olmsted. Portions of an abstract of the geologic report follow:

"The Sutter-Yuba area occupies the east-central Sacramento Valley and part of the western foothills of the Sierra Nevada. The Sacramento Valley is a trough that has been receiving sediments from both sides since the middle part of Cretaceous time. Most of the sediments in the Sutter-Yuba area have been derived from the Sierra Nevada on the east, which is a block mountain range tilted about 1½° westward. Evidence indicates that the block continues westward beneath the sediments of the valley trough.

"The Sutter Buttes, erosional remnants of a Pliocene volcano, occupy a circular area about 10 miles in diameter near the center of the Sacramento Valley.

"Rocks exposed in the Sutter-Yuba area range in age from pre-Cretaceous metamorphic and igneous rocks of the Sierra Nevada block to Recent alluvium still undergoing deposition. The rocks may be divided into two general categories: (1) the basement complex of the Sierra Nevada, which extends beneath the Sacramento Valley at depth, and (2) the superjacent rocks; a sedimentary blanket of marine and continental deposits transported from the Sierra Nevada and deposited in the Great Valley trough.

Deep Well and Turbine Pump Installation in Sutter-Yuba Area

"The water-bearing deposits considered in this report are included in the superjacent rocks, although weathered and fractured zones in the basement complex contain small quantities of ground water. The marine sediments of Cretaceous and Tertiary age are penetrated by water wells in only a few places in the Sutter-Yuba area. Where marine sediments are encountered they are generally impervious and contain water of poor chemical quality.

"Volcanic activity in the Sierra Nevada during the Tertiary period produced tuff-breccia of mud-flow origin which are impermeable and yield little water, but interbedded volcanic sands and gravels are moderately permeable and yield water to deep wells in the Marysville, Wheatland, Roseville, and Camp Beale districts.

"Local volcanic activity at Sutter Buttes during the Pliocene epoch produced two principal groups of rocks: (1) intrusive rhyolite and andesite and vent tuffs of the central core; and (2) andesitic tuff-breccias that encircle the core. The core is hard and impervious, but sands and gravels interbedded with the tuff-breccias yield some water to wells in the Pennington and Sutter City district.

"Following the close of volcanic activity in the Sierra Nevada the streams deposited predominantly fine-grained sediments during the remainder of the Pliocene epoch. These old alluvial deposits underlie the dissected uplands or 'red lands' along the valley margin and extend westward beneath younger alluvial deposits. Poorly sorted alluvium composed of silt, clay, and cemented sand and gravel as much as 350 feet thick represent this time interval. Many wells penetrate thick sections of these materials, but well yields are low to moderate.

"Uplift of the Sierra block at the beginning of the Pleistocene epoch caused the deposition of coarser materials. Alluvium of Pleistocene age as much as 100 feet thick underlies the low plains of the Sutter-Yuba area. These deposits are moderately permeable throughout and tongues of sand and gravel provide large supplies of water to irrigation wells.

"Recent alluvium, defined as those materials undergoing deposition, falls into three general categories: (1) alluvial fans of the Sutter Buttes, (2) basin deposits, and (3) stream-channel deposits. Most of the alluvial-fan deposits of Sutter Buttes are poorly sorted and groundwater yields from them are low. Basin deposits consist of an accumulation of relatively impermeable clays and silts which have been laid down by overflow waters of the Sacramento and Feather Rivers. Generally these deposits produce little water. Stream-channel deposits of the major streams contain well sorted sands and gravels to depths of 125 feet. Well defined channels are found beneath the flood plains of the Feather, Yuba, and Bear Rivers. Wells penetrating these coarse deposits are highly productive."

Specific Yield and Ground Water Storage Capacity

The term "specific yield," when used in connection with ground water, refers to the ratio of the volume of water a saturated soil will yield by gravity to its own volume, and is commonly expressed as a percentage. Ground water storage capacity is estimated as the product of the specific yield and the volume of material in the depth intervals considered.

In its investigation of the Sutter-Yuba ground water basin, the United States Geological Survey estimated specific yield of different depth zones after study of some 700 well logs. The estimates were based on previously determined characteristics of the various types of material classified in the well logs. Ground water storage capacity of the Sutter-Yuba Area was determined by the Geological Survey for depth intervals from 20 to 50 feet, 50 to 100 feet, 100 to 200 feet, and for the entire interval from 20 to 200 feet below ground surface. However, in an area of saline ground water centered near the southern end of the West Side Zone, where storage capacity in the 100- to 200-foot depth interval was considered not usable under present conditions, the determination was limited to the 20- to 50-foot, and 50- to 100-foot depth intervals.

Storage capacity of the ground water basin underlying the Sutter-Yuba Area and the weighted average specific yield, as estimated by the United States Geological Survey, are shown in Table 10.

TABLE 10

ESTIMATED SPECIFIC YIELD AND GROUND WATER STORAGE CAPACITY, SUTTER-YUBA AREA

Depth interval, in feet from ground surface	Weighted average specific yield, in percent	Ground water storage capacity, in acre-feet
20 to 50	7.4	840,000
50 to 100	6.9	1,290,000
100 to 200	6.0	1,760,000
20 to 200	6.6	3,890,000

Ground Water Levels

The first indication of a cone of depression in the water table in the Sutter-Yuba Area was found by Kirk Bryan and reported in 1913 in United States Geological Survey Water-Supply Paper 495. At that time a small cone had developed along Gilsizer Slough southwest of Shanghai Bend.

In 1931, in a "Report on Proposed Sutter Irrigation District," S. T. Harding described a study of ground water conditions in the eastern portion of Sutter County. A fully developed depression cone was found in the water table existing at that time. In discussing the growth of pumping draft in the Peach Bowl up to 1931, the author wrote:

"Draft in 1920 was probably double that in 1913, much of the orchards being young in 1920 less water would be used. From 1920 there has been a continual increase in area and draft. Since 1924 the annual draft has probably varied more largely with variations in rainfall than of area. For the past five years there has been little new orchard planting and the existing orchards have been sufficiently mature to represent full draft.

"These conclusions correspond generally with the ground water record. Some lowering occurred prior to 1920 but this was not sufficient to cause concern. Lowering appears to have attracted attention in 1924 and to have increased in below normal years since 1924 being particularly marked in the last 3 years."

The Division of Water Resources has measured fall water levels at a series of control wells throughout the Sacramento Valley during most years from 1929 through 1940, and each year from 1947 to date. Forty of these control wells are in or adjacent to the Sutter-Yuba Area. The Sutter County Farm Adviser furnished data on water levels at 25 additional wells in the area which were measured several times annually from 1931 through 1941. The Pacific Gas and Electric Company has made frequent measurements since 1946 at approximately 25 wells in or adjacent to the Sutter-Yuba Area. This company also furnished records of

standing and operating water levels measured during pump tests, together with results of the tests.

A complete series of measurements of static ground water levels at approximately 850 wells in the Sutter-Yuba Area was made in the spring and fall of each year during the period of investigation, beginning with the fall of 1947 and continuing through 1951. The wells were chosen to form a comprehensive grid covering the entire area. In addition, monthly measurements were made at approximately 90 control wells during the first half of 1948 and through 1949, in order to observe behavior of the ground water table under conditions of draft and recharge. Available records of depth to ground water at wells in or adjacent to the Sutter-Yuba Area are included as Appendix E to this report.

Depths to ground water throughout the Sutter-Yuba Area, as measured each fall from 1947 through 1951, were plotted on maps and lines of equal depth drawn. These are shown on Plates 7 to 11, inclusive, "Lines of Equal Depth to Ground Water." Plate 12, "Lines of Equal Elevation of Ground Water, Fall 1949," was prepared from the data used for Plate 9, depths to ground water being subtracted from elevations of the measuring points above sea level to obtain elevations of the water table.

Table 11 shows depths from the surface of the ground to the water table at selected representative wells in the several zones of the Sutter-Yuba Area during the fall of most years from 1929 through 1951. The measurements were made following the summer period of irrigation pumping draft and prior to recovery in ground water storage resulting from winter rains. The wells are numbered in accordance with the system utilized by the United States Geological Survey, and described in Appendix B. Fluctuations in depth to ground water at a representative well in each zone of the Sutter-Yuba Area are depicted graphically on Plate 13, "Measured Fall Depths to Ground Water at Representative Wells."

From study of all available well measurements, estimates were made of the approximate average depth to ground water in the Sutter-Yuba Area in the fall of each year from 1929 through 1951. These estimates, which constitute arithmetical averages of available measurements, are presented in Table 12 and are illustrated graphically in Plate 14, entitled "Average Fall Depth to Ground Water."

TABLE 12

ESTIMATED AVERAGE FALL DEPTH TO GROUND WATER IN SUTTER-YUBA AREA

(In feet)

Year	Depth to ground water	Year	Depth to ground water
1929	15.9	1940	12.3
		1941	12.0
1930	16.1	1942	11.9

1932	16.6	1944	13.1
1933	17.6		
1934	17.2	1945	14.2
		1946	16.2
1935	16.8	1947	17.6
1936	16.4	1948	18.3
1937	15.2	1949	19.8
1938	15.2		
1939	14.5	1950	21.7
		1951	21.8

It is indicated that a moderate lowering of the water table over the Sutter-Yuba Area occurred from 1929 until 1931, followed by a slight rise in 1932, and a lowering again in 1933. Although 1935 marked the end of a series of dry years, ground water levels rose in 1934 because of reduced pumping. The water table continued to rise during a generally wet series of years until 1943, and in that year the estimated average depth to ground water was the least during the entire period from 1929 through 1951. Since 1943, coincidental with dry years and expansion of irrigation, a continuous lowering of the water table has occurred, reaching its greatest average depth during the entire period in the fall of 1951.

In order to estimate weighted average changes in ground water elevations in the Sutter-Yuba Area during the nine-year base period and each investigational season, maps were drawn showing lines of equal change in elevation during these periods. An example of these maps is presented as Plate 15, "Lines of Equal Change in Ground Water Elevation from Fall of 1947 to Fall of 1951." By planimetering the areas between lines of equal change, the weighted average change in elevation of water levels was estimated for each zone of the Sutter-Yuba Area. The results of these estimates are presented in Table 13.

TABLE 13

ESTIMATED WEIGHTED AVERAGE SEASONAL CHANGES IN FALL GROUND WATER ELEVATION IN ZONES OF SUTTER-YUBA AREA

(In feet)

Change in Ground Water Storage

In an area of free ground water, the volume of soil unwatered or resaturated over a period of time, when multiplied by the specific yield, measures the change in ground water storage during that time. Available data on fluctuations of water levels at wells in the Sutter-Yuba Area were sufficient to estimate the volume of soil unwatered or resaturated during the base period, and during the two investigational seasons. Changes in ground water storage were estimated for each zone of the area by multiplying changes in elevation of ground water, presented in Table 13, by the area of each zone and by the average value of specific yield of 7.4 percent, found by the Geological Survey for the depth interval from 20 to 50 feet below ground surface. The results of these estimates are presented in Table 14.

TABLE 14

ESTIMATED WEIGHTED AVERAGE SEASONAL CHANGES IN GROUND WATER STORAGE IN ZONES OF SUTTER-YUBA AREA

(In acre-feet)

Zone	Area, in acres	1939-40 to 1947-48	1947-48	1948-49
West Side				
Peach Bowl	61,400	−3,000	−3,000	−7,000
Outside Peach Bowl	62,370	+500	0	−1,000
Northeast	42,860	+300	+1,000	−3,000
East Central	77,870	−4,000	−7,000	−13,000
South Side	82,460	−4,000	−8,000	−13,000
TOTALS	326,960	−10,200	−17,000	−37,000

It is indicated that an average seasonal net decrease in ground water storage in the Sutter-Yuba Area of about 10,000 acre-feet occurred during the nine-year base period, in which conditions of water supply and climate were approximately equivalent to conditions during the mean periods. The estimated net decrease in ground water storage during the two investigational seasons was approximately 17,000 acre-feet in 1947-48, and 37,000 acre-feet in 1948-49. It may be noted that the decrease in storage was substantial in the Peach Bowl portion of the West Side Zone, and in the East Central and South Side Zones. In the high water table lands of the Sutter Butte Canal service area in the West Side Zone, and in the Northeast Zone, changes in ground water storage were of minor importance.

Subsurface Inflow and Outflow

Lines of equal elevation of ground water in the Sutter-Yuba Area in the fall of 1949 are shown on Plate 12. Slopes of the water table as defined by these ground water contours, together with information on the permeabilities of the various subsurface geologic formations, indicate that the greater portion of subsurface inflow to the area probably came from the east, and a smaller amount from the north between Sutter Buttes and the eastern foothills. It is probable that about half of the subsurface inflow from the east entered from Placer County south of the historic Bear River flood plain, and that the other half moved across the investigational boundary from the east in Yuba

County, including the whole of the historic Bear River flood plain.

The ground water gradients shown on Plate 12 indicate that there was little subsurface outflow from the Sutter-Yuba Area during or immediately following the 1949 season of heavy pumping draft. Sufficient data were not available to depict ground water contours in the area during the wet years from 1939 to 1943, when there was substantial ground water replenishment and when subsurface outflow may have been significant. Study of available data, however, does show that average seasonal subsurface outflow from the Sutter-Yuba Area during the nine-year base period was probably small.

The ground water contours shown on Plate 12 indicate the presence of a depression cone in the water table extending approximately north and south through the Peach Bowl during 1949. There was a general convergence of ground water around the perimeter of the depression and into the trough, showing that such ground water movement as may have occurred was inflow to the cone, rather than outflow.

The northern and western portions of the West Side Zone, and adjacent areas outside of the Sutter-Yuba Area, are served with surface water supplies, and ground water levels have been fairly stable and close to the ground surface even in dry years. However, during dry years, ground water levels in the Peach Bowl have lowered as a result of increased pumping. These conditions have probably resulted in relatively greater subsurface inflow to the Peach Bowl during such dry years, owing to the steeper gradients existing in the water table.

An indirect method was used to estimate the net effect of subsurface inflow to and outflow from the Sutter-Yuba Area. This involved evaluation of the difference between subsurface inflow and outflow as the item necessary to effect a balance between water supply and disposal. The sum of the items comprising the water supply of a given hydrologic unit or area must be equal to the sum of the items of water disposal. This is a statement of what is referred to as the "equation of hydrologic equilibrium." In the case of the Sutter-Yuba Area, values for pertinent items other than the difference between subsurface inflow and outflow, including surface inflow and outflow, precipitation, change in ground water storage, and consumptive use of water, were quantitatively measured or estimated. Determination of values for consumptive use of water is explained in Chapter III. Retention of subsurface inflow, or the difference between subsurface inflow and outflow, was the remaining unknown quantity in the equation of hydrologic equilibrium. Table 15 sets forth this equation for the Sutter-Yuba Area.

Certain of the values in the equation of hydrologic equilibrium presented in Table 15 are of large magnitude as compared to the derived excess of subsurface inflow over subsurface outflow. Small percentage errors in these larger quantities might introduce relatively large errors in the derived remainders. In this connection, independent geologic analysis of the cross section of the perimeter of the Sutter-Yuba ground water basin, including consideration of the porosity of the aquifers, indicated that with existing slopes of the water table the derived values for net subsurface inflow might be excessive. However, study of disposal of water supplies in areas adjacent to the Sutter-Yuba Area tended to corroborate the derived values.

TABLE 15

ESTIMATED EXCESS OF SEASONAL SUBSURFACE INFLOW OVER SUBSURFACE OUTFLOW IN SUTTER-YUBA AREA

(In acre-feet)

Item	Average for 9-year base period 1939-40 through 1947-48	1947-48	1948-49
WATER SUPPLY			
Precipitation	635,000	529,000	448,000
Surface inflow	6,239,000	4,849,000	3,425,000
Decrease in ground water storage	10,000	17,000	37,000
TOTALS	6,884,000	5,395,000	3,910,000
WATER DISPOSAL

Consumptive use of water	710,000	764,000	794,000
TOTALS	7,026,000	5,554,000	4,090,000
REMAINDER — EXCESS OF SUBSURFACE INFLOW OVER SUBSURFACE OUTFLOW	142,000	159,000	180,000

Yield of Wells

Yield of wells is an important factor in the use of ground water in the Sutter-Yuba Area. In certain small portions of the area ground water is not utilized for irrigation because of inability to obtain wells of adequate capacity to meet the agricultural requirements. On the other hand, throughout most of the area adequate agricultural wells can generally be obtained.

Yield of wells in the Sutter-Yuba Area was analyzed by the United States Geological Survey, as reported in Appendix B, utilizing data obtained from well pumping tests made by the Pacific Gas and Electric Company during the period from 1933 through 1948. Results of the Geological Survey's analysis are summarized in Table 16, which shows for each zone of the Sutter-Yuba Area the number of wells tested, and their average discharge, specific capacity, depth, and yield factor. The term "specific capacity" refers to the number of gallons of water per minute produced by a pumping well per foot of drawdown. "Drawdown" refers to the lowering of the water level in a well caused by pumping, and is measured in feet. The "yield factor" reflects

the production of water per foot of depth of well, and is determined by multiplying the specific capacity by 100 and dividing by the depth of the well, in feet.

TABLE 16

ESTIMATED AVERAGE YIELD OF WELLS IN ZONES OF SUTTER-YUBA AREA

Zone	Number of wells tested	Average discharge, in gallons per minute	Average specific capacity, in gallons per minute per foot of drawdown	Average depth of wells, in feet	Average yield factor
West Side					
Peach Bowl	249	728	47	182	25.7
Outside Peach Bowl	48	878	54	320	16.8
Northeast	28	838	60	201	29.8
East Central	109	846	48	292	16.7
South Side	104	960	47	324	14.7

Insofar as may be determined from consideration of Table 16, it is indicated that the better wells of the Sutter-Yuba Area are located in the Peach Bowl and in the Northeast Zone. While wells of adequate capacity may generally be obtained throughout the remainder of the area, it is usually necessary to drill to greater depths for equivalent yields. However, although not apparent from the foregoing data, it was determined during the investigation that in the southeastern portion of the East Central Zone there is an area of approximately 3,400 acres of irrigable land upon which efforts to obtain wells of sufficient capacity to support irrigation demands have been unsuccessful.

High Water Table Areas

Under about 8,000 acres in the Northeast Zone, ground water was less than 10 feet from the ground surface continuously from November, 1947, through 1951, as was also the case under about 23,000 acres in the West Side Zone north of the East and West Intercepting Canals. Under about 1,000 acres of such lands in the Northeast Zone, and 4,500 acres in the West Side Zone, depth to the water table ranged from 0 to 5 feet from the ground surface.

The foregoing high water table lands were entirely irrigated by surface waters. It was indicated that the perennially high water table was largely caused by heavy applications of the abundant surface water supply to crops of rice and permanent pasture. The geologic investigations showed that the lands overlie good water-bearing formations which are capable of being developed by wells of relatively high yield, and that increase in use of ground water would probably result in lowering of ground water levels.

Studies indicated that the high water table lands would be suitable for a much wider range of crops than at present, if ground water levels were held at greater depths, and that an existing drainage problem would be eliminated. Furthermore, it is probable that consumptive use of water on these lands, as evidenced by heavy growth of native vegetation, is substantially in excess of such use on similar nearby lands where ground water levels are lower. The term "consumptive use of water," as used in this report, refers to water consumed by vegetative growth in transpiration and building of plant tissue, and to water evaporated from adjacent soil, from water surfaces, and from foliage. It also refers to water similarly consumed and evaporated by urban and nonvegetative types of culture.

Safe Ground Water Yield

The term "safe ground water yield" refers to the maximum rate of extraction of water from a ground water body which, if continued over an indefinitely long period of years, will result in the maintenance of certain desirable fixed conditions. Commonly, safe ground water yield is determined by one or more of the following criteria:

1. Mean seasonal extraction of water from the ground water body does not exceed mean seasonal replenishment to the body.

2. Water levels are not so lowered as to cause harmful impairment of the quality of the ground water by intrusion of other water of undesirable quality, or by accumulation and concentration of degradants or pollutants.

3. Water levels are not so lowered as to imperil the economy of ground water users by excessive costs of pumping from the ground water body.

Safe ground water yield, as derived in this report, was measured by net extraction of water from the Sutter-Yuba ground water basin, as differentiated from total pumpage from the basin. Since the Sutter-Yuba Area overlies a free ground water body, the unconsumed portion of total pumpage may return to the ground water body and become available for re-use. The net rate of extraction, therefore, was considered to be only that portion of total pumpage from the ground water basin which was consumptively used.

Under natural conditions, ground water is expended by consumptive use from seep lands and from lands where the water table is close to the ground surface, by effluent stream flow, and by subsurface outflow. Artificial development and utilization of ground water salvages all or a portion of such natural disposal, by lowering ground water levels. This, in turn, affords opportunity for additional replenishment of ground water.

With the present general patterns of water utilization in the Sutter-Yuba Area, the extraction of water from the ground water basin might be increased. Such increase in draft would undoubtedly be accompanied by recession of ground water levels in areas of pumping. However, this lowering of the water table would induce increased subsurface inflow to the areas of pumping and reduce natural disposal of the ground water, the probable effects of which would be to increase replenishment in an amount approximately equal to the increase in draft. This would probably hold true even in a series of dry years because of the continuous availability of large amounts of ground water in adjacent areas, maintained by percolation from relatively large surface water supplies. For this reason, the first of the foregoing criteria for determination of safe yield was not considered to be applicable in the Sutter-Yuba Area.

Because of expressed local concern over recent progressive lowering of pumping levels and deterioration in mineral quality of the ground water, the second and third of the foregoing criteria for determination of safe ground water yield were adopted as applicable to the Sutter-Yuba Area. It was therefore arbitrarily assumed that seasonal net extraction of ground water in 1948-49, with ground water levels prevailing at that time, defined the desirable limit beyond which net extraction should not be increased at the expense of further lowering of ground water levels.

As previously stated, consumptive use of ground water was considered to be equal to net extraction of water from the Sutter-Yuba ground water basin. An estimate of average seasonal consumptive use of ground water in the area during the nine-year base period is presented and explained in Chapter III. After correction for average seasonal change in ground water storage, this value was considered to represent average seasonal replenishment of the ground water basin during the base period. When further corrected for the increase in replenishment during 1948-49, over and above the base period average, as measured by increase in subsurface inflow, the value was considered to be equal to safe seasonal ground water yield.

The estimate of safe seasonal ground water yield is presented in Table 17.

Certain of the items included in the estimate of safe ground water yield are based on the assumption that present practice of irrigation by surface water supplies in and adjacent to the Sutter-Yuba Area will continue indefinitely. Under such circumstances adjacent ground water basins will remain the sources of sufficient subsurface inflow to areas of ground water pumping in the Sutter-Yuba Area to meet increases in pumping draft. While there is no assurance that surface irrigation practices will continue indefinitely as at present, there is reason to believe that any changes will not be of material significance to the estimated yield for many years in the future.

TABLE 17

ESTIMATED SAFE SEASONAL GROUND WATER YIELD IN SUTTER-YUBA AREA

Item	Acre-feet
Average seasonal consumptive use of ground water for 9-year base period, 1939-40 through 1947-48	158,100
Average seasonal decrement in ground water storage for base period	10,000
Average seasonal replenishment of ground water basin for base period	148,100
Increase in replenishment in 1948-49 over base period seasonal average	38,000
SAFE SEASONAL GROUND WATER YIELD	186,100

The foregoing estimate of safe seasonal ground water yield may be considered to represent the net seasonal extraction from the ground water basin that might be maintained without permanent lowering of the water table and degradation of mineral quality of the ground water beyond conditions prevailing in 1948-49. Having so chosen the determining criteria, estimated safe seasonal ground water yield may be considered to be a property of the ground water basin, not affected by changes in irrigation efficiency, patterns, or practices.

QUALITY OF WATER

The surface water supplies of the Sutter-Yuba Area are of excellent mineral quality and well suited from that standpoint for irrigation and other beneficial uses. With respect to ground water supplies, however, salinity sufficient to impair use of the ground water for irrigation, domestic, and many industrial uses has been observed at scattered wells throughout the area for many years. In the Peach Bowl, in the adjacent southern portion of the West Side Zone, and in the western portion of the South Side Zone this salinity of ground water has been general. The principal objectives of the water quality investigation, therefore, were to evaluate these conditions and to determine the extent of the area presently affected and the source of the saline ground waters.

It is desirable to define certain terms commonly used in connection with discussion of quality of water:

Contamination—This refers to impairment of the quality of water by sewage or industrial waste to a degree which creates a hazard to public health through poisoning or spread of disease.

Degradation—This refers to any impairment in the quality of water due to causes other than disposal of sewage and industrial wastes.

Pollution—This refers to impairment of the quality of water by sewage or industrial waste to a degree which does not create a hazard to public health, but which adversely and unreasonably affects such water for beneficial uses.

Quality of Water—This refers to those inherent characteristics of water affecting its suitability for beneficial uses.

The term "mineral analysis" refers to the quantitative determination of inorganic impurities or dissolved mineral constituents in the water. The complete mineral analysis included a determination of three cations, consisting of calcium, magnesium, and sodium; four anions, consisting of bicarbonate, chloride, sulphate, and nitrate; total soluble salts; boron; and computation of percent sodium. The partial analysis included determination of chlorides and total mineral solubles only.

With the exception of boron, the concentrations of cations and anions in a water sample are expressed in this report in terms of "equivalents per million." This was done because ions combine with each other on an equivalent basis, rather than on basis of weight, and a chemical equivalent unit of measurement provides a better and more convenient expression of concentration. This is especially true when it is desired to compare the composition of waters having variable concentration of mineral solubles. In the case of boron, concentrations are expressed on a weight basis of "parts per million" of water. In order to convert equivalents per million to parts per million, the concentration, expressed in equivalents per million, should be multiplied by the equivalent weight of the cation or the anion in question. Equivalent weights of the common cations and anions are presented in the following tabulation:

Cation	*Equivalent weight*	*Anion*	*Equivalent weight*
Calcium	20.0	Bicarbonate	61.0
Magnesium	12.2	Chloride	35.5
Sodium	23.0	Sulphate	48.0
		Nitrate	62.0

Data used to determine the quality of water in the Sutter-Yuba Area included complete mineral analyses of eight surface water samples and complete mineral analyses of water samples collected from 38 wells. The data also included partial analyses of water samples collected from 226 wells during the 1948 irrigation season and partial analyses of samples collected from 296 wells during the 1949 irrigation season. Other data used during the course of the investigation included well water analyses that were obtained from the Federal Land Bank in Berkeley and the Rubidoux Laboratory of the United States Department of Agriculture at Riverside, California.

Standards of Quality for Water

Investigation and study of the quality of surface and ground waters of the Sutter-Yuba Area, as reported herein, were largely limited to consideration of mineral constituents of the waters, with particular reference to their suitability for irrigation use. However, it may be noted that, within the limits of the mineral analyses herein reported, a water which is determined to be suitable for irrigation may also be considered as being either generally suitable for municipal and domestic use, or susceptible to such treatment as will render it suitable for that purpose.

The major criteria which were used as a guide to judgment in determining suitability of water for irrigation use comprised the following: (1) chloride concentration, (2) total soluble salts, (3) boron concentration, and (4) percent sodium.

1. The chloride anion is usually the most troublesome element in most irrigation waters. It is not considered essential to plant growth, and excessive concentrations will inhibit growth.

2. Total soluble salts furnishes an approximate indication of the over-all mineral quality of water. It may be approximated by multiplying specific electrical conductance ($Ec \times 10^6$ at 25° C.) by 0.7. The presence of excessive amounts of dissolved salts in irrigation water will result in reduced crop yields.

3. Crops are sensitive to boron concentration, but require a small amount (less than 0.1 per million) for growth. They will usually not tolerate more than 0.5 to 2 parts per million, depending on the crop in question.

4. Percent sodium reported in the analyses is the proportion of the sodium cation to the sum of all cations, and is obtained by dividing sodium by the sum of calcium, magnesium, and sodium, all expressed in equivalents per million, and multiplying by 100. Water containing a high percent sodium has an adverse effect upon the physical structure of the soil by dispersing the soil colloids and making the soil "tight," thus retarding movement of water through the soil, retarding the leaching of salts, and making the soil difficult to work.

The following excerpts from a paper by Dr. L. D. Doneen, of the Division of Irrigation of the University of California at Davis, may assist in interpreting water analyses from the standpoint of their suitability for irrigation:

"Because of diverse climatological conditions, crops, and soils in California, it has not been possible to establish rigid limits for all conditions involved. Instead, irrigation waters are divided into three broad classes based upon work done at the University of California, and at the Rubidoux, and Regional Salinity laboratories of the U. S. Department of Agriculture.

"Class 1. *Excellent to Good*—Regarded as safe and suitable for most plants under any condition of soil or climate.

"Class 2. *Good to Injurious*—Regarded as possibly harmful for certain crops under certain conditions of soil or climate, particularly in the higher ranges of this class.

"Class 3. *Injurious to Unsatisfactory*—Regarded as probably harmful to most crops and unsatisfactory for all but the most tolerant.

"Tentative standards for irrigation waters have taken into account four factors or constituents, as listed below.

Factor	*Class 1 excellent to good*	*Class 2 good to injurious*	*Class 3 injurious to unsatisfactory*
Conductance (Ec × 10⁶ at 25° C.)	Less than 1000	1000–3000	More than 3000
Boron, ppm	Less than 0.5	0.5–2.0	More than 2.0
Percent sodium	Less than 60	60–75	More than 75
Chloride, epm	Less than 5	5–10	More than 10

(End of quotation)

Quality of Surface Water

Analyses of surface water samples, collected in March, 1949, from the Feather River and four of its tributaries, showed that at that time the waters in these streams were of excellent mineral quality and well suited for irrigation and other beneficial uses. The waters were characterized by a very low content of total mineral solubles, chloride, and boron, and by low percent sodium. The occurrence of excellent quality water in the Feather River is also indicated by analyses of water from that stream which are presented in the Sacramento-San Joaquin Water Supervision Reports of the Division of Water Resources dating from 1946. Analyses of drainage water samples collected from Sutter By-pass and Snake Slough indicated that both drainage waters contain higher concentrations of mineral solubles than waters of Feather River and its tributaries, but that they are well within the limits of Class 1 irrigation waters. Analyses of representative surface waters of the Sutter-Yuba Area, sampled in 1949, are presented in Table 18.

Quality of Ground Water

Although in the course of the present investigation surveys were made of the mineral quality of ground water throughout the Sutter-Yuba Area, particular emphasis was placed on those areas where saline degradation has been general, and of a degree sufficient to limit beneficial use of the ground water. Results of the surveys are presented and discussed in this section under the headings "Area of Degraded Ground Water" and "Source of Ground Water Salinity."

Area of Degraded Ground Water. Two comprehensive surveys of the average mineral quality of ground water in the Sutter-Yuba Area were made during the irrigation seasons of 1948 and 1949. Both surveys involved the partial analysis of water samples collected from numerous wells to determine total mineral solubles and chlorides. Results of the two surveys are summarized in Table 19, and show that in 1948 and 1949 the mineral quality of native ground water supplies was excellent or good in all zones of the Sutter-Yuba Area, except in that portion of the West Side Zone south of Oswald Road where abnormally high concentrations of chloride were found in many of the well water samples. The 1949 survey embraced a larger area than the 1948, and included lands south and west of Sutter By-pass. Results of this extended survey showed that high chloride salinity of ground water also occurred locally near the town of Robbins, some seven miles westerly from Nicolaus.

The foregoing present areas of comparatively high chloride salinity are shown on Plate 16, "Lines of Equal Concentration of Chlorides in Ground Water, July 1949." It may be noted that the concentration of chlorides in the ground water decreased progressively with distance from both of the affected areas, in the

West Side Zone south of Oswald Road and near the town of Robbins. It may be inferred from this condition that, when hydraulic conditions are favorable, saline ground water from these two areas may move laterally, thus causing degradation in the mineral quality of remaining fresh ground water resources of surrounding areas.

The areas delimited by the lines of equal chloride concentration on Plate 16 indicate that at the present time wells on approximately 4,500 acres of land in the West Side Zone south of Oswald Road yield water containing chlorides in amounts exceeding 10 equivalents per million, which amount is considered to be the upper limit for safe irrigation use. When such saline waters are used for irrigation, quantities of water exceeding normal crop demands are commonly applied in order to dilute the soil solution and leach accumulations of excess salts away from the root zone.

Source of Ground Water Salinity. The presence of saline ground waters in and adjacent to the Sutter-Yuba Area has been observed to exist for many years, and was remarked upon in reports of salt balance studies conducted by the Division of Soil Management and Irrigation of the United States Department of Agriculture. These studies, which were made in cooperation with the Sutter Mutual Water Company during 1931, 1932, 1933, 1946, and 1947, showed that the amount of dissolved solids in water drained from lands adjacent to and west of the southern portion of the Sutter-Yuba Area greatly exceeded the amount brought onto the lands in irrigation water. The salt output during each of the five years, expressed as a proportion of the input, is reported to have ranged between 248 and 655 percent, and the average was about 407 percent.

The opinion was expressed in a report on the foregoing 1947 salt balance study that the salt in the drainage waters was probably derived from saline waters underlying the area. Preliminary studies made by the Division of Water Resources similarly indicated that the chloride salinity in many of the wells was due to admixture of deep-seated brines with native fresh ground waters. There is evidence that such brines may underlie aquifers of good quality water throughout large areas of the Sacramento and San Joaquin Valleys, and that they may have originated during past geologic time when the floor of the valley was inundated by the ocean. Such brines sometimes appear in water pumped from the deeper wells in the two valleys, or from areas wherein the fresh ground water levels are markedly lowered through overdraft. In many instances these relatively deep-seated brines are under considerable pressure and readily rise to the surface through defective, abandoned, or improperly constructed wells. A case in point is a natural gas well located near the town of Robbins which yields water under artesian and/or gas pressure, at a rate of about 200 gallons a minute. The water from this well, No. 12N/2E-18, has a conductivity of about 8,600, a chloride content of about 100 equivalents per million, and about 10.8 parts per million of boron.

A geochemical study was made to determine whether salinity of ground water in the Sutter-Yuba Area was caused principally by a common degradant, and whether the foregoing deep-seated brines constituted that degradant. The study to identify the degradant was made on the basis of complete mineral analyses of water samples collected from 38 scattered wells located in the West Side Zone south of Oswald Road and in adjacent lands to the west. These water samples were first classified into eight groups according to the range in concentration of total anions. For purposes of the study it was considered that native fresh ground waters contained total anions in amounts less than about 7 equivalents per million, chlorides in amounts less than about 2.5 equivalents per million, and that degradation had occurred if these amounts were ex-

ceeded. A discussion of the characteristics of each group follows:

Group 1. This comprised unaltered normal ground water. Four analyses were available for Group 1 water. The wells which yielded this water were located within the present zone of high chloride concentration, and the samples were taken and analyses made in 1934 and 1935 prior to recent degradation of ground water in the zone. The water had total anions ranging from 4.72 to 6.31 equivalents per million, and chlorides from 0.85 to 2.06 equivalents per million. Its mineral quality was excellent.

Group 2. This group comprised waters containing a trace of salinity. Total anions ranged from 8.95 to 10.68 equivalents per million, and chlorides from 5.45 to 6.39 equivalents per million. Four analyses repre-

senting wells yielding Group 2 waters were available. These waters were classed as of good mineral quality and suitable for general irrigation use.

Group 3. This group comprised slightly saline ground waters. Total anions ranged from 12.19 to 13.40 equivalents per million, and chlorides ranged from 3.40 to 10.15 equivalents per million. Six analyses were available for wells yielding Group 3 waters. These waters were considered to be generally satisfactory for irrigation use.

Group 4. This group comprised moderately saline ground waters, with total anions ranging from 14.32 to 15.38 equivalents per million, and chlorides ranging from 7.49 to 11.68 equivalents per million. Six analyses were available for wells yielding Group 4 waters. These waters were classed as usable with caution for general irrigation under most conditions.

Group 5. This group comprised saline ground waters with total anions ranging from 16.53 to 17.63 equivalents per million, and chlorides ranging from 10.95 to 14.08 equivalents per million. Five analyses were available for wells yielding Group 5 waters. These waters would normally be considered usable for irrigation only after dilution with water of better mineral quality.

Group 6. This group comprised saline ground waters having total anions ranging from 18.35 to 21.69 equivalents per million, and chlorides ranging from 13.61 to 18.08 equivalents per million. Five analyses were available for wells yielding Group 6 water. This water was classed as unsuitable for irrigation use.

Group 7. This group comprised highly saline ground waters, having total anions ranging from 25.54 to 34.88 equivalents per million, and chlorides ranging from 19.26 to 29.04 equivalents per million. Analyses were available for six wells yielding Group 7 waters. These waters were not considered usable for irrigation or domestic purposes.

Group 8. This group comprised briny ground waters. Group 8 waters were yielded in June 1949 by a reputedly shallow well, and in April 1930 and March 1947 by a nearly 1500-foot abandoned gas well, both located near Robbins to the west of the Sutter-Yuba Area. These waters had total anions in excess of 100 equivalents per million. Chlorides accounted for about 95 per cent or more of the anions.

Results of complete mineral analyses of ground waters in the zone of degradation, segregated into the foregoing groups, are presented in Table 20.

The character formula of a water expresses the percent of each cation and anion of mineral constituents of the water with respect to their total, and is useful in comparing mineral quality characteristics of several waters. In order to compare the groups of saline ground waters in and adjacent to the Sutter-Yuba Area, the average equivalents per million of each cation and anion in unaltered normal ground water, represented by Group 1, were first subtracted from corresponding average mineral constituents in ground water of each of the other groups, with exception of those of Group 8. The character formulae of waters of Groups 2 to 7 were then derived as determined by use of these remainders. Both the character formulae of these differences and the mineral constituents are shown in Table 21. They may be considered to represent the mineral characteristics of the ground water degradant as they were prior to alteration through mingling of the degradant with fresh ground water, but after being subjected to base exchange during movement of the degradant from its source. It may be noted that both the concentration and composition of waters in Group 8 were taken directly from the average analysis presented in Table 20. This was done on the assumption that the brines of that group were not significantly diluted with fresh water.

TABLE 21

AVERAGE MINERAL CHARACTER AND CONSTITUENTS OF SALINE GROUND WATERS IN AND ADJACENT TO SUTTER-YUBA AREA

(Corrected for effects of dilution with unaltered normal ground water)

Ground water group	Mineral constituents in equivalents per million and character formulae in percent

2	1.35 13.3%	2.24 22.2%	1.47 14.5%	0.20 2.0%	4.60 47.6%	0.04 0.4%
3	2.32 14.0%	3.26 20.8%	2.26 14.4%	0.68 4.6%	6.54 44.6%	0.11 0.8%
4	2.69 14.3%	3.47 18.4%	3.27 17.3%	0.66 3.5%	8.45 45.0%	0.28 1.5%
5	2.91 12.2%	4.54 19.1%	4.46 18.7%	0.23 1.0%	11.21 48.1%	0.20 0.9%
6	3.71 13.7%	4.81 15.6%	6.38 20.7%	0.09 0.3%	14.66 49.3%	0.12 0.4%
7	6.88 15.4%	8.58 19.1%	6.93 15.5%	0.33 0.8%	21.17 48.2%	0.44 1.0%
8	25.10 21.0%	21.26 10.0%	58.01 28.0%	3.40 1.7%	99.67 48.0%	0.06 0.3%

Table 21 shows that, irrespective of variations in concentration, the character formula of the degradant in each of the ground water Groups 2 through 7 is strikingly similar to that of the brines comprising Group 8. This is especially true of the anions which are not subject to base exchange reactions. This similarity in composition, together with apparent absence of any other like degradant, indicates that degradation of the native ground waters is due to admixture of deep-seated brines of the type exemplified by Group 8.

Although the chloride content of water from wells in the area of saline ground water is generally high, it is quite variable with respect to the depth of wells. Examination of analyses of water from 33 wells of known depth in the West Side Zone south of Oswald Road did not indicate any correlation between chloride content of the water and depth. The wells studied for this purpose ranged in depth from about 50 to 300 feet, and the average depth was of the order of 145 feet. The lack of any significant correlation in this matter cannot be fully explained on the basis of data compiled during the course of the present investigation. However, it is probable that the explanation may lie in precise identification of the aquifers which contribute water to the respective wells. For example, wells pumping from both fresh and saline aquifers would probably yield water containing lower concentrations of chlorides than wells pumping only from saline aquifers. In this connection it is noted that additional more detailed investigation of the quality of the water resources of the Sutter-Yuba Area is in progress under the provisions of Section 229 of the Water Code. This work is being conducted by the Division of Water Resources in connection with its assigned responsibilities for a state-wide survey of quality of surface and ground waters, the results of which will be published at a later date.

Studies to date of saline ground water conditions in the Sutter-Yuba Area indicate that the brines of Group S may migrate upward into fresh water aquifers both through permeable zones in the alluvium and through unplugged test wells and abandoned, defective, or improperly constructed water wells. Furthermore, when the water table is lowered by heavy irrigation pumping, it is probable that upward movement of the brines is accelerated. Possible subsequent lateral movement of the brines may be inferred from the observed progressive decrease in ground water chloride concentrations with distance from the two areas of high chloride salinity, in the West Side Zone south of Oswald Road and near Robbins.

CHAPTER III

WATER UTILIZATION AND SUPPLEMENTAL REQUIREMENTS

The nature and extent of water utilization and requirements for supplemental water in the Sutter-Yuba Area, both at the present time and under probable conditions of ultimate development, are considered in this chapter. In connection with the discussion, the following terms are used as defined:

Water Utilization—This term refers to the sum of consumptive use of water and those irrecoverable losses of water incidental to its beneficial use.

Consumptive Use of Water—This term refers to water consumed by vegetative growth in transpiration and building of plant tissue, and to water evaporated from adjacent soil, from water surfaces, and from foliage. It also refers to water similarly consumed and evaporated by urban and nonvegetative types of culture.

Supplemental Requirement—This term refers to the amount of water, over and above the sum of safe ground water yield and safe surface water yield, which must be developed to satisfy water utilization.

Ultimate—This term refers to an unspecified but long period of years into the future when cultural development will be essentially stabilized. (It is realized that any present forecasts of the nature and extent of such ultimate cultural development, and resultant water utilization, are inherently subject to possible large errors in detail and appreciable error in the aggregate. However, such forecasts, when based upon best available data and present judgment, are of value in establishing long-range objectives for development of water resources. They are so used herein, with full knowledge that their re-evaluation after the experience of a period of years may result in considerable revision.)

Present water utilization in the Sutter-Yuba Area was estimated by the application of appropriate unit consumptive use of water factors to the present cultural pattern. Probable ultimate water utilization was similarly estimated, by the use of an ultimate cultural pattern projected from the present pattern on the basis of land classification data, the assumption being made that under ultimate conditions of cultural development all irrigable lands would be irrigated. As indicated by the foregoing definition, supplemental requirements for water were estimated as the differences between derived values of safe yield and utilization, under both present and ultimate conditions of cultural development.

Water utilization is considered and evaluated in this chapter under the general headings "Present Water Supply Development," "Land Use," "Unit Use of Water," "Past and Present Water Utilization," "Probable Ultimate Water Utilization," and "Demands for Water." Supplemental water requirements are similarly treated under the two general headings "Present Supplemental Requirements" and "Probable Ultimate Supplemental Requirements."

WATER UTILIZATION

Of the total amount of water presently utilized in the Sutter-Yuba Area, approximately 65 percent is consumed in the production of irrigated crops, while the remainder is consumed by dry-farmed crops and fallow lands, native vegetation, and miscellaneous culture including domestic and municipal. It is considered probable that the predominant importance of irrigated agriculture, as related to utilization of water in the area, will continue to prevail in the future.

Present Water Supply Development

Approximately two-thirds of the acreage under water service in the Sutter-Yuba Area is presently supplied by water pumped from the underlying ground water basin. Irrigated lands utilizing ground water are generally served by individually owned wells and pumps. Because of this fact and the extensive ground water utilization, the amount of water developed for irrigation use by individuals is larger than by organized agencies. As of April 1, 1949, there were 2,198 wells and pumping plants of heavy draft, powered with motors of more than five horsepower, and of this number 2,159 were used for irrigation. The 39 remaining wells supplied water for urban and industrial uses. A number of additional wells of light draft supplied limited amounts of water for noncommercial gardens and orchards, and for domestic purposes. Lands served principally with ground water comprise the Peach Bowl, the East Central Zone, and the portion of the South Side Zone adjacent to and south of Bear River.

Surface diversions for irrigation in the Sutter-Yuba Area are made from the Sacramento and Feather Rivers and tributary streams, and from the Wadsworth and Natomas Canals, various surface drains, and the Sutter By-pass. The major diversions are made by irrigation companies and districts, with service to the lands being largely by means of open ditch transmission and distribution systems. Minor surface diversions are made for the most part by individuals whose lands are adjacent to the surface supplies. The Sutter Butte Canal Company is the principal diverter of water from Feather River, serving lands in the West Side Zone outside of the Peach Bowl. The joint diversion of the Hallwood Irrigation Company and the

Cordua Irrigation District is the largest of a number of irrigation diversions from Yuba River, and serves water to lands in the Northeast Zone. The Nevada Irrigation District supplies some surface water to lands in the South Side Zone through ditches diverting from Auburn Ravine. Lands served principally by surface waters comprise the Northeast Zone, the West Side Zone outside the Peach Bowl, and the west portion of the South Side Zone.

Water used for municipal, industrial, and domestic purposes in the Sutter-Yuba Area is obtained almost entirely from wells. The greater part of such use is in the Cities of Marysville and Yuba City, and is scattered and of relatively minor significance throughout the remainder of the area.

The City of Marysville is served by the California Water Service Company, a public utility which pumps water from wells into storage tanks, from which it is delivered to consumers by gravity. Water services are metered. The quantity of water pumped for use in Marysville in the calendar year 1948 was 506,000,000 gallons, or 1,550 acre-feet. With an approximate population of 7,500 in July, 1948, the daily production averaged about 185 gallons per capita.

Yuba City is served by the Yuba City Municipal Water Works, which charges for water on a flat-rate basis. It was estimated that the quantity of water pumped for use in Yuba City in the calendar year 1948 was about 750,000,000 gallons, or 2,300 acre-feet. With an approximate population of 6,300 in March, 1948, the daily per capita production was about 330 gallons.

In addition to the foregoing figures regarding ground water pumped in 1948 under the municipal systems of Marysville and Yuba City, it was estimated that approximately 1,000 acre-feet was pumped and used by industries operating their own wells within the cities. Wheatland has a community water system that distributes water from a storage tank supplied by two wells. The estimated amount of water pumped in Wheatland during the calendar year 1948 was approximately 200 acre-feet. Assuming that the per capita water production in remaining small towns and communities in the Sutter-Yuba Area was about 200 gallons per day, it was estimated, on the basis of 1948 population estimates, that total annual pumpage from ground water for these communities was about 700 acre-feet.

The respective areas within the several zones of the Sutter-Yuba Area served by ground water and surface water are shown in Table 22. The data presented for the two investigational seasons resulted from field surveys during the current investigation, while the averages for the base period were largely based on records of crop surveys made by the Division of Water Resources in connection with the Sacramento-San Joaquin Water Supervision, and on pumping power consumption records furnished by the Pacific Gas and Electric Company.

TABLE 22

GROUND AND SURFACE WATER SERVICE AREAS IN ZONES OF SUTTER-YUBA AREA

(In acres)

Zone	Ground water		Surface water	
	1948	1949	1948	1949
West Side	48,990	44,650	18,750	21,590
Northeast	6,050	8,240	11,540	11,850
East Central	24,230	33,140	2,500	990
South Side	11,280	10,770	15,420	18,070
TOTALS	90,550	96,800	48,210	52,500
Averages for 9-year base period, 1939-40 through 1947-48	68,490		42,810	

Table 23 lists the principal water service agencies, together with notations on their sources of water supply, locations of service areas within the Sutter-Yuba Area, and acreages within the area irrigated by water served by each agency in 1948. Areas included within the boundaries of these agencies are shown on Plate 2.

TABLE 23

PRINCIPAL WATER SERVICE AGENCIES SUTTER-YUBA AREA

Agency	Source of water supply	Service area, by zones	Acreage irrigated in 1948
California Water Service Company	Ground water	Northeast	Municipal use in Marysville
Camp Far West Irrigation District	Bear River	East Central	1,580
Cordua Irrigation District	Yuba River	Northeast	4,736
Farm Lands Investment Company	Feather River	East Central	1,833
Feather River Water Company	Feather River	West Side	0
Garden Highway Mutual Water Company	Feather River	West Side	2,075
Hallwood Irrigation Company	Yuba River	Northeast	6,365

Nevada Irrigation District	Yuba and Bear Rivers	South Side	1,240
Oswald Water District	Feather River	West Side	608
Sutter Butte Canal Company	Feather River	West Side	12,840
Sutter Extension Water District	Feather River	West Side	Formed in 1949
Yuba City Municipal Water Works	Ground water	West Side	Municipal use

* Included in acreage of Natomas Central Mutual Water Company.

Rice Field in Sutter-Yuba Area

Land Use

As a first step in estimating the amount of water utilization in the Sutter-Yuba Area during the base period and investigational seasons, determinations were made of the nature and extent of land use prevailing during these periods. Similarly, the probable nature and extent of ultimate land use, as related to water utilization, was forecast on the basis of land classification survey data which segregated lands of the area in accordance with their suitability for irrigated agriculture.

Past and Present Cultural Patterns. In connection with the Sacramento-San Joaquin Water Supervision, the Division of Water Resources for some 25 years has made annual crop surveys of those lands in the Sutter-Yuba Area utilizing surface water. In 1946 the United States Bureau of Reclamation made a complete crop survey of the area. A comprehensive cultural survey was made during the season of 1947-48 as a part of the current investigation. Additional data on culture were obtained in 1948-49 from a supplementary survey made in order to determine any changes in land use since the preceding season.

Data available from the foregoing surveys were sufficient to estimate the average cultural pattern in the Sutter-Yuba Area during the nine-year base period. For purposes of this report, the cultural pattern existing during the 1948-49 season was considered to represent "present" conditions of culture and development in the area, and is so referred to in subsequent discussion.

Summaries of the results of the cultural surveys of 1947-48 and 1948-49 and the estimated average cultural pattern for the base period are presented in Table 24. The Sutter Buttes, comprising some 22,300 acres of waste land in the West Side Zone, are not included in the tabulation. Lands irrigated in the Sutter-Yuba Area during the 1947-48 season are shown on Plate 17, "Irrigated and Irrigable Lands, 1948."

The most significant indicated recent trend in irrigated agriculture in the Sutter-Yuba Area is toward increased plantings of rice and permanent pasture. The data presented in Table 24 show that the area of rice increased from an estimated average of some 25,500 acres during the base period to over 44,000 acres in 1948-49. At the same time, permanent pasture increased from some 17,500 to 25,500 acres. Deciduous orchard, which had long been the largest irrigated crop in the area on an acreage basis, showed an increase of less than 3,000 acres in 1948-49 over the base period average, and was surpassed by the acreage of rice during the latter season. The foregoing increases in irrigated agriculture were largely reflected by corresponding decreases in acreage of dry-farmed and fallow lands. Table 24 shows that there was moderate increase in farmstead and urban development in 1948-49 over the base period averages, but no very significant changes in remaining types of culture in the Sutter-Yuba Area.

Probable Ultimate Cultural Pattern. Classification of lands of the Sutter-Yuba Area with respect to their suitability for irrigated agriculture was largely accomplished by other agencies prior to the Sutter-Yuba Counties Investigation. Many valuable data on land classification were available from and furnished by the United States Bureau of Reclamation. The available data were supplemented and checked as required in the course of field surveys conducted as a part of the investigation.

On the basis of their suitability for irrigation, agricultural lands of the Sutter-Yuba Area were segregated into the following five classes:

Class 1. This class comprises lands that are highly desirable in every respect for continuous irrigated agricultural use, and capable of producing all climatically adapted crops. The soils are deep, with good surface and subsoil drainage, of medium to fairly fine texture, and of good water-holding capacity. The soil structure is such as to permit easy penetration of roots, air, and water, and the land surface is smooth and gently sloping.

Class 2. This class comprises lands that are generally limited in their use to climatically adapted crops of medium root depths. Restrictive features with regard to use of the lands are soil depth and, to some extent, topography or drainage.

Class 3. This class comprises lands that are generally limited in their use to climatically adapted shallow-rooted crops, owing to deficiencies in soil depth, topography, or drainage characteristics. This class of lands is suitable for development under irrigation, but because of shallow soil depths, greater care and skill are required in the application of water than are necessary in the case of lands of Classes 1 and 2.

Class 4. This class comprises lands that fail to meet the standards of Classes 1, 2, and 3, as to topography, drainage, and depth of soil. These lands are generally suitable only for permanent pasture or similar crops.

Class 6. This class comprises all lands that do not meet the minimum requirements of suitability for irrigation use.

In addition to agricultural lands, 5,550 acres in the Sutter-Yuba Area were classified as urban, and 22,270 acres comprising the waste lands of the Sutter Buttes were not otherwise classified. Results of the land classification of the Sutter-Yuba Area, summarized by zones, are presented in Table 25.

By use of the land classification data a probable ultimate cultural pattern for the Sutter-Yuba Area was forecast. The general assumption was made that under

an increasing pressure of demand for agricultural products all irrigable but presently dry lands would eventually be provided with irrigation service. Provision was also made for probable increase in lands devoted to farmsteads, roads, urban, and other miscellaneous purposes under conditions of probable ultimate development.

The estimated ultimate cultural pattern of the Sutter-Yuba Area, summarized by general classes of culture and by zones of the area, is presented in Table 26. Irrigable lands, as determined by the land classification survey data and as indicated by the probable ultimate cultural pattern, are shown on Plate 17.

Unit Use of Water

The second step in evaluation of water utilization involved the determination of unit values of consumptive use of water for each type of water consuming culture. Estimates of these unit values were largely based on the results of prior investigations and studies in other areas.

A procedure suggested by Harry F. Blaney and Wayne D. Criddle of the Soil Conservation Service, United States Department of Agriculture, in their reports entitled "A Method of Estimating Water Requirements in Irrigated Areas from Climatological Data," dated December, 1947, and "Determining Water Requirements in Irrigated Areas from Climatological and Irrigation Data," dated August, 1950, was generally utilized for adjustment of available data on unit consumptive use by irrigated crops in other localities to correspond with conditions existing in the Sutter-Yuba Area. This method involved correlation of the data on the basis of variations in average monthly temperatures, monthly percentages of annual daytime hours, precipitation, and lengths of growing season. It disregarded certain generally unmeasured factors such as wind movement, humidity, etc. Average monthly temperatures at Marysville were considered representative of the Sutter-Yuba Area. Monthly percentages of annual daytime hours were determined for latitude 39° N., which passes approximately through the center of the area.

The following is an outline of the procedure utilized for estimating unit values of consumptive use:

1. The unit value for each irrigated cultural type during its growing season was taken as the product of available heat and an appropriate coefficient of consumption, where: (a) the available heat was the product of average monthly temperature and monthly percent of daytime hours, and (b) the coefficient of consumption was one which had been selected as appropriate for California by Harry F. Blaney as a result of his studies for the Soil Conservation Service. Certain exceptions involved the use of coefficients estimated from consumptive use data available from other sources.

2. The unit value for each irrigated cultural type during its nongrowing season was taken as the amount of precipitation available, but not exceeding one to two inches of depth per month, depending upon the type of culture and cover crop.

3. The seasonal unit value for each irrigated cultural type was taken as the summation of values determined under items 1 and 2 for that type.

4. Unit seasonal values for native annual grasses were taken as equal to the available precipitation up to but not exceeding 1.3 feet in depth.

5. Unit seasonal values for native vegetation other than annual grasses were estimated on the basis of available data on corresponding consumptive use in similar localities, due consideration being given to density and type of vegetation and depth to ground water.

6. Unit seasonal values for free water surfaces were estimated from available records of evaporation at Gridley.

7. Unit seasonal values for remaining miscellaneous types of culture were estimated on the basis of available data on corresponding consumptive use in similar localities.

Estimated unit seasonal values of consumptive use of water in the Sutter-Yuba Area, including consumption of precipitation, are presented in Table 27. In view of the indicated water supply and climatological similarities of the mean and base periods, the estimated average unit seasonal values of consumptive use for the base period were considered to approximate corresponding values for the mean period.

TABLE 27

Past and Present Water Utilization

The total amount of utilization of water in the Sutter-Yuba Area was estimated by multiplying the acreage of each type of culture by its respective unit value of consumptive use of water. The results of the estimates of seasonal water utilization during the base period and investigational seasons are presented in Table 28, summarized by general classes of culture. These estimates include consumptive use of precipitation.

TABLE 28

ESTIMATED SEASONAL UTILIZATION OF WATER IN SUTTER-YUBA AREA DURING BASE PERIOD AND INVESTIGATIONAL SEASONS

(In acre-feet)

Class of culture	Average for 9-year base period, 1939-40 through 1947-48	1947-48	1948-49
Irrigated lands	382,000	469,000	524,000
Dry-farmed and fallow lands	234,000	195,000	171,000
Native vegetation	49,000	49,000	49,000
Miscellaneous	45,000	51,000	50,000
TOTALS	710,000	764,000	794,000

Mean seasonal water utilization in the Sutter-Yuba Area was also estimated as it would be with present cultural development but under mean conditions of water supply and climate. The estimate was based on the cultural pattern determined by the 1949 survey, and on estimated average unit seasonal values of consumptive use of water for the nine-year base period which were considered to approximate those for the mean period. The estimate, which includes consumptive use of precipitation, is presented in Table 29, summarized for the four zones of the area and segregated by general cultural classes.

In order to facilitate certain phases of the analysis of ground water hydrology, presented in Chapter II, it was desirable to estimate seasonal utilization of ground water in the Sutter-Yuba Area. Unit seasonal values of consumptive use of ground water were derived by subtracting the amount of available precipitation, up to but not exceeding 1.3 feet of depth, from the appropriate unit seasonal values presented in Table 27. The corrected values were then multiplied by the acreages of each cultural type served by ground water during the respective periods. These included native vegetation in high water table areas. The 1949 cultural pattern was considered representative of present conditions, and average unit seasonal values of consumptive use for the base period were considered to be equal

to corresponding mean period values. The estimates of utilization of ground water are summarized by general classes of culture in Table 30.

TABLE 29

ESTIMATED MEAN SEASONAL UTILIZATION OF WATER IN ZONES OF SUTTER-YUBA AREA UNDER PRESENT CULTURAL DEVELOPMENT

Probable Ultimate Water Utilization

The total seasonal amount of water utilization in the Sutter-Yuba Area was estimated as it would be under probable ultimate conditions of cultural development and under mean conditions of water supply and climate. This was accomplished by multiplying acreages of cultural types derived in the forecast of the ultimate cultural pattern by corresponding average unit seasonal values of consumptive use of water for the base period. It was considered that unit consumptive use during the base period was equal to that under mean conditions of water supply and climate. The estimate of probable ultimate water utilization is summarized in Table 31 by general cultural classes and by zones of the Sutter-Yuba Area. The estimate includes consumptive use of precipitation.

TABLE 31

Demands for Water

The term "demands for water," as used in this report, refers to those factors pertaining to rates, times, and places of delivery of water, imposed by the control, development, and use of the water for any and all beneficial purposes. Certain possible present or future nonconsumptive demands for water in the Sutter-Yuba Area, such as those for hydroelectric power generation, flood control, conservation of fish and wildlife, recreation, etc., were considered to be outside the scope of the current investigation. Since they would have little significance in preliminary design of works to meet supplemental requirements for water in the Sutter-Yuba Area, they are not further discussed herein.

Irrigation practice in the Sutter-Yuba Area, as determined by rates of application, gross diversions, monthly demands, and permissible deficiencies in application of water, must be given consideration in preliminary design of works to meet supplemental water requirements. These demand factors, which were not measured or considered in the foregoing estimates of water utilization, are discussed in the following sections.

Application of Water. The term "applied water," as used in this report, refers to that water other than precipitation which is delivered to a farmer's headgate in the case of irrigation use, or to an individual's meter in the case of urban use, or its equivalent. During each of the two seasons of the investigation measurements were made of the amount of water applied for irrigation of selected plots of principal crops grown on various soil types in the Sutter-Yuba Area. Records of such application of water pumped from wells were obtained for 35 plots during 1948, and 21 plots during 1949. For each well the pump discharge, acreage of each type of crop irrigated, number of irrigations, periods of irrigation, and amounts of water applied in each irrigation were recorded. From these data, monthly and total seasonal applications of water to

each crop were determined. Results of these studies, which may be considered representative of prevailing irrigation practice in the Sutter-Yuba Area, are summarized in Table 32. Detailed results of the plot studies are presented in Appendix F, and location of the plots is indicated on Plate 17.

TABLE 32

MEASURED AVERAGE SEASONAL APPLICATION OF IRRIGATION WATER ON REPRESENTATIVE PLOTS OF PRINCIPAL CROPS IN SUTTER-YUBA AREA

Crop	Number of plots			Applied water, in feet of depth		
	1948	1949	Total	1948	1949	Weighted average for the two seasons

Sugar beets	1	0	1	1.45	--	1.45
Walnuts	4	1	5	2.04	1.90	2.00

Studies were made to determine the approximate average irrigation efficiency realized from application of ground water in the Sutter-Yuba Area during the 1947-48 season. "Irrigation efficiency" is defined as the ratio of consumptive use of applied water to the total amount of applied water, and is commonly expressed as a percentage.

In order to estimate the total amount of ground water applied for irrigation in the Sutter-Yuba Area in 1947-48, appropriate crop acreages, as mapped in the cultural survey, were multiplied by average seasonal values of depth of applied water for the several crops, as measured at the representative plots listed in Table 32. This computation resulted in an estimate of 347,000 acre-feet. As a check on this figure, the Pacific Gas and Electric Company furnished a corresponding estimate of 317,000 acre-feet based on records of electric power consumption for pumping. The company's estimate gave consideration to the relationship between pumping plant horsepower, drawdown, and power consumption per unit of water pumped at various lifts, as determined by pump performance tests conducted in the area by the company. In view of the nature of the basic data, the check furnished was believed to have been reasonably close.

By dividing the estimated value of 165,600 acre-feet for consumptive use of ground water on irrigated lands in the Sutter-Yuba Area in 1947-48, presented in Table 30, by the foregoing estimated value of 347,000 acre-feet, it was estimated that the irrigation efficiency realized from application of ground water in the Sutter-Yuba Area during 1947-48 was approximately 48 percent. This efficiency may be considered to be indicative of average irrigation practice in the Sacramento Valley. It was impracticable to make a corresponding estimate of irrigation efficiency realized from use of surface water in the Sutter-Yuba Area because of lack of sufficient data regarding application of surface water for irrigation purposes.

Gross Diversion of Water. The amount of the gross diversion for irrigation by ground water in the Sutter-Yuba Area was considered to be equivalent to the amount of applied ground water. As discussed in the preceding section, this was estimated to have totaled 347,000 acre-feet during 1947-48.

The gross diversion for irrigation by surface water in the Sutter-Yuba Area was estimated to have totaled about 362,000 acre-feet during 1947-48. This estimate was based on records of measurement of all surface diversions in the area, plus the estimate of importation by the Sutter Butte Canal system presented in Chapter II.

By subtracting from total consumptive use of water on irrigated lands the corresponding consumptive use of ground water and precipitation, the approximate amount of consumptive use of applied surface water was estimated. An estimate of total consumptive use of water on irrigated lands of the Sutter-Yuba Area in 1947-48, in the amount of 469,000 acre-feet, was presented in Table 28. Consumptive use of ground water on irrigated lands was estimated to have been 165,600 acre-feet in 1947-48, as shown in Table 30. It was further estimated that consumptive use of precipitation on the 138,700 acres of irrigated lands in the Sutter-Yuba Area in 1947-48 was equal to 1.3 feet of depth, or a total amount of 180,400 acre-feet. It follows that the estimated amount of consumptive use of surface water applied for irrigation in the area was approximately 123,000 acre-feet in 1947-48.

It is indicated from the foregoing that only about 123,000 acre-feet, or about 34 percent of the estimated 362,000 acre-feet of gross surface diversion for irrigation in the Sutter-Yuba Area in 1947-48, was actually consumed in production of crops. It should be noted that this figure is not comparable with estimated irrigation efficiency attained in connection with use of ground water in the area, evaluated in the preceding section, since it is based on the amount of gross diversion rather than the amount of applied water. Insufficient data were available to permit evaluation of transmission and other losses encountered in connection with use of surface water between points of diversion and places of use.

Monthly Demands for Irrigation Water. Because of the wide variety of crops produced in the Sutter-Yuba Area there is considerable variation in both rate and period of demand for irrigation water. On the

average, the irrigation demand occurs during the months of April through October. Studies of irrigation practice in the Sutter-Yuba Area indicated that for certain crops the maximum monthly demand might be as much as 45 percent of the seasonal total. Based on these studies, and on similar studies made in other areas, the estimated average monthly distribution of demand for irrigation water in the West Side Zone and in the remainder of the Sutter-Yuba Area is set forth in Table 33. Because of the predominance of orchard and truck crops in the West Side Zone, monthly distribution in that zone varies somewhat from that in the remainder of the area. Early applications to rice and irrigated pasture account for the greater part of the demand for water in April and May.

Permissible Deficiencies in Application of Irrigation Water. Studies to determine deficiencies in the supply of irrigation water that might be endured without permanent injury to perennial crops were not made in connection with the Sutter-Yuba Counties Investigation. However, the results of past investigation and study of endurable deficiencies in the Sacramento River Basin are believed to be applicable to the Sutter-Yuba Area. In this respect, the following is quoted from Division of Water Resources Bulletin No. 26, "Sacramento River Basin," 1931.

"* * * A full irrigation supply furnishes water not only for the consumptive use of the plant but also for evaporation from the surface during application and from the moist ground surface, and for water which is lost through percolation to depths beyond the reach of the plant roots. Less water can be used in years of deficiency in supply by careful application and by more thorough cultivation to conserve the ground moisture. In these ways the plant can be furnished its full consumptive use with much smaller amounts of water than those ordinarily applied and the yield will not be decreased. If the supply is too deficient to provide the full consumptive use, the plant can sustain life on smaller amounts but the crop yield will probably be less than normal.

"It is believed from a study of such data as are available that a maximum deficiency of 35 per cent of the full seasonal requirement can be endured, if the deficiency occurs only at relatively long intervals. It is also believed that small deficiencies occurring at relatively frequent intervals can be endured. * * *"

SUPPLEMENTAL WATER REQUIREMENTS

The previously presented data, estimates, and discussion regarding water supply and utilization in the Sutter-Yuba Area indicate that present and probable future water problems of the area are largely limited to those connected with ground water and that their effects are largely related to irrigated agriculture. It is further indicated that ground water problems, including those created in various portions of the area by progressive lowering of water levels, degradation of mineral quality of ground water, and low yield of wells, may be eliminated or prevented if adequate supplemental water supplies are developed and utilized in the area. The estimated present and probable ultimate requirements for supplemental water in the Sutter-Yuba Area are discussed and evaluated in the following sections. As previously defined, requirement for supplemental water refers to the amount of water, over and above the sum of safe ground water yield and safe surface water yield, which must be developed to satisfy water utilization. Water utilization in turn refers to the sum of consumptive use of water and those irrecoverable losses of water incidental to its beneficial use.

Present Supplemental Requirement

The present requirement for supplemental water in the Sutter-Yuba Area was evaluated as the difference between safe yield of ground water and present consumptive use of ground water. It might be argued that this evaluation fails to give consideration to possible inadequacies in service of surface water to portions of the area. However, in the solution of the equation of hydrologic equilibrium, presented in Table 15, upon which the estimate of safe ground water yield was based, the unit consumptive use factors chosen assumed a full and sufficient application of water on all irrigated lands whether from surface sources or ground water. It follows that any possible present inadequacy in surface water service was taken into account and provided for in the estimate of safe ground water yield.

It was estimated in Chapter II that safe seasonal ground water yield in the Sutter-Yuba Area amounted to 186,100 acre-feet. This was determined as the seasonal net extraction of water from the ground water basin that might be maintained, under mean conditions of water supply and climate, without further progressive lowering of the water table below levels prevailing in 1948-49. Seasonal consumptive use of ground water in the area, with present culture and under mean conditions of water supply and climate, was estimated to be 264,700 acre-feet, as shown in Table 30. The estimated present requirement for supplemental water in the Sutter-Yuba Area, therefore, is 78,600 acre-feet per season. This estimate is presented in Table 34, which shows distribution of the supple-

mental water requirement among the several zones of the area. The distribution was based on the assumption that lowering of water levels which occurred during the season of 1948-49 would have been proportionately the same had mean water supply and climatic conditions prevailed.

TABLE 34

ESTIMATED PRESENT MEAN SEASONAL SUPPLEMENTAL WATER REQUIREMENT IN ZONES OF SUTTER-YUBA AREA

Zone	Acre-feet
West Side	
Peach Bowl	14,900
Outside Peach Bowl	2,100
Northeast	6,400
East Central	27,600
South Side	27,600
TOTAL	78,600

It was shown in Chapter II that an area of about 4,500 acres in the West Side Zone south of Oswald Road was irrigated in the summer of 1950 with ground water containing chlorides at or above the upper limit of safe use for irrigation. A substitute water supply is presently required for these lands, the amount of which may be determined by the required amount of applied water. This is true because any unconsumed portion of applied water would be so degraded after percolating to the underlying saline ground water as to preclude its re-use. Seasonal application of water to the orchard and truck crops grown in the Peach Bowl averages about 3.0 feet of depth, as determined by plot studies conducted during the investigation. However, if water of good mineral quality were substituted for the inferior ground water now used, leaching irrigations would not be required. It was estimated that under such conditions the seasonal application of water would be about 2.5 feet of depth, corresponding to average good practice in the Sutter-Yuba Area for irrigation of orchard and truck crops. On this basis the estimated amount of the substitute water supply presently required in the West Side Zone in lieu of ground water of excessive salinity is about 11,300 acre-feet per season. This is less than the estimated present supplemental requirement of 17,000 acre-feet per season required to prevent progressive and permanent lowering of water levels in the West Side Zone. Therefore, by furnishing a supplemental surface water supply to the West Side Zone sufficient to prevent progressive and permanent lowering of the water table, the present problem with respect to inferior mineral quality of the ground water would be eliminated.

Probable Ultimate Supplemental Requirement

The probable ultimate requirement for supplemental water in the Sutter-Yuba Area was evaluated as the difference between present and probable ultimate utilization of water, plus the present requirement for supplemental water. Development and utilization of a supplemental water supply in the amount of this forecast would assure an adequate supply of water for lands presently irrigated in the area, as well as for those irrigable lands not presently served with water. Furthermore, present problems resulting from progressive and permanent lowering of water levels, degradation of mineral quality of ground water, and low yield of wells would be eliminated.

Estimates of present and probable ultimate utilization of water in the Sutter-Yuba Area, under mean conditions of water supply and climate, were presented in Tables 29 and 31, respectively, and a corresponding estimate of the present requirement for supplemental water was developed in the preceding section. Utilizing these estimates, the forecast of probable ultimate seasonal requirement for supplemental water by zones of the Sutter-Yuba Area, under mean conditions of water supply and climate, is presented in Table 35.

TABLE 35

PROBABLE ULTIMATE MEAN SEASONAL SUPPLEMENTAL WATER REQUIREMENT IN ZONES OF SUTTER-YUBA AREA

(In acre-feet)

Zone	1	2	3	4	5
	Present water utilization	Probable ultimate water utilization	Probable increase in water utilization (2 — 1)	Present supplemental water requirement	Probable ultimate supplemental water requirement (3 + 4)
West Side	310,700	384,300	73,600	17,000	90,600
Northeast	112,500	136,200	23,700	6,400	30,100
East Central	201,200	255,500	54,300	27,600	81,900
South Side	193,700	278,300	84,600	27,600	112,200
TOTALS	818,100	1,054,300	236,200	78,600	314,800

CHAPTER IV

PLANS FOR WATER DEVELOPMENT

It has been shown heretofore that the present basic water problems in the Sutter-Yuba Area are progressive and permanent lowering of ground water levels and attendant degradation of mineral quality of the ground water. Elimination of these problems, prevention of their recurrence in the future, and irrigation of irrigable lands not presently served with water will require further conservation development of available water supplies. In the preceding chapter, estimates were presented as to the amount of supplemental water required for these purposes both at the present time and under probable ultimate conditions of cultural development.

It has been shown that large surplus flows of water are presently available to the Sutter-Yuba Area from the highly productive watershed of the Feather River system, including the Yuba and Bear Rivers and minor tributary streams. This surface water is available during the snowmelt period of every season, and, in all but very dry seasons, flows sufficient to meet present supplemental requirements of the area are available into the summer months. Studies which are described in this chapter indicate that the surplus flows, if properly controlled and regulated, would more than supply the probable ultimate water requirements of the Sutter-Yuba Area.

As was stated in Chapter I, the Division of Water Resources is presently conducting surveys and studies for the State-wide Water Resources Investigation, under direction of the State Water Resources Board. This investigation has as its objective the formulation of The California Water Plan, for full conservation, control, and utilization of the State's water resources, to meet present and future water needs for all beneficial purposes and uses in all parts of the State, insofar as practicable. Surveys and studies are also being conducted by the Division of Water Resources for the Survey of Mountainous Areas. This investigation, which is coordinated with the state-wide investigation, has as its primary objective the determination of probable ultimate water requirements of certain counties of the Sierra Nevada, and the formulation of plans for projects which will meet those requirements. Although these investigations are still in progress, they are sufficiently advanced to permit tentative description of certain major features of The California Water Plan which would provide supplemental water to meet the probable ultimate requirements of the Sutter-Yuba Area. The projects would also provide supplemental water supplies for other water-deficient areas of California. In addition, benefits from the projects would include hydroelectric power, flood and salinity control, mining debris storage, and incidental benefits in the interests of recreation and the preservation of fish and wildlife.

In general, the major features of The California Water Plan, which were mentioned in the preceding paragraph, would be large multipurpose projects requiring relatively large capital expenditures. Their scope, with regard to both location of the works and benefits derived from their operation, would not be limited to the Sutter-Yuba Area, but would embrace other portions of California. Much additional study will be required to estimate costs and to determine possible means of financing these large projects. Under the Sutter-Yuba Counties Investigation, therefore, numerous surveys and studies were made in order to estimate costs of supplemental water supplies for the Sutter-Yuba Area under more localized plans that might be suitable for current financing, construction, and operation by appropriate local public agencies. These plans for initial development generally are such that the works could be integrated into future major projects. Their purposes are largely limited to conservation of new water supplies sufficient to meet the present requirements of the Sutter-Yuba Area and to provide for limited future growth in water demands of the area.

Major features of The California Water Plan which would be pertinent to solution of the ultimate water problems of the Sutter-Yuba Area are described in general terms in this chapter under the heading "The California Water Plan." These projects will be more specifically described in future reports of the State Water Resources Board. The several plans for possible initial local development of supplemental water supplies which were given consideration in connection with the Sutter-Yuba Counties Investigation are described in this chapter under the heading "Plans for Initial Local Development." All such plans considered would be subject to vested rights. Specific plans are presented for the more favorable of these local projects, together with estimates of capital and annual costs and unit costs of the developed supplemental water supplies. Location of the principal features of the several possible plans, for both initial and future construction, are shown on Plate 18, "Potential Water Storage Developments."

THE CALIFORNIA WATER PLAN

The Feather River Project, an adopted feature of The California Water Plan, is described in the following section, where it is shown that it will provide supplemental water to meet the probable ultimate

requirement of the West Side Zone. Several other major projects, which would involve multipurpose water resources developments on the Yuba and Bear Rivers and other tributaries of the Feather River, are briefly described in an ensuing section. These latter projects would provide supplemental water to meet the probable ultimate requirements of the Northeast, East Central, and South Side Zones, and are tentatively being considered as possible features of The California Water Plan.

Feather River Project

The probable ultimate supplemental water requirement in the West Side Zone could be met under a plan which would provide upstream regulatory storage on the Feather River to enhance and firm the summer flow of the stream. Such storage will be made available by construction of Oroville Dam and Reservoir, units of the Feather River Project, which are described in detail in a publication of the State Water Resources Board entitled "Report on Feasibility of Feather River Project and Sacramento-San Joaquin Delta Diversion Projects Proposed as Features of The California Water Plan," dated May, 1951. These projects were authorized and adopted by the 1951 Legislature in an act which authorized their construction, operation, and maintenance by the Water Project Authority of the State of California. Provision was made in the authorizing act for financing construction of the proposed works through issuance and sale of revenue bonds and through receipt of contributions from other sources. In May, 1952, the Legislature provided $800,000, by budgetary appropriation to the Division of Water Resources, for necessary investigations, surveys, and studies, and preparation of plans and specifications for the Feather River and Sacramento-San Joaquin Delta Diversion Projects.

The multipurpose Feather River Project contemplates construction of a gravity concrete dam, 710 feet in height above stream bed, at a point on the Feather River 1.7 miles below the junction of the North and Middle Forks and 5.5 miles above the City of Oroville. The dam will have an overpour spillway. It will create a reservoir of 3,500,000 acre-foot storage capacity, and will provide a large measure of control of the runoff of the Feather River for purposes of conservation, flood control, hydroelectric power generation, and other beneficial uses. Provision will be made for a power plant located at the dam, of 440,000 kilowatt capacity, and for an afterbay dam, and power plant of 25,000 kilowatt capacity, located four miles downstream from the main dam. The foregoing features of the Feather River Project are shown on Plate 18. The project also includes construction of a power transmission line from the Oroville power plants to Bethany, near Tracy in San Joaquin County, and a switch yard at the terminal. A channel crossing of the Sacramento-San Joaquin Delta will be required to carry Oroville Reservoir releases from the Sacramento River to the San Joaquin River Delta for subsequent transmission to water-deficient areas in other parts of California.

In studies for the cited feasibility report of the State Water Resources Board, Oroville Reservoir was operated to first meet the water requirements of the Feather River Service Area, shown on Plate 18. The West Side Zone of the Sutter-Yuba Area is contained within the described Feather River Service Area.

Under the plan of operation of Oroville Reservoir described in the foregoing feasibility report, releases of water would be made sufficient to meet gross demands of the Feather River Service Area under ultimate conditions of irrigation development. The estimate of seasonal gross demand for water under such conditions was 970,000 acre-feet, which, with an assumed irrigation efficiency of 65 percent, would provide for consumptive use of water, over and above effective rainfall, in the amount of 631,000 acre-feet per season. Of this estimated ultimate consumptive use of applied water in the Feather River Service Area, 311,000 acre-feet per season would be new water over and above present utilization. Studies indicate that the probable ultimate supplemental water requirement of the West Side Zone, estimated to be some 90,000 acre-feet per season, could readily be supplied from the foregoing 311,000 acre-feet of new water from Oroville Reservoir.

Detailed estimates of cost of the Feather River Project are presented in the feasibility report. A summary of estimated capital costs of the project is given in Table 36. The estimates of capital cost were based on prices prevailing in 1951, and included allowances of 10 percent for administration and engineering, 15 percent for contingencies, and 3 percent for interest during one-half of the estimated construction period.

TABLE 36

SUMMARY OF ESTIMATED CAPITAL COSTS OF FEATHER RIVER PROJECT

Oroville Dam and Reservoir	$342,626,000
Oroville Power Plant	64,509,000
Oroville Afterbay and Power Plant	14,146,000
Oroville Transmission Line	17,124,000
Terminal Switchyard	2,610,000
Delta Cross Channel	3,798,000
TOTAL	$444,813,000

It was assumed in the cost analyses presented in the feasibility report that the Federal Government would contribute to the Feather River Project the sum of $50,000,000, without reimbursement, in the interest of flood control. Substantial flood control benefits to land

and communities along the Feather River would result from operation of the project. There is well-established federal policy for such financial participation in projects of this character. It was also assumed that the State of California would contribute to the Feather River Project the sum of $86,926,000 in the interests of flood control and water development. This contribution would likewise be without reimbursement, and would be accomplished by assuming the costs of lands and improvements flooded and of necessary relocation of utilities. Such financial participation by the State would be justified under the policy set forth in the State Water Resources Act of 1945, as amended. If these federal and state contributions to the Feather River Project were forthcoming, capital costs shown in Table 36 would be reduced to $307,887,000. Based on this estimated capital cost, it was further estimated that annual costs of the project would be about $14,791,000 based upon 2 percent interest, and about $16,272,000 based on 3 percent interest. The annual costs included interest, repayment, replacement, operation and maintenance, insurance, and general expenses. In the cost analysis it was shown that annual costs based upon the 2 percent interest rate could be met under the schedule of revenues shown in the following tabulation, but that an annual deficit of some $1,426,000 would occur with the 3 percent rate.

Item	*Unit charge*	*Annual revenue*
311,000 acre-feet of new water delivered to Feather River Service Area (includes West Side Zone)	$1.00	$311,000
2,845,000 acre-feet of new water delivered to Delta	1.00	2,845,000
1,670,000,000 kilowatt-hours of electrical energy at terminal substation	0.007	11,690,000
TOTAL		$14,846,000

Based on the foregoing assumptions, the estimated cost of water from the Feather River Project to water users in the West Side Zone would be about $1 per acre-foot at the streamside. This estimate does not include costs for diverting the water from the Feather River and conveying it to and distributing it in areas of use in the West Side Zone. Studies indicate that a practicable means for diverting the water from the river would be by pumping plants strategically located along the river, discharging into appropriate conveyance and distribution systems. Diversion also could be made by gravity with construction of a diversion weir and headgates at a suitable upstream site.

Other Major Projects Under Consideration

Surveys and studies in connection with the Statewide Water Resources Investigation and the Survey of Mountainous Areas indicate that it would be feasible from the engineering standpoint to so regulate and conserve the relatively large flood flows of the Yuba and Bear Rivers and other tributaries of the Feather River as to yield firm water supplies considerably in excess of the probable ultimate supplemental water requirements of the Northeast, East Central, and South Side Zones. Existing water resources developments on these streams, together with tentative locations of possible future dams and reservoirs, are shown on Plate 18.

In addition to the studies by the Division of Water Resources, the Oroville-Wyandotte Irrigation District is currently investigating a plan for multipurpose development of the water resources of the South Fork of the Feather River. Principal features of this project, which is in an advanced planning phase, are delineated on Plate 19, "Plans for Development of South Fork of Feather River." The district is considering the diversion of waters of both the South Fork of the Feather River and Slate Creek through tunnels to the proposed Lost-Sly Creek Reservoir, to be created by construction of a dam immediately above the flow line of the existing Lost Creek Reservoir on the stream of that name. Conservation and regulatory storage would be created on the South Fork by construction of Little Grass Valley Reservoir, and on Slate Creek by construction of the small Slate Creek Reservoir. Water released from Lost-Sly Creek Reservoir would flow into Lost Creek Reservoir, and then through a proposed pressure tunnel to the penstock of the proposed Woodleaf Power House, to be located on the South Fork about one mile below its junction with Lost Creek. From the afterbay of this plant the water would flow through another tunnel to the penstock of the proposed Forbestown Power House, also to be located on the South Fork. Construction of a canal is proposed from the Forbestown Power House afterbay along the left or south bank of the South Fork of the Feather River to a point about two miles west of Lake Wyandotte, to serve lands of the Oroville-Wyandotte Irrigation District to the west of the canal. It is feasible from an engineering standpoint to extend the canal in a southerly direction a distance of some 25 miles to South Honcut Creek.

As a possible alternative to the Oroville-Wyandotte Irrigation District's project, the Division of Water Resources is studying another plan for multipurpose development of the South Fork of the Feather River. This plan contemplates construction of the proposed Little Grass Valley Reservoir on the South Fork, and diversion of the conserved water at a point about 1½ miles below the dam through a tunnel to Fall River. Water would also be diverted from South Branch of Middle Fork of Feather River to Fall River through a tunnel. A dam on Fall River would divert its own flows and water from the two foregoing diversions through a tunnel to the penstock of the proposed Lumpkin Power House on the South Fork of Feather River. A tunnel would convey the water from the afterbay of this plant to an enlarged Lost Creek Reservoir, which

would be created by construction of a higher dam approximately at the site of the existing structure. The plan also contemplates construction of a small reservoir on Canyon Creek, and a diversion tunnel to the proposed Slate Creek Diversion Dam. From this dam the Slate Creek water and water from Canyon Creek would be diverted through a tunnel to a point on Lost Creek above the proposed enlarged reservoir. Releases from Lost Creek Reservoir would be made through a tunnel to a diversion dam on Grizzly Creek and from this dam through a canal and siphons to the penstock of the proposed Golden Gate Power House, to be located on Golden Gate Canyon at the headwaters of French Dry Creek. From the afterbay of this plant, a conduit, including canal and siphon sections, would lead to the penstock of the proposed Brownsville Power House, to be located on French Dry Creek at Brownsville. A canal would lead from the afterbay of the Brownsville plant to a saddle between the drainage areas of French Dry and South Honcut Creeks. At this point the canal would divide, with one branch bearing generally westerly and discharging into the existing Forbestown Ditch and thence into Lake Wyandotte. The other branch would bear southwesterly and terminate at the penstock of the proposed Honcut Power House, to be located on South Honcut Creek below its confluence with Natchez Creek. From the afterbay of the Honcut Power House a canal would extend along the right bank of South Honcut Creek and then bear northerly, terminating east of Oroville. This canal would serve lands of the Oroville-Wyandotte Irrigation District and adjacent irrigable lands lying to the west of the canal. Construction of a dam on South Honcut Creek is contemplated under the plan to create a reservoir the flow line of which would extend to the Honcut Power House afterbay. Water released from South Honcut Creek Reservoir would be diverted at appropriate downstream points on South Honcut Creek to serve lands in Browns Valley and on the Sacramento Valley floor east of the Feather River. Other diversions for irrigation and other beneficial uses in remaining water service areas between the Feather and Yuba Rivers could be made from the system.

Tentative plans for ultimate development of the Yuba River contemplate increasing the storage capacity of the existing Bullards Bar Reservoir on the North Yuba River, or providing equivalent increased capacity upstream at Kellys Bar, together with hydroelectric power development of the upper North Yuba River. Construction of a dam and reservoir on the Middle Yuba River at Granite Point is also under consideration, together with a diversion tunnel to the existing afterbay of the Bullards Bar Power House. Waters of the South Yuba River would be diverted at Edwards Crossing and conveyed by a proposed tunnel to the Granite Point Reservoir. Both the Middle and South Yuba Rivers offer possibilities for construction of dams and reservoirs, principally in the interests of mining debris storage and flood control.

The State Water Plan, as adopted by the Legislature in 1941, contemplates a storage capacity in the Englebright Reservoir on the Yuba River of about 850,000 acre-feet, as compared to the 70,000 acre-foot capacity of the existing Englebright Reservoir. This additional capacity would provide substantial conservation, flood control, and hydroelectric power, but would inundate the existing Colgate Power House, recently enlarged by the Pacific Gas and Electric Company. As a possible alternative, construction of offstream storage for waters of the Yuba River at the Waldo site, on Dry Creek, about nine miles northeast of Wheatland, is under consideration. This plan would involve construction of a conduit, diverting from Englebright Reservoir at the spillway elevation, to convey flood waters of the Yuba River to the proposed Waldo Reservoir. Under the plan, Waldo Reservoir in turn would spill into the proposed enlarged Camp Far West Reservoir on Bear River, which is hereinafter described. Consideration is also being given to possible construction of one or more additional reservoirs at the Garden Bar, Parker, or Rollins sites, upstream from the Camp Far West site on the Bear River, to effect more complete conservation of flood waters of that stream.

Studies indicate that the Northeast Zone could be served with an ultimate supplemental water supply either from the South Fork of the Feather River under the plan of development hereinbefore described, or from the Yuba River. Service from the Yuba River could be made by enlargement of the existing Hallwood-Cordua system or by diversion from the Yuba River at a suitable site in the vicinity of Parks Bar, and distribution by gravity from a main conduit bearing in a northerly direction roughly along the eastern boundary of the zone. It has been estimated that the amount of the probable ultimate mean seasonal supplemental water requirement of the Northeast Zone will be about 30,000 acre-feet. A water supply in this amount, under an appropriate schedule of demands, could be made available to the Northeast Zone by construction of one or more of the previously described major upstream projects.

It is indicated that under ultimate conditions of development the East Central Zone could also be served with supplemental water from the Yuba River. It has been estimated that the amount of the probable ultimate mean seasonal water requirement of the zone will be about 82,000 acre-feet. A portion of the required supplemental supply could be diverted, under an appropriate schedule of demands, directly from the Yuba River above Hammonton, and conveyed in a southerly direction to Hutchinson Creek, by rehabilitation and extension of the abandoned Yuba River Ditch of the Yuba Consolidated Gold Fields. Conserved water of the Yuba River to meet the remainder of the ultimate

supplemental water requirement of the East Central Zone could be released from the proposed Waldo Reservoir for downstream diversion and conveyance to areas of use.

Studies also indicate that under ultimate conditions of development the South Side Zone could be served with a supplemental water supply released, under an appropriate schedule of demands, from the proposed Camp Far West Reservoir. It has been estimated that the amount of the probable ultimate mean seasonal supplemental water requirement of the zone will be about 112,000 acre-feet. A supply in this amount would be available in Camp Far West Reservoir, and would consist of waters of the Yuba and Bear Rivers and Dry Creek conserved jointly by the proposed Waldo Reservoir, Camp Far West Reservoir, and upstream reservoirs on the Bear River. It could be conveyed to points of use in the South Side Zone by an enlarged system similar to that described hereinafter in connection with the Camp Far West Project.

PLANS FOR INITIAL LOCAL DEVELOPMENT

Possible plans for initial local development of supplemental water supplies for the Sutter-Yuba Area, together with cost estimates, are described in this section. Design of features of the plans was necessarily of a preliminary nature and primarily for cost estimating purposes. More detailed investigation, which would be required in order to prepare plans and specifications, might result in designs differing in detail from those presented in this report. However, it is believed that such changes would not be significant.

Capital costs of dams, reservoirs, diversion works, conduits, pumping plants, and appurtenances, included in the considered conservation, conveyance, and distribution systems, were estimated from preliminary designs based largely on data from surveys made during the current investigation. Approximate construction quantities were estimated from these preliminary designs. Unit prices of construction items were determined from recent bid data on projects similar to those in question, or from manufacturers' cost lists, and are considered representative of prices prevailing in April, 1952. The estimates of capital cost included costs of rights of way and construction, and interest during one-half of the estimated construction period at 3 percent per annum, plus 10 percent for engineering, and 15 percent of construction costs for contingencies. Estimates of annual costs included interest on the capital investment at 3 percent, amortization over a 50-year period on a 3 percent sinking fund basis, replacement, operation, and maintenance costs, and costs of electrical energy for pumping.

Because of geographical considerations, and respective types of water service and water supplies in the several zones of the Sutter-Yuba Area, possible plans for initial water development are presented in this section separately for the West Side, Northeast, East Central, and South Side Zones.

West Side Zone

In Chapter III it was shown that the present requirement for supplemental water in the West Side Zone is about 17,000 acre-feet per season. However, in the design of projects for initial local development to meet this requirement, it was considered desirable to provide some capacity for future growth in water demand which would occur through development of irrigable lands not presently irrigated. This additional capacity was estimated at about 7,000 acre-feet per season, giving consideration to the extent of undeveloped irrigable lands that might readily be served, and to the available sources of water supply. For reasons hereinafter discussed it was considered that the new water supply would be applied to about 7,000 acres of land in the Peach Bowl, of which about 4,500 acres are presently irrigated by ground water containing chlorides at or above the safe limit for irrigation use, and 2,500 acres are irrigable lands not presently served with water. These lands are contained within a service area lying generally to the south of Oswald Road, and delineated on Plate 20, "Peach Bowl Project."

Three possible alternative plans of works for initial construction to provide supplemental water to the West Side Zone were considered. For reasons hereinafter mentioned, after preliminary investigation and study the first two plans were given no further consideration for present cost estimating purposes, but may warrant future study. The third plan is described in some detail later in this section.

Alternative Plans Considered. The first of the alternative plans considered for initial construction included salvage of water in high water table lands of the Sutter Butte Canal service area, and its conveyance to and use in the Peach Bowl. This would involve the installation of batteries of wells in the high water table area, conveyance of the pumped ground water to the Peach Bowl either in conduits or in the channel of the Feather River, and distribution of the water in a strategically situated service area of heavy ground water pumping draft in the Peach Bowl. The new water supply would largely replace ground water presently used in the Peach Bowl service area, thereby preventing progressive and permanent lowering of ground water levels and attendant degradation of mineral quality of the ground water throughout the Peach Bowl and adjacent ground water service areas. However, preliminary investigation and study indicated that changes in the crop pattern and in irrigation practice in the Sutter Butte Canal service area, which would be necessary for consummation of this plan, would be difficult to effect, and that cost of the salvaged water would be greater than for water yielded under the third plan

Feather River in the Vicinity of Starr Bend, Looking Upstream

herein described. For these reasons, this plan was given no further present consideration.

Consideration was also given to the provision of a supplemental water supply to the Peach Bowl service area from the Feather River, by extension of the conveyance and distribution system of the Sutter Butte Canal. As in the case of the first plan described, use of the new surface water supply would prevent progressive and permanent lowering of water levels, and attendant degradation of mineral quality of ground water, in the area served and in adjacent areas. Preliminary investigation and study of this second plan for initial construction indicated that existing diversion facilities might be adequate for such purpose, but that conveyance facilities would require enlargement. Furthermore, a canal to serve lands requiring supplemental water in the Peach Bowl would have to be constructed on a relatively flat slope over a long distance through highly developed orchard lands. The canal would also pass through urban areas lying immediately south and west of Yuba City. It was indicated from investigation and study that cost of the new water supply would be greater than under the third plan hereinafter described. For these reasons, this plan was given no further present consideration.

The third of the alternative plans considered for initial construction would provide for the present supplemental water requirement in the West Side Zone, and for growth in water utilization for a number of years in the future. It would include the construction of facilities for pumping water directly from the Feather River and for its conveyance to and distribution in the service area in the Peach Bowl. As in the case of the two previous plans, use of the new surface water supply would prevent progressive and permanent lowering of ground water levels and degradation of mineral quality of the ground water, in the area served and in adjacent areas. This plan is hereinafter referred to as the "Peach Bowl Project," and its principal features are delineated on Plate 20.

Peach Bowl Project. Satisfactory sites for a pumping plant to divert flow of the Feather River exist on the right or west bank of the river along the reach one-half mile north and south of the prolongation of Hutchinson Road. The site selected for cost estimating purposes is at a point about four miles south of Shanghai Bend, near the center of Section 26, Township 13 North, Range 3 East, M.D.B. & M. Conveyance and distribution of water pumped from the Feather River to the area of use would be accomplished by means of a combination system including lined and unlined canals, and ditches, and the utilization of existing individual distribution systems insofar as possible. The lands which would be irrigated with the new water supply comprise the aforementioned 7,000 acres within the service area shown on Plate 20, ranging in elevation from approximately 45 feet at the north boundary to approximately 30 feet in the southerly portion.

Since the Peach Bowl constitutes a free ground water area, water losses in conveyance and distribution of the new water supply would largely percolate to the ground water. For this reason it was assumed that these losses, plus the unconsumed portion of the new water supply applied to irrigation would be effective in preventing progressive and permanent lowering of ground water levels and degradation of mineral quality of the ground water. The acreage to be irrigated by the supplemental supply would depend on the amount of the gross diversion, water losses encountered in conveyance and distribution, and the requirement for application of water to the lands irrigated.

For cost estimating purposes the Peach Bowl Project was designed to provide a gross seasonal supplemental surface water supply of approximately 24,000 acre-feet, of which about 17,000 acre-feet is necessary to meet the present supplemental requirement, and the remainder would be available for additional development of irrigable lands. An estimate of the monthly distribution of demand for irrigation water in the West Side Zone was presented in Table 33. Based on these data, the monthly gross demand for water for the Peach Bowl Project would be as shown in Table 37.

TABLE 37

ESTIMATED MONTHLY DISTRIBUTION OF GROSS DEMAND FOR WATER FOR THE PEACH BOWL PROJECT

Month	Percent of seasonal total	Demand for water, in acre-feet
April	2	480
May	13	3,120
June	21	5,040
July	27	6,480
August	21	5,040
September	12	2,880
October	4	960
TOTALS	100	24,000

Based upon known soil characteristics in the Peach Bowl and upon irrigation experience elsewhere, it was assumed that water losses in conveyance and distribution of a new surface water supply would amount to about 25 percent of the gross diversion, leaving about 18,000 acre-feet per season for application to irrigated lands. Lands in the Peach Bowl to be served with the new water supply and presently irrigated by ground water comprise about 4,500 acres of highly developed orchard. From results of the plot studies of water application described in Chapter III, it was estimated that these orchard lands would require a

seasonal application of irrigation water in an amount of about 2.5 acre-feet per acre, or a total of about 11,000 acre-feet. The remaining 7,000 acre-feet of water per season available under the Peach Bowl Project, as designed, would serve about 2,500 acres of irrigable lands, presently not served with water, lying to the west of the foregoing orchard lands. If developed, it was considered that these irrigable lands would probably largely be devoted to truck and general row crops, with limited amounts of rice and irrigated pasture. Based on results of the cited plot studies, it was estimated that these lands would require a seasonal application of irrigation water in an amount of about 2.8 acre-feet per acre.

No record was available of flow in the Feather River at the proposed point of pumping diversion. However, records were available of monthly flow at Shanghai Bend some four miles upstream from the proposed diversion point, and at Nicolaus some 11 miles downstream therefrom. The Shanghai Bend record dated from 1940, while that for Nicolaus was continuous since 1921, although prior to 1939 records of stream flow at the latter station were obtained only during summer months of low flow. Studies were made of these records and of measurements of diversions from the Feather River in the reach between the two stations. These studies indicated that during the irrigation season probable flow at the proposed diversion for the Peach Bowl Project was greater than recorded flow in the Feather River at Nicolaus. Therefore, the assumption that flows available for the pumping diversion were equal to those measured at Nicolaus was considered to be conservative.

It was determined that during the critical months of July, August, and September, tributary inflow to the Feather River from the Bear River was negligible. For this reason, any future conservation development on this tributary would not adversely affect the assumption as to flow in the Feather River at the proposed point of diversion during the critical summer months. Furthermore, records of the Sacramento-San Joaquin Water Supervision indicated that the amount of existing diversions from the Feather River between Nicolaus and the confluence with the Sacramento River, during the critical summer months of low flow, is insufficient to materially affect the estimates of water supply available in the Feather River for diversion to the Peach Bowl.

Available records of monthly stream flow of the Feather River at Nicolaus during the irrigation season are presented in Table 38. Comparison of these recorded flows with the estimated monthly gross demands of the Peach Bowl Project, presented in Table 37, indicates that during the period from 1921 through 1950 ample water was available from the Feather River to meet demands of the project, as designed, except during the two seasons of 1924 and 1931. During these seasons irrigation deficiencies of approximately 40 and 25 percent, respectively, would have occurred. From past experience in the Sacramento Valley, it is considered probable that such deficiencies could be endured without permanent damage.

TABLE 38

MEASURED MONTHLY FLOW OF FEATHER RIVER AT NICOLAUS DURING THE IRRIGATION SEASON, 1921 THROUGH 1950

(In acre-feet)

Year	Runoff index	April	May	June	July	August	September	October
1921	129				61,870	23,195	25,035	49,140
1922	109				181,000	48,300	49,200	49,200
1923	67				111,000	52,100	72,000	126,000
1924	28			6,780	1,780	609	20,900	93,500

1949	57	809,700	533,500	98,060	13,920	9,230	27,480	39,430
1950	84	1,099,000	834,900	327,200	40,030	18,230	71,500	163,500

Studies indicated that the maximum monthly diversion for the Peach Bowl Project would occur in July, and that it would amount to about 27 percent of the total seasonal diversion of 24,000 acre-feet, equivalent to a continuous flow of about 105 second-feet throughout the month. For cost estimating purposes the pumping plant for the project was designed with a total pumping capacity of 135 second-feet. This installation would meet the estimated maximum rate of demand, provide additional capacity for shorter-term peaking in excess of the average monthly rate, and provide stand-by capacity to assure continuous service in case of breakdown.

Features of the pumping plant considered for the Peach Bowl Project are shown on Plate 20. In order to permit flexibility in operation of the project, design of the pumping plant was based on the installation of three electrically driven vertical axial-flow propellor type pumping units. Each of the units would comprise a 36-inch diameter pump with capacity of 45 second-feet, driven by a 100-horsepower motor. The pumps would operate at a maximum pumping head of about 15 feet, pumping from an estimated minimum water surface elevation in the river of about 31 feet to a discharge elevation of about 46 feet. The pumping units would be of the all-weather type, mounted on steel beams, and supported on concrete piles driven into the stream bed at the toe of the river face of the right bank levee of the Feather River. The battery of pumps would be operated from a corrugated metal control house, also mounted on the concrete piles, and would be served by a steel trestle from the levee crest. The units would pump from a reinforced-concrete sump into three 30-inch diameter steel pipes supported by ring girders and reinforced-concrete piers on the slopes of the levee. The pipes would pass through the levee five feet beneath the crest, and discharge into a reinforced-concrete sand trap at the landward base of the levee.

From the sand trap the water would be conveyed by gravity to areas of use by the system of lined and unlined canals shown on Plate 20. The main canal extending in a southerly direction along the levee would be concrete-lined, in order to prevent seepage which might otherwise damage orchards or the toe of the Feather River levee. This canal would be approximately 6.1 miles in length, and would be of trapezoidal section, with 1.5:1 side slopes, bottom width of 8.0 feet, depth of 3.4 feet, and 1.0 foot freeboard. The slope would be approximately 1.0 foot per mile, the velocity about 2.5 feet per second, and the capacity would be 100 second-feet. A second main canal would extend from the sand trap in a westerly direction a distance of approximately 0.7 mile to a concrete division box near the Southern Pacific Railroad right of way. This canal would have characteristics similar to the one already described. From the division box a lateral would extend south along the railroad right of way a distance of approximately 4.8 miles. This lateral would also be concrete-lined, to prevent possible damage by seepage to adjacent orchards and to the railroad. It would be of trapezoidal section, with 1.5:1 side slopes, bottom width of 6.0 feet, depth of 2.4 feet, and freeboard of 1.0 foot. The slope would be approximately 1.5 feet per mile, the velocity about 2.3 feet per second, and the capacity 50 second-feet. A second lateral from the division box would extend in a westerly and then southerly direction a distance of approximately 5.2 miles. This canal would be unlined, since seepage from it would probably result in no damage. The canal would be of trapezoidal section, with 2:1 side slopes, bottom width of 6.0 feet, depth of 3.2 feet, and freeboard of 1.0 foot. Its slope would be approximately 1.5 feet per mile, its velocity about 1.3 feet per second, and its capacity 50 second-feet. Cost estimates for the conveyance canals were based on preliminary designs utilizing data from field location surveys.

Detailed design of works for distribution of water from the conveyance canals was considered to be outside the scope of the current investigation. Existing pressure irrigation systems of individuals and agencies could be adapted to use of the new surface water supply by means of gravity diversions or individual low-head pumps, as required. Cost estimates for the distribution systems were based on known costs of similar irrigation works elsewhere in California, adjusted to correspond with conditions prevailing in the Sutter-Yuba Area.

Pertinent data with respect to general features of the Peach Bowl Project, as designed for cost estimating purposes, are presented in Table 39.

TABLE 39

GENERAL FEATURES OF PEACH BOWL PROJECT

Pumping Plant

- Pumps—3 each, vertical, propeller type, axial-flow, 45 second-foot capacity
- Estimated minimum water surface elevation in Feather River—31 feet
- Discharge elevation—46 feet
- Estimated maximum pumping head—15 feet
- Installed pumping capacity—135 second-feet
- Estimated maximum monthly demand—105 second-feet
- Estimated gross seasonal diversion—24,000 acre-feet
- Motors—3 each, all-weather type, 100 horsepower
- Pump support—steel beams on concrete pile structure
- Pumping sump—reinforced-concrete, 13 feet by 65 feet, 5 feet deep, equipped with trash racks
- Discharge lines—3 each, 30-inch diameter, welded-steel, supported on concrete piers by ring girders
- Sand trap—reinforced-concrete, 10 feet by 40 feet, 6 feet deep, equipped with baffles and sluice gates

Conveyance System

	Main canals	Central lateral	West lateral
Type	Trapezoidal, concrete-lined	Trapezoidal, concrete-lined	Trapezoidal, unlined
Length, in miles	6.8	4.8	5.2
Side slopes	1.5:1	1.5:1	2:1
Bottom width, in feet	8.0	6.0	6.0
Depth, in feet	3.4	2.4	3.2
Freeboard, in feet	1.0	1.0	1.0
Slope, in feet per mile	1.0	1.5	1.5
Velocity, in feet per second	2.5	2.3	1.3
Capacity, in second-feet	100	50	50

Daguerre Point Weir on Yuba River

Capital cost of the Peach Bowl Project, based on prices prevailing in April, 1952, was estimated to be about $1,384,900. Corresponding annual costs of the Peach Bowl Project were estimated to be about $100,900. Resultant estimated average unit cost of the 24,000 acre-feet of water per season diverted at the river was about $4.20 per acre-foot. The estimated average unit cost of the 18,000 acre-feet of water per season actually applied for irrigation was about $5.60 per acre-foot.

Estimated capital and annual costs of the Peach Bowl Project are summarized in the following tabulation. Detailed cost estimates are presented in Appendix H.

	Estimated costs	
	Capital	*Annual*
Pumping plant	$107,900	$16,000
Conveyance system	813,900	43,800
Distribution system	463,100	41,100
TOTALS	$1,384,900	$100,900

Northeast Zone

In Chapter III it was shown that the present requirement for supplemental water in the Northeast Zone is about 6,000 acre-feet per season. However, in the design of projects for initial local development to meet this requirement, it was considered desirable to provide some capacity for future growth in water demand which would occur through development of irrigable lands not presently irrigated. This additional capacity was estimated at about 6,000 acre-feet per season, giving consideration to the extent of undeveloped irrigable lands that might readily be served, and to the available sources of water supply as determined by engineering and economic limitations on size of the proposed conservation works. For reasons hereinafter discussed, it was considered that the new water supply would be applied to about 2,300 acres in the Northeast Zone, of which about 1,700 acres are presently irrigated by ground water and 600 acres are irrigable lands not presently served with water. These lands are contained within a service area adjoining and lying to the east and north of the Cordua Irrigation District, and delineated on Plate 21, "South Honcut Creek Project."

Three possible alternative plans of works for initial construction to provide supplemental water to the Northeast Zone were considered. For reasons hereinafter mentioned, after preliminary investigation and study, the first two plans were given no further consideration for present cost estimating purposes, but may warrant future study. The third plan is described in some detail in this section.

Alternative Plans Considered. The first of the alternative plans considered for initial construction involved the substitution of surface water from the Yuba River to replace ground water presently utilized in the foregoing service area. The substitute supply would be furnished by extension and enlargement of portions of the Cordua Irrigation District canal system. Its use would prevent progressive and permanent lowering of ground water levels in the described service area and in adjacent areas. The Cordua Irrigation District and the Hallwood Canal Company jointly divert from the Yuba River through a 1,200-foot tunnel with capacity of 325 second-feet, heading at the northwest end of the Daguerre Point Weir. Surface flow in the Yuba River at Daguerre Point during the peak of the irrigation season is generally not greater than present demands of the Cordua and Hallwood systems, and at times these demands cannot be met. Much of the surface flow in the Yuba River during such periods as measured at Marysville does not occur on the surface at the Daguerre Point Weir. Measurements indicate that this water is lost to surface flow by percolation in an extensive area of dredger tailings above the weir, and reappears at the Marysville gaging station. For this reason, a preliminary survey was made to determine the feasibility of diverting the Cordua-Hallwood water supply from the Yuba River at a site upstream from the area of dredger tailings. This would be excessively expensive because of the necessity for increasing capacity of the Cordua-Hallwood system, providing a diversion structure, and providing a closed conduit for the diverted water for a considerable distance until stable bank could be reached. For these reasons, and because of uncertainty regarding the available water supply, this plan was given no further present consideration.

The second of the alternative plans considered for initial construction involved the purchase of Feather River water from the Oroville-Wyandotte Irrigation District at a point of delivery on South Honcut Creek, diversion of the water from South Honcut Creek, and its conveyance to and distribution in the Northeast Zone. As in the case of the first plan described, use of the new surface water supply would prevent progressive and permanent lowering of ground water levels in the area served and in adjacent areas. The water purchased and utilized would be a portion of that which the district proposes to develop on the South Fork of the Feather River under the multipurpose project described earlier in this chapter, principal features of which are shown on Plate 19. The water would be delivered to South Honcut Creek at an elevation of about 600 feet, by the district. The amount of water that might be made available to the Northeast Zone would depend upon design of features of the proposed Oroville-Wyandotte Irrigation District project, and in turn upon the outcome of possible negotiations between the district and an agency representing interests of the Northeast Zone. For these reasons, features of the plan were not surveyed and studied in detail, nor estimates of cost prepared.

The third plan considered for initial construction would include the construction of a dam and reservoir on South Honcut Creek, facilities for diversion of flood

South Honcut Creek Dam Site Viewed From Point Within Reservoir Area

waters of French Dry Creek to the reservoir, and facilities for diversion of the conserved waters from South Honcut Creek below the dam, and for their conveyance to and distribution in both the Northeast Zone and the Browns Valley service area. This latter area, lying to the east of the Northeast Zone, is also in need of a supplemental water supply and could be advantageously served as indicated. As in the case of the two previous plans, use of the new surface water supply would prevent progressive and permanent lowering of ground water levels in the area served in the Northeast Zone and in adjacent areas. This plan is hereinafter referred to as the "South Honcut Creek Project," and its principal features are delineated on Plate 21.

South Honcut Creek Project. The proposed dam would be an earthfill structure with side channel spillway, located on South Honcut Creek near Sugar Loaf, in Section 25, Township 18 North, Range 5 East, M. D. B. & M., some 20 miles upstream from the confluence of Honcut Creek with the Feather River. The stream bed elevation at this point is about 730 feet. Flood waters of French Dry Creek would be diverted at a point on that stream at an elevation of approximately 2,125 feet, about one-half mile below Brownsville, and conveyed a distance of about two miles in a canal, discharging into a tributary of South Honcut Creek above the reservoir. The conserved waters of both South Honcut and French Dry Creeks, after release from the reservoir, would be diverted from South Honcut Creek at a point about two miles downstream from the dam and 300 feet downstream from the county bridge southeast of Bangor, at an elevation of about 600 feet. From this diversion point the waters would be conveyed by a conduit a distance of about 4.7 miles to a point about one mile northeast of Loma Rica, where the elevation is about 500 feet. Diversions could be made for the Browns Valley service area along the conduit and at its terminus. Water for the Northeast Zone would be conveyed from this terminus in a natural drainage channel, a short canal section, and the natural channel of Prairie Creek to a diversion point for the Northeast Zone on Prairie Creek about one mile upstream from its confluence with South Honcut Creek, at an elevation of approximately 135 feet. From this point the waters would be conveyed to and distributed in the Northeast Zone by means of an unlined canal and ditch system. The lands which would be served by the new water supply comprise the aforementioned 2,300 acres contained within the service area shown on Plate 21, ranging in elevation from about 150 feet along its eastern boundary to about 75 feet on the west.

As a first step in determination of size of the project, estimates were made of yield of the proposed works for various reservoir storage capacities. It was estimated that mean seasonal runoff of South Honcut Creek, from the approximately 24 square miles of watershed above the dam site, was about 23,400 acre-feet. Estimated mean seasonal runoff of French Dry Creek at the proposed point of diversion to South Honcut Creek was about 27,100 acre-feet, from some 22 square miles of watershed. Of these French Dry Creek waters, studies indicated that flood flows in an estimated mean seasonal amount of about 22,000 acre-feet could be diverted to the proposed South Honcut Creek Reservoir through a 200 second-foot capacity conduit, during the months from November to April, inclusive.

Based upon records and estimates of runoff during the critical dry period which occurred in the Sacramento Valley from 1920-21 through 1934-35, yield studies were made for five sizes of reservoir at the South Honcut Creek site. It was assumed that a seasonal irrigation deficiency up to 35 percent could be endured in one season of the period. Monthly demands on the reservoir were assumed to be proportional to the estimated distribution of irrigation demands in the Sutter-Yuba Area, as presented in Table 33. A summary of results of the yield studies is presented in Table 40.

TABLE 40

ESTIMATED SAFE SEASONAL YIELD OF SOUTH HONCUT CREEK RESERVOIR WITH FRENCH DRY CREEK DIVERSION, BASED ON CRITICAL DRY PERIOD FROM 1920-21 THROUGH 1934-35

(In acre-feet)

Reservoir storage capacity	Safe seasonal yield
12,000	12,800
20,000	16,400
30,000	20,900
38,000	24,300
70,000	27,100

After consideration of the results of the yield studies, together with topography of the dam site and cost analyses hereinafter discussed, a reservoir of 38,000 acre-foot storage capacity, with estimated safe seasonal yield of 24,300 acre-feet, was chosen for purposes of cost estimates to be presented in this report. The yield study for this size of reservoir is included in Appendix G.

Although the estimate of the present requirement for supplemental water in the Northeast Zone was only about 6,000 acre-feet per season, essentially all irrigable but presently nonirrigated lands in the zone would be physically susceptible of irrigation under the South Honcut Creek Project. However, a substantial acreage of irrigable lands lying in the Browns Valley service area could be developed with water from the South Honcut Creek Project. For this reason, studies of present utilization of water from the South

Honcut Creek Project were based on an assumed release of water for the Northeast Zone equal to approximately one-half of the estimated safe yield of the project. It was assumed that remaining safe yield of the project would be made available to the Browns Valley service area.

For design purposes it was assumed that minor losses of water released from South Honcut Creek Reservoir would occur in the stream channel between the dam and the downstream point of diversion and in the lined canal leading to the point of release north of Loma Rica, and would amount to about 300 acre-feet per season. Thus a gross supplemental water supply of approximately 12,000 acre-feet per season would be made available to the Browns Valley service area. It was estimated that losses in conveyance and distribution of this supply would be about 25 percent, leaving some 9,000 acre-feet per season for application to irrigation. On the assumption that the imported water would be largely used on irrigated pasture, with an estimated average unit seasonal application of about 3.5 acre-feet per acre, about 2,600 acres of irrigable but presently nonirrigated lands in the Browns Valley service area could be served by the new water supply.

It was assumed that seasonal losses by transpiration, evaporation, and percolation in conveying the new water supply to the point of diversion on Prairie Creek would be about 10 percent of the gross reservoir release, or about 1,200 acre-feet, leaving approximately 10,800 acre-feet for distribution in the zone. Since the Northeast Zone constitutes a free ground water area, water losses in the unlined canal and ditch system would largely percolate to the ground water. For this reason it was assumed that these losses, plus the unconsumed portion of the new water supply applied to irrigation, would be effective in preventing progressive and permanent lowering of ground water levels.

The acreage to be irrigated by the supplemental supply in the Northeast Zone would depend on the gross amount of the import, water losses encountered in conveyance and distribution, and the requirement for application of water to the lands irrigated. It was assumed that losses to be encountered in conveyance and distribution within the zone would be 25 percent of the gross import, or about 2,700 acre-feet per season, leaving some 8,100 acre-feet for application to irrigated lands. It was also assumed that water imported to the Northeast Zone would largely be used on irrigated pasture, and that the average seasonal application of the new water would be 3.5 acre-feet per acre. On this basis it was estimated that the imported supply would be applied to some 2,300 acres in a service area adjoining and lying to the east and north of the Cordua Irrigation District. Of the lands which would be served with the new water supply, about 1,700 acres are presently irrigated by ground water and 600 acres are irrigable lands not presently irrigated.

An estimate of the monthly distribution of demand for irrigation water in the Sutter-Yuba Area was presented in Table 33. Based on these data, the monthly demand on the South Honcut Creek Project would be as shown in Table 41.

TABLE 41

ESTIMATED MONTHLY DISTRIBUTION OF DEMAND FOR WATER FROM SOUTH HONCUT CREEK PROJECT

(In acre-feet)

Month	Percent of seasonal total	Reservoir release	Gross import to Northeast Zone	Gross import to Browns Valley
April	10	2,430	1,080	1,200
May	16	3,890	1,730	1,920
June	17	4,130	1,830	2,040
July	22	5,350	2,380	2,640
August	17	4,130	1,830	2,040
September	11	2,670	1,190	1,320
October	5	1,210	540	600
November	2	490	220	240
TOTALS	100	24,300	10,800	12,000

Plane table topographic surveys were made of the South Honcut Creek dam and reservoir sites by the Division of Water Resources in 1949. The reservoir site was mapped at a scale of 1 inch to 400 feet, and the dam site at a scale of 1 inch to 100 feet, both with 10-foot contour intervals. Storage capacities of South Honcut Creek Reservoir at various stages of water surface elevation are given in Table 42.

Based upon preliminary geological reconnaissance, the South Honcut Creek dam site is considered suitable for an earthfill dam of any height up to a maximum of 200 feet. Foundation rock at the site consists of a slightly metamorphosed series of igneous rocks, chiefly of volcanic origin. The original nature of the rocks ranged from basalt to gabbro. The bulk of the material is a blue-gray, hard, very slightly metamorphosed basalt. The entire mass has been intruded by a number of small dikes, of later origin, consisting of unmetamorphosed andesite and/or basalt. The foundation bedrock as a whole is relatively hard and unweathered where exposed in outcrops. Joints are prominently developed in several sets. The predominant set has a strike approximately parallel to the stream course and apparently controls the primary drainage pattern in the vicinity. Small shears are common throughout the rock mass but these have generally been recemented. Some of the joints also have been recemented by deposition of minerals from percolating waters. Seepage may be observed from remaining open seams in the bedrock in several places.

TABLE 42

AREAS AND CAPACITIES OF SOUTH HONCUT CREEK RESERVOIR

Depth of water at dam, in feet	Water surface elevation, USGS datum, in feet	Water surafce area, in acres	Storage capacity, in acre-feet

168	898	720	38,000
180	910	801	47,600
200	930	933	65,000
205	935	976	70,000
220	950	1,070	85,100

Three hundred feet downstream from the axis a fault zone is encountered which follows the base of the right abutment longitudinally for an additional 200 feet before lensing out. The plane of this fault apparently has a dip of 55 degrees into the left abutment. The zone appears to die out rapidly in both upstream and downstream directions but at the point of maximum development it is eight feet in width. There is some gouge and much crushed rock along this fault. The inconsistency of the zone on the surface would seem to indicate that it may also lens out vertically at a relatively shallow depth. Indications are that there has been no recent movement on the fault. Special treatment of the dam foundation in the area of this fault would undoubtedly be necessary.

Stripping for the foundation of an earthfill type of dam at this site should not exceed, for the right abutment, five feet of overburden, consisting chiefly of soil, plus three feet of weathered bedrock, and for the left abutment, three feet of overburden plus three feet of weathered bedrock. These estimates apply only under the impervious section of an earthfill type of dam and are for any height of dam up to a maximum of 200 feet. Only the overburden would have to be stripped from under the pervious sections of such a dam. The stated depths are estimated normal to the surface. Stripping in the channel section should consist of about two feet of gravel and one foot of weathered bedrock.

A satisfactory location for a spillway for an earthfill dam at this site would be around the end of the structure, with the excavation being largely in hard bedrock. The material from such excavation, as well as the weathered rock stripped from the abutments, should prove about 80 percent recoverable for construction use as pervious fill, rockfill, or riprap. Tailings from former hydraulic mining operations which choke the channel one mile upstream from the dam site could also be used as pervious fill material. A small quantity of concrete aggregate could be recovered locally for use in appurtenant structures for an earthen dam, but large amounts would either have to be crushed at the site or imported. Soil suitable for use in the construction of an impervious embankment is available in limited quantities from sloping flats of the reservoir area. Although the depth of this material is probably not great, it is believed that enough could be obtained from this source to provide for a minimum impervious earth section.

As a result of yield studies, geologic reconnaissance, and preliminary economic analysis, an earthfill dam, 168 feet in height from stream bed to spillway lip, and with a crest elevation of 910 feet, was selected to illustrate estimates of cost of the South Honcut Creek Project. The dam would have a crest length of about 670 feet and a crest width of 30 feet, and 2.5:1 upstream and down-stream slopes. The central impervious core would have a top width of 10 feet and 0.8:1 slopes, and would be blanketed with sand and gravel filters. The outer pervious zones of the dam would consist of dredger tailings and materials excavated in construction of the spillway. The volume of the fill would be an estimated 919,000 cubic yards. The maximum depth of water above the spillway lip would be 8 feet, and an additional 4 feet of freeboard would be provided. The spillway would be of the side channel type, excavated from rock of the right abutment and concrete-lined. It would have a capacity of 10,000 second-feet, required for an assumed discharge of 400 second-feet per square mile of drainage area, and would discharge into South Honcut Creek below the dam. Outlet works would consist of a 42-inch diameter steel pipe placed in a trench excavated in rock beneath the dam, and encased in concrete. Releases from the dam would be controlled at the upstream end by two 30-inch hydraulically controlled high pressure slide gates located at a submerged inlet upstream from the dam, and operated by hydraulic controls from the crest of the dam. The outlet would be controlled at the downstream end by a Howell-Bunger valve.

The diversion works on French Dry Creek would be located approximately at the site of a former diversion weir, portions of which are still in existence. The site was examined and cross sections taken during the

course of the investigation. The proposed diversion weir would consist of a concrete gravity overpour section and apron, 7 feet in height above stream bed and some 55 feet in length. An opening at the right end of the weir would provide entrance to a side channel leading downstream about 100 feet to the headworks of the diversion canal. The side channel would have a concrete gravity parapet wall of the overpour type, and a 5- by 4-foot sluice gate would be provided for sand clearance. The headworks would consist of a concrete headwall across the end of the side channel, in which there would be two 5- by 4-foot slide gates. The diversion canal, which for a portion of its route would be aligned roughly along an abandoned canal, would be about 2.0 miles in length, discharging into an unnamed tributary of South Honcut Creek. Location of the canal was based on a map study, and was checked in the field. The canal chosen for cost estimating purposes would have a capacity of 200 second-feet, a shotcrete-lined trapezoidal section with 1:1 side slopes, bottom width and depth of 4.0 feet, and freeboard of 1.0 foot, and a slope of approximately 7.0 feet per mile. The velocity would be about 6.3 feet per second.

The diversion works on South Honcut Creek to serve Browns Valley and the Northeast Zone would be similar to those described for the French Dry Creek diversion, except that the weir would be 9 feet high and 84 feet in length, and the headworks would be located at the left end of the weir. The site was examined and cross-sectioned during the course of the investigation. The diversion conduit chosen for cost estimating purposes would have a capacity of 150 second-feet and would bear in a general southerly direction a distance of approximately 4.7 miles. Location of the conduit was based on a map study, and was checked in the field. For the most part the conduit would consist of a shotcrete-lined canal, but would include a steel pipe siphon, 5.5 feet in diameter and about 1,500 feet in length, across Tennessee Creek. The canal portion would have a trapezoidal section with 1:1 side slopes, bottom width of 5.0 feet, depth of 4.0 feet, and freeboard of 1.0 foot. Its slope would be approximately 4.0 feet per mile, and the velocity would be about 4.2 feet per second. Releases of water for use in Browns Valley could be made along the conduit and at its terminus.

From the terminus, about one mile northeast of Loma Rica, water for the Northeast Zone would be released to flow southerly in a tributary of Little Dry Creek for about 6,000 feet, and then would be diverted by temporary earthen works into a short unlined canal leading westerly and discharging into an unnamed tributary of Prairie Creek. The water would flow in Prairie Creek and its tributary a distance of about six miles to the point of diversion for the Northeast Zone. This diversion site and the route of the conduit to serve the Northeast Zone were surveyed during the course of the investigation. The diversion works would consist merely of a temporary earthen structure, replaced each season. The conduit from the diversion to the Northeast Zone would bear in a general southerly direction a distance of approximately 6.3 miles, terminating in a tributary of Nigger Jack Slough. It would be an unlined canal, having capacities of 75 second-feet at the diversion point and 25 second-feet at the terminus. At the diversion point the canal would have a trapezoidal section with 2:1 side slopes, bottom width of 4.0 feet,

TABLE 43

GENERAL FEATURES OF SOUTH HONCUT CREEK PROJECT

Earthfill Dam
- Crest elevation—910 feet
- Crest length—670 feet
- Crest width—30 feet
- Height, spillway lip above stream bed—168 feet
- Side slopes—2.5:1
- Freeboard, above spillway lip—12 feet
- Elevation of stream bed—730 feet
- Volume of fill—919,000 cubic yards

Reservoir
- Surface area at spillway lip—720 acres
- Capacity at spillway lip—38,000 acre-feet
- Drainage area
  - Honcut Creek—24 square miles
  - French Dry Creek—22 square miles
- Estimated mean seasonal runoff
  - Honcut Creek—23,400 acre-feet
  - French Dry Creek—27,100 acre-feet
- Estimated mean seasonal diversion from French Dry Creek—22,000 acre-feet
- Estimated safe seasonal yield—24,300 acre-feet
- Type of spillway—Side channel, concrete-lined
- Spillway capacity—10,000 second-feet
- Type of outlet—42-inch diameter steel pipe beneath dam

Diversion Works
- French Dry Creek—Concrete gravity weir, with ogee overpour section, 55 feet in length, and 7 feet high above stream bed elevation of about 2,125 feet; side channel diversion box, with overpour parapet wall, and 5- by 4-foot slide sluice gate; two 5- by 4-foot slide headgates in concrete headwall.
- South Honcut Creek—Concrete gravity weir, with ogee overpour section, 84 feet in length, and 9 feet high above stream bed elevation of 600 feet; side channel diversion box, with overpour parapet wall, and 5- by 4-foot slide sluice gate; two 5- by 4-foot slide headgates in concrete headwall.
- Prairie Creek—Temporary earthen structure, at stream bed elevation of 135 feet.

Conduits

	French Dry Creek Diversion	South Honcut Creek Diversion	Prairie Creek Diversion
Type	Trapezoidal, shotcrete-lined canal	Trapezoidal, shotcrete-lined canal, and 1,500 feet of 5.5-foot diameter steel pipe siphon	Trapezoidal, unlined canal
Length, in miles	2.0	4.7	6.3
Side slopes	1:1	1:1	2:1
Bottom width, in feet	4.0	4.0	1.0 (maximum)
Depth, in feet	4.0	5.0	3.7 (maximum)
Freeboard, in feet	1.0	1.0	1.0
Slope, in feet per mile	7.0	4.0	2.5
Velocity, in feet per second	6.3	4.2	1.7
Capacity, in second-feet	200	150	75 to 25

depth of 3.7 feet, and freeboard of 1.0 foot. Its slope would be approximately 2.5 feet per mile, and the velocity would be about 1.7 feet per second.

Cost estimates for the canals to convey water to the service areas in Browns Valley and the Northeast Zone were based on designs utilizing data obtained by reconnaissance field location surveys. Detailed design of the distribution systems in Browns Valley and the Northeast Zone, however, was considered to be outside the scope of the current investigation. Cost estimates for the systems were based on known costs of similar irrigation works elsewhere in California, adjusted to correspond with conditions prevailing in the Sutter-Yuba Area.

Pertinent data with respect to the general features of the South Honcut Creek Project, as designed for cost estimating purposes, are presented in Table 43.

The capital cost of the South Honcut Creek Project, based on prices prevailing in April, 1952, was estimated to be about $3,009,600. Corresponding annual costs of the South Honcut Creek Project were estimated to be about $154,200. The resultant estimated average unit cost of the 24,300 acre-feet of water per season conserved by South Honcut Creek Reservoir was about $6.40 per acre-foot. The estimated unit costs of water applied for irrigation in the Northeast Zone and in the Browns Valley service area were about $9.70 and $8.40 per acre-foot, respectively.

Estimated capital and annual costs of the South Honcut Creek Project are summarized in the following tabulation. Detailed cost estimates are presented in Appendix H.

	Estimated costs	
	Capital	*Annual*
Dam and reservoir	$2,225,600	$94,400
French Dry Creek diversion and conduit	151,100	8,100
South Honcut Creek diversion and conduit	379,100	20,500
Prairie Creek diversion and conduit	131,300	7,100
Browns Valley distribution system	65,000	14,400
Northeast Zone distribution system	57,500	9,700
TOTALS	$3,009,600	$154,200

East Central Zone

In Chapter III it was shown that the present requirement for supplemental water in the East Central Zone is about 28,000 acre-feet per season. However, in the design of projects for initial local development to meet this requirement, it was considered desirable to provide some capacity for future growth in water demand which would occur through development of irrigable lands not presently irrigated. This additional capacity was estimated at about 12,000 acre-feet per season, giving consideration to the extent of undeveloped irrigable lands that might readily be served, and to the available sources of water supply. For reasons hereinafter discussed it was considered that the new water supply would be applied to about 8,500 acres in the East Central Zone, of which about 3,300 acres are presently irrigated by ground water and 5,200 acres are irrigable lands not presently served with water. These lands are contained within a service area lying generally south of Hutchinson Creek and east of the Western Pacific Railroad, and delineated on Plate 22, "Camp Far West Project."

Four possible alternative plans of works for initial construction to provide supplemental water to the East Central Zone were considered. For reasons hereinafter mentioned, after preliminary investigation and study the first three plans were given no further consideration for present cost estimating purposes, but may warrant future study. The fourth plan is described in some detail in this section.

Alternative Plans Considered. The first of the alternative plans considered for initial construction involved the substitution of surface water from the Yuba River to replace ground water presently utilized in an area in the East Central Zone. The substitute supply would be diverted at a point on the Yuba River about four miles upstream from Daguerre Point by means of existing headworks of the Yuba River Ditch, owned by the Yuba Consolidated Gold Fields. The Yuba River Ditch, an abandoned canal some four miles in length, with a designed capacity of approximately 115 second-feet, would be rehabilitated and extended in a southerly direction to Hutchinson Creek. Use of the new surface water supply would prevent progressive and permanent lowering of ground water levels in the area served and in adjacent areas. During study of the plan it was determined that surplus flows are available in the Yuba River at the proposed point of diversion during the snowmelt period and into summer months in all but the driest years. However, during the peak of the irrigation season in many years, flows at the diversion point are no more than adequate to maintain the required downstream diversion at Daguerre Point for the Cordua and Hallwood systems. Until such time as additional upstream conservation storage and regulation of flood flows of the Yuba River are accomplished, excessive irrigation deficiencies would be experienced under this plan. For this reason the plan was given no further present consideration for initial construction.

The second of the alternative plans considered for initial construction would include the construction of a dam and reservoir at the Waldo site on Dry Creek, facilities for release of the conserved waters from the reservoir, and facilities for their downstream diversion, conveyance, and distribution in the East Central Zone. Preliminary studies indicated that this plan would not provide sufficient yield to meet the present requirement for supplemental water in the East Central Zone, and that the unit cost of the conserved water would be greater than the corresponding unit cost with the fourth plan described in this section. For these reasons the plan was given no further present consideration. Studies were also made of a plan which included a

Existing Camp Far West Dam and Reservoir

larger dam and reservoir at the Waldo site, together with facilities for diversion of flood waters of Yuba River to the larger reservoir. Yield studies and preliminary cost estimates indicated that this plan should probably be deferred for future development. It was indicated that only a portion of the yield of the enlarged project could be readily utilized in the Sutter-Yuba Area at the present time. The capital cost of the larger project would be more than twice that of the fourth plan for initial construction described in this section. Costs of developed water would be excessive until such time as the major portion of the yield could be put to beneficial use. For these reasons this plan was given no further present consideration for initial construction.

The third of the alternative plans considered for initial construction involved the possible purchase of water from the Nevada Irrigation District and conveyance to places of use in the natural channel of Dry Creek. Preliminary studies indicated that additional water could be supplied to the East Central Zone by development and extension of existing facilities of the district, including the China and Tarr Ditches. As in the case of the first plan described, use of the new surface supply would prevent progressive and permanent lowering of ground water levels in the area served and in adjacent areas. The amount of water that might be made available to the East Central Zone would depend upon construction and enlargement of works of the Nevada Irrigation District, and, in turn, upon the outcome of possible negotiations between the district and an agency representing interests of the Northeast Zone. For these reasons, features of the plan were not surveyed and studied in detail, nor estimates of cost prepared.

The fourth plan considered for initial construction would provide for the present supplemental water requirement in the East Central Zone and for growth in water utilization for a number of years in the future. In addition, it would provide corresponding benefits to the South Side Zone. The plan would include the construction of a larger dam and reservoir on the Bear River at the site of the existing Camp Far West Dam and Reservoir, and facilities for conveyance of the conserved water to and its distribution in both the East Central and South Side Zones. Use of the new surface water supply would prevent progressive and permanent lowering of ground water levels in the areas served and in adjacent areas. This plan is hereinafter referred to as the "Camp Far West Project," and its principal features are delineated on Plate 22.

Camp Far West Project. The proposed dam would be an earthfill structure with chute spillway, located on the Bear River, in Section 21, Township 14 North, Range 6 East, M. D. B. & M., some 16 miles upstream from the confluence with the Feather River, and 6.6 miles upstream from Highway 99E. Stream bed elevation at the site is 145 feet. The proposed dam would be superimposed upon an existing curved concrete gravity dam, 62 feet in height from stream bed to dam crest, which creates a reservoir of about 5,000 acre-foot capacity, and is owned by the Camp Far West Irrigation District. Flood waters of the Bear River conserved by the proposed reservoir would be released at an elevation of approximately 180 feet to canals serving the East Central and South Side Zones, respectively. The lands which would be served by the new water supply comprise the aforementioned 8,500 acres in the East Central Zone, and an additional 8,500 acres in the South Side Zone, in the respective service areas shown on Plate 22. Both service areas range in elevation from about 150 feet along their eastern boundaries to about 50 feet on the west.

In Chapter III it was estimated that the present requirement for supplemental water in the East Central Zone is about 28,000 acre-feet per season and in the South Side Zone an additional 28,000 acre-feet, a total of about 56,000 acre-feet per season. In the design of the Camp Far West Project for cost estimating purposes, it was considered necessary to provide about 10,000 acre-feet of water per season for the Camp Far West Irrigation District to replace yield of the existing reservoir. Based upon the area of lands irrigated by the district, this estimate is believed to be adequate. As has been stated, it was also considered desirable to provide some capacity for future growth in demand on the project, which would occur through development of irrigable lands not presently irrigated.

As a first step in determination of size of the project, estimates were made of yield of the proposed works for various storage capacities. It was estimated that mean seasonal runoff of the Bear River, from the approximately 280 square miles above the dam site, was 347,000 acre-feet. Based upon records and estimates of runoff during the critical dry period which occurred in the Sacramento Valley from 1920-21 through 1934-35, yield studies were made for three sizes of reservoirs at the Camp Far West site. It was assumed that a seasonal irrigation deficiency up to 35 percent could be endured in one season of the period. A summary of results of the yield studies is presented in Table 44.

TABLE 44

ESTIMATED SAFE SEASONAL YIELD OF CAMP FAR WEST RESERVOIR, BASED ON CRITICAL DRY PERIOD FROM 1920-21 THROUGH 1934-35

(In acre-feet)

Reservoir storage capacity	Safe seasonal yield
55,000	55,000
104,000	90,000
151,000	122,000

After consideration of the results of the yield studies, together with topography of the dam site and cost analyses hereinafter discussed, a reservoir of 104,000 acre-foot storage capacity, with estimated safe seasonal yield of 90,000 acre-feet was chosen for purposes of cost estimates to be presented in this report. The yield study for this size of reservoir is included in Appendix G.

For cost estimating purposes a tentative distribution of yield of the proposed Camp Far West Reservoir was made. Of the estimated 90,000 acre-feet of safe seasonal yield, 10,000 acre-feet per season was assigned to the Camp Far West Irrigation District. The remaining yield was divided equally between the East Central and South Side Zones, in the amount of 40,000 acre-feet per season to each zone.

Since the East Central Zone constitutes a free ground water area, water losses in the proposed canal and ditch system would largely percolate to the ground water. For this reason it was assumed that these losses, plus the unconsumed portion of the new water supply applied to irrigation would be effective in preventing progressive and permanent lowering of ground water levels. It was estimated that losses in conveyance and distribution of the 40,000 acre-feet of safe seasonal yield assigned to the East Central Zone would be about 25 percent, leaving some 30,000 acre-feet per season for application to irrigation. It was also assumed that water imported to the East Central Zone would be used largely on irrigated pasture, and that the average seasonal application of the new water would be 3.5 acre-feet per acre. On this basis it was estimated that the imported supply would be applied to some 8,500 acres in a service area lying generally south of Hutchinson Creek and east of the Western Pacific Railroad. Of the lands which would be served with the new water supply, about 3,300 acres are presently irrigated by ground water and about 5,200 acres are irrigable lands not presently irrigated.

An estimate of the monthly distribution of demand for irrigation water in the Sutter-Yuba Area was presented in Table 33. Based on these data, monthly demands on the Camp Far West Project would be as shown in Table 45.

A topographic survey of the Camp Far West reservoir site up to an elevation of 225 feet was made by the Camp Far West Irrigation District in 1922. This survey was extended to an elevation of 320 feet by the Division of Water Resources in 1930, and a map was drawn from both surveys at a scale of 1 inch equals 500 feet, with a contour interval of 10 feet. Storage capacities of the Camp Far West Reservoir at various stages of water surface elevation are given in Table 46.

Based upon preliminary geological reconnaissance, the Camp Far West dam site is considered suitable for an earthfill dam of any height up to a maximum of 180 feet. Bedrock at the site consists of a slightly

TABLE 45

ESTIMATED MONTHLY DISTRIBUTION OF DEMAND FOR WATER FROM CAMP FAR WEST PROJECT

Month	Percent of seasonal total	Gross release to Camp Far West Irrigation District, in acre-feet	Gross import to East Central Zone, in acre-feet	Gross import to South Side Zone, in acre-feet
April	10	1,000	4,000	4,000

October	5	500	2,000	2,000
November	2	200	800	800
TOTALS	100	10,000	40,000	40,000

TABLE 46

AREAS AND CAPACITIES OF CAMP FAR WEST RESERVOIR

Depth of water at dam, in feet	Water surface elevation, USGS datum, in feet	Water surface area, in acres	Storage capacity, in acre-feet
0	145	0	0
25	170	100	1,400
45	190	180	4,200
65	210	380	9,800
85	230	600	19,400
105	250	890	34,200
125	270	1,260	55,500
145	290	1,750	85,600
155	300	2,020	104,400
165	310	2,330	126,100
175	320	2,620	151,000

porphyritic, compact, and massive dark greenstone with gradations into coarse-grained phutonic rock. A complex joint system exists in this vicinity with joint cracks opened a few inches on the surface by weathering. The joints probably do not persist to appreciable depths other than as hairline cracks in the rock. However, some moderate grouting would be necessary. Shears are not abundant in the bedrock, and no serpentine was found locally. While slopes up to an elevation of about 160 feet above stream bed on

both abutments consist essentially of barren bedrock with scattered patches of overlying soil, the abutment slopes above 100 feet show only occasional bedrock outcrops with a much heavier mantle of overburden. Stripping under the impervious section of an earthfill type of dam at this site should not exceed four feet of depth of loose material up to 100 feet above stream bed on both abutments, and eight feet of depth above 100 feet on the abutments. Topographic considerations indicate that the spillway should be located across the ridge forming the right abutment of the dam, utilizing a natural saddle and drainage channel.

The material stripped from the foundation and abutments and excavated from the spillway should prove largely recoverable for construction use as pervious fill, rockfill, or riprap. Deposits of dredger tailings about two miles downstream from the dam, as well as sands and gravels accumulated in the existing reservoir, could be used as pervious fill material for the proposed dam. Soil suitable for use in the construction of an impervious embankment is available in limited quantities within a radius of about two miles from the dam. Although the depth of this material is probably not great, it is believed that enough could be obtained from several sources to provide for a minimum impervious earth section.

As a result of yield studies, geologic reconnaissance, and preliminary economic analysis, an earthfill dam, 155 feet in height from stream bed to spillway lip, and with a crest elevation of 311 feet, was selected to illustrate estimates of costs of the Camp Far West Project. The dam would have a crest length of about 2,980 feet and a crest width of 30 feet, and 3 :1 upstream and 2.5 :1 downstream slopes. The central impervious core would have a top width of 10 feet and 0.8 :1 slopes. The outer pervious zones of the dam would consist of stream bed gravels, dredger tailings, and salvaged material from stripping and excavation. A 3-foot blanket of gravel riprap would protect the upstream face of the dam. The volume of the fill would be an estimated 2,070,000 cubic yards. The spillway would be of the chute type, located across the ridge forming the right abutment, and concrete-lined. The maximum depth of water above the spillway lip would be 7 feet, and an additional 4 feet of freeboard would be provided. The spillway would have a capacity of 60,000 second-feet, required for an assumed discharge of 215 second-feet per square mile of drainage area. The spillway would discharge into a draw that joins the Bear River about 900 feet downstream from the toe of the dam. The outlet works would include a horseshoe type tunnel, 10 feet in diameter and 880 feet in length, excavated through the left abutment and concrete-lined. The tunnel would be used to divert flow of the Bear River during the construction period. After completion of the dam a concrete plug would be placed in the tunnel at the axis of the dam, and a 5- by 5-foot high pressure slide gate would be installed to control releases from the reservoir. A 66-inch diameter steel pipe, with capacity of 440 second-feet, would convey the water through the tunnel and terminate in a 60-inch diameter needle valve at a location about 250 feet downstream from the tunnel portal. This needle valve would discharge into a concrete-lined stilling basin, from which water would enter a concrete-lined canal at an elevation of 187 feet. Another needle valve, of 36-inch diameter, would be installed in the steel outlet pipe just outside of the tunnel portal, and would discharge directly into the Bear River.

The canal from the stilling basin would be of trapezoidal section, with 1 :1 side slopes, bottom width of 7.0 feet, depth of 6.0 feet, and freeboard of 1.0 foot. Its slope would be about 2.5 feet per mile, its velocity about 5.1 feet per second, and its capacity 400 second-feet. The canal would extend along the left bank of the Bear River a distance of about 8,000 feet, terminating in a concrete division box at an elevation of 183 feet. From this structure a steel pipe siphon, 66 inches in diameter and about 800 feet in length, with capacity of 200 second-feet, would convey water across the Bear River, discharging into a canal to serve the East Central Zone. The division box would also contain an outlet to a canal to serve the South Side Zone, and another outlet to a wasteway emptying into the Bear River.

The canals to serve both the East Central and South Side Zones would have capacities at their intakes of 200 second-feet. The canal to serve the East Central Zone would extend from the siphon outlet in a northwesterly direction a distance of approximately 3.6 miles, where about one-half of the water would be discharged into the channel of South Dry Creek to be diverted by downstream users. The remaining water would be carried a distance of about 0.8 mile and discharged into the channel of North Dry Creek for similar downstream rediversion. For an initial distance of about 3,500 feet from the Bear River siphon the canal would be shotcrete-lined and of trapezoidal section, with 1 :1 side slopes, bottom width of 6.0 feet, depth of 4.5 feet, and freeboard of 1.0 foot. The slope would be about 2.5 feet per mile, and the velocity about 4.3 feet per second. For the remainder of the distance to South Dry Creek the canal would be unlined and of trapezoidal section, with 2 :1 side slopes, bottom width of 8.0 feet, depth of 5.0 feet, and freeboard of 1.0 foot. The slope would be about 2.5 feet per mile, and the velocity about 2.2 feet per second. From South Dry Creek to North Dry Creek the canal would be unlined and of trapezoidal section, with 2 :1 side slopes, bottom width of 7.0 feet, depth of 3.7 feet, and freeboard of 1.0 foot. The slope would be about 2.5 feet per mile, and the velocity about 1.9 feet per second. Capacity of this portion of the canal would be 100 second-feet.

The canal to serve the South Side Zone would extend from the division box in a southerly direction a distance

of approximately 10.0 miles to Coon Creek, where about one-half of the flow would be discharged for rediversion by downstream users. The remaining water would be carried in a canal with capacity reduced to 100 second-feet, a distance of about 5.5 miles in a general southerly direction, where it would be similarly discharged into and conveyed in the natural channel of Markham Ravine for a distance of about 1.1 miles. The conserved water would be diverted from Markham Ravine by a flashboard dam and conveyed in a canal for a distance of about 1.2 miles where it would be discharged into Auburn Ravine for rediversion by downstream users. For an initial distance of about 1.0 mile from the division box the canal would be shotcrete-lined and of trapezoidal section, with 1:1 side slopes, bottom width of 6.0 feet, depth of 4.5 feet, and freeboard of 1.0 foot. The slope would be about 2.5 feet per mile, and the velocity about 4.3 feet per second. For the remainder of the distance to Coon Creek the canal would be unlined. It would be of trapezoidal section, with 2:1 side slopes, bottom width of 8.0 feet, depth of 5.0 feet, and freeboard of 1.0 foot. Its slope would be about 2.5 feet per mile, and its velocity about 2.2 feet per second. From Coon Creek to Auburn Ravine the constructed canal would be unlined and of trapezoidal section, with 2:1 side slopes, bottom width of 7.0 feet, depth of 3.7 feet, and freeboard of 1.0 foot. Its slopes would be about 2.5 feet per mile, and its velocity about 1.9 feet per second.

TABLE 47

GENERAL FEATURES OF CAMP FAR WEST PROJECT

Earthfill Dam
- Crest elevation—311 feet
- Crest length—2,980 feet
- Crest width—30 feet
- Height, spillway lip above stream bed—155 feet
- Side slopes—3:1 upstream; 2.5:1 downstream
- Freeboard, above spillway lip—11 feet
- Elevation of stream bed—145 feet
- Volume of fill—2,070,000 cubic yards

Reservoir
- Surface area at spillway lip—2,020 acres
- Capacity at spillway lip—104,000 acre-feet
- Drainage area—280 square miles
- Estimated mean seasonal runoff—347,000 acre-feet
- Estimated safe seasonal yield—80,000 acre-feet
- Type of spillway—Chute, concrete-lined
- Spillway capacity—60,000 second-feet
- Type of outlet—10-foot diameter pressure tunnel and 66-inch diameter steel pipe through left abutment

Conduits

	Outlet	Bear River Canal	Bear River Siphon	East Central Zone Conduit			South Side Zone Conduit		
Type	66-inch diameter steel pipe	Trapezoidal, concrete-lined	66-inch diameter	Trapezoidal			Trapezoidal		
				Lined section	Unlined section		Lined section	Unlined section	
Length, in miles	0.21	1.5	0.15	0.7	2.9	0.8	1.0	10.0	6.7
Side slopes		1:1		1:1	2:1	2:1	1:1	1:1	2:1
Bottom width, in feet		7.0		6.0	8.0	7.0	6.0	8.0	7.0
Depth, in feet		6.0		4.5	5.0	3.7	4.5	5.0	3.7
Freeboard, in feet		1.0		1.0	1.0	1.0	1.0	1.0	1.0
Slope, in feet per mile		2.5		2.5	2.5	2.5	2.5	2.5	2.5
Velocity, in feet per second	18.5	5.1	8.4	4.3	2.2	1.9	4.3	2.2	1.9
Capacity, in second-feet	440	100	200	200	200	100	200	200	100

Cost estimates for the canals to convey water to the service areas in the East Central and South Side Zones were based on designs utilizing data obtained by field location surveys. Detailed design of the distribution systems in the East Central and South Side Zones, however, was considered to be outside the scope of the current investigation. Cost estimates for the distribution systems were based on known costs of similar irrigation works elsewhere in California, adjusted to correspond with conditions prevailing in the Sutter-Yuba Area.

Pertinent data with respect to general features of the Camp Far West Project, as designed for cost estimating purposes, are presented in Table 47.

The capital cost of the Camp Far West Project, based on prices prevailing in April, 1952, was estimated to be about $5,592,900. The corresponding annual costs of the Camp Far West Project were estimated to be about $299,600. The resultant estimated unit cost of the 80,000 acre-feet per season of new water conserved by the Camp Far West Reservoir was about $3.70 per acre-foot. The estimated unit cost of water applied for irrigation in the East Central Zone was about $4.70 per acre-foot, and the estimate for water applied for irrigation in the South Side Zone was about $5.30 per acre-foot.

Estimated capital and annual costs of the Camp Far West Project are summarized in the following tabulation. Detailed cost estimates are presented in Appendix H.

	Estimated costs	
	Capital	*Annual*
Dam and reservoir	$3,979,900	$170,000
Bear River canal	233,000	12,600
East Central Zone canal and siphon	286,600	15,400
South Side Zone canal	668,400	36,000
East Central Zone distribution system	212,500	32,800
South Side Zone distribution system	212,500	32,800
TOTALS	$5,592,900	$299,600

South Side Zone

Three possible alternative plans of works for initial construction to provide supplemental water to the South Side Zone were considered. The first of these plans was the Camp Far West Project, which, as described in the preceding section, would provide supplemental water for both the East Central and South Side Zones. The second of the alternative plans con-

sidered for initial construction involved the possible purchase of water from the Nevada Irrigation District and conveyance to places of use in the natural channels of Coon Creek and Auburn Ravine. The amount of water that might be made available to the South Side Zone would depend upon design and construction of additional works of the Nevada Irrigation District, and in turn upon the outcome of possible negotiations between the district and an agency representing interests of the South Side Zone. For these reasons, features of the plan were not surveyed and studied in detail, nor estimates of cost prepared.

The third of the plans involved the construction of a dam and reservoir on Coon Creek, at a site approximately seven miles northeast of Lincoln, the utilization of an existing diversion works and ditch to convey flood flows of the Bear River to the reservoir, the reconstruction of existing abandoned facilities for diversion of the conserved waters from Coon Creek below the dam, and the construction of facilities for conveyance of the waters to and their distribution in the South Side Zone. This plan is hereinafter referred to as the "Coon Creek Project," and its principal features are delineated on Plate 23, "Coon Creek Project."

Under each of the alternative plans use of the new surface water supplies would prevent progressive and permanent lowering of ground water levels in the areas served and in adjacent areas. Each plan would provide for the present supplemental water requirement of the South Side Zone and for growth in water utilization for a number of years in the future.

Camp Far West Project. In the earlier description of the Camp Far West Project a reservoir of 104,000 acre-foot capacity, with estimated safe seasonal yield of 90,000 acre-feet, was chosen at the Camp Far West site on the Bear River for cost estimating purposes. A tentative distribution of this yield was made that would provide 40,000 acre-feet per season to the South Side Zone, some 12,000 acre-feet per season greater than the present requirement for supplemental water in the zone, which was estimated in Chapter III to be about 28,000 acre-feet per season. The 12,000 acre-feet per season of indicated present surplus yield was assigned to irrigation of irrigable lands not now served with water.

Since the South Side Zone constitutes a free ground water area, water losses in the proposed conveyance and distribution system for the new water supply would largely percolate to the ground water. For this reason it was assumed that these losses, plus the unconsumed portion of the new water supply applied to irrigation, would be effective in preventing progressive and permanent lowering of ground water levels. It was assumed that losses in conveyance and distribution of the 40,000 acre-feet per season of safe seasonal yield assigned to the South Side Zone would be about 25 percent, leaving some 30,000 acre-feet per season for application to irrigation. It was also assumed that water imported to the South Side Zone would largely be used on irrigated pasture and that the average seasonal application of the new water would be 3.5 acre-feet per acre. On this basis it was estimated that the imported supply would be applied to some 8,500 acres in a service area lying generally adjacent to Coon Creek and Auburn Ravine and easterly of the boundaries of Reclamation Districts 1000 and 1001. Elevation of this service area ranges from about 150 feet along the eastern boundary to about 50 feet on the west. Of the lands which would be served with the new water supply, about 3,300 acres are presently irrigated by ground water, and 5,200 acres are irrigable lands not presently irrigated. An estimate of monthly distribution of demand for the 40,000 acre-feet of gross seasonal import to the South Side Zone from the Camp Far West Project was presented in Table 45.

As described in the preceding section, direct releases would be made from Camp Far West Reservoir to the intake of a canal to serve the South Side Zone. The intake would be at a concrete division box, located on the left bank of the Bear River, about 1.5 miles downstream from Camp Far West Dam, at an elevation of 183 feet. From the intake the canal, with capacity of 200 second-feet, would extend in a southerly direction approximately 10.0 miles to Coon Creek. At this point about one-half of the flow would be discharged into Coon Creek for rediversion by downstream users. The remaining water would be carried in a general southerly direction an additional 5.5 miles, in a canal with capacity reduced to 100 second-feet, where it would be similarly discharged into and conveyed in the natural channel of Markham Ravine for a distance of about 1.1 miles. The conserved water would be diverted from Markham Ravine by a flashboard dam and conveyed in a canal for a distance of about 1.2 miles where it would be discharged into Auburn Ravine for rediversion by downstream users. Additional pertinent data with respect to general features of the Camp Far West Project, as designed for cost estimating purposes, were presented in Table 47.

The cost estimate for the canal to convey water to the South Side Zone was based on designs utilizing data obtained by field location surveys. Detailed design of the distribution system for the South Side Zone was considered to be outside the scope of the current investigation. The cost estimate for the distribution system was based on known costs of similar irrigation works elsewhere in California, adjusted to correspond with conditions prevailing in the Sutter-Yuba Area.

As stated in the preceding section, the capital cost of the Camp Far West Project, based on prices prevailing in April, 1952, was estimated to be about $5,592,900. Corresponding annual costs of the Camp Far West Project were estimated to be about $299,600. The resultant estimated unit cost of new water conserved by Camp Far West Reservoir was about $3.70 per acre-foot of safe seasonal yield. The estimated unit cost of

water applied for irrigation in the South Side Zone was about $5.30 per acre-foot, and the estimate for water applied for irrigation in the East Central Zone was about $4.70 per acre-foot. Detailed cost estimates for the Camp Far West Project are presented in Appendix H.

Coon Creek Project. The proposed Coon Creek Dam would be an earthfill structure, with two earthen auxiliary saddle dikes and a chute spillway. It would be located in Sections 8 and 17, Township 13 North, Range 6 East, M.B.D. & M., at a site on Coon Creek some 7.5 miles northeast of Lincoln and 8.3 miles upstream from Highway 99E. Stream bed elevation at this site is 345 feet. For cost estimating purposes, it was assumed that flood waters of the Bear River would be diverted by existing works, conveyed in the existing Upper Gold Hill and Combie-Ophir Canals for a distance of about 2.4 miles, and discharged into a tributary of Coon Creek above the proposed reservoir. These diversion works and the canals belong to the Nevada Irrigation District. The conserved waters of both Coon Creek and Bear River, after release from the proposed reservoir, would flow down Coon Creek for a distance of approximately six miles to an existing abandoned diversion structure. At this point about one-half of the released water would be diverted into a canal, and conveyed in a general southerly direction for a distance of some 5.5 miles where it would be discharged into and conveyed in the natural channel of Markham Ravine for a distance of about 1.1 miles. The conserved water would be diverted from Markham Ravine by a flashboard dam and conveyed in a canal for a distance of about 1.2 miles where it would be discharged into Auburn Ravine. The new water supply would be available in the natural channels of Coon Creek and Markham and Auburn Ravines for downstream diversion and use.

The lands which would be served by the new water supply comprise some 12,000 acres in a service area lying generally adjacent to Coon Creek and Auburn Ravine and easterly of the boundaries of Reclamation Districts 1000 and 1001. A portion of this service area, shown on Plate 23, is in Placer County and outside of the Sutter-Yuba Area. For reasons hereinafter discussed, it was assumed that water yielded by the Coon Creek Project would be entirely applied to irrigable lands not presently served with water. Use of the new surface water supply would prevent progressive and permanent lowering of ground water levels in the area served and in adjacent areas in the South Side Zone.

In Chapter III it was estimated that the present requirement for supplemental water in the South Side Zone is about 28,000 acre-feet per season. However, in design of projects for initial local development to meet this requirement, it was considered desirable to provide some capacity for future growth in water demand which would occur through development of irrigable lands not presently irrigated. In the case of the Camp Far West Project, described in the preceding section, this additional capacity was estimated to be 12,000 acre-feet per season. However, in connection with the Coon Creek Project, giving consideration to the extent of undeveloped irrigable lands that might readily be served, and to the available source of water supply, the corresponding additional capacity was estimated to be 28,000 acre-feet per season.

As a first step in determination of the size of the Coon Creek Project, estimates were made of yield of the proposed works for various reservoir storage capacities. It was estimated that mean seasonal runoff of Coon Creek, from the approximately 40 square miles of watershed above the dam site, was about 32,800 acre-feet. Of the Bear River waters, studies indicated that flood flows in an estimated mean seasonal amount of about 35,700 acre-feet could be diverted to the proposed Coon Creek Reservoir, through the existing Combie-Ophir Canal of about 106 second-foot capacity, during the months of November through April.

Based on records and estimates of runoff during the critical dry period which occurred in the Sacramento Valley from 1920-21 through 1934-35, yield studies were made of two sizes of reservoir at the Coon Creek site. The limited number of yield studies was largely determined by topographic considerations. It was assumed that a seasonal irrigation deficiency up to 35 percent could be endured in one season of the period. Monthly demands on the reservoir were assumed to be proportional to the estimated distribution of irrigation demands in the Sutter-Yuba Area, as presented in Table 33. A summary of the results of the yield studies is presented in Table 48.

TABLE 48

ESTIMATED SAFE SEASONAL YIELD OF COON CREEK RESERVOIR WITH BEAR RIVER DIVERSION, BASED ON CRITICAL DRY PERIOD FROM 1920-21 THROUGH 1934-35

(In acre-feet)

Reservoir storage capacity	Safe seasonal yield
25,500	34,000
59,000	56,000

After consideration of the results of the yield studies, together with topography of the dam site and cost analyses hereinafter discussed, a reservoir of 59,000 acre-foot capacity with estimated safe seasonal yield of 56,000 acre-feet was chosen for purposes of cost estimates to be presented in this report. The yield study for this size of reservoir is included in Appendix G.

Since the considered service area constitutes a free ground water area, water losses in the proposed canal

and ditch system would largely percolate to the ground water. For this reason it was assumed that these losses, plus the unconsumed portion of the new water supply applied to irrigation, would be effective in preventing progressive and permanent lowering of ground water levels in the area served and in adjacent areas in the South Side Zone.

It was assumed that seasonal losses in conveyance and distribution of the 56,000 acre-feet of safe seasonal yield would be about 25 percent, or 14,000 acre-feet, leaving some 42,000 acre-feet for application to irrigation. It was also assumed that the new water supply from the Coon Creek Project would largely be used on irrigated pasture, and that the average seasonal application of water would be 3.5 acre-feet per acre. On this basis it was estimated that the imported supply would be applied to some 12,000 acres in a service area lying generally adjacent to Coon Creek and Auburn Ravine and easterly of the boundaries of Reclamation Districts 1000 and 1001. Of the assumed average seasonal application of 3.5 acre-feet per acre, it was estimated that seasonal consumptive use would be about 2.3 acre-feet per acre, and that about 1.2 acre-feet per acre would be unconsumed. This unconsumed portion would aggregate about 14,400 acre-feet per season for the 12,000 acres which would be irrigated.

From the foregoing it was estimated that losses in conveyance and distribution of the new water supply, plus the unconsumed portion of the water actually applied to irrigation, both of which would largely percolate to ground water, would total about 28,400 acre-feet per season. Since the estimated present seasonal water requirement to prevent progressive and permanent lowering of ground water levels in the South Side Zone is about 28,000 acre-feet per season, no substitute water supply would have to be furnished lands presently irrigated by ground water in order to prevent such lowering. It was assumed, therefore, that lands to which the water supply from the Coon Creek Project would be applied would consist entirely of irrigable lands not presently served with water. In this connection, certain irrigable but unirrigated lands in Placer County lying immediately adjacent to the South Side Zone could readily and logically be served with water from the Coon Creek Project. For this reason the water service area shown on Plate 23 was extended outside the South Side Zone to include these lands.

An estimate of the monthly distribution of demand for irrigation water in the Sutter-Yuba Area was presented in Table 33. Based on these data, monthly demands on the Coon Creek Project would be as shown in Table 49.

TABLE 49

ESTIMATED MONTHLY DISTRIBUTION OF DEMAND FOR WATER FROM COON CREEK PROJECT

Month	Percent of seasonal total	Gross release to South Side Zone, in acre-feet
April	10	5,600
May	16	9,000
June	17	9,500
July	22	12,300
August	17	9,500
September	11	6,200
October	5	2,800
November	2	1,100
TOTALS	100	56,000

A topographic map of the Coon Creek dam and reservoir sites, at a scale of 1 inch equals 425 feet, with contour interval of 20 feet, was made by the Division of Water Resources in 1951, using photogrammetric methods. Topography of the dam site was shown on the map up to an elevation of 580 feet, while topography of the reservoir site was shown up to an elevation of 500 feet. Reservoir topography above that elevation was estimated. Storage capacities of Coon Creek Reservoir at various stages of water surface elevation are given in Table 50.

TABLE 50

AREAS AND CAPACITIES OF COON CREEK RESERVOIR

Depth of water at dam, in feet	Water surface elevation, USGS datum, in feet	Water surface area, in acres	Storage capacity, in acre-feet
0	345	0	0
15	360	5	50
35	380	25	300
55	400	65	1,200
75	420	110	3,000
95	440	180	5,800
115	460	260	10,300
135	480	360	16,600
155	500	500	25,500
175	520	610	37,600
195	540	740	51,000
205	550	810	58,000
207	552	820	59,000
215	560	880	65,000

Based upon preliminary geological reconnaissance, the Coon Creek dam site is considered suitable for an earthfill dam of any height up to a maximum of 220 feet. Foundation rock at the site consists essentially of

amphibolite schist. In the vicinity of the site the rock varies between schistose and massive material, striking across the channel and dipping vertically. The foundation bedrock as a whole is relatively hard and unweathered where exposed in outcrops. Joints are prominently developed in several sets, with a horizontal joint set predominating. Minor faulting may be involved at this site, as evidenced by the sharp change in attitude of the joint sets of the rock slightly downstream from the tentative axis position. The trend of such a possible fault may strike obliquely upstream into the right abutment where considerable talus material exists. There are no indications of recent movement in this area.

The stream at this site has cut through the resistant rib of rock, forming a narrow gorge with steep side slopes to an elevation of about 150 feet above stream bed. A dam of the height considered for cost estimating purposes would require a dike across the saddle south of the left abutment, and two dikes across smaller saddles north and east of the right abutment. However, it is indicated that the spillway could be located across the ridge forming the right abutment of the dam, utilizing one of the saddles and eliminating the need for construction of a dike therein.

It is probable that stripping under the impervious section of an earthfill dam at the Coon Creek site would be relatively heavy, due to the jointed blocky nature of the rock. On the left abutment no removal of overburden would be required for a height of about 50 feet above stream bed, while above that height stripping of overburden, consisting of earth and loose rock, should not exceed two feet of depth. On the right abutment for a height of about 60 feet above stream bed stripping of overburden, consisting of loose talus rocks but including occasional blocks in place, should not exceed 15 feet of depth. Above that height on the right abutment stripping of overburden, consisting of loose rock and earth, should not exceed three feet of depth. Beneath the described overburden on both abutments it is anticipated that required stripping would involve the removal of blocky hard rock to a maximum of 20 feet of depth.

For an earthfill dam at this site, a large proportion of the material obtained from stripping operations could be salvaged for use in the pervious sections of the dam or as riprap. Aggregates, particularly fines, are lacking in the area and might require hauling from the vicinity of the Bear River. Soil suitable for use in the construction of an impervious core is available in only limited quantities. Deposits of residual clay overburden are scattered and thin in the vicinity. However, based on a preliminary sampling program, sufficient material is believed to be available within two to three miles of the dam site to provide for a minimum impervious earth section. Materials for the pervious sections of the dam could be obtained from salvage from stripping, and from stream bed gravels of Coon Creek and the Bear River.

As a result of yield studies, geologic reconnaissance, and preliminary economic analysis, an earthfill dam 207 feet in height from stream bed to spillway lip, and with a crest elevation of 560 feet, was selected to illustrate estimates of cost of the Coon Creek Project. The dam would consist of three earthfill structures, a main dam across Coon Creek and two auxiliary saddle dams. The main dam would have a crest length of about 1,420 feet, a crest width of 30 feet, and 3:1 upstream and 2.5:1 downstream slopes. The south saddle dam would have a crest length of about 1,450 feet and a maximum height of about 64 feet. The north saddle dam would have a crest length of about 550 feet and a maximum height of about 39 feet. Both saddle dams would have crest widths of 20 feet, and 2.5:1 upstream and downstream slopes. The central impervious cores of all dams would have top widths of 10 feet and 0.8:1 slopes, and would be blanketed with sand and gravel filters. The outer pervious zones of the dams would consist of stream bed gravels and materials salvaged from stripping and excavation. The upstream face of the main dam would be protected by a 3-foot blanket of riprap, and similar blankets 2 feet in depth would protect the upstream faces of the saddle dams. The main dam would have an estimated volume of fill of 2,201,000 cubic yards, and the estimated volume of fill of the two saddle dams would be 449,000 cubic yards.

The concrete spillway would be of the ogee weir type, located in a saddle between the main dam and the north saddle dam. It would have a capacity of 14,000 second-feet, required for an assumed discharge of 350 second-feet per square mile of drainage area, and would discharge into a tributary of Coon Creek. The maximum depth of water above the spillway lip would be 4 feet, and an additional 4 feet of freeboard would be provided. Outlet works would consist of a 48-inch diameter steel pipe placed in a trench excavated in rock beneath the dam, and encased in concrete. Releases from the reservoir would be controlled at the upstream end by two 30-inch hydraulically controlled high-pressure slide gates, located at a submerged inlet upstream from the dam, and operated by hydraulic controls from a house on the left abutment. The outlet would be controlled at the downstream end by a Howell-Bunger valve.

The proposed diversion works on Coon Creek would incorporate remaining features of an abandoned diversion structure at a site approximately 3.3 miles upstream from Highway 99E. The site was examined and surveyed during the course of the investigation. The existing works consist of a concrete gate structure with concrete abutments. An earthen dike which formerly completed stream closure of the left abutment has been destroyed. Stream bed elevation at the site is 140 feet, and the gate structure is 17 feet in height above stream

bed. The gate opening is 35 feet in width, and contains seven bays to hold flashboards, each with an opening four feet in width.

For cost estimating purposes, it was planned to utilize the old concrete gate structure by installing removable flashboards to a height of 7 feet above stream bed elevation. The earthen dike would be replaced from the left abutment of the gate structure to the natural bank of Coon Creek, a distance of about 100 feet, to complete the stream closure. This embankment would be approximately 10 feet in height, with 2:1 side slopes and a crest elevation of 150 feet. A similar dike with crest elevation of 155 feet, portions of which are already in place, would extend upstream along the low left bank of Coon Creek for a distance of approximately 1,000 feet. At a point about 50 feet upstream from the main axis of the diversion structure a concrete headwall would be placed in the left side embankment, containing a 4- by 4-foot slide gate to control releases into a proposed canal. It was estimated that spillway capacity of the existing gate structure, after removal of the flashboards, would be in excess of 2,000 second-feet. It was considered that infrequent flood flows in Coon Creek in excess of this amount would wash out the closing earth embankment, and that the embankment would have to be replaced after such floods.

The proposed canal, with a capacity of 100 second-feet, would extend from the headgate in a general southerly direction a distance of approximately 5.5 miles to Markham Ravine. The conserved water would be conveyed in the natural channel of Markham Ravine for a distance of about 1.1 miles where it would be diverted by a flashboard dam and conveyed in a canal for a distance of about 1.2 miles and discharged into Auburn Ravine. For an initial distance of about 0.5 mile from the headgate the canal would be shotcrete-lined and of trapezoidal section, with 1:1 side slopes, bottom width of 4.0 feet, depth of 4.0 feet, and freeboard of 1.0 foot. Its slope would be approximately 2.5 feet per mile, and the velocity would be about 3.5 feet per second. The remaining portion of the constructed canal would be of an unlined trapezoidal section, with 2:1 side slopes, bottom width of 7.0 feet, depth of 3.7 feet, and freeboard of 1.0 foot. Its slope would be approximately 2.5 feet per mile, and the velocity would be about 1.9 feet per second. At a distance of about 1.3 miles before reaching Markham Ravine the conduit would cross Highway 99E and the Southern Pacific Railroad. The structure to carry the water underneath the highway and railroad tracks would be a steel pipe 48 inches in diameter.

Cost estimates for the canal were based on designs utilizing data obtained by a reconnaissance field location survey. Detailed design of the distribution system, however, was considered to be outside the scope of the current investigation. Cost estimates for the system were based on known costs of similar irrigation works elsewhere in California, adjusted to correspond with conditions prevailing in the Sutter-Yuba Area.

Pertinent data with respect to general features of the Coon Creek Project, as designed for cost estimating purposes, are presented in Table 51.

TABLE 51

GENERAL FEATURES OF COON CREEK PROJECT

Main Earthfill Dam
- Crest elevation—560 feet
- Crest length—1,420 feet
- Crest width—30 feet
- Height, spillway lip above stream bed—207 feet
- Side slopes—3:1 upstream
  2.5:1 downstream
- Freeboard, above spillway lip—8 feet
- Elevation of stream bed—345 feet
- Volume of fill—2,201,000 cubic yards

Auxiliary Earthfill Dams
- South saddle dam
  - Crest length—1,450 feet
  - Crest width—20 feet
  - Side slopes—2.5:1
  - Maximum height—64 feet
- North saddle dam
  - Crest length—550 feet
  - Crest width—20 feet
  - Side slopes—2.5:1
  - Maximum height—39 feet
- Volume of fill, both dams—449,000 cubic yards

Reservoir
- Surface area at spillway lip—820 acres
- Capacity at spillway lip—59,000 acre-feet
- Drainage area, Coon Creek—40 square miles
- Estimated mean seasonal runoff, Coon Creek—32,800 acre-feet
- Estimated seasonal diversion of Bear River water through Combie-Ophir Canal—35,700 acre-feet
- Estimated safe seasonal yield—56,000 acre-feet
- Type of spillway—Ogee weir, concrete-lined
- Spillway capacity—14,000 second-feet
- Type of outlet—48-inch diameter steel pipe beneath dam

Diversion Works
- Bear River—Existing concrete gravity weir, with overpour section, approximately 300 feet in length, and approximately 15 feet high above stream bed elevation of about 1,500 feet; side channel diversion box, with overpour parapet wall and sluice gate; headgates in concrete headwall.
- Coon Creek—Existing concrete diversion structure for flashboard control, with opening 35 feet in width and 17 feet in height above stream bed elevation of 140 feet; to be rehabilitated by installation of flashboards to height of 7 feet, construction of auxiliary earthen dikes, and installation of concrete headwall and 4- by 4-foot slide headgate.

Conduits
- Bear River Diversion—Existing conduit with estimated capacity of 106 second-feet, 2.4 miles in length, comprised of concrete-lined and unlined canal sections, wooden flume, and steel pipe siphons.

Coon Creek Diversion

Type	Trapezoidal, shotcrete-lined canal	Trapezoidal, unlined canal
Length, in miles	0.5	5.0
Side slopes	1:1	2:1
Bottom width, in feet	4.0	7.0
Depth, in feet	4.0	3.7
Freeboard, in feet	1.0	1.0
Slope, in feet per mile	2.5	2.5
Velocity, in feet per second	3.5	1.9
Capacity, in second-feet	100	100

The capital cost of the Coon Creek Project, based on prices prevailing in April, 1952, was estimated to be $5,303,500. The corresponding annual cost of the Coon

Creek Project was estimated to be about $254,100. The resultant estimated average unit cost of the 56,000 acre-feet per season of new water conserved by the Coon Creek Reservoir was about $4.50 per acre-foot. The estimated unit cost of water applied for irrigation in the service area considered for cost estimating purposes was about $6.10 per acre-foot. These estimates of cost do not include possible charges for use of the existing diversion works on the Bear River and the canals of the Nevada Irrigation District. They do, however, include estimated costs for acquiring the existing abandoned diversion structure on Coon Creek below the dam.

Estimated capital and annual costs of the Coon Creek Project are summarized in the following tabulation. Detailed cost estimates are presented in Appendix H.

	Estimated costs	
	Capital	*Annual*
Dam and reservoir	$4,773,700	$196,200
Coon Creek diversion and conduit	229,800	12,300
Distribution system	300,000	45,600
TOTALS	$5,303,500	$254,100

CHAPTER V

CONCLUSIONS AND RECOMMENDATIONS

As a result of field investigation, and study and analyses of available data on the water resources and water problems of the Sutter-Yuba Area, the following conclusions and recommendations are made.

CONCLUSIONS

It is concluded that:

1. The present basic water problems in the Sutter-Yuba Area are progressive and permanent lowering of ground water levels and attendant degradation of mineral quality of ground water. Elimination of these problems, prevention of their recurrence in the future, and irrigation of irrigable lands not presently served with water will require further development of available water supplies.

2. Mean seasonal depth of precipitation over the Sutter-Yuba Area is about 20.7 inches, and precipitation contributes water to the area in a mean seasonal amount of about 590,000 acre-feet.

3. The highly productive tributary watersheds of the Sierra Nevada constitute the most important source of water supply available to the Sutter-Yuba Area, and mean seasonal surface inflow of water to the area from these sources is about 6,240,000 acre-feet.

4. The ground water basin underlying the Sutter-Yuba Area functions as a natural regulatory reservoir, and at the present time about two-thirds of the lands irrigated in the area are irrigated with water pumped from this reservoir. The gross extraction of ground water in the Sutter-Yuba Area during 1948 was about 350,000 acre-feet.

5. The storage capacity of the ground water basin underlying the Sutter-Yuba Area is about 3,890,000 acre-feet between the levels of 20 and 200 feet below the ground surface.

6. Because of the continuing development and extensive use of ground water in the Sutter-Yuba Area, a substantial cone of depression exists in the ground water plane, and the average level of ground water has fallen about 10 feet since 1943. This lowering of the ground water level has resulted in increased agricultural production costs, and in saline degradation of the ground water in portions of the area.

7. Hydraulic gradients existing in the plane of ground water at the present time result in a seasonal excess of subsurface inflow over subsurface outflow from the Sutter-Yuba Area of about 180,000 acre-feet. This water is an important source of replenishment to the ground water basin.

8. Satisfactory wells with yields sufficient for irrigation purposes may be obtained in all but certain small portions of the Sutter-Yuba Area.

9. High water table lands in certain portions of the Sutter-Yuba Area served with surface water would be suitable for a wider range of crops than at present if ground water levels were held at greater depths. Furthermore, existing drainage problems in these areas would be eliminated and some salvage of water now excessively consumed would result.

10. Safe seasonal yield of the ground water basin underlying the Sutter-Yuba Area, with average maintenance of ground water levels prevailing in 1949, is about 190,000 acre-feet.

11. The surface water supplies of the Sutter-Yuba Area are of excellent mineral quality.

12. The ground water supplies of the Sutter-Yuba Area are generally of excellent to good mineral quality. However, salinity sufficient to impair use of ground water for irrigation, domestic, and many industrial uses, has been observed at scattered wells throughout the area for many years. This condition is particularly prevalent in the Peach Bowl. Saline degradation of ground water in the Sutter-Yuba Area probably results from the upward migration and diffusion of deep saline brines through permeable zones in the alluvium, and through unplugged test wells and abandoned, defective, or improperly constructed wells. This upward and lateral movement of degraded water is probably accelerated when the ground water plane is lowered by heavy irrigation pumping.

13. Due to geographic and water service considerations, the Sutter-Yuba Area is naturally divided into four principal zones. These have been designated "West Side Zone," "Northeast Zone," "East Central Zone," and "South Side Zone," and are shown on Plate 2.

14. At the present time there are approximately 150,000 acres of irrigated land in the Sutter-Yuba Area. The present distribution of the irrigated land among the several zones is as follows: West Side Zone, 66,200 acres; Northeast Zone, 20,100 acres; East Central Zone, 34,100 acres; and South Side Zone, 28,800 acres.

15. The probable ultimate cultural pattern of the Sutter-Yuba Area will include about 250,000 acres of irrigated land. The probable ultimate distribution of irrigated land among the several zones is as follows: West Side Zone, 100,000 acres; Northeast Zone, 31,000 acres; East Central Zone, 54,000 acres; and South Side

Zone, 65,000 acres. This and subsequent conclusions set forth with reference to future conditions are based upon the general assumptions that: (a) All irrigable lands in the Sutter-Yuba Area will ultimately be brought under irrigation; (b) The type of irrigated crops and irrigation practice will not alter materially; (c) There will be no significant changes in irrigation practice in adjacent areas served with surface supplies; (d) Rainfall, water supply, and climatic conditions will have annual and secular variations as in the past.

16. Of the total amount of water, including rainfall, presently utilized in the Sutter-Yuba Area, approximately 65 percent is consumed in the production of irrigated crops. Dry-farmed and fallow lands, native vegetation, and miscellaneous culture including urban areas, consume the remaining 35 percent. At the present time mean seasonal utilization of water in the area is about 820,000 acre-feet. The estimated distribution of seasonal water utilization among the several zones is as follows: West Side Zone, 311,000 acre-feet; Northeast Zone, 113,000 acre-feet; East Central Zone, 201,000 acre-feet; and South Side Zone, 194,000 acre-feet.

17. Under conditions of ultimate development the mean seasonal utilization of water will probably increase to about 1,050,000 acre-feet. The probable distribution of this use among the several zones is as follows: West Side Zone, 384,000 acre-feet; Northeast Zone, 136,000 acre-feet; East Central Zone, 256,000 acre-feet; and South Side Zone, 278,000 acre-feet.

18. The present requirement for supplemental water in the Sutter-Yuba Area, in order to prevent progressive and permanent lowering of ground water levels and attendant degradation of mineral quality of the ground water, is about 79,000 acre-feet per season. The estimated distribution of the supplemental seasonal water requirement among the several zones is as follows: West Side Zone, 17,000 acre-feet; Northeast Zone, 6,400 acre-feet; East Central Zone, 27,600 acre-feet; and South Side Zone, 27,600 acre-feet. The distribution among the zones was based on the assumption that lowering of water levels which occurred during the season of 1948-49 would have been proportionately the same had mean water supply and climatic conditions prevailed.

19. Under ultimate conditions of development the corresponding requirement for supplemental water probably will be about 315,000 acre-feet per season. The estimated distribution of ultimate mean seasonal supplemental water requirement among the several zones is as follows: West Side Zone, 90,600 acre-feet; Northeast Zone, 30,100 acre-feet; East Central Zone, 81,900 acre-feet; and South Side Zone, 112,200 acre-feet. The estimate for each zone was determined as the sum of the probable increase in water utilization and the present supplemental water requirement.

20. Major features of The California Water Plan, which is presently being formulated under direction of the State Water Resources Board, will provide supplemental water to meet the probable ultimate requirements of the Sutter-Yuba Area. The Feather River Project, an adopted feature of The California Water Plan, will provide supplemental water to meet the probable ultimate supplemental water requirements of the West Side Zone. It is feasible from an engineering standpoint to so regulate and conserve the relatively large flood flows of the Yuba and Bear Rivers and other tributaries of the Feather River as to yield firm water supplies considerably in excess of the probable ultimate supplemental water requirements of the Northeast, East Central, and South Side Zones.

21. New water sufficient to meet the present supplemental requirement of the West Side Zone, together with additional water for growth in water demand for a number of years in the future, could be furnished by construction of facilities for pumping water directly from the Feather River and for its conveyance to and distribution in the Peach Bowl. Cost estimates indicate that the average unit cost of water diverted at the river would be about $4.20 per acre-foot, and that applied to irrigation would be about $5.60 per acre-foot.

22. Preliminary studies indicate that supplemental water could be furnished the Northeast Zone from a multipurpose development of the South Fork of the Feather River and tributaries of the North Fork of the Yuba River.

23. New water sufficient to meet the present supplemental requirement of the Northeast Zone, together with additional water for growth in water demands for a number of years in the future in both the Northeast Zone and the Browns Valley service area, could be furnished by construction of a dam and reservoir on South Honcut Creek, facilities for diversion of flood waters of French Dry Creek to the reservoir, and facilities for conveyance to and distribution of the conserved waters in the Northeast Zone and the Browns Valley service area. The estimated average unit cost of the water so developed and applied to irrigation would be about $9.70 per acre-foot in the Northeast Zone, and about $8.40 per acre-foot in the Browns Valley service area.

24. Preliminary studies indicate that supplemental water could be furnished both the East Central and South Side Zones from a development involving enlargement and extension of facilities of the Nevada Irrigation District.

25. New water sufficient to meet the present supplemental requirements of the East Central and South Side Zones, together with additional water for growth in water demands for a number of years in the future, could be furnished by construction of a larger dam and reservoir on the Bear River at the site of the existing Camp Far West Dam and Reservoir, and

facilities for conveyance of the conserved water to and its distribution in both the East Central and South Side Zones. The estimated average unit cost of the water so developed and applied to irrigation would be about $4.70 per acre-foot in the East Central Zone, and about $5.30 per acre-foot in the South Side Zone.

26. New water sufficient to meet the present supplemental requirement of the South Side Zone, together with additional water for growth in water demand for a number of years in the future, could be furnished by construction of a dam and reservoir on Coon Creek, utilization of existing facilities of the Nevada Irrigation District for diversion of flood waters of the Bear River to the proposed reservoir, and facilities for conveyance to and distribution of the new water in the South Side Zone. The estimated average unit cost of the water so developed and applied to irrigation would be about $6.10 per acre-foot.

27. The unit costs of water as given in the foregoing paragraphs are based on current prices of construction, and are illustrative of the cost of new water for the various zones of the Sutter-Yuba Area developed by works exclusively for water conservation purposes. The costs exceed that of surface water presently served within the area, and it is probable that under present conditions ground water pumping costs are somewhat less than the estimated costs of water developed by the considered conservation projects. It is indicated that in order to obtain new water at lower unit costs in the Sutter-Yuba Area, multipurpose developments providing other benefits and revenues in addition to water conservation will be required.

RECOMMENDATIONS

It is recommended that:

1. Public districts endowed with appropriate powers be created for the purposes of proceeding with further study of the local water problems and with financing, construction, and operation of projects found financially feasible.

2. Local development of water resources be accomplished by an orderly progression of phases of development, and in accordance with The California Water Plan. Successive steps in proposed plans should first develop those projects with indicated lowest capital and unit cost of water, and thence proceed in order of expense to phases of greater unit cost.

3. Additional engineering investigation and study be made for design, financing, and construction of the Peach Bowl Project.

4. Additional engineering investigation and study be made as required for design, financing, and construction of other local projects for initial development outlined in this report, when the financial feasibility of these projects has been determined.

5. A program be initiated for the acquisition of lands, easements, and rights of way necessary for construction of required local water conservation works.

6. Consideration be given to the implementation of plans for securing a firm ultimate supplemental water supply for the West Side Zone from the Feather River Project.

7. Continuing support be given to the investigation and study of major multipurpose developments under The California Water Plan, including those on the Feather, Yuba, and Bear river systems.

APPENDIX A

AGREEMENT, AND ITS SUPPLEMENT, BETWEEN THE STATE WATER RESOURCES BOARD, THE COUNTIES OF SUTTER AND YUBA, AND THE DEPARTMENT OF PUBLIC WORKS

AGREEMENT BETWEEN THE STATE WATER RESOURCES BOARD, THE COUNTIES OF SUTTER AND YUBA, AND THE DEPARTMENT OF PUBLIC WORKS

THIS AGREEMENT, executed in quintuplicate, entered into by the State Water Resources Board, hereinafter referred to as the "Board"; the Counties of Sutter and Yuba, hereinafter referred to as the "Counties"; and the Department of Public Works, acting through the agency of the State Engineer, hereinafter referred to as the "State Engineer."

WITNESSETH:

WHEREAS, in the State Water Resources Act of 1945, as amended, the Board is authorized to make investigations, studies, surveys, hold hearings, prepare plans and estimates, and make recommendations to the Legislature in regard to water development projects, including flood control plans and projects; and

WHEREAS, by said act, the State Engineer is authorized to cooperate with any county, city, State agency or public district on flood control and other water problems and when requested by any thereof may enter into a cooperative agreement to expend money in behalf of any thereof to accomplish the purposes of said act; and

WHEREAS, each of the Counties desires and hereby requests the Board to enter into a cooperative agreement for the making of an investigation and report on the underground water supply of the valley floor lands in the Counties of Sutter and Yuba, including quality, replenishment and utilization thereof, and if possible, to incorporate findings in said report as to a method or methods of solving the problems involved; and

WHEREAS, the Board hereby requests the State Engineer to cooperate in making an investigation and report on the underground water supply of said valley floor lands in said Counties, including quality, replenishment and utilization thereof, and, if possible, to incorporate in said report a method or methods of solving the problems involved;

NOW THEREFORE, in consideration of the premises and of the several promises to be faithfully performed by each as hereinafter set forth, the Board, the Counties, and the State Engineer do hereby mutally agree as follows:

ARTICLE I—WORK TO BE PERFORMED:

The work to be performed under this agreement shall consist of investigation and report on the underground water supply of the valley floor lands in the Counties of Sutter and Yuba, including quality, replenishment and utilization thereof, and, if possible, a method or methods of solving the problems involved.

The Board by this agreement authorizes and directs the State Engineer to cooperate by making said investigation and report and by otherwise advising and assisting in making an evaluation of present and ultimate underground water problems in the valley floor lands of said Counties, and in formulating a solution or solutions of said problems.

During the progress of said investigation and report all maps, plans, information, data and records pertaining thereto which are in the possession of any party hereto shall be made fully available to any other party for the due and proper accomplishment of the purposes and objects hereof.

The work under this agreement shall be diligently prosecuted with the objective of completion of the investigation and report on or before December 31, 1949, or as nearly thereafter as possible.

ARTICLE II—FUNDS:

Each of the Counties, upon execution by it of this agreement, shall transmit to the State Engineer the sum of Five Thousand Dollars ($5,000) for deposit, subject to the approval of the Director of Finance, into the Water Resources Revolving Fund (also known as the Water Resources Fund) in the State Treasury, for expenditure by the State Engineer in performance of the work provided for in this agreement. Also, upon execution of this agreement by the Board, the Director of Finance is requested to approve the transfer of the sum of Ten Thousand Dollars ($10,000) from funds appropriated either by the Budget Act of 1947, or by Chapter 1541, Statutes of 1947, or in part from each of said appropriations, to said Water Resources Board for expenditure by the State Engineer in performance of the work provided for in this agreement and the State Controller is requested to make such transfer.

If the Director of Finance, within thirty (30) days after receipt by the State Engineer of said sums from the Counties, shall not have approved the deposit thereof into said Water Resources Revolving Fund, together with the transfer of said sum of Ten Thousand Dollars ($10,000) from funds appropriated to said Board either by the Budget Act of 1947, or by Chapter 1541, Statutes of 1947, or in part from each of said appropriations, said Water Resources Revolving Fund for expenditure by the State Engineer in performance of the work provided for in this agreement, said sums contributed by said Counties shall be returned thereto by the State Engineer.

It is understood by and between the parties hereto that the sum of Twenty Thousand Dollars ($20,000) to be made available as hereinbefore provided is adequate to perform approximately half of the above specified work and it is the present intention of each of said Counties to make a further sum of Five Thousand Dollars ($5,000) available at the commencement of the second year of said investigation which will be subject to a matching or contribution in equal sums by said Board for the completion of said investigation and report.

The Board and the State Engineer shall under no circumstances be obligated to expend for or on account of the work provided for under this agreement any amount in excess of the sum of Twenty Thousand Dollars ($20,000) as made available hereunder and when said funds are exhausted, the Board and the State Engineer may discontinue the work provided for in this agreement and shall not be liable or responsible for the resumption and completion thereof until the further sums as specified in the preceding paragraph are made available.

Approved:

Department of Public Works

Upon completion of and final payment for the work provided for in this agreement, the State Engineer shall furnish the Board and each of the Counties a statement of all expenditures made under this agreement. One-half of the total amount of all said expenditures shall be deducted from the sum advanced from funds appropriated to said Board, and one-fourth of the total amount of all said expenditures shall be deducted respectively, from the sum advanced by each of the Counties and any balances which may remain shall be returned to the Board, and to the counties, respectively.

ARTICLE III—EFFECTIVE DATE

This agreement shall become effective immediately upon its execution by all the parties hereto.

In Witness Whereof, the parties hereunto have affixed their signatures, the County of Sutter on the 22nd day of September, 1947, the County of Yuba on the 22nd day of September, 1947, the Board on the 6th day of October, 1947, and the State Engineer on the 7th day of October, 1947.

SUPPLEMENTAL AGREEMENT BETWEEN THE STATE WATER RESOURCES BOARD, THE COUNTIES OF SUTTER AND YUBA, AND THE DEPARTMENT OF PUBLIC WORKS

THIS AGREEMENT, executed in sextuplicate, entered into by the State Water Resources Board, hereinafter referred to as the "Board"; the Counties of Sutter and Yuba, hereinafter referred to as the "Counties"; and the Department of Public Works of the State of California, acting through the agency of the State Engineer, hereinafter referred to as the "State Engineer":

WITNESSETH:

WHEREAS, by agreement heretofore entered into by and between the parties hereto, executed by the Counties on the 22nd day of September, 1947, by the Board on the 6th day of October, 1947, and by the State Engineer on the 7th day of October, 1947, the making by the State Engineer of an investigation and report on the underground water supply of the valley floor lands in the Counties of Sutter and Yuba, including quality, replenishment and utilization thereof and, if possible, a method or methods of solving the problems involved, was provided for; and

WHEREAS, it was the expressed intention in said agreement that at the commencement of the second year of said investigation said Counties would make available in equal proportion a further sum of Ten Thousand Dollars ($10,000) subject to a matching or contribution in equal amount by the Board for the completion of said investigation and report; and

WHEREAS, said additional funds are required to complete said investigation and report, and it is the desire of the parties hereto that an additional sum of Twenty Thousand Dollars ($20,000) shall be provided, Five Thousand Dollars ($5,000) by each of the Counties, and Ten Thousand Dollars ($10,000) by the Board;

NOW THEREFORE, in consideration of the premises and of the several promises to be faithfully performed by each as hereinafter set forth, the Board, the Counties, and the State Engineer do hereby mutually agree as follows:

1. Each of the Counties, upon execution by it of this agreement, shall transmit to the State Engineer the sum of Five Thousand Dollars ($5,000) for deposit, subject to the approval of the Director of Finance, into the Water Resources Revolving Fund in the State Treasury for expenditure by the State Engineer in continuing performance of the work provided for in said prior agreement to which this agreement is supplemental.

2. Upon execution of this agreement by the Board, the Director of Finance will be requested to approve the transfer of the sum of Ten Thousand Dollars ($10,000) from funds appropriated to the Board by Item 335 of the Budget Act of 1948 for expenditure by the State Engineer in continuing performance of the work provided for in said prior agreement to which this agreement is supplemental, and the State Controller will be requested to make such transfer.

3. The Board and the State Engineer shall under no circumstances be obligated to expend for or on account of the work provided for in said prior agreement to which this agreement is supplemental any amount in excess of the sum of Forty Thousand Dollars ($40,000) as made available under said prior agreement and this supplemental agreement and if funds are exhausted before completion of said work the Board and the State Engineer may discontinue said work and shall not be liable or responsible for the completion thereof.

4. In so far as consistent herewith and to the extent adaptable hereto, all of the terms and provisions of said prior agreement to which this agreement is supplemental are hereby made applicable to this agreement and are hereby confirmed, ratified, and continued in effect.

5. This agreement shall become effective immediately upon its execution by all of the parties hereto.

In Witness Whereof, the parties hereunto have affixed their signatures, the County of Sutter on the 4th day of October, 1948, the County of Yuba on the 22nd day of November, 1948, the Board on the 3rd day of December, 1948, and the State Engineer on the 30th day of November, 1948.

GEOLOGICAL SURVEY

GROUND WATER BRANCH
2520 Marconi Avenue
SACRAMENTO 21, CALIFORNIA

May 22, 1950

Mr. A. D. EDMONSTON, *State Engineer*
Division of Water Resources
P. O. Box 1079, Sacramento 5, California

DEAR SIR: I take pleasure in transmitting herewith a report on "Geologic features and ground-water storage capacity of the Sutter-Yuba area, California" by G. H. Davis and F. H. Olmsted. This report has been prepared by the Geological Survey as a part of the program of cooperative ground-water investigations with the California Division of Water Resources.

The report has been approved by the Director of the Geological Survey for publication by the State Water Resources Board as an appendix to its Bulletin No. 6 entitled "Sutter-Yuba Counties Investigation."

Very truly yours,

(Signed) JOSEPH F. POLAND
District Geologist

GEOLOGIC FEATURES AND GROUND-WATER STORAGE CAPACITY OF THE SUTTER-YUBA AREA, CALIFORNIA

By G. H. Davis and F. H. Olmsted

INTRODUCTION

Purpose and Scope of Report

The Sutter-Yuba Area, as identified in this report, includes the parts of Sutter and Yuba Counties that are within the Sacramento Valley and the lower foothills of the Sierra Nevada, an area of 750 square miles. Its general physical and geomorphic features are shown by Plate 1. It is bounded on the east by the rugged Sierra Nevada, on the west by the Sacramento River, and is divided into two nearly equal parts by the southward flowing Feather River. Its importance as an agricultural area and its dependence on surface-water and ground-water supplies for existence and future development have been discussed in the main report by the California Division of Water Resources.

This report on the geology and ground-water storage capacity of the Sutter-Yuba Area has been prepared at the request of the Division of Water Resources, as one of the investigations of ground-water basins of the State now being made by the Geological Survey in accordance with the cooperative agreement with the State Water Resources Board entered into in March, 1948.

The geologic investigation of the Sutter-Yuba Area is in essence a part of a broader reconnaissance investigation of the geology and ground-water storage capacity of the Sacramento Valley which was begun by the Geological Survey in the spring of 1948 at the request of and in cooperation with the California Division of Water Resources. The findings of the valley-wide study are to be published in a separate bulletin under the title of "Geologic features and ground-water storage capacity of the Sacramento Valley, California." That bulletin is now being written.

This appendix has two principal purposes:

First, to describe the geology and general water-bearing character of the rocks. Treatment of the older, nonwater-bearing rocks is general and brief, but is a necessary element of the story because the sediments making up the water-bearing rocks are derived from the weathering and erosion of these older rocks and from their transportation from the Sierra Nevada to the Sacramento Valley. The water-bearing rocks of Tertiary and Quaternary age are described in considerable detail; those deposits are the important sources of ground water. Furthermore, certain geologic events which have uplifted, tilted, or folded the rocks or have produced volcanic deposits have been described because they have caused changes in the texture of sediments being transported to the valley by streams, by mud flows, or through the atmosphere, and thus have been primary factors in deposition of the coarse-grained water-bearing deposits.

Second, to describe the methods used and the results obtained in estimating the water-holding capacity of the water-bearing deposits considered to be within ultimate economic limits for pumping—that is, the deposits constituting the part of the underground reservoir that may be capable of dewatering and resaturation.

This appendix does not treat ground-water occurrence and movement, perennial yield, or chemical character of the ground waters because the hydrologic and water-quality phases of the problem have been carried out entirely by the State Division of Water Resources.

The investigation, which began in October, 1949, has been under the general direction of A. N. Sayre, geologist in charge of the Ground Water Branch, and under the immediate supervision of J. F. Poland, district geologist for California. The field work by the Geological Survey in the Sutter-Yuba area was confined chiefly to geologic mapping, which was done by G. H. Davis and F. H. Olmsted in October and November 1949. The geologic contacts actually traced in the field include the boundaries of the basement complex and of the Tertiary and Quaternary deposits near the basement-complex outcrop. The boundaries of the alluvial deposits of late Tertiary and Quaternary age were mostly drawn or modified on the basis of physiography, and from significant soil-type boundaries mapped by the United States Department of Agriculture, Bureau of Soils. The geology of the Sutter Buttes was taken from H. R. Johnson (1943) * "Marysville Buttes (Sutter Buttes) gas field."

Most of the information on subsurface geology and ground-water storage capacity of the water-bearing deposits was obtained from about 700 logs of water wells supplied by well drillers to the Bureau of Reclamation and the Geological Survey. The logs were turned over to the Division of Water Resources for field location. The cooperation of the well drillers in making available the well logs is greatly appreciated.

Numbers Applied to Wells

In its recent cooperative programs in California, the Geological Survey commonly has assigned well numbers that indicate locations according to the rectangular land surveys. For well 15 N 3E-21C1, for example, the

* References are listed at the end of this appendix alphabetically by the author's name and the year of publication.

first part of the number indicates the township and range (T. 15 N., R. 3 E., Mt. Diablo base line and meridian), the two digits following the hyphen indicate the section (Sec. 21), and the letter indicates the 40-acre subdivision as shown on the accompanying diagram.

D	C	B	A
E	F	G	H
M	L	K	J
N	P	Q	R

Within each 40-acre tract the wells are numbered serially as indicated by the final digit or digits of the number. Thus well 21C1 is in the NE ¼ NW ¼ Sec. 21 and is the first well in that tract to be listed.

In the parts of the area that once were public lands, the official Federal land survey is followed. In the few areas that never were Federally surveyed, the net is projected.

GEOLOGY

General Features

North-central California, which includes the Sutter-Yuba Area, comprises parts of four geomorphic provinces as delimited by Jenkins (1943, pp. 83-88): the Great Valley of California, the Sierra Nevada, the Coast Ranges, and the Cascade Range. The area described in this report lies mostly within the Great Valley of California province, but includes a narrow strip of the Sierra Nevada province to the east. The southernmost extension of the Cascade Range lies more than 20 miles to the north, and the eastern margin of the Coast Ranges lies 20 miles to the west of the Sutter-Yuba Area.

The rocks exposed in the area range from Recent alluvial deposits to Mesozoic and Paleozoic crystalline rocks. Their areal extent is shown on Plate B-1 and their subsurface character on Plates B-2, B-3, and B-4. Their stratigraphy and physical and water-bearing character are summarized in the following table. These rocks may be assigned to two broad categories: the basement complex and the superjacent rocks. The basement complex is exposed in the Sierra Nevada and extends beneath the superjacent rocks in the Sacramento Valley. The superjacent rocks cap many of the interstream divides in the Sierra and comprise the thick and extensive deposits of the valley. The water-bearing rocks considered in this report are entirely within the superjacent rocks, although the basement complex yields small amounts of water to wells in weathered and fractured zones.

Pre-Cretaceous Crystalline Rocks

The basement complex consists of metamorphosed igneous and sedimentary rocks of late Paleozoic and early Mesozoic age and a series of igneous rocks ranging in composition from granite to peridotite which were intruded during the late Jurassic or early Cretaceous Nevadan orogeny.

The rocks exposed immediately east of the Sutter-Yuba Area are predominantly greenstones that probably are metamorphosed basic igneous rocks.

Cretaceous and Tertiary Nonwater-bearing Rocks

The older superjacent rocks are Upper Cretaceous and early Tertiary sediments. A section of unnamed Upper Cretaceous siltstone and sandstone totaling 4,350 feet thick crops out in the Sutter Buttes and has been found in gas wells in the Sacramento Valley. These sediments were deposited in a sea which at times extended eastward to or beyond the present western edge of the basement complex outcrop.

Eocene and possible Paleocene sediments underlie most of the Sutter-Yuba Area. A lower and middle Eocene marine section is exposed in the Sutter Buttes. Stewart (1949) has assigned the 300 feet of lower Eocene in the Buttes to the Meganos formation, and the 130 feet of middle Eocene to the Ione formation. The Ione formation, described in some detail by Allen (1929) is exposed in places along the east side of the valley. There it is usually a brackish-water or deltaic deposit consisting largely of light-colored anauxitic clays and sands, dark reddish or brownish ferruginous sandstones, and minor amounts of lignitic material.

The Ione formation interfingers to the east with river gravels deposited by old Sierra Nevada streams. The ancient Yuba River was the main stream entering the Sutter-Yuba Area in Eocene time.

About 250 to 300 feet of upper Eocene or Oligocene rocks, called the Wheatland formation by Clark and Anderson (1938), are exposed along the southeast bank of the Dry Creek flood plain northeast of Wheatland. A fossiliferous conglomerate containing andesitic pebbles is near the base of the formation which lies unconformably on basement complex. Some of the finer-grained sediments above the conglomerate also contain volcanic detritus.

The Upper Cretaceous and Eocene sediments are not significant as ground-water reservoirs in the Sutter-Yuba Area. Probably none of the water wells in the area penetrates Upper Cretaceous rocks. Several water wells near Wheatland apparently penetrate Eocene rocks, but impermeable shale, siltstone, and sandstone predominate, and the water in the more permeable zones is generally of poor quality. How much of the chloride contamination in parts of the area comes from connate waters in the Eocene rocks is not known. In

STRATIGRAPHY OF THE SUTTER-YUBA AREA AND VICINITY, CALIFORNIA

(Generalized section[1])

Geologic age		Rock unit and symbol on pl. B-1		Thickness (feet)	Physical and water-bearing character
QUATERNARY	Recent	Young alluvial deposits	Stream-channel deposits (Qrc)	0 - 130	Sand, gravel, and silt, in large part well-sorted, in present stream channels and beneath flood plains; yield water in large quantities to irrigation wells. Where the Feather and Sacramento Rivers border the Sutter Basin, they have constructed natural levees composed largely of silt and fine sand deposited during flood stages.
			Basin deposits (Qrb)	0 - 100±	Largely impervious clays and silts deposited in the overflow basins during flood stages of the Feather and Sacramento Rivers. Thin, discontinuous sands supply small domestic and stock wells in the northern part of Sutter Basin; in the southern part of the basin brackish waters are likely to be encountered in wells of any depth.
			Alluvial fans of the Sutter Buttes (Qrf)	0 - 80	Poorly sorted alluvial deposits of gravel and clay, sandy clay, or silt, of low to moderate permeability; yield small supplies of good quality water to stock and domestic wells along the flanks of Sutter Buttes.
	Pleistocene	Local unconformity			
		Intermediate alluvial deposits (Qpal)		0 - 110+	Silt, sand, and gravel, in part well-sorted; moderately permeable throughout. Tongues and layers of fluviatile sand and gravel are highly permeable and supply large quantities of irrigation water. Deposits are coarsest and most permeable near the present major streams and along abandoned Pleistocene channels of the Yuba and Feather Rivers.
		Unconformity			
		Old alluvial deposits (TQal)		0 - 350±	Poorly-sorted silt, clay, sand, and gravel of moderate to low permeability supply water of good chemical quality to domestic, stock, and a few small irrigation wells. Essentially impervious strata of cemented sand and gravel are common. Well-sorted permeable alluvial materials are rare.
TERTIARY	Pliocene	Volcanic rocks of the Sutter Buttes	Andesite tuff-breccia (Tat)	0 - 800±	Andesitic tuffs and tuff-breccias, unsorted and generally of low permeability; some beds may be impermeable. Permeable tongues and stringers of volcanic sand and gravel interbedded with mudflow tuffs and tuff-breccias yield water of good quality to irrigation wells in the Pennington and Sutter City areas.
			Unconformity		
			Rhyolite and andesite (Tra)		Impervious, hard lavas forming core of Sutter Buttes; possibly could provide small water supplies from fractured zones. No wells are known in these rocks.
			Unconformity		
	Pliocene Miocene Oligocene	Volcanic rocks from the Sierra Nevada (Tfa)		0 - 1,800±	Andesitic and rhyolitic tuffs, tuff-breccias, conglomerates, sands, and gravels deposited by inter-volcanic streams from the Sierra Nevada. Sands and gravels yield water of good quality to deep wells in the Marysville and Bear River areas. Fluviatile "black sands" are prolific water producers at many places in the Sacramento Valley. Tuff and tuff-breccia have low permeability and yield little water.
		Unconformity			
	Eocene	Undivided Eocene sediments (Te)		0 - 700±	Marine and non-marine clay, shale and sandstone beneath the Sacramento Valley interfingering along the eastern margin of the valley with Eocene river gravels. These gravels ordinarily are cemented and partially decomposed and probably would yield little water. Coarser sediments in southern Yuba and northwestern Placer counties yield saline waters of probable marine origin to some deep wells. In structurally high positions the marine connate waters have been flushed out of the permeable strata and fresh water is found.
		Unconformity			
CRETACEOUS	Upper Cretaceous	Unnamed Upper Cretaceous sediments (Ku)		0 - 4,350	Sandstone, siltstone, and shale; not penetrated by water wells in Sutter-Yuba area. Connate marine water high in chloride could be expected in wells penetrating these sediments in the Sacramento Valley.
		Unconformity			
PRE-CRETACEOUS		Pre-Cretaceous crystalline rocks (pK)			Hard, impervious metamorphic and igneous rocks. Stock and domestic wells produce small supplies of water of good chemical quality from fractured and partly decomposed zones near the land surface.

[1] Dotted lines are used to separate units that are considered to be contemporaneous.

structurally high positions, for example just west of the outcrops of Wheatland formation, the marine connate waters have been flushed out, and fresh water is found in the more permeable strata.

Tertiary and Quaternary Water-bearing Rocks

Volcanic Rocks From the Sierra Nevada (Eocene-Pliocene)

Tertiary fragmental volcanic rocks having a source near the present crest of the northern Sierra Nevada are exposed at several localities and are encountered in many of the deep wells in the Sutter-Yuba Area. The exposures are found at three principal localities: south of the Yuba River and about 10 miles east of Marysville, on the Camp Beale Military Reservation; at the clay quarries one to two miles northwest of Lincoln; and in an extensive area east of the Southern Pacific railroad and U. S. Highway 99E between Lincoln and Roseville. The last two areas are in Placer County.

Tertiary volcanic rocks do not crop out in the foothill region between Lincoln and the Camp Beale exposure south of the Yuba River. However, many water wells farther west penetrate volcanic rocks, and the original eastward extent of those volcanics was probably greater than it is at present.

GEOLOGIC EVENTS IN SIERRA NEVADA AND ON EAST SIDE OF SACRAMENTO VALLEY

(Read from bottom up)

Recent	Hydraulic mining in Sierra Nevada in late 19th century chokes channels of Feather, Yuba and Bear Rivers with debris. Deposition of stream-channel, alluvial-fan, and basin deposits contemporaneous with mild dissection of intermediate alluvial deposits (Qpal).
Pleistocene	Deposition of intermediate alluvial deposits (Qpal), contemporaneous with moderate to severe dissection of old alluvial deposits (TQal). Several stages of glaciation in Sierra. Truncation and planation of Pliocene alluvial deposits and older rocks, and deposition of thin blanket of course gravel in many areas adjacent to the Sierra Nevada (uppermost part of TQal). Last major uplift of Sierra Nevada with additional regional westward tilting.
Pliocene	Eruptions of Sutter Buttes volcano cover slopes with tuff-breccia deposits from mud-flows. Deposition of old alluvium from Sierra continues. Deposition of old alluvial deposits by streams of low gradient from Sierra Nevada. May be in part contemporaneous with deposition of uppermost Sutter formation and with subsequent volcanic activity at Sutter Buttes. Intrusion of Sutter Buttes central area as plug of plastic andesite porphyry. Andesite mass subsequently intruded by rhyolite porphyry. Valley sediments pierced by volcanic plug are folded and fractured around central area. Great andesitic volcanic activity in Sierra wanes; consequent streams erode volcanic materials and deposit them in Sacramento Valley.
Miocene and Oligocene	Great mud flows of andesitic detritus originating near the crest of the Sierra cover most of the western slope. Old drainage in Sierra almost completely disrupted. Streams begin to erode detritus and deposit it in valley. Faulting and westward tilting of Sierra block during andesite eruptions. Volcanic eruptions near present Sierra crest continue; rhyolitic debris moves westward down canyons, locally damming and diverting streams. Deposition of Sutter formation (non-marine) begins in Sacramento Valley; continues until uplift of Sutter Buttes.
Oligocene or Eocene	Earliest volcanic activity in Sierra Nevada (andesitic and some rhyolitic); sea finally withdraws from Sacramento Valley after extending as far northeast as Wheatland during uppermost Eocene or Oligocene.
Eocene	Marine sedimentation in Sacramento Valley during middle and lower Eocene. Middle Eocene Ione formation, largely non-marine clay and quartzose sand, deposited on the lower slopes of the Sierra Nevada and as deltaic deposits in Sacramento Valley embayment. Moderate uplift of Sierra Nevada or change of base level causes dissection of weathered rocks on west slope of Sierra. Tropical climate and gentle slopes cause deep weathering of rocks in place on west slope of Sierra Nevada.
Upper Cretaceous	Regional upwarping at end of Upper Cretaceous interrupts marine deposition on east side of Sacramento Valley. Great erosion in Sierra Nevada; shallow-water marine deposition in Sacramento Valley.
Lower Cretaceous	At end of Lower Cretaceous—ancestral Coast Ranges formed by folding, faulting, and uplift; Sacramento Valley trough first outlined, though axis somewhat west of present valley. Erosion in ancestral Sierra Nevada.
Lower Cretaceous and/or Upper Jurassic	Formation of folded mountain range of great height, the ancestral Sierra Nevada, by Nevadan orogeny.

The volcanic deposits are chiefly andesitic stream-laid conglomerate and sandstone, and tuff-breccia of mud-flow origin, together with some fine-grained rhyolitic material, all from the Sierra Nevada. As encountered in wells, the conglomerate and sandstone often are loosely consolidated and in such cases are logged by drillers as gravel and sand.

The large area of volcanic rocks at Camp Beale is underlain by andesitic conglomerate, sandstone, and tuff-breccia with interbedded rhyolitic ash. The age of these deposits is probably Eocene, which is somewhat older than most of the other volcanic deposits in the Sutter-Yuba Area on the east side of the Sacramento Valley (Clark and Anderson, 1938).

Andesite tuff-breccia one mile northwest of Lincoln overlies altered rhyolitic ash, and also clay of the Ione formation. The extensive volcanic surface east of U. S. Highway 99E between Lincoln and Roseville is underlain by the same andesite tuff-breccia interbedded with andesitic sandstone and conglomerate. The age of these deposits is not certainly known, but they are believed to be equivalent in age to andesitic deposits in the Mokelumne River Area (the Mehrten formation), which is probably Miocene and may be in part Pliocene (Piper and others, 1939).

The Sutter formation of the Sutter Buttes unconformably overlies Eocene rocks and is in turn overlain unconformably by andesitic and rhyolitic tuffs and breccias of Pliocene age derived from the Buttes volcano. The lower part of the Sutter formation is probably correlative with the volcanic rocks from the Sierra Nevada, although the upper portion may consist of later reworked deposits. The maximum exposed thickness of the Sutter formation is approximately 1,800 feet (Johnson, 1943, p. 614)—considerably thicker than the volcanics from the Sierra Nevada farther east which are probably not over 250 feet thick in outcrop (see Plate B-1). The Sutter rocks are thin-bedded to massive tuff, conglomerate, sand, and clay.

The permeable sand and gravel in the volcanic rocks from the Sierra Nevada probably yield water to deep wells in the Sutter-Yuba Area. Deep wells in Marysville obtain some water from the volcanic sediments, and wells on the Camp Beale Military Reservation 10 miles east of Marysville obtain yields of several hundred gallons a minute from volcanic sands and gravel. Several wells south of the Bear River also produce water from the volcanic rocks from the Sierra Nevada.

Volcanic Rocks of the Sutter Buttes (Pliocene)

The Pliocene volcanic rocks of the Sutter Buttes may be divided into two principal groups: the intrusive rhyolite and andesite and the vent tuffs of the central core; and the andesitic and rhyolitic tuff-breccia that forms the ring encircling the core.

The rocks of the first group are principally porphyritic rhyolite and andesite. These rocks form the sharp peaks in the central area. They are unimportant as a source of ground water.

The tuff-breccia consists of angular blocks of rhyolite and andesite that were swept down the slopes of the old volcano in great mud flows. Many water wells near the periphery of the Buttes encounter the tuff-breccia and intercalated volcanic sediments (see Plates B-1 and B-2). The estimated maximum thickness of the deposits is about 800 feet.

In general, the volcanic sand and gravel yields some water, but the tuff-breccia is tight and nonwater-bearing. North of the Buttes, in the vicinity of Pennington, irrigation wells obtain part of their yield from the volcanic sands and gravels.

Old Alluvial Deposits (Pliocene-Pleistocene)

Location and Extent. The old alluvial deposits, which overlie the volcanics from the Sierra Nevada and older rocks, are exposed in a semicontinuous belt along the east side of the valley, between the outcrop of the basement complex and the volcanics to the east and the younger sediments to the west. A few scattered outliers of old alluvium extend west of the main outcrop from the northern edge of the Sutter-Yuba Area to Wheatland.

Physical Character. The old alluvial deposits are identified physiographically as dissected uplands near the eastern valley margin. Peculiar "hog wallow" topography, consisting of small mounds and undrained or poorly drained depressions often less than 100 feet across, is a common and striking characteristic.

A capping gravel, presumably early Pleistocene in age, and seldom more than 30 feet thick, is extensive near the eastern edge of the outcrops of old alluvium. The underlying silts and sands are presumably Pliocene in age and may be correlative with the Laguna formation to the south, in the Mokelumne Area, described by Gale (Piper and others, 1939).

The gravels almost always have a silty or fine sandy matrix with a distinctive reddish color. Silty and fine-sandy loams, usually with a hardpan layer, are typical soils.

The old alluvial deposits are extremely heterogeneous, and it is difficult to distinguish them in most well logs from younger and older sediments.

Reddish to yellowish-brown silt and silty sand are abundant, but light-gray moderately well-bedded indurated siltstone and fine sandstone are more distinctive and diagnostic. Many of the sand and gravel beds are cross-bedded, indicating fluviatile origin. The gravel is rarely clean or well-sorted; the silty matrix greatly reduces the permeability and porosity. This gravel may be distinguished from that in the underlying volcanics from the Sierra Nevada by the relative scarcity of volcanic rocks, but this distinction is often hard to make, and many drillers do not mention the composition of the pebbles and cobbles.

Water-bearing Character. The poorly-sorted sediments of the old alluvium generally do not yield as much water as the younger deposits. Cementation of the sand and gravel strata is a common feature and many wells are left uncased in the older alluvium; the cemented silt, sand, and gravel strata being sufficiently consolidated to stand without support.

Throughout the Sutter-Yuba Area, enough water can be obtained from the old alluvial deposits to supply domestic and stock wells. It is doubtful, however, that large-capacity irrigation wells could be developed in these deposits. Few wells tap only the old alluvium for sure and yields of these are not known. In the area between the Bear and Yuba Rivers, several irrigation wells produce between 1,000 and 2,000 gallons a minute, but these wells are several hundred feet deep and penetrate the intermediate alluvium, the old alluvium, and presumably the volcanic deposits from the Sierra Nevada. It is believed that the bulk of their yield comes from the volcanic deposits below and the intermediate alluvium above.

Intermediate Alluvial Deposits (Pleistocene)

Location and Extent. The intermediate alluvial deposits which rest on the old alluvium and in places are overlain by the young alluvium of Recent age crop out along a broad belt between the old alluvium on the east and the basin deposits on the west. A few small outliers of intermediate alluvium occur in the American Basin east of the Feather-Sacramento junction.

Physical Character. Topographically these deposits underlie moderately to slightly dissected low plains with a gentle westerly to southwesterly slope. Soils are quite variable but all have some hardpan development. The soils adjacent to the flood basins are fine-grained and dark in color. Soils farther east are coarser, frequently reddish, but almost never gravelly. (See soil surveys, U. S. Dept. Agriculture, in references.)

The intermediate alluvium consists of sand, silt, and gravel, in part well-sorted and well-stratified, deposited by the Feather River and its tributaries in building the low alluvial planes. These deposits are heterogeneous and lenticular in character because of their extremely varied mode of formation. In the eastern part of the area they are largely of alluvial-fan origin; the coarse sand and gravel beds extending 3 to 5 miles west from the present course of the Feather River are probably Pleistocene (Feather) river-channel deposits; and the predominantly fine-grained deposits farther west are chiefly of flood basin or lacustrine origin. Well logs indicate that the material penetrated in the top 100 feet becomes progressively finer toward the Sutter and Butte Basins. Sand and gravel give way to sandy clays and clays, and dark colors predominate. The proportion of sand and gravel to fine sediments in the upper 50 feet decreases from maxima of 80 to 90 percent to 5 to 10 percent. The proportion of blue and dark-gray fine-grained materials—indicative of a non-oxidizing environment—possibly flood-basin or lacustrine deposition—becomes greater as the proportion of fine sediments increases.

In general, the intermediate alluvium is not appreciably consolidated. The beds that are indurated have a high proportion of clay and silt which act as a binder. Hardpan layers, representing buried soil zones, are encountered at various depths. These hard layers usually are cemented with hydrous iron and aluminum silicates, although calcareous cementation is common in areas of high water table adjacent to the flood basins.

The intermediate alluvial deposits are inferred to be correlative with the Victor formation of Pleistocene age in the Mokelumne area described by Gale and Piper (Piper and others, 1939).

Thickness. From drillers' logs, it is inferred that the intermediate alluvial deposits do not exceed 110 feet in thickness in the Sutter-Yuba Area. West of the Feather River, these deposits consist of 50 to 110 feet of sandy clay, sand, and gravel. (See Plate B-2, Section B-B1.) North of Yuba City they overlie brown cemented sands and hard brown clays of the old alluvium. South of Yuba City and in the Marysville area the underlying old alluvium usually is blue clay.

In the area east of the Feather River and north of the Yuba River the intermediate alluvium reaches thicknesses of 70 to 100 feet and rests upon cemented sand, gravel, and clay of the old alluvium that crop out in the dissected uplands to the east.

Few wells penetrate the intermediate alluvium south of the Yuba River but the thickness does not appear to exceed 50 feet.

Water-bearing Character. The intermediate alluvium is moderately permeable throughout, but the tongues and layers of well-sorted sand and gravel are highly permeable and yield large quantities of water to wells. Nearly all the domestic and many small irrigation wells located on the low plains are completed in these deposits. Large wells for irrigation and municipal supply obtain much of their water from this material, but also obtain water from the older deposits at greater depths.

Deposits of this age are coarsest and most permeable near the Yuba and Feather Rivers, and less permeable close to the flood basins where dark colored silt and clay predominate.

Young Alluvial Deposits (Recent)

The Recent deposits of the Sacramento Valley may be defined as those sediments that are still accumulating, or would be accumulating under natural conditions. These deposits would include: silt, sand, and gravel laid down in stream channels during times of decreasing flood flow; silt and sand deposited on natural levees at times of overflow; silt and clay deposited in the flood basins; detritus of the alluvial fans surrounding the Sutter Buttes. In this report, the natural levee sediments are grouped with the stream-channel

deposits. The other two types of sediments are called "basin deposits" and "alluvial-fan deposits," respectively. Each of these subdivisions of the Recent sediments has certain unique physiographic, lithologic, and hydrologic characteristics which are discussed below.

Alluvial-fan Deposits of the Sutter Buttes. Alluvial fans of Pleistocene and Recent age form a ring surrounding the Sutter Buttes and extending toward their center in narrow valleys cut into andesite tuff-breccia. Small isolated patches of alluvium occupy valleys high in the Buttes. This alluvium is probably thin and is not continuous with the deposits farther down the flanks.

The fan material consists of volcanic and sedimentary detritus eroded from the Buttes and deposited around their perimeter. The deposits are usually poorly sorted and contain many volcanic fragments as large as boulder size. An average of several logs of wells near Pennington and Sutter City indicates the following proportion of materials: "clay," 70 percent; clay and gravel (including clay and volcanics), 20 percent; sand and gravel, 10 percent. The "clay" is usually yellow and is probably largely silt and fine sand.

Most of the alluvial-fan deposits are poorly sorted and ground-water yields are low. Moderately permeable sand strata yield water of good quality to wells near Pennington and Sutter City, but chances for developing large irrigation wells are generally poor.

Basin Deposits. The basins are nearly flat, poorly drained lands subject to natural overflow of the Sacramento and Feather Rivers during floods. The deposits have formed from the accumulation of silt and clay that were carried in suspension by the flood waters and settled slowly when the current slackened.

Dark-gray clays and clay adobes, often with more than 50 percent clay-size particles, are the chief basin soils. Depth of the soils is usually from three to six feet, and the underlying material is stratified and of lighter color.

Few water wells have been drilled in the basins, so it is difficult to work out the pattern of the subsurface geology from the meager data. Only eight water-well logs were available in Sutter Basin and four logs in the American Basin.

In Sutter Basin soil and yellow clay as much as 48 feet thick are reported above blue clay, blue sand, gray clay, or gravel. The change in color from yellow to blue indicates that the deeper sediments have been in a non-oxidizing environment since deposition. If the blue clay and coarse-grained deposits are Pleistocene in age the basin deposits of Recent age attain a thickness of at least 48 feet in the Sutter Basin and 100 feet in the American Basin.

The Recent basin deposits nearly all consist of relatively impermeable clay and silt. The older sediments, usually at least 50 to 100 feet below land surface, frequently include thin sand and gravel strata which yield moderate amounts of water. Generally, yields from the Sutter Basin deposits are too small to permit economic use of the ground-water for irrigation; and even in the deep wells penetrating permeable strata, poor quality (high chloride content) precludes use of the water. Locally, however, satisfactory deep wells might be developed by casing off strata containing the high-chloride water. Wells in the northern part of the American Basin get fair yields from deep permeable strata (probably in the intermediate alluvial deposits) and apparently do not encounter the chloride contamination present in the Sutter Basin.

Stream-channel Deposits. The stream-channel deposits comprise those sediments which under natural conditions of stream flow would still be in the process of accumulation. They include the sand and gravel deposited in the river channels during times of decreasing flow and the fine sediments deposited on the flood plains and natural levees during floods. The stream-channel deposits range in width from less than one mile to as much as six miles and extend as narrow bands along the major streams of the area.

The river channels are floored with sand and gravel, the flood plains by sand and silt. During stages of moderate flow the rivers occupy only their channels and roll sand and gravel along their beds. During floods muddy water spreads over the flood plain and deposits fine sediments. Flood channels, abandoned river channels, and lakes characterize the flood-plain surface. Natural levees bordering the Sacramento and lower Feather Rivers were deposited during flood stages along the boundary between high velocity flows in the river channels and still waters occupying the flood basins.

The Yuba and Bear Rivers offer a special case. The natural channel deposits of both streams have been completely buried by 15 to 20 feet of hydraulic mining debris deposited since 1870. Levees now confine this debris, which stands as raised channelways subdivided into braided gravelly channels. (See Pl. B-3.) Large quantities of debris choke the lower Feather below the Yuba junction, although the flood plain has not been altered to the same extent as those of the Yuba and Bear Rivers.

Well defined channels of coarse gravel, deposited in trenches excavated in the intermediate alluvial deposits and older sediments, underlie the flood plains of the Feather, Yuba, and Bear Rivers. Coarse gravel deposits from one to two miles in width can be traced beneath the Feather River flood plain from Oroville south 10 miles to the highway bridge east of Gridley. The depth of the base of the gravel is about 30 feet near Oroville, increasing to 105 feet at the Gridley bridge. No subsurface information is available on the river channel deposits between the Gridley bridge and the Feather-Yuba junction. Wells on the Feather River flood plain south of the Yuba-Feather junction en-

counter gravel between depths of 35 and 90 feet that may correspond to the Recent gravel deposits upstream.

Records of wells drilled on the Yuba River flood plain two miles east of Marysville show coarse gravel deposits to a depth of 110 to 130 feet. (See Pl. B-3.)

Sand and gravel underlies the Bear River flood plain for eight miles downstream from the canyon mouth. This gravel deposit which occurs between 25 and 65 feet beneath the surface near Wheatland is terminated rather abruptly about three miles southeast of Wheatland.

Little is known of the subsurface extent of the Recent deposits of the Sacramento River. Wells drilled on the natural levees pass through varicolored sand, gravel, silt, and clay. Well logs show no systematic changes either laterally or vertically. Lateral discontinuity of beds is a marked feature—even closely spaced wells penetrate completely different sections.

Clean, well-sorted sand and gravel of the stream-channel deposits yield water in large quantity and of good chemical quality to irrigation wells on the flood plains of the Feather, Yuba, and Bear Rivers. A few irrigation wells are bottomed in the Recent deposits but wells of large capacity commonly penetrate older sediments as well.

Wells drilled in the natural-levee deposits of the Feather and Sacramento Rivers obtain large supplies of water from thin, discontinuous tongues of gravel and sand which are buried stream-channel deposits. The fine sand and silt of these deposits supply some small stock and domestic wells.

Yields of Wells

Data on yields of wells in the Sutter-Yuba Area for the period 1933 to 1949 have been furnished by the Pacific Gas and Electric Company. The results of tests are summarized in the following table, which shows averages of discharge and specific capacity for 595 wells in five areas within the area. Specific capacity is obtained by dividing the yield in gallons per minute by the drawdown from static to pumping level in feet. It is a measure of the productivity of the well per foot of drawdown.

Area	*Average discharge (gpm)*	*Average specific capacity (gpm/ft. dd)*	*Number of wells*
1. Eastern Sutter County	728	47	261
2. Northwestern Sutter County	878	54	82
3. Southeastern Sutter County	960	47	121
4. Southern Yuba County	846	48	108
5. Northern Yuba County	838	60	23

The table shows that the wells having the highest specific capacities are in areas two and five. A hasty conclusion (based on this relation) might be drawn that the best irrigation wells are to be obtained in the areas of highest average specific capacity. However, a study of well depths in relation to specific capacity changes the picture somewhat. Drillers' logs of 528 irrigation wells were used to obtain a yield factor that would give a reasonable idea of production per foot of well. The yield factor was computed by the following formula:

$$\text{Yield factor} = \frac{\text{Average specific capacity} \times 100.}{\text{Average well depth}}$$

The results are summarized in the following table.

Area	*Number of irrigation wells*	*Total footage drilled*	*Average depth (feet)*	*Yield factor*
1	249	45,270	182	25.7
2	48	15,341	320	16.8
3	104	33,709	324	14.7
4	109	31,828	292	16.7
5	28	5,623	201	29.8

It can be seen from comparison of yield factors that the ratio of well production to depth of wells is higher in areas 1 and 5 than in areas 2, 3, and 4. Plate B-4, showing ground-water storage units, and well-yield areas indicates that areas 1 and 5 lie largely in group A (river flood-plain and channel deposits). Area 2 comprises the Sutter Buttes, the alluvial fans surrounding the Buttes (storage group B) and a large area of basin deposits (storage group D). Only a small part of this area is within storage group A. Most of the wells in area 2 are in the Pennington-Live Oak district, where many wells are 500 feet or more deep.

The other two areas with low yield factors are areas 3 and 4 east of the Feather River in southeastern Sutter and southern Yuba Counties; they embrace extensive areas of low alluvial-plain deposits (storage group B), and smaller areas of basin deposits (storage group D) and dissected alluvial deposits (storage group C). Although area 4 includes large areas of river flood-plain deposits (storage group A) the yield factor approximates that of the poor-yield areas rather than that of high-yield areas as might be expected.

In conclusion, generally speaking, areas of high-yield factor generally correspond to areas of high specific yield as determined from statistical analysis of drillers' logs.

GROUND-WATER STORAGE CAPACITY

Most of the information on ground-water storage capacity of the Sutter-Yuba Area was derived from well logs obtained from water well drillers. In connection with their Sutter-Yuba investigation the Division of Water Resources located in the field about 700 water wells for which drillers' logs were available. The Geological Survey located about 50 wells in western and northwestern Sutter County.

Clay, gravel, sand, and volcanic rocks are usually recognized in the drillers' logs, and the more complete logs mention color, hardness, degree of cementation, and other readily identified lithologic features.

A peg model based on drillers' logs was used to subdivide the shallow sediments of the area into hydro-

logic units. In constructing the model only the deeper well records were used where wells were located within 1,500 feet of each other. In this way 576 well logs were selected. In order to smooth out the effect of close well spacing in residential districts supplied by domestic wells, only the wells selected for the peg model were used in computing storage capacity.

Selection of Depth Zones

The storage capacity of the Sutter-Yuba Area has been estimated for three depth zones: 20 to 50 feet, 50 to 100 feet, and 100 to 200 feet below the land surface. The only exception to this three-zone treatment was in the area south of Yuba City between the natural levee deposits of the Sacramento River and the channel of the Feather River (storage units A 5 and D 2). Water of poor quality underlies that area at relatively shallow depths, and the California Division of Water Resources believes that it would be impractical in general to draw down the water level below 100 feet without causing saline intrusion. Accordingly, in that area the storage capacity was calculated only for the deposits between depths of 20 and 100 feet.

It is believed that for the Sutter-Yuba Area it would be inefficient to store water in the deposits less than 20 feet below land surface, even where permeable. Also, for economic reasons, it is unlikely that water levels will be lowered below 200 feet. In the near future, drawdown of the water table in the Sutter-Yuba Area probably will not extend below the 100-foot depth.

Classification of Materials in Drillers' Logs

In order to estimate the ground-water storage capacity of the water-bearing deposits it was necessary to classify the drillers' logs into a few general categories to which specific-yield values could be assigned. Although many logs reported only gravel, sand, and clay or gradations between these units, some logs reported as many as 10 to 20 different types of materials. It was decided to group the sediments logged into five general classes, namely: (1) gravel; (2) sand, including gravelly sand and gravel and sand; (3) tight sand, hard sand, sandstone and other materials of similar hydrologic character; (4) cemented gravel, clay and gravel, etc.; and (5) "clay," which included silt, clay, shale, and related materials of low permeability including "lava."

Assignment of Specific-yield Values

The specific yield of a rock is the ratio of (1) the volume of water which, after being saturated, it will yield by gravity to (2) its own volume. This ratio is customarily expressed in percent. The procedure followed in assigning specific-yield values to the various types of material classified in the well logs of the Sacramento Valley is discussed in detail in the valley-wide report now in preparation and has been summarized in an appendix to Bulletin 1 of the State Water Resources Board (Poland and others, 1950). The table below indicates the values assigned:

Material	*Specific yield (percent)*
Gravel	25
Sand, including sand and gravel, and gravel and sand	20
Fine sand, hard sand, tight sand, sandstone, and related deposits	10
Clay and gravel, gravel and clay, cemented gravel, and related deposits	5
"Clay," silt, sandy clay, lava rock, and related fine-grained deposits	3

Subdivision of Sutter-Yuba Area Into Storage Units

For the purpose of estimating underground storage capacity, the Sutter-Yuba Area was divided into four storage groups, and these in turn were subdivided into 14 storage units. (See Pl. B-4). Boundaries of the storage units were first drawn on significant soil and physiographic changes, then were modified on the basis of the subsurface character of the deposits above a depth of 200 feet below land surface. Special emphasis was placed on the hydrologic character of the sediments in the top 100 feet. There are three reasons for this. First, it is believed that the storage units should be representative for the depth range most widely subject to unwatering or resaturation under present conditions. Second, for nearly all the storage units in the valley except the basin deposits, the specific yield is greater above the 100-foot depth than below it. Lastly, with reference to natural or artificial recharge at or near the land surface, the distribution of water-bearing beds in the near-surface deposits is of primary importance. In this respect, the coarse sand and gravel tongues or blankets that are so well defined at shallow depths beneath or near the channels of the Feather, Yuba, and Bear Rivers are noteworthy.

In the table summarizing the ground-water storage capacity of the Sutter-Yuba Area, the 14 storage units have been assembled within the four groups. Briefly summarized, the groups are:

A. River Flood-plain and Channel Deposits. These deposits contain a high proportion of sand and gravel deposited by streams mostly during the Pleistocene and Recent epochs, although some of the sands and gravels in the 100- to 200-foot depth zone may be of Pliocene age. In general, the river flood-plain and channel deposits have the highest specific yield of the four groups in all three depth zones. The specific yield decreases markedly in the 100- to 200-foot depth zone, but still is higher than in the other three storage groups.

B. Low Alluvial-plain and Alluvial-fan Deposits. These deposits are variable in physical character but are generally much less permeable than the river flood-plain and channel deposits, particularly in the top two depth zones. The near-surface sediments in this group include the alluvial fans of the Sutter Buttes, intermediate alluvial deposits (Pleistocene), old alluvial deposits (Pliocene and Pleistocene) and smaller areas of

Recent stream-channel deposits. Most of the low alluvial-plain deposits above the 200-foot depth are old and intermediate alluvial deposits, however.

C. Dissected Alluvial Deposits. This group is represented in Sutter and Yuba Counties by two widely separated small areas—the northern between Honcut Creek and the Yuba River on the east margin of the valley, and the southern in Sutter County east of the American Basin. The specific yield and physical character of the dissected alluvial deposits and the low alluvial-plain and alluvial-fan deposits are similar, and the geologic units contained are essentially the same, although the dissected alluvial deposits contain a somewhat greater percentage of old alluvium.

D. Basin Deposits. These sediments to a depth of 200 feet include the Recent basin deposits, the intermediate alluvial deposits of Pleistocene age and probably some old alluvium. Silt and clay predominate and permeability and specific yield are correspondingly low. The 100- to 200-foot depth zone in the northern part of the American Basin (D1) contains a rather high proportion of sand which may represent buried Sacramento River channels, but the deep zone in the Butte Basin (D3) has fine-grained material of low permeability. The specific yield of the deep zone in the Sutter Basin (D2) was not calculated because of salt-water contamination, but the well logs record mostly fine-grained material.

Summary of Results

The following table summarizes the estimated ground-water storage capacity of the Sutter-Yuba Area for the four storage groups. This summary is followed by a tabulation of storage capacity for each of the 14 storage units, listed by groups.

The summary for the Sutter-Yuba Area by storage groups first gives total storage capacities for all deposits, including those beneath the basin lands. The totals are then given with the storage capacity of the basin deposits eliminated. There are several reasons for omitting the storage capacity of these deposits from consideration. The deposits in the Sutter and Butte Basins are relatively impermeable in all three depth zones, and those in the American Basin in the top two depth zones. Therefore, well yields would be low and it would be difficult to draw down the water level extensively within the basins unless many closely spaced wells were drilled. Although the basin water levels are close to the surface, the altitude of land surface in the basins is lower than that in all the surrounding lands. Because of the low altitude and the low permeability of the basin deposits, it is believed there would not be appreciable dewatering by lateral drainage to adjacent pumped areas. For the same reasons, recharging the basin deposits would be slow and costly. Because of low well yields and the availability of surface water, it is ordinarily more economical to use surface water than ground water for irrigation of the basin lands.

Excluding the basin storage, the estimated ground-water storage capacity for the Sutter-Yuba Area between limits of 20 and 200 feet below the land surface is about 3,900,000 acre-feet. More than half this storage is in the deposits 20 to 100 feet below the surface. As discussed previously, how much of this ground-water storage capacity is economically usable is not known.

ESTIMATED TOTAL GROUND-WATER STORAGE CAPACITY OF SUTTER-YUBA AREA IN ACRE-FEET

Best Areas for Ground-water Storage

As can be seen from the ground-water storage table, the best areas for storing water underground are the five river flood-plain and channel deposits units. Excluding basin deposits, about 70 percent of the total storage capacity is in these five areas which include about 40 percent of the Sutter-Yuba Area, and most of the soils and near-surface sediments are sufficiently permeable to permit recharge from the surface. Sand and gravel beds are most continuous in the river-channel deposits of the Feather River, and the deposits west of the river from Yuba City south to the vicinity of Nicolaus seem to be especially favorable for storing ground-water (See Pl. B-2). Unfortunately, however, this area is contaminated with salt water in the lower depth zone, and storage in this zone may not be practicable.

The low alluvial-plain and alluvial-fan deposits and the dissected alluvial deposits are both rather unfavorable for ground-water storage. Soils are generally tight and impervious hardpan is prevalent, and recharge from land surface would be difficult.

APPENDIX E

RECORDS OF DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

TABLE OF CONTENTS

RECORDS OF DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Table		Page
1	Depths to Ground Water at Measurement Wells in Sutter-Yuba Area, Measurements Made by Division of Water Resources	115
2	Depths to Ground Water at Measurement Wells in Sutter-Yuba Area, Measurements Made by S. T. Harding	151
3	Depths to Ground Water at Measurement Wells in Sutter-Yuba Area, Measurements Made by Sutter County Farm Advisor	155

The wells are numbered in accordance with a system adopted by the United States Geological Survey. The numbering system indicates the well locations according to the rectangular land surveys. An explanation of the numbering system is given on page 93 of Appendix B.

Reference point elevations given to the nearest foot have been estimated from United States Geological Survey topographic maps. Reference point elevations given to the nearest 0.1 foot have been established by field surveys.

TABLE 1

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Meosurements Made by Division of Water Resources
(Depths to woter in feet meosured from reference point)

10N/3E-1A1—Reference point—top of 12-inch casing, elevation 23 feet. West side of Garden Highway at toe of levee, 0.75 mile southwest of Riego Road. 12/7/48, 15.1; 4/6/49, 10.7; 11/30/49, 15.7; 3/30/50, 6.4; 11/9/50, 15.6; 4/5/51, 10.2; 12/4/51, 14.0; 4/4/52, 0.0.

10N/4E-6K1—Reference point—top of 14-inch casing under pump, elevation 20 feet, 0.06 mile south of Riego Road, 0.47 mile west of Power Line Road. 12/23/47, 10.9; 3/4/48, 11.0; 12/7/48, 10.0; 4/6/49, 5.0; 12/1/49, 8.2; 3/30/50, 6.9; 1/9/50, 8.0; 12/4/51, 7.7; 4/4/52, 6.3.

10N/4E-12A1—Reference point—top of casing, elevation 43.1 feet, 0.10 mile west of Pleasant Grove Road, 0.70 mile south of Riego Road. 12/23/47, 22.0; 3/3/48, 20.6; 12/7/48, 28.1; 4/6/49, 23.2; 11/23/49, 36.1; 12/1/49, 27.2; 3/15/50, 29.5; 3/30/50, 28.7; 11/9/50, 35.0; 4/5/51, 25.9; 12/5/51, 26.7; 4/4/52, 24.4.

10N/5E-6J1—Reference point—top of wooden shoring for pit, 12.5 feet above casing, elevation 46 feet, 0.12 mile south of Riego Road, 0.82 mile east of Pleasant Grove Road. 12/24/47, 27.1; 3/3/48, 27.0; 12/7/48, 33.9 (operating); 4/6/49, 29.6; 12/1/49, 33.6; 3/30/50, 34.9; 11/9/50, 40.3; 4/5/51, 38.2; 12/5/51, 33.1; 4/8/52, 42.4 (operating).

10N/5E-8N1—Reference point—top of casing, elevation 37 feet, 1.5 miles south of Riego Road, 1.06 miles east of Pleasant Grove Road. 12/24/47, 25.3.

11N/3E-1D1—Reference point—hole in side of pump base, elevation 25.6 feet. South side of West Catlett Road, 0.18 mile east of Garwood Road. 12/19/47, 12.0; 3/4/48, 11.6; 12/15/48, 11.0; 3/30/49, 6.5; 5/26/49, 20.1; 6/29/49, 23.4; 7/28/49, 23.1; 8/26/49, 23.4; 12/5/49, 14.5; 3/24/50, 8.3; 11/16/51, 12.5; 4/7/52, 5.9.

11N/3E-2B1—Reference point—top of concrete base, elevation 23.8 feet. South side of West Catlett Road, 0.37 mile west of Garwood Road. 12/19/47, 11.0; 3/4/48, 10.8; 12/15/48, 12.3; 3/3/49, 5.9; 12/5/49, 14.1; 3/24/50, 7.4; 11/6/50, 12.4; 4/2/51, 5.1; 11/16/51, 11.7; 4/8/52, 6.1.

11N/3E-2Q1—Reference point—top of casing, elevation 20 feet, 0.50 mile east of Vernon Road, 0.89 mile south of West Catlett Road. 12/9/48, 11.9; 4/6/49, 5.7; 11/28/49, 14.0; 3/30/50, 7.1; 11/8/50, 11.2; 4/3/51, 5.1; 12/5/51, 11.0.

11N/3E-3C2—Reference point—west side of pump base, elevation 26.1 feet. South side of West Catlett Road, 1.57 miles north of Garwood Road. 12/19/48, 13.4; 3/4/48, 11.4; 12/15/48, 13.1; 3/30/49, 7.5; 12/5/49, 15.2; 3/34/50, 7.6; 11/6/50, 13.0; 4/2/51, 5.0; 4/8/52, 1.7.

11N/3E-3N1—Reference point—hole in pump base, elevation 25 feet, 0.85 mile west of Vernon Road, 0.93 mile south of West Catlett Road. 12/9/48, 13.1; 3/31/49, 6.2; 11/28/49, 14.9; 3/30/50, 5.9; 11/18/50, 13.1; 4/1/52, 0.0.

11N/3E-3P1—Reference point—hole in pump base, elevation 22 feet, 0.74 mile west of Vernon Road, 0.82 mile south of West Catlett Road. 12/9/48, 12.4; 11/8/50, 13.1; 4/3/51, 6.2, 12/5/51, 11.9; 4/1/52, 5.3.

11N/3E-10N1—Reference point—pipe in pump base, elevation 26 feet, 0.80 mile west of Vernon Road, 1.75 miles south of West Catlett Road. 3/31/49, 11.3; 11/28/49, 19.1.

11N/3E-11D1—Reference point—top of casing, elevation 21 feet, 0.14 mile east of Vernon Road, 1.08 miles south of West Catlett Road. 12/9/48, 8.3; 4/6/49, 4.5; 11/28/49, 12.2; 3/30/50, 4.9; 11/8/50, 7.7; 4/3/51, 2.7; 4/2/52, 1.9.

11N/3E-13A1—Reference point—top of casing, elevation 20 feet, 0.70 mile north of north levee of Natomas Cross Canal, 1.15 miles northeast of Garden Highway. 12/9/48, 7.6; 4/6/49, 3.3; 11/29/49, 9.4; 3/30/50, 3.6; 11/8/50, 10.0; 4/2/51, 3.0; 12/5/51, 9.5.

11N/3E-13D1—Reference point—hole in pump base, elevation 20 feet, 1.10 miles north of north levee of Natomas Cross Canal, 0.86 mile northeast of Garden Highway. 12/9/48, 11.9; 4/6/49, 7.4; 11/29/49, 13.0; 3/30/50, 8.5; 11/8/50, 13.5; 4/2/51, 7.5; 12/5/51, 13.0.

11N/3E-13F1—Reference point—hole in pump base, elevation 20 feet, 0.75 mile north of north levee of Natomas Cross Canal, 1.13 miles northeast of Garden Highway. 12/9/48, 12.5; 4/6/49, 8.3; 14/29/49, 14.2.

11N/3E-13P1—Reference point—hole in pump base, elevation 20 feet. At toe of north levee of Natomas Cross Canal, 1.37 miles northeast of Garden Highway. 4/6/49, 7.7; 11/29/49, 11.8.

11N/3E-14N1—Reference point—hole in pump base, elevation 25 feet, 0.14 mile east of Vernon Road, 0.60 mile north of Garden Highway. 12/9/48, 12.7.

11N/3E-15C1—Reference point—hole in pump base, elevation 25 feet, 1.50 miles north of Garden Highway, 0.78 miles west of Vernon Road. 12/24/47, 16.9; 3/4/48, 16.2; 12/9/48, 16.1; 3/31/49, 9.9; 11/28/49, 17.9; 3/30/50, 7.9; 11/8/50, 16.1; 4/3/51, 10.3; 12/4/51, 15.0; 4/1/52, 1.1.

11N/3E-22H1—Reference point—top of casing, elevation 27 feet. North side of Garden Highway, 0.23 mile northwest of Verona. 12/24/47, 18.8; 3/4/48, 18.2; 12/9/48, 18.0; 3/31/49, 11.6; 11/28/49, 18.2; 3/30/50, 9.9; 11/8/50, 16.2; 4/3/51, 11.4; 12/5/51, 15.7; 4/1/52, 3.3.

11N/3E-22H2—Reference point—top of casing, elevation 29 feet. Northeast side of Garden Highway, east side of Vernon Road. 11/7/29, 24.3; 9/27/30, 24.3; 12/15/31, 24.3; 11/23/32, 25.2; 12/21/33, 21.6; 10/27/34, 27.3; 11/28/34, 20.3; 11/25/36, 24.8; 11/6/37, 23.8; 1/10/39, 20.8.

11N/3E-22H3—Reference point—top of casing, elevation 29 feet, 300 feet north of Garden Highway, west side of Vernon Road. 12/20/40, 19.9.

11N/3E-23E2—Reference point—top of casing, elevation 27 feet, 100 feet north of Garden Highway, 0.07 mile east of Vernon Road. 11/11/47, 19.7; 12/16/48, 19.0; 12/9/49, 19.0; 11/13/50, 19.3; 12/6/51, 5.9.

11N/3E-23L1—Reference point—top of casing, elevation 29 feet, 0.12 mile north of Garden Highway, 0.47 mile southeast of Vernon Road. 12/23/47, 12.3; 3/4/48, 11.9; 12/9/48, 10.9; 3/31/49, 3.9; 11/28/49, 12.9.

11N/3E-23R1—Reference point—top of casing, elevation 20 feet. At toe of south levee of Natomas Cross Canal, 0.11 mile north of Garden Highway. 12/23/47, 12.1; 3/4/48, 16.0; 12/8/48, 15.2; 3/31/49, 6.9; 11/28/49, 16.1.

11N/3E-25C1—Reference point—top of casing, elevation 23 feet, 0.24 mile south of Sankey Road, 0.44 mile east of Garden Highway. 12/9/48, 11.3; 4/6/49, 7.3; 3/30/50, 7.6; 11/9/50, 10.9; 4/5/51, 5.6; 12/5/51, 11.3; 4/4/52, 4.4.

11N/3E-25P1—Reference point—top of casing, elevation 25 feet, 265 feet northwest of Garden Highway, 1.27 miles north of Riego Road. 11/7/29, 19.0; 9/27/30, 19.3; 12/15/31, 19.5; 11/23/32, 20.2; 12/21/33, 16.6; 10/27/34, 18.1; 11/28/34, 15.6; 11/25/36, 19.2; 11/6/37, 14.7; 1/10/39, 15.6; 12/20/40, 15.0; 11/11/47, 15.5; 12/23/47, 16.6; 3/4/48, 16.0; 12/1/49, 15.6; 4/6/49, 11.9; 11/13/50, 13.5; 12/6/51, 8.3.

11N/4E-1F1—Reference point—top of casing, elevation 49.3 feet, 0.80 mile south of Catlett Road, 0.25 mile east of Pleasant Grove Road. 12/22/47, 21.5; 3/22/48, 19.3; 12/18/48, 23.3; 3/29/49, 19.5; 12/2/49, 25.9; 3/27/50, 22.8; 11/8/50, 27.0; 11/16/51, 27.0; 4/8/52, 17.5.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet measured from reference point)

11N/4E-1M1—Reference point—concrete floor of pump house, elevation 45 feet, 0.55 mile north of Howsley Road, 0.12 mile east of Pleasant Grove Road. 11/8/29, 13.8; 9/26/30, 13.3; 12/10/31, 14.9; 11/23/32, 14.3; 12/20/33, 15.9; 10/27/34, 16.2; 11/23/36, 13.9; 11/1/37, 12.3; 1/10/39, 11.3; 1/4/41, 11.4; 11/11/47, 22.9; 12/16/48, 22.1; 12/9/49, 24.4; 11/13/50, 24.2; 12/6/51, 27.8.

11N/4E-1R1—Reference point—joint in cover plate around casing, elevation 50 feet. North side of Howsley Road, 1.0 mile east of Pleasant Grove Road. 12/23/47, 24.7; 3/3/48, 22.6; 12/8/48, 25.1; 3/31/49, 22.8; 11/30/49, 25.9; 11/14/50, 28.7.

11N/4E-2M1—Reference point—top of casing, elevation 40 feet, West side of Western Pacific Railroad, 0.29 mile north of Howsley Road. 3/15/48, 11.9; 12/8/48, 15.5; 3/29/49, 9.5; 12/2/49, 16.4.

11N/4E-3P1—Reference point—hole in base of pump, elevation 33 feet, 0.15 mile north of Howsley Road, 0.47 mile east of Pacific Avenue. 12/22/47, 19.8; 3/15/48, 18.1; 12/18/48, 21.1; 3/29/49, 14.4; 12/2/49, 21.3; 3/24/50, 16.3; 11/8/50, 21.6; 4/2/51, 12.3; 11/19/51, 20.8; 4/8/52, 13.2.

11N/4E-4R1—Reference point—top of casing, elevation 30 feet, 0.03 mile north of Howsley Road, 0.16 mile west of Pacific Avenue. 12/23/47, 14.7; 3/15/48, 13.1; 12/15/48, 10.2; 2/30/49, 3.9; 12/2/49, 15.9; 3/24/50, 9.8; 11/8/50, 16.0; 4/2/51, 8.0; 11/19/51, 14.7; 4/6/52, 6.1.

11N/4E-5A1—Reference point—top of casing, elevation 27 feet, 1.10 miles north of Natomas Cross Canal. 12/18/47, 9.9; 12/15/48, 9.9; 3/30/49, 3.8; 5/26/49, 18.1; 7/29/49, 20.1.

11N/4E-6B1—Reference point—hole in pump base, elevation 30 feet. South side of West Catlett Road, 1.50 miles west of Electric Avenue. 12/18/47, 11.5; 12/15/48, 15.1; 3/24/50, 7.9; 11/19/51, 14.0.

11N/4E-7H1—Reference point—edge of pump base, elevation 23 feet, 0.47 mile north of Natomas Cross Canal, 3 miles northeast of Garden Highway. 4/6/49, 10.1; 11/30/49, 12.3; 3/30/50, 10.6; 11/8/50, 14.5; 4/2/51, 9.3.

11N/4E-9C1—Reference point—top of casing, elevation 27 feet, 0.56 mile west of Sacramento Northern Railroad, 0.21 mile south of Howsley Road. 5/5/48, 37.0 (operating); 5/31/48, 10.8; 7/2/48, 49.0 (operating); 7/23/48, 50.5 (operating); 4/6/49, 7.7; 11/30/49, 14.0.

11N/4E-9L1—Reference point—top of casing, elevation 26 feet, 0.45 mile west of Sacramento Northern Railroad crossing on Howsley Road, 0.57 mile south of Howsley Road. 5/5/48, 48.2 (operating) 5/31/48, 12.7; 7/23/48, 50.5 (operating); 4/6/49, 8.8; 11/30/49, 14.2.

11N/4E-11C1—Reference point—top of casing, elevation 41 feet, 0.35 mile east of Western Pacific Railroad, 0.16 mile south of Howsley Road. 3/3/48, 19.9; 3/31/49, 18.8.

11N/4E-11C2—Reference point—top of casing, elevation 45 feet, 0.18 mile south of Howsley Road, 0.40 mile east of Western Pacific Railroad. 12/22/47, 23.1; 12/8/48, 25.1; 3/31/49, 21.0; 11/30/49, 25.8; 3/30/50, 21.2; 11/9/50, 28.1; 4/5/51, 19.2; 12/4/51, 27.1; 1/4/52, 17.6.

11N/4E-11N1—Reference point—top of casing, elevation 38 feet. North side of Fifield Road, west side of Western Pacific Railroad. 12/23/47, 21.2; 3/3/48, 18.6; 12/8/48, 25.5; 4/6/49, 18.0; 11/30/49, 25.1.

11N/4E-12C1—Reference point—top of casing, elevation 46 feet, 0.03 mile east of Pleasant Grove Road, 0.03 mile south of Howsley Road. 11/26/48, 27.2.

11N/4E-12C2—Reference point—top of casing, elevation 50.0 feet, 0.12 mile east of Pleasant Grove Road, 0.02 mile south of Howsley Road. 12/22/47, 23.4; 3/3/48, 20.9; 12/8/48, 23.6; 3/31/49, 22.1; 11/30/49, 23.9.

11N/4E-12H1—Reference point—top of casing, elevation 56.8 feet, 0.76 mile east of Pleasant Grove Road, 0.57 mile south of Howsley Road. 12/7/48, 27.8.

11N/4E-12J2—Reference point—top of casing, elevation 56.8 feet, 0.58 mile south of Howsley Road, 0.78 mile east of Pleasant Grove Road. 12/23/47, 27.3; 3/3/48, 25.2; 12/8/48, 28.2; 3/31/49, 24.7; 11/17/49, 30.8; 11/30/49, 28.9; 3/30/50, 28.0; 4/11/50, 26.9; 11/8/50, 32.5; 11/14/50, 32.4; 4/5/51, 28.9; 11/15/51, 34.0; 4/3/52, 29.2; 4/4/52, 29.6.

11N/4E-12M1—Reference point—slot in base, elevation 44.7 feet, 0.62 mile south of Howsley Road, 0.07 mile west of Pleasant Grove Road. 12/23/47, 22.8; 3/3/48, 19.8; 12/8/48, 24.6; 3/31/49, 20.4; 5/26/49, 26.2; 6/29/49, 25.1; 7/28/49, 32.8; 11/30/49, 27.2; 3/30/50, 23.1; 11/6/50, 28.2; 4/10/51, 23.5; 11/14/51, 35.0; 4/4/52, 23.2.

11N/4E-13D1—Reference point—top of casing, elevation 47.6 feet. West side of Pleasant Grove Road, 0.09 mile south of Fifield Road. 12/8/48, 28.5; 4/6/49, 18.0; 11/30/49, 27.0; 3/15/50, 23.3; 3/30/50, 24.1; 11/8/50, 30.1; 4/5/51, 25.0; 11/14/51, 32.6; 4/4/52, 29.5; 4/10/52, 25.2.

11N/4E-13M1—Reference point—top of casing in pit, elevation 46 feet, 0.12 mile west of Pleasant Grove Road, 0.37 mile north of Keys Road. 12/23/47, 15.9; 12/8/48, 19.1; 3/31/49, 14.0; 11/30/49, 21.7.

11N/4E-14B1—Reference point—top of casing, elevation 40 feet, 0.10 mile south of Howsley Road, 0.52 mile west of Pleasant Grove Road. 12/23/47, 25.8; 3/3/48, 21.8; 12/8/48, 27.8; 3/31/49, 21.1; 11/30/49, 29.6.

11N/4E-14D1—Reference point—top of casing, elevation 36.5 feet, 0.21 mile west of Western Pacific Railroad, 0.26 mile south of Fifield Road. 12/23/47, 21.2; 3/3/48, 18.6; 12/8/48, 25.5; 4/6/49, 18.0; 11/30/49, 25.1.

11N/4E-15C1—Reference point—top of casing, elevation 31.2 feet. South side of Fifield Road, 0.11 mile west of Sacramento Northern Railroad. 12/23/47, 16.9; 3/3/48, 14.9; 12/8/48, 20.0; 4/6/49, 12.9; 11/30/49, 18.8; 3/30/50, 14.4; 11/8/50, 19.5; 4/3/51, 11.0; 12/4/51, 19.1; 4/4/52, 7.2.

11N/4E-15Q1—Reference point—hole in pump base, elevation 33.6 feet, 0.80 mile west of Sacramento Northern Railroad, 0.22 mile north of Keys Road. 12/23/47, 18.5; 3/3/48, 16.8; 12/8/48, 23.5; 4/6/49, 16.0; 11/30/49, 22.2; 3/30/50, 17.9; 11/8/50, 23.5; 4/3/51, 14.7; 12/5/51, 23.0; 4/4/52, 12.6.

11N/4E-21R1—Reference point—top of casing, elevation 24.9 feet, 1.06 miles east of Burns Road, 0.22 mile north of Sankey Road. 12/23/47, 9.9; 3/3/48, 9.6; 12/8/48, 12.3; 4/6/49, 8.0.

11N/4E-22A1—Reference point—top of casing, elevation 32.7 feet, 0.18 mile west of Sacramento Northern Railroad crossing. 12/8/48, 23.5; 4/6/49, 15.2; 11/30/49, 22.6.

11N/4E-23C1—Reference point—top of casing, elevation 37 feet, 0.09 mile south of Keys Road, 0.09 mile east of Western Pacific Railroad. 12/23/47, 21.0; 3/3/48, 18.6; 11/30/49, 26.6; 3/30/50, 22.1; 11/8/50, 28.7; 4/3/51, 20.3; 12/4/51, 28.0; 4/4/52, 20.1.

11N/4E-23H1—Reference point—top of casing, elevation 53.1 feet, 0.02 mile west of Pleasant Grove Road, 0.46 mile south of Keys Road. 12/23/47, 19.5; 3/3/48, 18.0; 12/8/48, 24.1; 4/6/49, 19.8; 11/30/49, 32.2; 3/30/50, 24.6; 11/8/50, 30.7; 4/5/51, 21.6; 12/4/51, 29.2.

11N/4E-23N1—Reference point—top of concrete pit wall, elevation 33 feet, 0.06 mile west of Sacramento Northern Railroad, 0.11 mile north of Sankey Road. 12/23/47, 21.3.

11N/4E-25M1—Reference point—hole in base, elevation 37 feet, 0.58 mile south of Sankey Road, 0.06 mile east of Pleasant Grove Road. 12/23/47, 19.0; 3/3/48, 20.2; 12/8/48, 24.9; 4/6/49, 21.0; 12/1/49, 34.6; 3/30/50, 29.9; 4/4/50, 34.9.

11N/4E-26F1—Reference point—hole in base of pump, elevation 37 feet, 0.40 mile south of Sankey Road, 0.05 mile west of Sacramento Northern Railroad. 12/8/48, 28.0; 4/6/49, 23.0; 12/8/48, 119; 3/30/50, 29.9; 11/9/50, 29.1; 12/6/51, 37.0.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet measured from reference point)

11N/4E-28J1—Reference point—top of casing, elevation 34.3 feet, 0.70 mile south of Sankey Road, 0.40 mile west of Pacific Avenue. 3/4/48, 20.4; 12/8/48, 23.6; 4/6/49, 19.2; 12/1/49, 25.3; 3/30/50, 22.5; 11/9/50, 29.1; 4/5/51, 21.4; 12/6/51, 30.5; 4/4/52, 22.8.

11N/4E-33J1—Reference point—top of casing, elevation 25.6 feet, 0.03 mile west of Pacific Avenue, 0.28 mile north of Riego Road. 3/4/48, 13.4; 12/7/48, 15.7; 4/6/49, 12.2; 5/26/40, 11.0; 12/1/49, 17.4; 3/30/50, 14.0; 11/9/50, 14.6; 4/5/51, 12.7; 12/6/51, 14.1; 4/4/52, 14.9.

11N/4E-36E1—Reference point—top of concrete pit wall, elevation 39 feet, 0.07 mile east of Pleasant Grove Road, 0.70 mile north of Riego Road. 12/24/47, 22.3; 3/3/48, 23.0; 12/7/48, 28.9; 4/6/49, 24.9; 12/1/49, 38.7; 3/30/50, 23.2; 11/9/50, 44.4; 4/4/52, 19.0.

11N/5E-6N1—Reference point— top of casing, elevation 59 feet. North side Howsley Road, 0.80 mile east of Pleasant Grove Road. 12/23/47, 24.7; 3/3/48, 22.6; 12/8/48, 25.1; 3/31/49, 22.8; 11/30/49, 25.9; 11/14/50, 28.7; 3/22/51, 26.2.

11N/5E-18N1—Reference point— top of casing, elevation 50 feet. North side of Keys Road, 0.85 mile east of Pleasant Grove Road. 12/24/47, 27.3; 3/3/48, 26.5; 12/8/48, 30.1; 11/30/49, 31.8; 11/14/50, 33.1; 3/22/51, 31.2.

11N/5E-30M1—Reference point—top of casing, elevation 47 feet, 1.05 miles east of Pleasant Grove Road, 0.59 mile south of Sankey Road. 12/24/47, 18.8; 3/3/48, 18.7; 12/8/48, 22.4; 12/1/49, 23.4; 3/30/50, 24.4; 11/9/50, 23.4; 12/5/51, 23.4; 4/4/52, 32.5.

12N/3E-1E1—Reference point—top of casing, elevation 33 feet, 0.10 mile northeast of Garden Highway, 0.20 mile northwest of Sutter Avenue. 12/4/47, 13.6; 3/10/48, 10.0; 12/11/48, 13.2; 3/16/49, 8.3; 12/6/49, 12.6; 3/29/50, 7.5; 11/15/51, 11.1; 4/4/52, 5.9.

12N/3E-1L1—Reference point—top of casing, elevation 31 feet, 150 feet northwest of Sutter Avenue, 0.12 mile northeast of Garden Highway. 12/4/47, 12.6; 3/10/48, 12.1; 12/11/48, 12.9; 3/16/49, 8.0; 12/6/49, 12.5; 11/3/50, 13.2; 4/2/51, 5.3; 11/3/51, 13.2; 4/4/52, 3.3.

12N/3E-2B1—Reference point—top of casing, elevation 31 feet, 0.08 mile east of Garden Highway, 0.49 mile north of Chandler Road. 12/4/47, 9.1; 3/10/48, 9.4; 12/11/48, 9.7; 3/16/49, 6.5; 12/6/49, 8.6.

12N/3E-2E1—Reference point—top of casing, elevation 29 feet, North side of Chandler Road, 0.48 mile west of Garden Highway. 12/4/47, 9.9; 3/10/48, 5.8; 5/11/48, 4.7; 12/11/48, 8.8; 3/16/49, 4.1; 5/26/49, 3.1; 6/29/49, 3.2; 7/27/49, 2.6; 8/25/49, 3.3. Well destroyed.

12N/3E-2J1—Reference point—top of casing, elevation 30 feet, South side of Garden Highway, 0.30 mile northwest of Sutter Avenue. 12/4/47, 12.2; 3/10/48, 8.9; 12/11/48, 12.8; 3/16/49, 8.3; 12/6/49, 11.7.

12N/3E-2K1—Reference point—top of casing, elevation 30 feet, South side of Garden Highway, 0.54 mile west of Sutter Avenue. 12/4/47, 12.2; 3/10/48, 4.9; 5/11/48, 6.7; 3/16/49, 4.8; 12/6/49, 7.5.

12N/3E-3K1—Reference point—top of casing, elevation 25 feet, 0.89 mile west of Garden Highway, 0.08 mile south of Chandler Road. 11/7/29, 8.0; 9/27/30, 6.4; 12/12/31, 6.5; 11/25/32, 10.1; 12/20/33, 8.3; 11/10/34, 9.1; 11/25/36, 10.8; 11/24/37, 5.9; 1/25/39, 9.6; 1/13/41, 4.6; 11/7/47, 8.5; 12/15/48, 8.3; 12/6/49, 9.2.

12N/3E-3K2—Reference point—top of casing, elevation 25 feet, 0.20 mile south of Chandler Road, 0.89 mile west of Garden Highway. 11/13/50, 24.7; 12/6/51, 3.9.

12N/3E-3Q1—Reference point—hole in base of pump, elevation 32 feet, 0.32 mile south of Chandler Road, 0.89 mile west of Garden Highway. 11/6/50, 27.4; 4-2-51, 4.8.

12N/3E-12C1—Reference point—top of casing, elevation 30 feet, 0.15 mile southwest of west end of Nicolaus bridge. 12/9/47, 14.9; 3/11/48, 11.9; 12/11/48, 15.0; 12/6/49, 14.7.

12N/3E-13G1—Reference point—top of casing, elevation 30 feet, 0.68 mile north of Lee Road, 0.38 mile southeast of Garden Highway. 12/5/47, 14.3; 3/15/48, 12.4; 12/14/48, 13.8; well destroyed.

12N/3E-13M1—Reference point—top of pit wall, elevation 29 feet, 0.45 mile southwest of Garden Highway, 0.37 mile northwest of Lee Road. 12/5/47, 14.4; 3/11/48, 13.8; 3/25/49, 12.5; well destroyed.

12N/3E-14H1—Reference point—top of pit wall, elevation 30 feet. East side of Garden Highway, 0.99 mile northeast of Lee Road. 12/5/47, 14.7; 3/15/48, 14.2; 12/11/48, 15.0; 3/25/49, 10.1; 12/6/49, 16.1.

12N/3E-14Q1—Reference point—top of casing, elevation 26 feet, South side of Lee Road, 0.12 mile southeast of Garden Highway. 12/5/47, 14.2; 3/11/48, 13.1; 12/11/48, 14.1; 3/25/49, 9.3; 12/6/49, 14.7; 3/29/50, 9.8.

12N/3E-22R1—Reference point—top of casing, elevation 26 feet, East side of Garden Highway, 1.30 miles south of Lee Road. 11/7/29, 12.0; 9/27/30, 12.7; 12/15/31, 13.0; 11/25/32, 14.9; 12/21/33, 11.3; 10/27/34, 14.5; 11/25/36, 14.1; 11/6/37, 13.5; 1/10/39, 11.1; 12/20/40, 8.4; 11/10/47, 14.1.

12N/3E-22R2—Reference point—top of casing, elevation 26 feet, East side of Garden Highway, 1.30 miles south of Lee Road. 12/16/48, 12.3; 12/9/49, 14.0.

12N/3E-22R3—Reference point—top of casing, elevation 26 feet, 0.15 mile southeast of Garden Highway, 1.30 miles south of Lee Road. 11/13/50, 12.8; 12/6/51, 5.5.

12N/3E-23N1—Reference point—top of casing, elevation 25 feet, 0.09 mile east of Garden Highway, 1.10 miles south of Lee Road. 12/19/47, 12.6; 3/4/48, 11.2; 12/15/48, 12.3; 3/30/49, 6.6; 12/5/49, 15.9; 3/24/50, 5.8; 11/6/50, 12.6; 4/2/51, 6.6; 11/16/51, 11.4.

12N/3E-24A1—Reference point—top of casing, elevation 25 feet, South side of Lee Road, 0.58 mile west of Power Line Road. 12/5/47, 12.4; 3/11/48, 11.2; 12/11/48, 12.6; 3/25/49, 9.4; 12/6/49, 13.3.

12N/3E-24Q1—Reference point—top of casing, elevation 25 feet, 0.10 mile north of Striplin Road, 0.30 mile east of Garwood Road. 12/18/47, 11.6; 3/4/48, 10.8; 12/15/48, 12.9; 3/30/49, 7.9; 12/5/49, 14.1; 3/24/50, 9.1; 11/8/50, 12.1; 4/2/51, 4.3; 11/16/51, 12.8; 4/7/52, 3.5.

12N/3E-26N1—Reference point—lower end of flange around discharge pipe, elevation 22 feet, 0.08 mile southwest of Worth Road, 0.90 mile west of Garwood Road. 12/19/47, 11.1; 3/4/48, 9.9; 12/15/48, 14.1; 3/30/49, 7.9; well destroyed.

12N/3E-27Q1—Reference point—hole in base of pump, elevation 22 feet, 0.10 mile east of Garden Highway, 1.30 miles north of Catlett Road. 11/6/50, 12.5; 4/2/51, 7.0.

12N/4E-1B1—Reference point—top of casing, elevation 58 feet, South side of Cornelius Avenue, 0.54 mile east of Pleasant Grove Road. 12/22/47, 21.7; 3/11/48, 20.0; 12/15/48, 21.4; 3/18/49, 20.3; 12/7/49, 26.2.

12N/4E-2B1—Reference point—hole in base of pump, elevation 53 feet, 0.05 mile south of Cornelius Avenue, 0.50 mile north of Pleasant Grove Road. 12/22/47, 19.8; 3/11/48, 21.8; 12/13/48, 27.2; 3/29/49, 20.8; 12/7/49, 26.2; 3/27/50, 22.1; 11/6/50, 30.9; 4/5/51, 24.0; 4/4/52, 24.0.

12N/4E-2Q1—Reference point—hole in base of pump, elevation 51 feet, 0.46 mile north of Trowbridge Road, 0.34 mile west of Pleasant Grove Road. 3/11/48, 15.7; 5/5/48, 13.3; 5/31/48, 14.7; 6/17/48, 35.2; 6/23/48, 38.0; 7/2/48, 20.3; 12/15/48, 17.9; 3/28/49, 11.6; 5/26/49, 19.5; 6/29/49, 20.9; 7/28/49, 21.7; 8/26/49, 21.2; 12/7/49, 19.0; 3/27/50, 15.4; 11/6/50, 23.9; 4/5/51, 15.5; 4/4/52, 13.2.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Meosurements Mode by Division of Woter Resources
(Depths to woter in feet meosured from reference point)

12N/4E-3A1—Reference point—top of casing, elevation 52.4 feet. Southwest corner of intersection of Cornelius Avenue and Pleasant Grove Road. 3/11/48, 19.9; 12/14/48, 22.5; 3/29/49, 19.8; 12/7/49, 24.5.

12N/4E-3B1—Reference point—top of casing, elevation 49 feet. South side of Cornelius Avenue, 0.55 mile east of Pacific Avenue. 12/22/47, 21.4; 12/14/48, 23.7; 3/29/49, 19.9; 12/7/49, 24.2.

12N/4E-4A1—Reference point—top of casing, elevation 47 feet. Southwest corner of intersection of Cornelius Avenue and Pacific Avenue. 12/21/40, 19.1; 12/4/47, 24.5; 12/16/48, 26.0; 12/8/51, 31.4.

12N/4E-4A2—Reference point—top of casing, elevation 47 feet. 70.0 feet south of southwest corner of Cornelius Avenue and Pacific Avenue. 11/7/47, 23.7; 12/16/48, 24.8; 12/9/49, 26.0; 11/10/50, 30.0; 12/8/51, 29.8.

12N/4E-4D1—Reference point—top of casing, elevation 42 feet. 0.06 mile south of Cornelius Avenue, 0.12 mile east of Electric Avenue. 12/9/47, 24.1; 3/11/48, 24.2; 5/11/48, 22.4; 12/14/48, 24.9; 3/28/49, 23.4; 12/6/49, 25.8.

12N/4E-4M1—Reference point—top of casing, elevation 40 feet. 0.24 mile east of Electric Avenue, 0.25 mile north of Watts Avenue. 3/11/48, 21.9; 12/14/48, 24.6; 3/28/49, 21.8; 12/7/49, 24.8.

12N/4E-5B1—Reference point—top of wooden pit, elevation 38 feet. South side of Cornelius Avenue, 0.36 mile west of Electric Avenue. 12/9/47, 20.9; 3/11/48, 20.8; 12/14/48, 22.1; 3/28/49, 19.4; 12/6/49, 22.5.

12N/4E-6B1—Reference point—top of wooden pit, elevation 32 feet, 0.29 mile west, 0.14 mile south of west end of Cornelius Avenue. 12/8/47, 14.2; 3/25/48, 12.0; 12/18/48, 13.9; 3/28/49, 8.4; 12/7/49, 15.2.

12N/4E-6Q1—Reference point—top of casing, elevation 30 feet, 1.50 miles west of Electric Avenue, 0.18 mile north of Nicolaus Avenue. 12/8/47, 15.7; 3/25/48, 14.1; 3/16/49, 12.9; 12/6/49, 16.8.

12N/4E-6R1—Reference point—top of casing, elevation 36 feet, 0.22 mile north of Nicolaus Avenue, 1.16 miles west of Electric Avenue. 12/8/47, 6.8; 12/14/48, 7.5; 3/16/49, 4.7; 12/6/49, 8.7.

12N/4E-7B1—Reference point—hole in base of pump, elevation 30 feet. South side of Nicolaus Avenue, 1.41 miles west of Electric Avenue. 12/8/47, 14.8; 5/11/48, 9.8; 12/13/48, 14.5; 3/16/49, 11.4; 6/30/49, 15.0; 7/27/49, 17.1; 12/6/49, 15.8; 3/25/50, 11.1; 11/6/50, 16.5; 4/2/51, 6.6; 11/16/51, 15.7; 4/4/52, 5.5.

12N/4E-7N2—Reference point—bottom of 6" x 14" plank bridge over pit, elevation 30 feet, 0.41 mile southeast of Garden Highway, 0.19 mile southwest of Markham Road. 12/5/47, 14.6; 3/15/48, 12.8; 12/11/48, 14.3; 3/25/49, 10.8; 12/6/49, 15.0.

12N/4E-7P2—Reference point—top of wooden pit, elevation 28 feet, 0.67 mile southeast of Garden Highway, 0.06 mile southwest of Markham Road. 12/5/47, 11.1; 3/11/48, 13.0; 5/11/48, 11.1; 12/11/48, 14.2; 3/25/49, 11.0; 12/6/49, 15.0.

12N/4E-8A1—Reference point—top of casing, elevation 37 feet. South side of Nicolaus Avenue, 0.07 mile west of Electric Avenue. 12/8/47, 19.2; 3/11/48, 17.4; 12/14/48, 19.6; 3/16/49, 17.4; 12/6/49, 20.4.

12N/4E-8C1—Reference point—top of casing, elevation 36 feet, 0.05 mile south of Nicolaus Avenue, 0.50 mile west of Electric Avenue. 12/8/47, 18.6; 3/11/48, 17.3; 5/11/48, 16.0; 12/14/48, 19.0; 3/16/49, 17.1; 12/6/49, 20.2; 3/29/50, 17.0; 11/6/50, 23.1; 1/2/51, 13.8; 11/16/51, 22.2; 1/1/52, 13.1.

12N/4E-8D1—Reference point—hole in base of pump, elevation 32 feet, 0.16 mile south of Nicolaus Avenue, 0.80 mile west of Electric Avenue. 12/8/47, 20.8; 3/25/48, 18.2; 12/11/48, 22.0.

12N/4E-9A1—Reference point—top of casing, elevation 44 feet. West side of Pacific Avenue, 0.24 mile south of Nicolaus Avenue. 12/23/47, 19.4; 3/11/48, 18.1; 12/14/48, 20.9; 3/28/49, 16.6; 12/7/49, 20.3; 3/27/50, 17.5; 11/6/50, 27.6; 4/2/51, 16.7; 11/16/51, 26.0; 4/4/52, 16.6.

12N/4E-9D1—Reference point—hole in pump base, elevation 40 feet. South side of Nicolaus Avenue, 0.13 mile east of Electric Avenue. 3/11/48, 17.9; 12/14/48, 20.0; 3/28/49, 17.3; 5/25/49, 21.0; 6/29/49, 22.7; 7/27/49, 23.9; 8/31/49, 25.1; 12/7/49, 20.6; 3/27/50, 18.2; 11/6/50, 24.8; 4/2/51, 16.1; 11/16/51, 24.0; 4/4/52, 15.8.

12N/4E-9J1—Reference point—top of casing, elevation 42 feet, 0.11 mile west of Pacific Avenue, 0.53 mile south of Nicolaus Avenue. 3/11/48, 18.7; 12/14/48, 21.1; 3/28/49, 16.7; 12/7/49, 20.5.

12N/4E-9J2—Reference point—top of casing, elevation 42 feet, 0.13 mile west of Pacific Avenue, 0.53 mile south of Nicolaus Avenue. 3/11/48, 19.1; 12/14/48, 21.4; 3/28/49, 16.9; 12/7/49, 20.8.

12N/4E-10A1—Reference point—hole in base of pump, elevation 50 feet, 0.09 mile south of Nicolaus Avenue, 0.90 mile east of Pacific Avenue. 3/11/48, 17.4; 4/2/48, 15.8; 5/5/48, 15.6; 5/31/48, 17.0; 6/17/48, 42.5; 7/2/48, 23.2; 12/15/48, 20.0; 3/28/49, 14.1; 7/1/49, 46.7 (operating); 8/1/49, 47.0 (operating); 8/31/49, 46.8 (operating); 12/7/49, 20.6; 3/27/50, 15.3; 11/6/50, 26.1; 4/5/51, 17.5; 4/4/52, 17.5.

12N/4E-10C1—Reference point—top of casing, elevation 47 feet. South side of Nicolaus Avenue, 0.51 mile east of Pacific Avenue. 3/11/48, 18.6; 12/14/48, 21.3; 3/28/49, 16.6; 12/7/49, 21.1.

12N/4E-11H1—Reference point—hole in base of pump, elevation 46 feet, 0.04 mile south of Trowbridge Road, 0.20 mile west of Pleasant Grove Road. 11/19/51, 22.9.

12N/4E-12D1—Reference point—top of casing, elevation 52 feet. West side of Pleasant Grove Road, 0.24 mile north of Trowbridge Road. 12/22/47, 13.4; 3/11/48, 12.5; 12/14/48, 14.0; 3/28/49, 6.9; 12/7/49, 15.8.

12N/4E-13C1—Reference point—hole in base of pump, elevation 51 feet, 0.11 mile south of Marcum Road, 0.53 mile east of Pleasant Grove Road. 3/11/48, 13.4; 12/14/48, 14.3; 12/22/48, 12.6; 3/29/49, 9.3; 11/10/49, 18.0; 3/15/50, 13.9; 3/27/50, 13.8; 4/10/50, 13.4; 11/6/50, 19.6; 11/14/50, 19.9; 3/23/51, 12.3; 11/19/51, 23.5; 4/4/52, 14.6; 4/10/52, 14.6.

12N/4E-13D1—Reference point—top of casing, elevation 50 feet. Southeast of intersection of Pleasant Grove Road and Marcum Road. 12/22/47, 12.1; 3/11/48, 12.3; 12/14/48, 12.2; 3/29/49, 6.6; 2/7/49, 13.9.

12N/4E-14P1—Reference point—top of casing, elevation 43 feet, 1.72 miles south of Trowbridge Road, 0.53 mile west of Pleasant Grove Road. 3/11/48, 9.1; 12/18/48, 8.8; 3/29/49, 3.3; 12/7/49, 10.8; 3/27/50, 7.1; 11/6/50, 4.3; 4/5/51, 5.3; 4/4/52, 4.3.

12N/4E-16A2—Reference point—top of casing, elevation 40 feet, 0.07 mile west of Pacific Avenue, 1.30 miles south of Nicolaus Avenue. 12/23/47, 16.1; 3/11/48, 15.2; 5/11/48, 17.7; 12/14/48, 16.5; 3/28/49, 12.0; 3/27/50, 13.8; 11/6/50, 22.6; 4/2/51, 11.8; 11/16/51, 26.6; 4/4/52, 11.6.

12N/4E-16L1—Reference point—top of 16-inch casing, elevation 34 feet, 0.50 mile east of Electric Avenue, 0.60 mile south of Markham Road. 3/11/48, 13.1; 12/14/48, 12.9; 3/28/49, 8.7; 12/7/49, 16.1; 11/6/50, 19.9; 4/2/51, 8.4.

12N/4E-16L2—Reference point—top of casing, elevation 34 feet, 0.25 mile east of Electric Avenue, 0.50 mile south of Markham Road. 3/11/48, 11.0; 12/13/48, 21.6; 3/28/49, 7.2; 12/7/49, 13.9.

12N/4E-17C1—Reference point—top of 16-inch casing under pump, elevation 35 feet, 0.25 mile south of Markham Road, 0.50 mile west of Electric Avenue. 12/8/47, 16.5; 3/25/48, 15.0; 12/11/48, 16.1; 3/28/49, 13.1; 12/7/49, 17.5.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Divisian of Water Resaurces
(Depths to water in feet measured from reference paint)

12N/4E-17J1—Reference point—top of 16-inch casing, elevation 32 feet. 300 feet west of Electric Avenue, 0.52 mile south of Markham Road. 12/8/47, 13.0; 3/11/48, 12.6; 5/11/48, 12.6; 12/11/48, 13.2; 3/28/49, 9.1; 5/26/49, 14.2; 6/29/49, 15.7; 7/27/49, 16.4; 8/26/49, 17.2; 12/7/49, 15.3; 11/16/51, 18.2; 4/4/52, 6.1.

12N/4E-18A1—Reference point—top of 12-inch casing under pump, elevation 30 feet. 600 feet south of Markham Road, 0.50 mile east of Power Line Road. 12/5/47, 14.3; 3/11/48, 14.9; 12/11/48, 14.7; 3/28/49, 12.4; 12/7/49, 15.6; 3/29/50, 13.3; 11/6/50, 17.1; 4/2/51, 6.4; 11/16/51, 16.4; 4/4/52, —3.0.

12N/4E-18D1—Reference point—top of concrete pit wall, south side, elevation 30 feet, 0.56 mile southeast of Garden Highway, 300 feet southwest of road. 12/5/47, 16.2; 12/11/48, 15.9; 3/25/49, 13.1; 12/6/49, 16.5; 11/6/50, 18.1; 4/2/51, 6.4.

12N/4E-18P1—Reference point—bottom of 4" x 12" plank across wooden pit, elevation 25 feet, 0.27 mile west of Power Line Road, 460 feet north of Lee Road. 12/5/47, 13.4; 3/11/48, 12.2; 12/11/48, 15.2; 3/25/49, 10.8; 12/6/49, 13.9.

12N/4E-19A1—Reference point—top of 14-inch casing, elevation 28 feet, 0.44 mile east of junction of Power Line and Lee Roads. 12/5/47, 12.9; 3/15/48, 12.1; 12/11/48, 13.1; 3/28/49, 10.0; 12/6/49, 14.2; 3/29/50, 11.9; 11/6/50, 13.1; 4/2/51, 4.5; 11/16/51, 15.5.

12N/4E-19C1—Reference point—hole in pump base, elevation 25 feet, 100 feet south of Lee Road, 200 feet west of Power Line Road. 12/5/47, 15.6; 3/11/48, 14.3; 3/25/49, 11.8; 12/6/49, 14.8.

12N/4E-19F1—Reference point—top of casing, elevation 27 feet, 300 feet west of Power Line Road, 0.40 mile south of Lee Road. 12/20/47, 14.6; 3/4/48, 14.0; 12/15/48, 14.8; 3/31/49, 11.3; 12/5/49, 15.9.

12N/4E-20A1—Reference point—top of casing, elevation 30 feet, 150 feet east of Electric Avenue, 0.76 mile north of Striplin Road. 12/20/47, 12.6; 3/4/48, 12.5; 12/15/48, 13.8; 3/30/49, 8.1; 12/2/49, 19.3.

12N/4E-20J1—Reference point—slot in concrete base, elevation 30 feet, 100 feet west of Electric Avenue, 0.42 mile north of Striplin Road. 5/5/48, 11.9; 5/31/48, 63.0 (operating); 7/2/48, 62.0 (operating); 12/15/48, 12.8; 4/13/49, 8.5; 6/30/49, 31.4; 8/1/49, 57.0 (operating); 8/31/49, 56.0 (operating); 12/7/49, 16.6; 3/24/50, 12.3; 11/8/50, 19.6; 4/2/51, 8.2; 11/19/51, 19.0; 4/7/52, 5.7.

12N/4E-20Q1—Reference point—top of 14-inch casing, elevation 30 feet, 0.35 mile west of Electric Avenue on Striplin Road. 5/5/48, 9.9; 5/31/48, 16.2; 12/15/48, 10.8; 4/13/49, 7.0; 6/2/49, 20.6; 8/1/49, 47.6 (operating); 8/31/49, 62.0 (operating); 12/7/49, 14.9.

12N/4E-20R1—Reference point—slot in concrete base, elevation 30 feet, 100 feet west of Electric Avenue, 0.21 mile west of Striplin Road. 5/5/48, 12.4; 5/31/48, 42.0 (operating); 7/2/48, 43.0 (operating); 12/15/48, 13.3; 4/13/49, 9.6; 6/2/49, 28.9; 6/30/49, 33.3; 8/1/49, 52.0 (operating); 8/31/49, 66.0 (operating); 12/7/49, 18.6.

12N/4E-21M1—Reference point—top of 16-inch casing outside of pump house, elevation 32 feet, 0.25 mile east of Electric Avenue, 0.80 mile north of Striplin Road. 12/23/47, 12.4; 3/15/48, 12.4; 12/15/48, 12.8; 3/30/49, 6.7; 12/2/49, 17.9.

12N/4E-24A1—Reference point—top of 14-inch casing, elevation 56 feet, South side of Lee Road, 0.5 mile west of Power Line Road. 12/20/48, 16.5; 4/1/49, 13.4; 11/10/49, 21.8; 3/15/50, 18.0; 4/10/50, 17.8; 10/2/50, 29.5; 11/13/50, 23.8; 3/21/51, 17.8; 5/9/51, 26.6; 11/14/51, 27.9; 3/13/52, 21.1.

12N/4E-24F1—Reference point—top of 14-inch casing, elevation 49 feet, 0.50 mile east of Pleasant Grove Road, 0.75 mile north of Striplin Road. 5/31/48, 11.3; 12/18/48, 13.1; 3/29/49, 8.7; 12/2/49, 16.2; 4/10/50, 13.2; 11/13/50, 18.2; 3/21/51, 11.7; 11/16/51, 21.4.

12N/4E-24M1—Reference point—top of 14-inch casing, elevation 50.9 feet, 75 feet east of Pleasant Grove Road, 0.25 mile north of Striplin Road. 12/22/47, 12.9; 3/22/48, 13.1; 12/18/48, 14.2; 3/29/49, 9.2; 5/26/49, 14.0; 6/29/49, 19.4; 7/28/49, 17.6; 8/26/49, 18.0; 12/2/49, 17.2; 3/15/50, 14.4; 3/27/50, 14.6, 11/6/50, 18.8; 4/5/51, 12.1; 11/16/51, 20.9; 11/19/51, 20.9; 4/8/52, 12.5; 4/10/52, 12.2.

12N/4E-25F1—Reference point—top of 16-inch casing, elevation 50 feet, 0.50 mile east of Pleasant Grove Road, 0.44 mile south of Striplin Road. 11/16/51, 27.1.

12N/4E-25M1—Reference point—hole in pump base, elevation 51.3 feet, 250 feet east of Pleasant Grove Road, 0.70 mile south of Striplin Road. 12/22/47, 15.7, 3/22/48, 15.1; 12/18/48, 17.4; 3/29/49, 13.3; 12/2/49, 20.6; 3/27/50, 17.5; 11/8/50, 22.8; 4/5/51, 15.7; 11/19/51, 29.0; 4/8/52, 19.8.

12N/4E-26M1—Reference point—hole in pump base, elevation 41 feet, 0.75 mile west of Pleasant Grove Road, 1.0 mile north of Catlett Road. 3/22/48, 12.9; 12/18/48, 14.8; 3/29/49, 10.6; 12/2/49, 18.5; 11/8/50, 19.4; 4/5/51, 12.7; 4/8/52, 11.3.

12N/4E-28F1—Reference point—hole in pump base, elevation 32 feet, 0.50 mile west of Pacific Avenue, 0.36 mile south of Striplin Road. 3/15/48, 11.0; 12/18/48, 12.5.

12N/4E-28H1—Reference point—hole in top of discharge pipe, elevation 36 feet. West of Pacific Avenue, 0.36 mile south of Striplin Road. 12/22/47, 11.1; 3/15/48, 11.0; 12/18/48, 11.2; 3/24/50, 11.1; 11/8/50, 15.7; 4/2/51, 8.1; 11/19/51, 11.9; 4/7/52, 8.0.

12N/4E-29A1—Reference point—north side base of pump, elevation 31 feet, 200 feet south of Striplin Avenue, 450 feet west of Electric Avenue. 12/18/47, 12.3; 3/14/48, 12.7; 12/15/48, 11.7; 3/30/49, 6.2; 12/2/49, 17.6; 3/24/50, 12.4; 11/8/50, 18.2; 4/2/51, 9.4; 11/19/51, 19.9; 4/7/52, 4.9.

12N/4E-29R1—Reference point—pump base at hole in concrete, elevation 30 feet, 300 feet west of Electric Avenue, 0.75 mile north of Catlett Road. 12/18/47, 10.2; 3/4/48, 10.8; 12/5/49, 20.8; 3/24/50, 8.0; 11/8/50, 13.5; 4/2/51, 5.6; 11/19/51, 14.0; 4/7/52, 3.9.

12N/4E-30F1—Reference point—pump base, elevation 25 feet, 100 feet east of Power Line Road, 0.50 mile south of Striplin Road. 12/20/47, 11.1; 3/4/48, 10.4; 12/15/48, 11.8; 3/30/49, 4.9; 12/5/49, 12.2; 3/27/50, 8.1; 11/8/50, 10.6; 4/2/51, 3.7; 11/16/51, 10.9; 4/8/52, 4.8.

12N/4E-32K1—Reference point—top of 16-inch casiug, elevation 28 feet, 1,500 feet west of Electric Avenue, 0.52 mile north of West Catlett Road. 3/30/49, 3.2.

12N/4E-33E1—Reference point—top of 18-inch casing, elevation 30 feet, 150 feet north of Catlett Road, 1,000 feet east of Electric Avenue. 3/15/48, 10.6; 12/18/48, 10.4.

12N/4E-33L3—Reference point—top of casing, elevation 31 feet. At dwelling south side of road, 300 feet east of Catlett Station, Sacramento Northern Railroad. 11/8/29, 15.4; 9/28/30, 16.0; 12/10/31, 16.4; 12/5/32, 12.2; 12/20/33, 15.6; 9/27/34, 16.3; 11/23/36, 12.5; 11/24/37, 9.4; 1/10/39, 8.9; 1/13/41, 3.4; 11/10/47, 11.5; 12/16/48, 11.0; 12/9/49, 13.4; 11/10/50, 13.0; 12/6/51, 12.0.

12N/4E-33R1—Reference point—top of 8-inch casing, elevation 31 feet, 100 feet west of Pacific Avenue, 0.32 mile south of Catlett Road. 12/22/47, 11.2; 3/18/48, 10.9; 12/18/48, 11.9; 3/30/49, 6.0; 12/2/49, 13.2; 3/24/50, 9.3; 11/8/50, 12.7; 4/2/51, 7.9; 11/19/51, 13.9; 4/8/52, 5.1.

12N/4E-34J1—Reference point—top of 4-inch casing, elevation 36 feet. Windmill 100 feet south of Catlett Road, 1.0 mile east of Pacific Avenue. 12/22/47, 14.8; 3/22/48, 13.7; 12/18/48, 15.9; 3/29/49, 9.8; 12/2/49, 17.9; 3/27/50, 13.8; 11/8/50, 16.7; 4/5/51, 10.2; 11/19/51, 22.0.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Meosurements Mode by Division of Woter Resources
(Depths to woter in feet meosured from reference point)

12N 4E-35H1—Reference point—top of 16-inch casing, elevation 48.8 feet, 0.1 mile west of Pleasant Grove Road, 0.2 mile north of Catlett Road. 12/22/47, 13.3; 3/22/48, 12.0; 12/18/48, 15.2; 3/29/49, 12.0; 12/2/49, 18.3; 3/27/50, 16.4; 11/8/50, 20.1; 4/5/51, 13.3; 5/10/51, 16.7; 7/11/51, 25.1; 8/22/51, 28.2; 9/26/51, 27.3; 11/16/51, 22.2; 11/19/51, 24.7; 4/8/52, 15.2; 4/10/52, 13.6.

12N 4E-36Q1—Reference point—top of casing in bottom of pit, elevation 48 feet, ground surface, 0.47 mile south of Catlett Road, 0.63 mile east of Pleasant Grove Road. 4/11/51, 22.0; 11/16/51, 28.9.

12N 5E-18P1—Reference point—top of 14-inch casing, elevation 61 feet, 0.50 mile west of Brewer Road, 1.0 mile south of Mareum Road. 3/22/48, 15.4.

13N 3E-2C1—Reference point—top of air gage hole, elevation 42.7 feet, 50 feet west of Garden Highway, 0.25 mile north of Tudor Road. 11/13/47, 25.6; 3/24/48, 21.0; 3/29/48, 19.7; 11/10/48, 20.4; 1/24/49, 19.2; 3/23/49, 16.9; 6/30/49, 30.3; 7/27/49, 29.0; 8/25/49, 25.2; 12/6/49, 21.2; 3/29/50, 17.5; 11/7/50, 23.1; 3/25/51, 12.2; 11/15/51, 22.6; 4/3/52, 9.1.

13N 3E-2H1—Reference point—hole in pump base, elevation 43.4 feet, 150 feet south of Shannon Road, 0.5 mile east of Garden Highway. 11/13/47, 21.4; 3/8/48, 19.4; 11/10/48, 18.0; 3/23/49, 14.5; 12/6/49, 19.5; 3/29/50, 13.4; 11/7/50, 19.0; 3/29/51, 12.2; 11/15/51, 18.3; 4/3/52, 6.2.

13N 3E-2L1—Reference point—top of 10-inch casing, elevation 41.2 feet, 0.5 mile west of Garden Highway, 0.1 mile south of Tudor Road. 1/19/48, 18.3; 5/6/48, 15.9; 6/1/48, 15.1; 6/3/48, 25.8; 8/2/48, 16.1; 9/1-48, 21.8; 3/23/49, 16.9.

13N 3E-2P1—Reference point—hole in pump base, elevation 39.9 feet, 200 feet west of Garden Highway, 0.3 mile south of Tudor Road. 11/13/47, 19.9; 3/8/48, 26.0; 11/10/48, 18.0; 3/23/48, 15.9; 12/6/49, 19.8.

13N 3E-3D1—Reference point—hole in pump base, elevation 38.9 feet, 50 feet east of State Highway 24, 0.3 mile north of Tudor Road. 11/14/47, 20.9; 3/8/48, 20.8; 3/29/48, 19.5; 11/10/48, 21.1; 1/24/49, 19.7; 3/25/49, 18.1; 6/1/49, 28.6; 6/28/49, 25.4; 7/29/49, 32.3; 8/30/49, 26.1; 12/6/49, 23.3.

13N 3E-3F1—Reference point—hole in pump base, elevation 38.9 feet, 0.15 mile north of Tudor Road, 0.4 mile east of State Highway 24. 11/14/47, 20.8; 3/18/48, 22.9; 11/10/48, 21.3; 3/25/49, 19.2; 12/6/49, 23.4; 3/29/50, 20.6; 11/7/50, 24.6; 3/29/51, 19.0; 11/15/51, 22.9; 4/3/52, 9.0.

13N 3E-4B1—Reference point—top of wood pit east edge, elevation 36 feet, 0.45 mile west of State Highway 24, 0.4 mile north of Tudor Road. 11/14/47, 18.1; 3/8/48, 14.8; 11/10/48, 20.7; 3/25/49, 17.5; 12/6/49, 23.1.

13N 3E-4P1—Reference point—top of 12-inch casing, elevation 34.7 feet, 0.05 mile west of Hobbs Road, 0.3 mile south of Tudor Road. 12/12/47, 14.6; 3/10/48, 14.7; 3/12/48, 14.6; 11/18/48, 16.5; 3/24/49, 13.8; 3/29/50, 15.9.

13N 3E-4P2—Reference point—top of casing, elevation 34 feet, 100 feet west of Hobbs Road, 0.4 mile south of Tudor Road. 11/7/50, 22.9; 3/29/51, 15.8.

13N 3E-5B1—Reference point—top of 4" x 12" plank bridge over earth pit, elevation 39.1 feet, 50 feet east of Bailey Road, 750 feet south of Tudor Road. 12/12/47, 14.3; 3/10/48, 16.9; 3/12/48, 17.1; 3/29/48, 16.7; 11/8/48, 18.3; 3/24/49, 15.4; 12/5/49, 18.6.

13N 3E-5E1—Reference point—top of 2" x 6" sill, north wall of wooden pit, elevation 38.1 feet, 300 feet east of George Washington Boulevard, 1,000 feet north of Tudor Road. 12/12/47, 14.2; 3/10/48, 11.8; 11/8/48, 13.0; 3/24/49, 12.5; 3/29/50, 12.5; 11/7/50, 17.8; 3/29/51, 13.1; 11/15/51, 15.8; 4/3/52, 10.1.

13N 3E-5J1—Reference point—top of 16-inch casing, elevation 27 feet, 0.1 mile south of Tudor Road, 0.5 mile west of Hobbs Road. 12/12/47, 13.7; 3/10/48, 12.8; 3/12/48, 12.8; 12/5/49, 17.0.

13N 3E-5L1—Reference point—top of 12-inch casing, elevation 37.4 feet, 50 feet south of State Highway 24, 650 feet west of Bailey Road. 12/12/47, 15.6; 3/10/48, 15.6; 3/12/48, 15.6; 5/12/48, 15.1; 11/8/48, 16.3; 1/19/49, 14.8; 3/24/49, 14.9; 6/1/49, 16.7; 6/28/49, 21.2; 7/27/49, 22.0; 8/25/49, 20.4; 12/2/49, 17.3.

13N 3E-6K1—Reference point—top of 16-inch casing, elevation 34 feet, South side of Tudor Road, 0.5 mile west of George Washington Boulevard. 12/15/48, 9.0; 12/9/49, 9.7; 11/10/50, 12.7; 12/6/51, 13.3.

13N 3E-6M1—Reference point—top of 12-inch casing, elevation 34 feet, 400 feet south of Tudor Road, 0.34 mile east of Roberts Road. 12/11/47, 9.9; 3/10/48, 8.2; 3/12/48, 8.3; 11/8/48, 6.2; 3/24/49, 6.6; 12/2/49, 9.0.

13N 3E-7A1—Reference point—top of casing, 20 feet north of pump house, elevation 35.2 feet, 250 feet south of Thompson Road, 300 feet west of State Highway 24. 12/12/47, 10.8; 3/10/48, 11.1; 3/12/48, 11.2; 11/8/48, 11.7; 3/24/49, 10.5; 12/2/49, 12.3.

13N 3E-7J1—Reference point—top of 8-inch casing, elevation 35.1 feet, 0.45 mile north of Everglade Road, 0.15 mile west of George Washington Boulevard, 250 feet south to well. 12/11/47, 9.7; 3/10/48, 10.5; 3/12/48, 10.7; 11/3/48, 12.0; 1/24/49, 11.7; 3/24/49, 10.3; 12/2/49, 12.8.

13N 3E-8B1—Reference point—top of 16-inch casing, elevation 35 feet, 0.05 mile south of Thompson Road, 0.8 mile west of Hobbs Road. 12/12/47, 10.8; 3/10/48, 13.9; 3/12/48, 14.0; 11/18/48, 15.1; 3/25/49, 13.0; 12/5/49, 17.1.

13N 3E-8M1—Reference point—top of wood floor under pump, elevation 35.9 feet, 0.2 mile east of George Washington Boulevard, 0.7 mile south of Thompson Road. 12/11/47, 10.3; 3/10/48, 10.8; 3/12/48, 10.8; 11/8/48, 13.1; 3/24/49, 11.0; 12/2/49, 13.8.

13N 3E-9C1—Reference point—hole in pump base, elevation 36.2 feet, 150 feet west of Hobbs Road, 0.60 mile south of State Highway 24. 12/12/47, 15.4; 3/10/48, 15.8; 3/12/48, 15.7; 11/8/48, 17.7; 1/24/49, 16.3; 3/24/49, 14.8; 6/1/49, 19.1; 6/28/49, 20.9; 7/27/49, 21.8; 8/30/49, 22.4; 12/5/49, 19.8.

13N 3E-9H1—Reference point—top of east wall of concrete pit, elevation 35 feet, 200 feet west of Sawtelle Avenue, 0.57 mile south of Tudor Road. 12/12/47, 16.8; 3/10/48, 17.9; 3/17/48, 18.0; 11/8/48, 19.2; 3/24/49, 16.3.

13N 3E-11A1—Reference point—hole in pump base, elevation 40 feet, 350 feet north of O'Conner Road, 0.55 mile east of Garden Highway. 11/13/47, 20.1; 3/8/48, 20.8; 11/10/48, 19.0; 1/24/49, 18.6; 3/23/49, 15.5; 12/5/49, 20.7.

13N 3E-11L1—Reference point—top of casing, elevation 38 feet, 0.05 mile west of Garden Highway, 1.1 miles south of Tudor Road. 11/14/47, 16.4.

13N 3E-11M1—Reference point—top of casing, elevation 36 feet, 0.4 mile west of Garden Highway, 0.2 mile north of Wilkie Avenue. 1/20/48, 17.5.

13N 3E-11Q2—Reference point—hole in pump base, elevation 39.3 feet, 50 feet west of Garden Highway, 0.15 mile south of Wilkie Avenue. 11/19/47, 16.5; 3/9/48, 19.8; 5/11/48, 13.4; 11/4/48, 16.1; 1/19/49, 15.3; 3/8/49, 14.8; 6/1/49, 17.2; 6/29/49, 23.9; 8/3/49, 23.7; 8/25/49, 19.1; 12/8/49, 17.2.

13N 3E-12L1—Reference point—hole in pump base, elevation 41 feet, 300 feet north of Wilkie Avenue, 0.7 mile east of Garden Highway. 11/14/47, 18.2; 3/8/48, 19.0; 11/10/48, 16.7; 3/23/49, 12.1; 12/5/49, 17.9; 11/7/50, 17.1; 3/29/51, 11.3; 11/15/51, 16.3; 4/3/52, 6.9.

13N 3E-12N1—Reference point—top of casing, elevation 39.5 feet, 0.2 mile south of Wilkie Avenue, 0.45 mile east of Garden Highway. 11/19/47, 15.4; 3/9/48, 18.2; 5/12/48, 10.3; 11/4/48, 16.3; 3/8/49, 13.7; 12/8/49, 16.2.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet measured from reference point)

13N/3E-13C1—Reference point—hole in pump base, elevation 42.3 feet, 0.7 mile east of Garden Highway, 0.25 mile south of Wilkie Avenue. 11/19/47, 16.9; 3/9/48, 20.3; 11/4/48, 17.0; 3/8/49, 13.8; 12/8/49, 17.9; 3/29/50, 10.8; 11/7/50, 17.1; 3/29/51, 16.7; 11/15/51, 16.7; 4/2/52, 7.3.

13N/3E-13D1—Reference point— edge of pump base, elevation 39 feet, 0.55 mile east of Garden Highway, 0.25 mile south of Wilkie Avenue. 5/5/48, 9.4; 6/1/48, 9.3; 2/6/52, 6.0.

13N/3E-13E1—Reference point—hole in pump base, elevation 37 feet, 0.5 mile east of Garden Highway, 0.75 mile south of Wilkie Avenue. 11/19/47, 15.4; 3/25/48, 14.7; 11/4/48, 15.1; 3/8/49, 13.3; 12/8/49, 15.9.

13N/3E-13L1—Reference point—top of casing, elevation 38 feet, 0.75 mile east of Garden Highway, 0.95 mile south of Wilkie Avenue. 11/19/47, 15.5; 3/9/48, 19.0; 11/4/48, 14.1; 3/8/49, 13.3; 12/7/49, 16.0.

13N/3E-14C1—Reference point—hole in pump base, elevation 35 feet, 0.25 mile west of Garden Highway, 0.35 mile south of Wilkie Avenue. 11/26/29, 15.4; 9/27/30, 15.6; 12/12/31, 15.4; 12/2/32, 15.2; 12/20/33, 16.3; 11/10/34, 16.7; 11/25/36, 13.4; 11/24/37, 11.8; 1/25/39, 10.8; 1/13/41, 8.2; 11/6/47, 15.3; 11/19/47, 15.9; 5/12/48, 13.9; 11/4/48, 15.7; 12/16/48, 14.7; 3/8/49, 14.9; 12/8/49, 16.6; 12/9/49, 16.0; 11/10/50, 16.0; 12/6/51, 13.4.

13N/3E-14G1—Reference point—hole in pump base, elevation 30.8 feet, 50 feet west of Garden Highway, 0.65 mile south of Wilkie Avenue. 3/25/48, 8.8; 11/4/48, 8.9; 3/8/49, 7.9; 12/8/49, 9.9; 3/29/50, 7.5; 11/7/50, 10.3; 3/39/51, 6.7; 11/15/51, 8.9; 4/2/52, 0.2.

13N/3E-14L3—Reference point—hole in pump base, elevation 34.9 feet, 50 feet south of Wilson Road, 0.1 mile west of Garden Highway. 11/19/47, 12.1; 3/25/48, 12.2; 11/4/48, 10.2; 3/8/49, 10.9; 12/7/49, 13.0; 4/2/52, 3.8.

13N/3E-14M2—Reference point—hole in pump base, elevation 35.7 feet, 0.1 mile south of Wilson Road, 0.4 mile west of Garden Highway. 11/19/47, 16.9; 3/9/48, 16.2; 11/5/48, 14.1; 3/8/49, 12.9; 12/7/49, 14.8.

13N/3E-14P1—Reference point—top of casing, elevation 35.6 feet, 0.25 mile west of Garden Highway, 0.4 mile south of Wilson Road. 11/19/47, 11.1; 3/9/48, 14.1; 11/4/48, 12.9; 3/8/49, 11.7; 12/7/49, 13.8.

13N/3E-14Q1—Reference point—top of casing, elevation 35.1 feet, 350 feet west of Garden Highway, 0.45 mile south of Wilson Road. 11/19/47, 14.9; 3/8/49, 11.0; 12/7/49, 12.8.

13N/3E-14R1—Reference point—hole in pump base, elevation 38.4 feet, 0.4 mile east of Garden Highway, 1.0 mile south of Wilkie Avenue. 11/19/47, 15.9; 3/9/48, 17.8; 11/4/48, 14.2; 3/8/49, 12.5; 12/7/49, 14.8.

13N/3E-15C2—Reference point—top of casing, elevation 36.1 feet, 0.3 mile north of Wilson Road, 100 feet west of Southern Pacific Railroad tracks. 12/18/47, 15.1; 3/11/48, 15.6; 11/4/48, 18.2; 3/16/49, 15.0.

13N/3E-15H1—Reference point—top of wooden pit, north side, elevation 37.8 feet, 0.2 mile north of Wilson Road, 0.6 mile west of Garden Highway. 12/18/47, 16.2; 3/11/48, 17.8; 11/4/48, 17.0; 3/8/49, 15.5.

13N/3E-15P1—Reference point—bottom of 2" x 12" over pit, elevation 34.0 feet, 0.25 mile east of Sawtelle Avenue, 100 feet southeast of most southerly corner of Wilson Road. 12/18/47, 13.2; 3/11/48, 13.0; 11/4/48, 6.7; 3/8/49, 12.9; 12/7/49, 14.7; 3/29/50, 12.8. Well destroyed.

13N/3E-15Q1—Reference point—top of casing, elevation 37 feet, 0.15 mile east of Southern Pacific Railroad tracks, 0.5 mile south of Wilson Road. 3/11/48, 13.2; 11/4/48, 13.6; 3/16/49, 11.7; 12/7/49, 13.1.

13N/3E-15R1—Reference point—top of plug in "T" discharge pipe, elevation 36 feet, 0.65 mile west of Garden Highway, 0.5 mile south of Wilson Road. 3/11/48, 14.5; 11/4/48, 13.6; 3/16/49, 13.2; 12/7/49, 14.3.

13N/3E-16A1—Reference point—top of casing, elevation 35 feet. South of Everglade Road, west of Sawtelle Avenue at intersection. 12/12/47, 15.7; 3/10/48, 14.7; 3/12/48, 14.7; 11/8/48, 17.1; 3/25/49, 14.6; 12/5/49, 16.3; 3/29/50, 15.1; 11/7/50, 17.0; 3/29/51, 11.7; 11/15/51, 15.4; 4/3/52, 9.5.

13N/3E-16H1—Reference point—hole in pump base, elevation 36.8 feet, 0.25 mile south of Everglade Road on west side of Sawtelle Ave. 12/18/47, 16.6; 3/4/48, 17.8; 11/4/48, 18.7; 1/24/49, 16.5; 3/8/49, 15.7; 12/7/49, 18.2.

13N/3E-16R1—Reference point—hole in pump base, elevation 38.1 feet, 60 feet west of Sawtelle Avenue, 0.9 mile south of Everglade Road. 12/18/47, 16.4; 3/11/48, 17.3; 11/4/48, 16.3; 3/16/49, 15.2; 12/7/49, 17.7; 3/29/50, 14.7; 11/7/50, 15.2; 3/29/51, 10.8; 11/15/51, 14.0; 4/2/52, 8.0.

13N/3E-17A1—Reference point—top of casing, elevation 31 feet, 0.1 mile south of Everglade Road, 0.9 mile east of George Washington Boulevard. 12/18/47, 9.4; 3/11/48, 9.8; 11/4/48, 8.3; 3/16/49, 6.6; 12/7/49, 10.3.

13N/3E-17B1—Reference point—top of casing, elevation 34.1 feet, 260 feet south of Everglade Road, 0.7 mile east of George Washington Boulevard. 12/12/47, 6.7; 3/10/48, 8.1; 3/12/48, 8.1; 11/8/48, 12.2; 12/5/49, 12.0.

13N/3E-17D1—Reference point—top of casing, elevation 30 feet. South side of Everglade Road, 0.2 mile east of George Washington Boulevard. 12/18/47, 7.9; 3/11/48, 8.7. Well destroyed.

13N/3E-18A1—Reference point—top of casing, elevation 30 feet, 0.25 mile south of Everglade Road, 0.2 mile west of George Washington Boulevard. 12/18/47, 10.2; 3/11/48, 10.7; 11/4/48, 10.7. Well destroyed.

13N/3E-23B1—Reference point—top of concrete pit, elevation 34 feet, 0.1 mile east of Garden Highway, 0.15 mile north of Central Avenue. 11/19/47, 12.3; 3/25/48, 12.3; 11/4/48, 11.9; 3/8/49, 11.2; 12/7/49, 12.7.

13N/3E-23D1—Reference point—top of concrete, elevation 38.3 feet, 0.4 mile west of Garden Highway, 0.25 mile north of Central Avenue. 11/19/47, 14.8; 3/9/48, 16.7; 5/11/48, 13.0; 11/4/48, 16.0; 3/8/49, 14.6.

13N/3E-23F1—Reference point—hole in pump base, elevation 34 feet, 0.15 mile west of Garden Highway, 0.1 mile south of Central Avenue. 11/20/47, 12.8; 3/10/48, 15.1; 11/4/48, 13.7; 3/8/49, 11.3; 12/7/49, 13.1.

13N/3E-23L1—Reference point—hole in pump base, elevation 35 feet, 0.15 mile west of Garden Highway, 0.4 mile south of Central Avenue. 11/20/47, 13.3; 3/10/48, 16.0; 5/11/48, 11.0; 11/4/48, 13.7; 1/24/49, 13.6; 3/8/49, 12.7; 6/7/49, 16.3; 6/29/49, 17.2; 7/27/49, 16.9; 8/25/49, 17.8; 12/7/49, 14.6; 3/29/50, 12.2; 11/7/50, 14.1; 3/29/51, 9.4; 11/15/51, 11.6; 4/2/52, 6.0.

13N/3E-24C2—Reference point—bottom of pump base, elevation 39.6 feet, 0.25 mile north of Central Avenue, 0.8 mile east of Garden Highway. 11/20/47, 15.4; 3/9/48, 16.0; 11/4/48, 14.7; 3/8/49, 13.1; 3/29/50, 11.5; 11/7/50, 15.3; 3/29/51, 7.6; 11/16/51, 14.6; 4/2/52, 7.6.

13N/3E-24D1—Reference point—hole in concrete base, elevation 36.5 feet, 0.45 mile east of Garden Highway, 0.45 mile south of Wilson Road. 11/19/49, 12.2; 3/25/48, 11.9; 5/11/48, 9.1; 11/4/48, 11.9; 3/8/49, 10.6; 6/1/49, 12.0; 8/25/49, 15.4; 12/7/49, 13.1

13N/3E-24E1—Reference point—top of casing, elevation 35 feet, 0.2 mile south of Central Avenue, 0.6 mile east of Garden Highway. 11/20/47, 10.8; 3/9/48, 11.4; 11/5/48, 11.4.

13N/3E-24G1—Reference point—top of casing, elevation 39 feet, 100 feet south of Central Avenue, 1.05 miles east of Garden Highway. 11/20/47, 24.2; 3/9/48, 18.9; 11/4/48, 20.7; 1/24/49, 18.8; 3/8/49, 17.1; 12/7/49, 19.9.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet measured from reference point)

13N/3E-25N1—Reference point—top of casing, elevation 35 feet, 200 feet north of Oak Avenue, 0.7 mile east of Garden Highway. 11/20/47, 10.9; 3/10/48, 11.9; 11/4/48, 9.3; 1/24/49, 9.3; 3/8/49, 7.6; 12/7/49, 11.0.

13N/3E-26J1—Reference point—top of casing, elevation 35 feet, 300 feet south of Cypress Avenue, 0.4 mile east of Garden Highway. 11/20/47, 9.2; 3/10/48, 9.9.

13N/3E-35H1—Reference point—hole in casing, elevation 32 feet, 0.1 mile north of Laurel Avenue, 0.45 mile east of Garden Highway. 11/20/47, 9.7; 3/10/48, 8.0; 11/4/48, 8.8; 1/24/49, 9.0; 3/8/49, 7.0; 12/7/49, 10.4.

13N/3E-36N1—Reference point—top of 2" x 4" at top of west side of pit, elevation 33 feet, 0.3 mile south of Laurel Avenue, 0.55 mile east of Garden Highway. 12/5/47, 11.9; 3/10/48, 12.2; 5/11/48, 7.0; 12/11/48, 11.6; 3/16/49, 8.2; 12/6/49, 12.8; 3/29/50, 7.7; 11/3/50, 12.0; 4/3/51, 5.2; 11/16/51, 10.2; 4/4/52, 3.6.

13N/4E-1P1—Reference point—top of 14-inch casing, elevation 62 feet, 100 feet west of farm road, 1.1 miles south of Dairy Road. 11/28/47, 18.8.

13N/4E-1Q1—Reference point—bottom of slot inside of casing by air line, elevation 63.2 feet, 800 feet east of farm road, 1.1 miles south of Dairy Road. 11/28/47, 19.4; 2/11/48, 17.5; 2/21/48, 18.1; 3/29/48, 17.4; 5/5/48, 15.2; 6/3/48, 17.9; 7/2/48, 66.0 (operating); 11/12/48, 21.0; 3/24/49, 17.0; 11/28/49, 24.2.

13N/4E-2A1—Reference point—top of 12-inch casing, bottom of pit, elevation 52 feet, Ground elevation 66 feet, 300 feet south of Dairy Road, 2.2 miles southwest of U. S. Highway 99E. 11/28/47, 13.4; 3/2/48, 11.0; 11/12/48, 14.8; 3/25/49, 11.3; 11/23/49, 17.3; 3/28/50, 14.3; 11/8/50, 19.1; 4/4/51, 12.8; 11/30/51, 29.4.

13N/4E-2C1—Reference point—top of 14-inch casing, elevation 64 feet, West of Pleasant Grove Road (Forty Mile Road) about 1.5 miles southeast of Plumas School. 11/28/47, 28.0; 3/1/48, 26.2; 3/22/48, 28.3; 3/29/48, 26.4; 5/5/48, 24.5; 8/13/48, 78.8 (operating); 11/8/48, 29.4; 1/25/49, 27.7; 3/25/49, 26.1; 11/23/49, 31.8.

13N/4E-2K1—Reference point—lower left hole in pump base, elevation 66 feet, 100 feet southeast of Leach Road, 200 feet west of Pleasant Grove Road (Forty Mile Road). 11/29/47, 29.0; 3/1/48, 26.6; 4/8/48, 29.9; 3/25/49, 26.7; 11/23/49, 26.7; 3/28/50, 32.3; 11/6/50, 34.0; 4/3/51, 26.9; 11/30/51, 33.1; 4/1/52, 30.9.

13N/4E-3F1—Reference point—top of concrete pit, elevation 57 feet, West of Hoffman Road, 1.4 miles south of Plumas School. 11/8/48, 30.1.

13N/4E-3G1—Reference point—slot in side of casing, elevation 58 feet, East of Hoffman Road, 1.4 miles south of Plumas School. 11/28/47, 25.6; 11/8/48, 27.0; 11/25/49, 28.7; 3/28/50, 26.0; 11/6/50, 30.4; 4/4/51, 26.0; 12/5/51, 32.8; 4/1/52, 25.9.

13N/4E-4J1—Reference point—top of casing, bottom of pit, elevation 47 feet, ground elevation 52.0 feet, 250 feet west of farm road, 0.75 mile north of Leach Road. 11/29/47, 18.3; 3/1/48, 16.8; 11/8/48, 20.5; 3/25/49, 15.9; 11/26/49, 21.1.

13N/4E-4J2—Reference point—hole in side of casing, elevation 52 feet, 100 feet west of farm road, 0.75 mile north of Leach Road. 11/8/48, 26.1; 3/25/49, 21.1; 11/26/49, 26.0.

13N/4E-7E1—Reference point—hole in pump base, elevation 39 feet, 0.05 mile west of Feather River Boulevard, 2.9 miles south of Country Club Avenue. 11/17/47, 14.3; 3/9/48, 13.1; 5/5/48, 9.1; 5/31/48, 9.1; 7/2/48, 42.0 (operating); 8/1/48, 49.1 (operating); 9/2/48, 44.0 (operating); 9/30/48, 13.5; 11/10/48, 13.9; 1/21/49, 13.8; 3/22/49, 10.8; 6/1/49, 10.8; 6/29/49, 12.8; 7/28/49, 14.2; 8/26/49, 15.8; 12/2/49, 15.3; 3/29/50, 9.7; 11/6/50, 11.7; 3/30/51, 7.8; 11/16/51, 13.7; 4/1/52, 5.5.

13N/4E-9A1—Reference point—top of 14-inch casing, elevation 52 feet, West of farm road, 0.45 mile north of Leach Road. 11/29/47, 19.8; 3/1/48, 17.9; 11/8/48, 20.5; 3/25/49, 17.0; 11/26/49, 22.1; 3/28/50, 19.0; 11/6/50, 23.0; 4/3/51, 16.4; 12/6/51, 22.4; 4/1/52, 18.0.

13N/4E-9R1—Reference point—top of casing, elevation 50 feet, 0.30 mile south of Leach Road. 11/8/48, 21.4; 3/25/49, 17.2; 11/26/49, 24.1; 3/28/50, 18.7; 11/6/50; 25.4; 4/4/51, 14.8; 12/5/51, 23.0; 4/1/52, 14.9.

13N/4E-10D1—Reference point—top of 14-inch casing, elevation 54 feet, 0.25 mile east of farm road, 0.50 mile north of Leach Road. 11/29/47, 25.0; 3/1/48, 23.0; 11/8/48, 26.5; 3/25/49, 22.4; 11/26/49, 27.4; 4/1/52, 24.6.

13N/4E-10J1—Reference point—slot in side of casing, elevation 55 feet, 200 feet south of Leach Road. 11/8/48, 25.6; 3/25/49, 23.0; 11/26/49, 27.6; 3/28/50, 23.5; 11/6/50, 29.6; 4/3/51, 21.5; 4/1/52, 21.0.

13N/4E-11J1—Reference point—bottom of slot in top of casing, elevation 61.3 feet, 200 feet west of Pleasant Grove Road, 0.75 mile north of Four Corners. 12/2/47, 19.6; 2/11/48, 17.8; 2/21/48, 17.7; 3/8/48, 26.5; 3/22/48, 26.4; 3/29/48, 17.8; 5/5/48, 16.0; 6/3/48, 17.8; 9/30/48, 27.2; 11/15/48, 21.2; 1/26/49, 19.5; 3/31/49, 18.3; 12/2/49, 23.6; 3/29/50, 19.6; 11/8/50, 25.5; 4/3/51, 18.6; 11/20/51, 24.4; 4/4/52, 15.7.

13N/4E-12C2—Reference point—top of flange in bottom of pit, elevation 44 feet, Ground elevation 55 feet, 1,000 feet north of Wheatland-Rio Oso Road, 0.45 mile east of Pleasant Grove Road (Forty Mile Road). 11/25/47, 9.2; 2/11/48, 6.9; 2/21/48, 6.0; 3/29/48, 4.8; 11/12/48, 10.5; 3/24/49, 5.5; 6/6/49, 14.0; 7/1/49, 17.4; 8/1/49, 21.6; 8/31/49, 45.0 (operating); 11-26-49, 13.4.

13N/4E-12E1—Reference point—top of 14-inch casing, elevation 60 feet, 150 feet west of Wheatland-Rio Oso Road, 300 feet east of Pleasant Grove Road (Forty Mile Road). 11/29/47, 18.9.

13N/4E-12E2—Reference point—bottom of slot in top of 14-inch casing, elevation 60.8 feet, 100 feet west of Wheatland-Rio Oso Road, 400 feet east of Pleasant Grove Road (Forty Mile Road). 11/29/47, 18.5; 2/11/48, 16.2; 2/21/48, 16.0; 3/2/48, 16.6; 3/11/48, 16.6; 3/29/48, 14.9; 5/18/48, 13.2; 11/12/48, 19.7; 3/24/49, 15.2; 11/23/49, 24.5; 3/29/50, 16.6; 11/8/50, 23.0; 4/3/51, 14.0; 12/3/51, 24.2; 4/2/52, 10.8.

13N/4E-12G1—Reference point—hole in pump base, elevation 65 feet, North of Wheatland-Rio Oso Road, 0.85 mile east of Pleasant Grove Road (Forty Mile Road). 11/28/47, 22.1.

13N/4E-12H1—Reference point—hole in pump base, elevation 67.3 feet, 100 feet north of Wheatland-Rio Oso Road, 1.0 mile east of Pleasant Grove Road (Forty Mile Road). 11/28/47, 22.6; 2/11/48, 20.5; 2/21/48, 21.0; 3/29/48, 21.0; 11/12/48, 23.8; 3/24/49, 19.4; 11/26/49, 26.8.

13N/4E-12H2—Reference point—top of slot in pump base, elevation 67.2 feet, 100 feet north of Wheatland-Rio Oso Road, 0.90 mile east of Pleasant Grove Road (Forty Mile Road). 11/28/47, 22.2; 3/29/48, 19.8; 11/12/48, 23.4; 3/24/49, 19.0; 11/26/49, 26.6.

13N/4E-12H3—Reference point—top of 8-inch casing, elevation 68 feet, 200 feet south of Wheatland-Rio Oso Road, 1.0 mile east of Pleasant Grove Road (Forty Mile Road). 12/2/47, 24.2; 3/8/48, 25.4.

13N/4E-12K1—Reference point—groove in base plate, elevation 69.4 feet, 0.30 mile south of Wheatland-Rio Oso Road, 0.50 mile east of Pleasant Grove Road (Forty Mile Road). 12/2/47, 24.6; 3/8/48, 28.2; 3/29/48, 22.4; 11/15/48, 25.7; 3/31/49, 21.9; 12/2/49, 28.4.

13N/4E-12K2—Reference point—top ridge on base plate, elevation 70 feet, 1,000 feet south of Wheatland-Rio Oso Road, 0.75 mile east of Pleasant Grove Road (Forty Mile Road). 12/2/47, 24.4; 3/8/48, 29.6.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet meosured from reference point)

13N/4E-12L1—Reference point—pipe in base, elevation 65.6 feet, 1,100 feet south of Wheatland-Rio Oso Road, 0.25 mile east of Pleasant Grove Road (Forty Mile Road). 12/2/47, 23.2; 3/8/48, 30.9; 3/22/48, 32.7; 3/29/48, 21.6; 5/5/48, 19.2; 6/3/48, 21.2; 9/30/48, 30.7; 11/15/48, 24.8; 1/26/49, 23.0; 12/2/49, 27.6.

13N/4E-12L2—Reference point—slot in top of casing, elevation 65.1 feet, 800 feet south of Wheatland-Rio Oso Road, 0.30 mile east of Pleasant Grove Road (Forty Mile Road). 12/2/47, 21.6; 3/8/48, 28.3; 3/22/48, 29.0; 3/29/48, 19.9; 9/30/48, 29.3; 11/15/48, 23.4; 3/31/49, 22.8.

13N/4E-12Q1—Reference point—pipe in concrete base, elevation 70.5 feet, 0.30 mile north of Bear River Drive, 0.70 mile east of Pleasant Grove Road. 12/3/47, 26.0; 3/30/48, 24.4; 11/4/48, 27.9; 3/31/49, 23.5; 12/2/49, 30.2.

13N/4E-12R1—Reference point—hole in pump base, elevation 72.4 feet, 0.30 mile north of Bear River Drive, 0.90 mile east of Pleasant Grove Road. 12/3/47, 45.5; 3/30/48, 24.9; 11/4/48, 28.9; 1/26/49, 26.6; 3/31/49, 24.4; 12/2/49, 31.3.

13N/4E-13A1—Reference point—hole in pump base, elevation 71.6 feet, 1,200 feet north of Bear River Drive, 0.75 mile east of Pleasant Grove Road. 12/3/47, 26.5; 3/8/48, 31.6; 3/30/48, 24.9; 11/4/48, 28.3; 3/31/49, 24.0; 12/2/49, 30.8.

13N/4E-13B1—Reference point—hole in pump base, elevation 70 feet, 850 feet north of Bear River Drive, 0.60 mile east of Pleasant Grove Road. 11/4/48, 28.3.

13N/4E-13C1—Reference point—top of 14-inch casing, elevation 69.2 feet, 900 feet north of Bear River Drive, 0.40 mile east of Pleasant Grove Road. 12/3/47, 25.7; 11/4/48, 27.7; 3/31/49, 23.3; 12/2/49, 30.0.

13N/4E-13E1—Reference point—top of 14-inch casing, elevation 60.7 feet, 150 feet south of Bear River Drive, 700 feet east of Four Corners. 12/3/47, 19.5; 3/8/48, 24.2; 3/30/48, 18.1; 11/4/48, 21.6; 3/31/49, 17.0; 12/2/49, 23.6; 3/30/50, 19.8; 11/8/50, 25.4; 11/20/51, 23.1; 4/4/52, 16.7.

13N/4E-13F1—Reference point—bottom of pump base, elevation 62.9 feet, 150 feet south of Bear River Drive, 0.25 mile east of Four Corners. 12/2/47, 21.2; 3/10/48, 31.2; 11/4/48, 23.5; 3/31/49, 19.0; 12/2/49, 25.6.

13N/4E-13F2—Reference point—top of casing, elevation 65.5 feet, North side Bear River Drive, 0.30 mile east of Four Corners. 12/2/47, 23.2; 3/30/48, 21.8; 5/14/48, 19.5; 11/4/48, 25.5; 1/26/49, 23.0; 3/31/49, 21.0.

13N/4E-13F3—Reference point—top of 12-inch casing, elevation 66.9 feet, South side Bear River Drive, 0.50 mile east of Four Corners. 12/2/47, 23.6; 3/8/48, 28.2; 11/4/48, 25.5; 3/31/49, 21.2; 12/2/49, 27.9.

13N/4E-13G1—Reference point—top of 12-inch casing, elevation 67.8 feet, 200 feet south of Bear River Drive, 0.50 mile east of Four Corners. 12/2/47, 24.2; 3/8/48, 27.3; 11/4/48, 25.7; 3/31/49, 21.6; 12/2/49, 28.2.

13N/4E-13G2—Reference point—top of 14-inch casing, elevation 69.1 feet, South side Bear River Drive, 0.70 mile east of Four Corners. 12/2/47, 24.6; 3/10/48, 28.1; 3/30/48, 23.2; 11/4/48, 25.9; 3/31/49, 22.0; 12/2/49, 28.5; 3/30/50, 24.8; 11/8/50, 30.9; 4/3/51, 20.7; 11/20/51, 24.4; 4/4/52, 16.7.

13N/4E-13H1—Reference point—slot in concrete base, elevation 66 feet, 150 feet south of Bear River Drive, 0.95 mile east of Four Corners. 12/3/47, 22.4; 11/4/48, 24.4; 3/31/49, 21.7; 12/2/49, 27.1.

13N/4E-13K1—Reference point—top of twin holes in pump base, elevation 63 feet, 0.40 mile north of Gallagher Road, 0.50 mile east of Pleasant Grove Road. 12/5/47, 18.7.

13N/4E-13M1—Reference point—top of concrete foundation, elevation 60.8 feet, 700 feet east of Pleasant Grove Road, 0.30 mile north of Gallagher Road. 12/5/47, 19.6; 3/8/48, 25.7; 11/15/48, 21.6; 3/31/49, 17.7; 11/30/49, 25.1.

13N/4E-13M2—Reference point—top of casing, elevation 62.2 feet, 0.25 mile east of Pleasant Grove Road, 0.30 mile north of Gallagher Road. 12/5/47, 21.9; 3/8/48, 22.5; 3/31/48, 20.1; 11/15/48, 22.9; 4/1/49, 17.5; 11/30/49, 25.5.

13N/4E-13P1—Reference point—top of 14-inch casing, elevation 20.2 feet, 900 feet north of Gallagher Road, 0.40 mile east of Pleasant Grove Road. 12/5/47, 18.2; 3/8/48, 23.4; 11/5/48, 20.8; 4/1/49, 17.2; 11/30/49, 23.2.

13N/4E-13R1—Reference point—top of 14-inch casing, elevation 69.3 feet, 0.50 mile east of end of Gallagher Road, 1.00 mile east of Pleasant Grove Road. 12/8/47, 25.6; 3/10/48, 27.8; 3/31/48, 24.3; 11/5/48, 28.4; 4/1/49, 24.0; 11/30/49, 31.3; 3/30/50, 27.1; 11/9/50, 34.0; 4/4/51, 25.0; 11/21/51, 33.7.

13N/4E-14A1—Reference point—bottom of cutout in top of casing, elevation 59.28 feet, 900 feet north of Bear River Drive, 1,000 feet west of Pleasant Grove Road. 12/3/47, 19.1; 11/15/48, 20.4; 3/31/49, 16.7; 12/1/49, 22.9.

13N/4E-14D1—Reference point—bottom edge of pump base, elevation 55.0 feet, 900 feet east of Warren Road, 0.25 mile north of Bear River Drive. 12/3/47, 14.8; 2/10/48, 14.6; 3/31/48, 12.4; 11/15/48, 15.3; 3/31/49, 10.5; 12/1/49, 17.2.

13N/4E-14F1—Reference point—top of 12-inch casing, elevation 55.0 feet, 350 feet north of Bear River Drive, 0.30 mile east of Warren Road. 12/3/47, 17.7; 3/8/48, 20.0; 11/15/48, 18.6; 3/31/49, 14.2; 12/1/49, 20.8; 3/30/50, 15.9; 11/9/50, 22.2; 4/3/51, 13.0; 11/20/51, 19.2; 4/4/52, 6.0.

13N/4E-14F3—Reference point—top of casing, elevation 55.2 feet, 250 feet south of Bear River Drive, 0.40 mile east of Warren Road. 12/4/47, 17.4; 11/15/48, 18.9; 3/31/49, 14.8; 12/1/49, 21.3.

13N/4E-14J1—Reference point—hole in pump base, elevation 54 feet, 1,000 feet west of Pleasant Grove Road, 0.30 mile south of Bear River Drive. 12/4/47, 17.4; 11/15/48, 19.4; 3/31/49, 15.4; 12/1/49, 22.3.

13N/4E-14N1—Reference point—top of 14-inch casing in bottom of pit, elevation 48.5 feet, 400 feet east of Warren Road, 0.40 mile south of Bear River Drive. 12/4/47, 14.5; 3/31/48, 12.9; 11/15/48, 15.2; 3/31/49, 10.7; 12/1/49, 17.1.

13N/4E-14N2—Reference point—top of 14-inch casing, elevation 54.4 feet, 1,200 feet east of Warren Road, 0.35 mile south of Bear River Drive. 12/4/47, 21.0; 3/31/48, 19.5; 11/15/48, 21.8; 3/31/49, 17.2; 12/1/49, 23.9.

13N/4E-14Q1—Reference point—top of 14-inch casing, elevation 56 feet, 0.45 mile west of Pleasant Grove Road, 0.50 mile south of Bear River Drive. 12/4/47, 22.5; 11/15/48, 23.9; 3/31/49, 18.7; 12/1/49, 26.3.

13N/4E-14Q2—Reference point—top of 12-inch casing, elevation 59.1 feet, 0.25 mile west of Pleasant Grove Road, 0.25 mile north of Betz Road. 12/5/47, 23.2; 3/10/48, 33.3; 11/15/48, 24.6.

13N/4E-14R1—Reference point—hole in pump base, elevation 60.4 feet, West side Pleasant Grove Road, 1,000 ft. north of Gallagher Road. 12/5/47, 21.2; 3/8/48, 25.1; 3/31/48, 19.5; 5/8/48, 17.3; 11/5/48, 23.6; 11/15/48, 22.4; 1/26/49, 20.3; 3/31/49, 18.1; 11/30/49, 25.4.

13N/4E-14R2—Reference point—top of concrete pit, elevation 60.1 feet, West side Pleasant Grove Road, 1,100 feet north of Gallagher Road. 12/5/47, 21.8; 3/8/48, 21.5; 11/5/48, 23.6.

13N/4E-15A1—Reference point—top of pump base, elevation 54.7 feet, 350 feet west of Warren Road, 0.30 mile north of Bear River Drive. 12/3/47, 17.9; 3/8/48, 19.5; 3/31/48, 16.2; 11/15/48, 19.1; 3/31/49, 14.2; 12/1/49, 21.1.

13N/4E-15J2—Reference point—bottom edge of pump base, elevation 53.2 feet, South side Bear River Drive, 100 feet west of Warren Road. 12/4/47, 19.2; 3/10/48, 19.0.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Meosurements Mode by Division of Water Resources
(Depths to woter in feet meosured from reference point)

13N 4E-15K1—Reference point—hole in pump base, elevation 51.8 feet, North side Bear River Drive, 1,200 feet northeast of Swanson Road. 12/4/47, 16.4; 3/30/48, 14.2; 5/5/48, 12.2; 6/3/48, 13.8; 7/2/48, 56.2; 11/15/48, 17.2; 1/26/49, 15.3; 3/31/49, 12.0; 5/25/49, 18.1; 6/29/49, 25.9; 8/26/49, 24.7; 12/1/49, 19.4.

13N 4E-15N1—Reference point—bottom of pump base, elevation 50.8 feet, North side Bear River Drive, 0.40 mile southwest of Swanson Road. 12/4/47, 19.2; 3/10/48, 18.2; 11/15/48, 19.0; 3/31/49, 12.5; 12/1/49, 21.3.

13N 4E-15N2—Reference point—hole in pump base, elevation 52.9 feet, 350 feet south of Bear River Drive, 0.30 mile southwest of Swanson Road. 12/4/47, 21.2; 3/10/48, 20.9; 11/15/48, 21.0; 3/31/49, 14.4; 12/1/49, 23.2.

13N 4E-15P1—Reference point—bottom of pump base, elevation 54.3 feet, 350 feet west of Swanson Road, 1,000 feet south of Bear River Drive. 12/4/47, 22.3; 3/10/48, 21.4; 11/15/48, 22.2; 3/31/49, 15.9; 12/1/49, 24.4.

13N 4E-15P2—Reference point—hole in pump base, elevation 51 feet, 200 feet north of junction of Swanson Road and Bear River Drive. 12/4/47, 17.0; 3/31/48, 14.2; 11/15/48, 17.0; 3/31/49, 11.1; 12/1/49, 18.8; 3/30/50, 11.6; 11/20/50, 19.1; 4/4/52, 5.9.

13N 4E-15R1—Reference point—bottom of slot in concrete base, elevation 54 feet, 100 feet west of Warren Road, 0.45 mile south of Bear River Drive. 12/4/47, 21.4; 3/8/48, 24.0; 11/15/48, 21.7; 3/31/49, 17.0; 12/1/49, 24.0.

13N 4E-16N1—Reference point—hole in pump base, elevation 43.7 feet, 600 feet west of Fourth Avenue, 0.75 mile north of Rio Oso Road. 12/6/47, 14.4; 3/30/48, 9.8; 5/5/48, 7.3; 5/31/48, 7.4; 11/16/48, 12.7; 4/1/49, 6.0; 5/25/49, 11.3; 6/2/49, 9.3; 7/1/49, 11.6; 8/1/49, 17.0; 8/31/49, 16.7; 11/30/49, 16.0; 3/30/50, 7.0; 11/9/50, 15.8; 4/3/51, 4.9; 11/20/51, 13.7; 4/4/52, 3.4.

13N 4E-17A1—Reference point—hole in base of pump, elevation 41 feet, 250 feet west of farm road, 1.25 miles north of Feather River Boulevard at Bear River Bridge. 11/21/47, 11.9; 3/10/48, 10.5; 12/8/49, 14.4.

13N 4E-17G2—Reference point—hole in base of pump, elevation 40 feet, 0.35 mile northeast of Feather River Boulevard at a point 0.60 mile northwest of Bear River Bridge. 11/21/47, 14.1; 3/10/48, 14.9; 11/5/48, 13.6; 3/15/49, 8.3; 12/7/49, 15.8.

13N 4E-17P1—Reference point—bottom of pump base, elevation 39 feet, 300 feet south of Feather River Boulevard, 0.60 mile northwest of Bear River Bridge. 11/20/47, 13.9; 3/10/48, 11.9; 5/8/48, 6.9; 11/5/48, 11.2; 1/24/49, 10.4; 3/15/49, 7.9; 6/1/49, 7.9; 7/29/49, 15.0; 8/26/49, 15.2; 12/8/49, 13.8; 3/29/50, 6.9; 11/6/50, 13.7; 3/30/51, 11.9; 11/16/51, 11.9.

13N 4E-17Q1—Reference point—top of floor board, elevation 42 feet, 800 feet east of Feather River Boulevard at a point 0.45 mile northwest of Bear River Bridge. 11/21/47, 13.1; 3/10/48, 11.9; 3/15/49, 7.2; 12/8/49, 14.9.

13N 4E-18F1—Reference point—hole in base of pump, elevation 35 feet, South side of curve in Feather River Boulevard, approximately 2.0 miles northwest of Bear River Bridge. 3/9/48, 13.0; 5/5/48, 9.0; 5/31/48, 9.0; 11/5/48, 11.5; 1/24/49, 13.0; 3/15/49, 11.3; 12/8/49, 15.9; 3/29/50, 10.6; 11/6/50, 15.1; 3/30/51, 7.5; 11/16/51, 13.8.

13N 4E-18L1—Reference point—top of tin casing, elevation 35 feet, 100 feet south of farm road, 1,200 feet southwest of Feather River Boulevard. 11/20/47, 11.8; 3/9/48, 13.3; 11/5/48, 14.7; 3/15/49, 11.1; 12/8/49, 15.8.

13N 4E-19Q1—Reference point—top of concrete under pump, elevation 35 feet, 0.25 mile northwest of Levee Road, 1.1 miles southwest of Feather River Boulevard at Bear River Bridge. 11/21/47, 13.7; 11/5/48, 15.7; 3/15/49, 9.9; 12/7/49, 17.0; 3/29/50, 10.1; 11/8/50, 15.6; 3/30/51, 10.2.

13N 4E-20B1—Reference point—top of casing, elevation 42 feet, Northeast of Feather River Boulevard just across Bear River Bridge. 11/21/47, 16.4; 3/10/48, 15.8; 11/5/48, 15.0.

13N 4E-20F1—Reference point—top of concrete under pump, elevation 39 feet, 900 feet west of Levee Road, 0.30 mile southwest of Feather River Boulevard at Bear River Bridge. 11/21/47, 12.3; 11/5/48, 12.2; 3/15/49, 7.0; 12/7/49, 13.7.

13N 4E-20G1—Reference point—base of pump, elevation 41 feet, 300 feet west of Levee Road, 700 feet southwest of Feather River Boulevard at Bear River Bridge. 11/21/47, 13.6; 11/5/48, 15.1; 3/15/49, 8.2; 12/7/49, 15.7.

13N 4E-20J1—Reference point—top of casing, elevation 41 feet, 400 feet south of Feather River Boulevard, 500 feet west of Sacramento Northern Railroad. 11/21/47, 12.9; 3/10/48, 11.9; 11/5/48, 11.8; 1/24/49, 10.4; 3/15/49, 6.6; 12/8/49, 14.3; 3/29/50, 6.9; 11/8/50, 14.4; 3/30/51, 3.8; 11/16/51, 12.2.

13N 4E-20N1—Reference point—top of casing, elevation 37 feet, North side of the west levee of Bear River, 0.99 mile south of Feather River Boulevard at Bear River Bridge. 11/21/47, 14.8; 11/5/48, 14.3; 3/15/49, 8.6; 12/7/49, 16.0.

13N 4E-20R2—Reference point—hole in pump base, elevation 41 feet, West of Sacramento Northern Railroad, 0.35 mile south of Rio Oso Road. 11/21/47, 15.9; 3/10/48, 14.9; 5/11/48, 11.4; 3/15/49, 11.0; 12/8/49, 16.3.

13N 4E-21A1—Reference point—bottom edge of pump base, elevation 50 feet, 560 feet south of west end of Bear River Drive. 12/4/47, 19.2; 3/10/48, 18.3; 3/31/48, 15.9; 11/15/48, 19.0; 1/26/49, 17.6; 3/31/49, 11.8; 12/1/49, 21.4; 3/30/50, 12.0; 11/9/50, 21.0; 4/3/51, 9.2; 11/20/51, 18.7; 4/4/52, 6.6.

13N 4E-21B1—Reference point—pipe elbow in casing, elevation 47.8 feet, 0.25 mile west of west end of Bear River Drive. 12/4/47, 16.7; 3/10/48, 19.0; 11/15/48, 16.6; 3/31/49, 9.8; 12/1/49, 18.8; 11/20/51, 16.3; 4/4/52, 5.9.

13N 4E-21C1—Reference point—bottom of flanged coupling, elevation 45.1 feet, 630 feet east of Fourth Avenue, 0.25 mile north of Rio Oso Road. 12/6/47, 17.0; 3/9/48, 15.3; 11/16/48, 15.9; 4/1/49, 8.9; 11/30/49, 18.4.

13N 4E-21D1—Reference point—top of flanged coupling, elevation 43 feet, West side of Fourth Avenue, 0.25 mile north of Rio Oso Road. 12/6/47, 15.0; 3/9/48, 12.8; 3/31/48, 11.7; 11/16/48, 13.5; 4/1/49, 7.9; 11/30/49, 16.4.

13N 4E-21E1—Reference point—top of 12-inch casing, elevation 42 feet, 250 feet north of Rio Oso Road, 800 feet west of Fourth Avenue. 12/6/47, 17.1; 3/11/48, 16.3.

13N 4E-21F1—Reference point—top of 14-inch casing, elevation 43 feet, 600 feet north of Rio Oso Road, 0.2 mile east of Fourth Avenue. 12/6/47, 17.4.

13N 4E-21H1—Reference point—hole in pump base, elevation 46.2 feet, 250 feet north of Rio Oso Road, 800 feet west of Pacific Avenue. 12/5/47, 17.1; 3/9/48, 15.4; 3/31/48, 14.6; 5/8/48, 11.5; 11/16/48, 16.9; 4/1/49, 10.0; 11/29/49, 18.8.

13N 4E-21L1—Reference point—top of 12-inch casing, elevation 42.5 feet, East side of Fourth Avenue, 250 feet south of Rio Oso Road. 12/8/47, 15.6; 3/9/48, 13.8; 11/15/48, 14.7; 4/1/49, 9.6; 11/30/49, 17.0.

13N 4E-21P1—Reference point—bottom of flanged coupling, elevation 36.1 feet, 250 feet east of Fourth Avenue, 300 feet north of Kempton Road. 12/8/47, 9.6; 3/9/48, 8.6.

13N 4E-21P2—Reference point—edge of pump base, elevation 41.7 feet, 600 feet north of Kempton Road, 0.25 mile east of Fourth Avenue. 12/8/47, 17.4; 3/9/48, 16.5; 3/31/48, 15.3; 11/16/48, 17.2; 4/1/49, 12.1; 11/30/49, 19.2; 3/30/50, 13.4; 11/9/50, 20.1; 1/3/51, 9.1; 11/21/51, 18.1; 4/4/52, 8.3.

13N 4E-21R1—Reference point—top of 8-inch casing, elevation 45 feet, 350 feet north of Kempton Road, 650 feet west of Pacific Avenue. 12/16/47, 20.7; 3/10/48, 19.9; 11/16/48, 21.2; 4/1/49, 17.0; 11/29/49, 23.2.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Divisian of Water Resaurces
(Depths to water in feet measured from reference paint)

13N/4E-22A1—Reference point—top of 16-inch casing, elevation 51 feet, 350 feet west of Warren Road, 700 feet north of Betz Road. 12/5/47, 22.6; 3/31/48, 21.1.

13N/4E-22E1—Reference point—top of 12-inch casing, bottom of pit, elevation 40.4 feet, 1,000 feet north of Rio Oso Road, 0.35 mile west of Swanson Road. 12/5/47, 10.4; 3/9/48, 8.8.

13N/4E-22F1—Reference point—hole in pump base, elevation 53.1 feet, 300 feet west of Swanson Road, 500 feet north of Rio Oso Road. 12/5/47, 22.2; 3/10/48, 21.6; 11/16/48, 22.1; 4/1/49, 16.9; 11/30/49, 24.4.

13N/4E-22G1—Reference point—top of 12-inch casing, elevation 55.1 feet, North side of Rio Oso Road, 700 feet east of Swanson Road. 12/5/47, 23.9; 3/9/48, 23.6; 11/16/48, 23.8; 4/1/49, 19.8; 11/30/49, 26.5; 3/30/50, 21.5; 11/9/50, 27.5; 4/4/51, 18.7; 11/20/51, 25.7; 4/3/52, 16.9.

13N/4E-23B1—Reference point—bottom of pump base, elevation 58.6 feet, South side of Gallagher Road, 0.30 mile west of Pleasant Grove Road. 12/5/47, 21.3; 3/10/48, 27.8; 3/31/48, 20.8; 11/15/48, 23.0; 3/31/49, 19.0; 11/30/49, 25.7.

13N/4E-23C1—Reference point—hole in pump base, elevation 55 feet, 0.25 mile north of Betz Road, 0.30 mile east of Warren Road. 12/5/47, 22.7; 3/8/48, 26.9; 3/31/48, 21.9; 11/15/48, 23.6; 3/31/49, 19.6; 11/30/49, 26.2.

13N/4E-23D1—Reference point—bottom of pump base, elevation 51 feet. East side of Warren Road, 1,000 feet north of Betz Road. 12/5/47, 23.4; 3/10/48, 27.6; 11/15/48, 23.8; 3/31/49, 19.5; 11/30/49, 26.4.

13N/4E-23Q1—Reference point—top of 14-inch casing, elevation 62.7 feet, 500 feet north of Kempton Road, 0.25 mile west of Pleasant Grove Road. 12/16/47, 26.2; 3/9/48, 26.2; 5/8/48, 22.9; 11/5/48, 27.3; 1/26/49, 25.4; 4/1/49, 24.0; 11/30/49, 30.0; 3/30/50, 26.9; 11/9/50, 33.1; 4/3/51, 26.5; 11/20/51, 31.4; 4/3/52, 26.8.

13N/4E-24D1—Reference point—top of 14-inch casing, elevation 61.8 feet, 800 feet south of Gallagher Road, 1,000 feet east of Pleasant Grove Road. 12/5/47, 21.0; 3/10/48, 25.2; 3/31/48, 19.8; 11/5/48, 23.8; 3/31/49, 19.4; 11/30/49, 26.1; 3/30/50, 22.4; 11/9/50, 28.5; 4/4/51, 20.6; 11/21/51, 26.4; 4/4/52, 18.0.

13N/4E-24Q1—Reference point—top of 12-inch casing, bottom of pit, elevation 53.8 feet, 100 feet north of Kempton Road, 0.75 mile east of Pleasant Grove Road. 12/8/47, 11.8.

13N/4E-26B1—Reference point—top of 14-inch casing, elevation 58 feet, 200 feet south of Kempton Road, 0.45 mile west of Pleasant Grove Road. 3/9/48, 25.3; 11/5/48, 25.6; 4/1/49, 21.3; 11/30/49, 27.4.

13N/4E-26H1—Reference point—hole in pump base, elevation 57 feet, 350 feet west of Pleasant Grove Road, 0.45 mile south of Kempton Road. 11/8/47, 24.2; 3/9/48, 24.6; 11/16/48, 26.4; 4/4/49, 22.0; 11/30/49, 28.5.

13N/4E-26R1—Reference point—top of 14-inch casing, elevation 59 feet, West side of Pleasant Grove Road, 0.85 mile south of Kempton Road. 12/8/47, 25.5; 3/8/48, 24.9; 3/31/48, 24.2; 11/16/48, 28.1; 1/26/49, 26.5; 4/4/49, 23.7; 5/25/49, 34.0; 6/29/49, 42.4; 7/29/49, 48.8; 8/26/49, 49.0; 11/30/49, 29.6; 3/30/50, 26.4; 11/9/50, 33.9; 11/21/51, 33.7; 4/3/52, 26.9.

13N/4E-27C1—Reference point—bottom of flanged coupling, bottom of pit, elevation 46 feet, 400 feet south of Kempton Road, 0.40 mile east of Pacific Avenue. 12/16/47, 18.0.

13N/4E-27N1—Reference point—hole in pump base, elevation 51 feet, 250 feet east of Pacific Avenue, 0.90 mile south of Kempton Road. 12/16/47, 24.0; 3/11/48, 25.2.

13N/4E-28D1—Reference point—top of 12-inch casing, bottom of pit, elevation 27.7 feet, 600 feet south of Kempton Road, 700 feet west of Fourth Avenue. 12/8/47, 2.7; 3/11/48, 1.3; 3/31/48, 0.4; 11/16/48, 2.4; 4/1/49, —2.8; 11/30/49, 3.3.

13N/4E-28F1—Reference point—access hole to casing in bottom of pit, elevation 32.7 feet, 100 feet east of Fourth Avenue, 0.25 mile south of Kempton Road. 12/8/47, 6.8; 4/1/49, 2.6.

13N/4E-28R1—Reference point—hole in base, elevation 46 feet, 250 feet west of Pacific Avenue, 0.80 mile south of Kempton Road. 12/16/47, 23.2; 3/10/48, 22.4; 11/16/48, 25.1; 4/5/49, 21.5; 11/29/49, 26.1; 11/21/51, 27.9; 4/3/52, 22.5.

13N/4E-29F1—Reference point—top of east concrete wall, elevation 36 feet, 400 feet west of junction of Mark Hopkins Avenue and Berry Road. 11/21/47, 14.7; 3/10/48, 13.1; 11/5/48, 14.3; 1/24/49, 12.5; 3/15/49, 9.5; 5/25/49, 10.5; 6/29/49, 14.5; 7/28/49, 18.3; 8/26/49, 18.4; 12/7/49, 15.7; 3/29/50, 9.5; 11/8/50, 16.4; 3/30/51, 6.2; 11/16/51, 14.8.

13N/4E-29G1—Reference point—top of casing, elevation 37 feet, 0.10 mile southeast of Berry Road, 0.20 mile northeast of Mark Hopkins Avenue. 11/21/47, 13.2; 3/10/48, 11.8; 5/11/48, 8.9; 11/5/48, 13.1; 3/15/49, 8.4; 12/8/49, 14.4.

13N/4E-29M2—Reference point—bottom 2" x 6" floor, elevation 34 feet, 150 feet northwest of Berry Road, 0.25 mile southwest of Mark Hopkins Avenue. 11/21/47, 15.4; 3/10/48, 13.1; 11/5/48, 14.5; 12/7/49, 16.0.

13N/4E-30R2—Reference point—top of casing, elevation 33 feet, 400 feet south of southwest end of Berry Road. 11/21/47, 15.1; 3/11/48, 13.8; 11/5/48, 15.1; 3/16/49, 13.6; 12/8/49, 16.0.

13N/4E-31J1—Reference point—top of casing, elevation 52 feet, 0.25 mile north of Cornelius Avenue, 0.70 mile west of Mark Hopkins Avenue. 12/8/47, 14.8; 3/11/48, 13.1; 5/11/48, 9.2; 12/14/48, 15.6; 3/28/49, 10.2; 12/7/49, 15.8.

13N/4E-32B1—Reference point—top of south concrete wall, elevation 34 feet, 100 feet north of Cramer Road, 150 feet west of Mark Hopkins Avenue. 12/9/47, 14.9; 3/11/48, 13.2; 12/15/48, 16.9; 3/16/49, 12.9; 12/7/49, 16.1.

13N/4E-32D1—Reference point—top of east concrete wall, elevation 34 feet, 200 feet north of Cramer Road, 0.50 mile west of Mark Hopkins Avenue. 12/9/47, 15.1; 3/11/48, 13.2; 12/15/48, 16.9; 3/16/49, 12.3; 12/7/49, 16.1.

13N/4E-32H1—Reference point—top of north concrete wall, elevation 40 feet, East side of Mark Hopkins Avenue, 0.55 mile north of Cornelius Avenue. 12/8/47, 13.6; 3/11/48, 12.8; 5/11/48, 11.1; 12/13/48, 13.9; 3/16/49, 20.3; 12/6/49, 18.0; 3/29/50, 14.6; 11/6/50, 21.0; 3/30/51, 13.5; 11/16/51, 20.8; 4/4/52, 13.4.

13N/4E-32L1—Reference point—top of south concrete wall, elevation 35 feet, 0.25 mile west of Mark Hopkins Avenue, 0.40 mile north of Cornelius Avenue. 12/8/47, 20.6; 3/11/48, 19.4; 12/14/48, 21.9; 3/28/49, 18.4; 12/7/49, 22.3.

13N/4E-33A2—Reference point—pipe in base, elevation 50 feet, 200 feet west of Pacific Avenue, 0.9 mile north of Cornelius Avenue. 12/16/47, 25.6; 3/10/48, 24.6; 3/31/48, 25.7; 11/16/48, 27.9; 1/26/49, 26.0; 4/5/49, 24.4; 11/29/49, 28.7; 3/30/50, 25.7; 11/9/50, 31.6; 4/3/51, 24.0; 11/21/51, 31.8; 4/3/52, 24.1.

13N/4E-33G1—Reference point—bottom of pump base, elevation 47 feet, 0.4 mile west of Pacific Avenue, 0.5 mile north of Cornelius Avenue. 12/16/47, 28.6; 3/10/48, 27.5; 3/31/48, 27.3; 5/11/48, 26.7; 11/16/48, 30.9; 4/5/49, 27.5; 11/29/49, 31.3.

13N/4E-33L1—Reference point—top of casing, elevation 45 feet, 0.3 mile north of Cornelius Avenue, 0.5 mile east of Electric Avenue. 3/29/49, 24.1.

13N/4E-33P1—Reference point—hole in pump base, elevation 45 feet, 0.5 mile east of Electric Avenue, 0.2 mile north of Cornelius Avenue. 3/11/48, 22.1; 12/14/48, 24.7; 3/29/49, 22.3; 12/7/49, 22.6; 3/27/50, 25.7; 11/6/50, 32.0; 4/2/51, 25.0; 11/16/51, 30.6; 4/3/52, 24.6.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet measured from reference point)

13N 4E-33R1—Reference point—top of concrete pit, elevation 46 feet, 200 feet west of Pacific Avenue, 600 feet north of Cornelius Avenue. 11 8 29, 21.5; 9 8 30, 20.6; 12 30 30, 20.9; 12 10 31, 21.6; 12 11 32, 20.9; 12 20 33, 21.3; 10 27 34, 21.3; 11 23 36, 23.5; 11 24 37, 25.6; 1 30 39, 19.8; 12 22 47, 24.2; 3 11 48, 22.5; 3 31 48, 22.6; 12 14 48, 26.1; 3 29 49, 23.6; 12 7 49, 26.1; 3 27 50, 24.2; 11 6 50, 29.7; 4 2 51, 23.5; 11 16 51, 23.3; 12 6 51, 31.1; 1 4 52, 24.3.

13N 4E-34L1—Reference point—top of casing, elevation 48 feet, 0.2 mile east of Pacific Avenue, 0.4 mile north of Cornelius Avenue. 12 16 47, 23.6; 3 10 48, 22.8; 3 31 48, 22.7; 10 16 48, 26.1; 4 5 49, 23.2; 11 29 49, 27.1; 3 30 50, 24.5; 11 9 50, 30.6; 4 3 51, 24.1; 11 21 51, 30.5; 4 3 52, 24.5.

13N 4E-35J1—Reference point—top of floor of pit, elevation 42 feet, 0.4 mile north of Cornelius Avenue, 0.02 mile west of Pleasant Grove Road. 12 8 47, 8.8; 3 31 48, 7.2; 11 16 48, 11.6; 4 4 49, 8.4; 11 30 49, 13.8; 3 30 50, 11.3; 11 9 50, 19.0.

13N 4E-35Q1—Reference point—top of casing, elevation 56.6 feet, 0.4 mile west of Pleasant Grove Road, 132 feet north of Cornelius Avenue. 3 11 48, 19.9; 12 13 48, 25.1; 3 29 49, 21.1; 12 7 49, 26.0; 11 19 51, 30.4.

13N 4E-36G1—Reference point—top of casing, elevation 58 feet, 528 feet north of Hicks Road, 0.6 mile east of Pleasant Grove Road. 12 16 47, 23.8; 3 9 48, 22.6; 11 16 48, 26.7; 4 4 49, 24.2; 11 30 49, 29.1.

13N 5E-3Q1—Reference point—top of casing at bottom of 10.6-foot pit, elevation 84 feet, 0.25 mile northeast of U. S. Highway 99E, 0.20 mile southeast of Bear River. 11 25 47, 4.4; 3 5 48, 5.5; 11 7 49, 6.0; 4 4 50, 4.9; 11 14 50, 5.7; 3 27 51, 2.6; 11 19 51, 6.3.

13N 5E-4J1—Reference point—top of pump base, elevation 83 feet, 0.2 mile southwest of U. S. Highway 99E at a point 0.45 mile northwest of Bear River bridge. 11 24 47, 14.8; 3 29 48, 12.7; 5 14 48, 11.9; 11 12 48, 15.6; 3 23 49, 12.9; 11 26 49, 17.3; 3 29 50, 14.1; 11 8 50, 17.5; 4 4 51, 12.5; 12 3 51, 16.6; 4 2 52, 11.3.

13N 5E-4J2—Reference point—top of casing, elevation 80 feet, 0.25 mile southwest of U. S. Highway 99E at a point 0.3 mile northwest of Yuba-Placer county line. 4 1 48, 9.2; 5 5 48, 7.9; 6 3 48, 8.5; 7 2 48, 64.0 (operating); 7 1 49, 60.7 (operating); 8 1 49, 65.8 (operating); 8 31 49, 28.8.

13N 5E-4L1—Reference point—hole in pump base, elevation 82.6 feet, 0.3 mile southwest of U. S. Highway 99E in Wheatland on south side of T. H. Richards' farm road. 11 24 47, 19.9; 3 4 48, 21.1; 11 12 48, 21.0; 3 24 49, 27.0; 11 26 49, 22.7.

13N 5E-4N1—Reference point—top of concrete base, elevation 79.9 feet, At T. H. Richards' ranch house, 0.8 mile southwest of Wheatland. 11 25 47, 17.7; 3 5 48, 21.6; 3 29 48, 15.4; 11 12 48, 18.7; 3 24 49, 14.9; 11 26 49, 20.4.

13N 5E-4R1—Reference point top of concrete crib, south of pump, elevation 84 feet, 0.35 mile southwest of U. S. Highway 99E at a point 0.2 mile northwest of Yuba-Placer county line. 11 24 47, 13.7; 5 14 48, 10.2; 11 12 48, 14.1; 1 26 49, 13.4; 3 23 49, 10.8; 11 26 49, 15.3.

13N 5E-5B1—Reference point—top of casing, elevation 69.9 feet, 0.4 mile northeast of Oakley Avenue, 0.45 mile northwest of Wheatland Avenue. 11 24 47, 15.2; 3 5 48, 14.1.

13N 5E-5C1—Reference point—hole in pump base, elevation 68.1 feet, 0.25 mile northeast of Oakley Avenue, 0.45 mile northwest of Wheatland Road. 11 22 47, 14.5; 3 5 48, 13.1; 3 29 48, 12.2; 5 14 48, 11.6; 11 11 48, 16.0; 1 26 49, 14.2; 3 23 49, 12.1; 11 28 49, 18.5; 3 29 50, 14.9; 11 8 50, 20.7; 4 1 51, 11.5; 11 29 51, 19.3; 1 2 52, 8.2.

13N 5E-5C2—Reference point—top of pump base, elevation 72.2 feet, 0.15 mile northeast of Oakley Avenue, 0.35 mile northwest of Wheatland Road. 11 20 47, 18.5; 3 5 48, 17.1.

13N 5E-5D1—Reference point—top of concrete pit, elevation 66.5 feet, 0.1 mile southwest of Oakley Avenue, 0.6 mile northwest of Wheatland Road. 11 20 47, 15.7; 3 5 48, 15.1.

13N 5E-5L1—Reference point—top of casing, elevation 80.6 feet, Southeast side of Wheatland Road, 0.15 mile southwest of Oakley Avenue. 11 20 47, 27.5; 3 8 48, 27.5; 11 11 48, 30.6; 3 24 49, 24.1; 11 26 49, 31.1.

13N 5E-5L2—Reference point—top of concrete curb around casing, elevation 68.1 feet, Southeast side of Wheatland Road, 0.15 mile southwest of Oakley Avenue. 11 20 47, 15.6; 3 8 48, 14.3; 11 11 48, 17.3; 3 24 49, 11.7.

13N 5E-5L3—Reference point—top of casing, elevation 78.1 feet, 300 feet southwest of Oakley Avenue, 0.1 mile northwest of Wheatland Road. 11 20 47, 24.3; 3 5 48, 23.2; 11 11 48, 25.9; 3 25 49, 21.0; 11 28 49, 28.6.

13N 5E-5N1—Reference point—top of concrete crib nearest pump, elevation 70.4 feet, 0.2 mile southeast of Wheatland Road, 0.45 mile southwest of Oakley Avenue. 11 21 47, 19.2; 3 29 48, 16.0; 11 12 48, 21.9; 3 24 49, 15.2; 11 26 49, 23.5.

13N 5E-5P1—Reference point—top of pump base, elevation 71.1 feet, 0.2 mile southwest of Oakley Avenue, 0.25 mile southeast of Wheatland Road. 11 20 47, 17.6; 3 8 48, 18.3; 3 24 49, 14.2; 11 26 49, 21.2.

13N 5E-5Q1—Reference point—top of casing, elevation 75 feet, Southwest side of Oakley Avenue, 0.3 mile southeast of Wheatland Road. 11 20 47, 23.4; 3 8 48, 21.1; 3 24 49, 18.0.

13N 5E-6E1—Reference point—hole in west side pump base, elevation 63.0 feet, 0.7 mile northwest of Wheatland Road, 1.05 miles southwest of Oakley Avenue. 11 21 47, 17.8; 2 21 48, 15.6; 11 12 48, 19.5; 1 26 49, 17.0; 3 24 49, 15.1; 11 23 49, 22.9; 3 20 50, 18.4; 11 8 50, 25.2; 4 3 51, 14.8; 11 30 51, 24.3; 4 2 52, 23.1.

13N 5E-6E2—Reference point—hole in pump base, elevation 63.3 feet, 0.9 mile northwest of Wheatland Road, 1.0 mile southwest of Oakley Avenue. 11 21 47, 19.4; 2 21 48, 16.7; 5 5 48, 13.7; 6 3 48, 15.1; 7 2 48, 21.4; 11 12 48, 21.0; 3 24 49, 16.5; 5 3 49, 21.2; 6 2 49, 22.0; 7 1 49, 51.6 (operating); 8 1 49, 30.1; 8 31 49, 28.8; 11 28 49, 24.3.

13N 5E-6J1—Reference point—top of casing, elevation 67.6 feet, 0.15 mile northwest of Wheatland Road, 0.55 mile southwest of Oakley Avenue. 11 21 47, 19.1; 11 12 48, 21.0; 3 24 49, 15.4; 11 26 49, 23.5.

13N 5E-6L1—Reference point—top of casing, elevation 61.9 feet, 0.5 mile northwest of Wheatland Road, 0.8 mile southwest of Oakley Avenue. 11 21 47, 20.1; 3 5 48, 20.1; 11 12 48, 21.7; 3 24 49, 16.6; 11 26 49, 24.8.

13N 5E-7B1—Reference point—notch in concrete casing, elevation 72.2 feet, Northwest side of Wheatland Road, 0.9 mile southwest of Oakley Avenue. 11 21 47, 24.5; 3 5 48, 26.1; 11 12 48, 25.7; 3 24 49, 20.5; 11 26 49, 28.8; 3 9 50, 23.4; 11 18 50, 30.0; 1 3 51, 19.3; 12 3 51, 29.3; 4 2 52, 16.5.

13N 5E-7C1—Reference point—top of casing, elevation 71.4 feet, Northwest side of Wheatland Road, 1.3 mile southwest of Oakley Avenue. 11 28 47, 24.3; 3 2 48, 25.9; 11 12 48, 25.4; 3 24 49, 20.9.

13N 5E-7C2—Reference point—hole in top of pump base, elevation 68.3 feet, Northwest side of Wheatland Road, 1.2 miles southwest of Oakley Avenue. 11 21 47, 21.5; 3 8 48, 25.1; 3 29 48, 18.6; 5 5 48, 16.3; 6 3 48, 17.5; 7 2 48, 33.0; 11 12 48, 22.7; 3 24 49, 18.1; 6 2 49, 29.8; 8 1 49, 48.1; 8 31 49, 36.3; 11 26 49, 25.7.

13N 5E-7E1—Reference point—slot in casing, elevation 69 feet, Northwest side of Wheatland Road, 1.5 miles southwest of Oakley Avenue. 11 28 47, 23.6; 3 2 48, 26.9; 11 12 48, 24.8; 3 24 49, 20.2; 11 23 49, 28.9.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Mode by Division of Water Resources
(Depths to water in feet measured from reference point)

13N/5E-7G1—Reference point—top of casing, elevation 80.5 feet. At Bear River north levee, 0.35 mile southeast of Wheatland Road, 1.1 miles southwest of Oakley Avenue. 11/21/47, 31.7; 3/5/48, 37.6; 3/29/48, 28.4; 5/14/48, 25.5; 11/12/48, 31.5; 1/26/49, 29.5; 3/24/49, 27.2; 11/23/49, 34.4.

13N/5E-7F1—Reference point—top of concrete base, elevation 77.3 feet. At Bear River north levee, 0.35 mile southeast of Wheatland Road, 1.3 miles southwest of Oakley Avenue. 11/21/47, 29.3; 3/8/48, 33.7; 11/12/48, 30.3; 3/24/49, 26.1; 11/23/49, 34.9; 3/29/50, 28.6; 11/6/50, 35.9; 4/3/51, 25.0; 12/3/51, 33.7; 4/2/52, 22.7.

13N/5E-7H1—Reference point—bottom of pump base, elevation 80.4 feet, 0.3 mile southeast of Wheatland Road, 0.9 mile southwest of Oakley Avenue. 11/21/47, 31.1; 3/5/48, 35.7; 11/12/48, 31.8; 3/24/49, 27.3; 11/23/49, 34.0

13N/5E-7K1—Reference point—hole in pump base, elevation 74.9 feet. West side of Huffaker Road, 0.55 mile north of Bear River Drive. 12/3/47, 26.4; 3/8/48, 29.4; 11/8/48, 27.9; 3/31/49, 23.2; 12/6/49, 30.3; 3/30/50, 26.0; 11/8/50, 33.0; 4/3/51, 21.7; 4/3/52, 18.7.

13N/5E-7L1—Reference point—edge of pump base, elevation 74.8 feet, 0.5 mile north of Bear River Drive on west side of Hudson Road extended. 12/3/47, 27.5; 3/30/48, 25.2; 11/4/48, 29.5; 3/30/49, 25.0; 12/2/49, 33.9.

13N/5E-7M1—Reference point—top of casing, elevation 73.4 feet. At Bear River north levee, 0.25 mile south of Wheatland Road, 1.1 miles east of Pleasant Grove Road. 12/24/47, 28.1; 3/8/48, 33.7; 3/29/48, 25.9; 11/15/48, 29.1; 3/31/49, 25.1; 12/2/49, 31.9.

13N/5E-8B1—Reference point—hole in pump base, elevation 76.7 feet, 0.1 mile southwest of Oakley Avenue, 0.5 mile southeast of Wheatland Road. 11/21/47, 20.6; 3/5/48, 21.3; 11/11/48, 23.3; 3/24/49, 17.3; 11/26/49, 24.2; 3/29/50, 20.1; 11/8/50, 24.5; 4/3/51, 16.6; 12/3/51, 22.2; 4/2/52, 13.2.

13N/5E-8G1—Reference point—hole in pump base, elevation 81.3 feet. At Bear River north levee, 0.1 mile southwest of Oakley Avenue, 11/21/37, 20.1; 3/5/48, 19.3; 11/11/48, 20.1; 3/24/49, 16.3. Well filled.

13N/5E-8H1—Reference point—hole in pump base, elevation 83.7 feet. At Bear River north levee, 0.1 mile northeast of Oakley Avenue. 11/25/47, 21.5; 3/5/48, 21.4; 3/29/48, 19.4; 11/12/48, 22.3; 3/24/49, 18.2; 11/26/49, 23.8.

13N/5E-8J1—Reference point—hole in pump base, elevation 84.4 feet, 0.7 mile north of Bear River Drive, 0.85 mile east of Brewer Road. 11/26/47, 26.6; 3/22/48, 25.5; 11/4/48, 28.5; 3/30/49, 24.0; 12/6/49, 30.3; 3/30/50, 17.9; 11/9/50, 31.0; 4/3/51, 24.0; 11/20/51, 29.8; 4/3/52, 14.6.

13N/5E-8L1—Reference point—hole in pump base, elevation 75 feet, 0.25 mile east of Brewer Road, 0.75 mile north of Bear River Drive. 11/26/47, 26.7; 3/22/48, 23.9; 11/4/48, 26.8; 3/30/49, 22.3; 12/6/49, 29.2.

13N/5E-8N1—Reference point—bottom of pump base by air line, elevation 76.4 feet, 0.15 mile east of Brewer Road, 0.5 mile north of Bear River Drive. 11/26/47, 25.0; 3/22/48, 23.0; 11/4/48, 25.8; 3/30/49, 21.8; 12/6/49, 28.0.

13N/5E-8P1—Reference point—top of casing, elevation 76.6 feet, 0.4 mile north of Bear River Drive, 0.5 mile east of Brewer Road. 11/26/47, 20.6; 3/22/48, 19.0; 3/30/48, 18.2; 11/4/48, 22.1; 3/30/49, 17.7; 12/6/49, 24.6.

13N/5E-8R1—Reference point—pipe in concrete base, elevation 75 feet, 0.5 mile north of Bear River Drive, 0.75 mile east of Brewer Road. 11/4/48, 25.1; 3/30/49, 20.4; 12/6/49, 27.1.

13N/5E-9C1—Reference point—slot in concrete base, elevation 76.8 feet, 0.1 mile north of Bear River north levee, 0.3 mile southeast of T. H. Richards' ranch house, 0.8 mile southwest of Wheatland. 11/25/47, 11.9; 3/5/48, 12.1; 3/29/48, 9.7; 11/12/48, 12.5; 3/24/49, 9.4; 11/26/49, 14.0.

13N/5E-9D1—Reference point—top of base under air line, elevation 82.3 feet. At Bear River north levee, 0.4 mile southeast of T. H. Richards' ranch house, 0.8 mile southwest of Wheatland. 11/25/47, 13.9; 3/5/48, 13.4; 3/29/48, 12.3; 11/12/48, 14.0; 3/24/49, 11.5; 11/26/49, 14.6; 3/29/50, 11.2; 11/8/50, 14.0; 4/3/51, 9.9; 12/3/51, 13.7; 4/2/52, 8.6.

13N/5E-9E1—Reference point—inside edge of tapered base, elevation 83.5 feet. At Bear River north levee, 0.45 mile south of T. H. Richards' ranch house, 0.8 mile southwest of Wheatland. 11/25/47, 18.1; 3/5/48, 17.6; 11/12/48, 18.2; 3/24/49, 15.2. Well destroyed.

13N/5E-9G1—Reference point—hole in pump base, elevation 85.1 feet, 0.3 mile west of Placer Road, 0.75 mile north of Bear River Drive. 11/26/47, 15.9; 11/4/48, 17.2; 3/30/49, 14.2; 12/6/49, 20.4.

13N/5E-9H1—Reference point—top of casing, elevation 86.4 feet, 1.0 mile north of Bear River Drive, 500 feet west of Placer Road extended. 11/26/47, 15.3; 11/4/48, 15.8; 3/30/49, 14.4; 11/7/49, 18.8; 12/6/49, 18.4; 11/9/50, 19.8. Well destroyed.

13N/5E-9H2—Reference point—hole in pump base, elevation 86.4 feet, 1.0 mile north of Bear River Drive, 600 feet west of Placer Road extended. 11/20/51, 20.1; 4/3/52, 13.5.

13N/5E-9P1—Reference point—hole in pump base, elevation 80.4 feet, 0.5 mile north of Bear River Drive, 0.7 mile west of Placer Road. 12/26/47, 17.6; 11/4/47, 19.5; 3/30/49, 15.6; 12/6/49, 21.0.

13N/5E-9R1—Reference point—hole in pump base, elevation 83.6 feet. West side of Placer Road, 0.5 mile north of Bear River Drive. 11/26/47, 15.7; 3/22/48, 14.5; 3/30/48, 13.8; 5/8/48, 12.9; 11/4/48, 17.2; 1/26/49, 16.7; 2/18/49, 16.3; 3/16/49, 15.7; 3/30/49, 14.8; 7/29/49, 50.5 (operating); 11/7/49, 19.9; 12/6/49, 19.6; 2/15/50, 17.6; 3/15/50, 17.2; 4/4/50, 16.7; 5/9/50, 18.1; 6/7/50, 20.0; 8/3/50, 21.9; 10/3/50, 22.2; 11/14/50, 20.3; 12/14/50, 16.5; 1/4/51, 15.2; 2/7/51, 13.2; 3/7/51, 12.8; 3/27/51, 12.6; 7/16/51, 23.7; 8/22/51, 24.9; 9/26/51, 19.5; 11/19/51, 19.6; 2/28/52, 13.5; 4/4/52, 12.0.

13N/5E-16D1—Reference point—hole in casing, elevation 78 feet. North side of Bear River Drive, 0.8 mile west of Placer Road. 11/26/47, 18.1; 3/22/48, 17.8; 3/30/48, 16.2; 5/8/48, 15.0; 11/4/48, 21.2; 1/26/49, 18.3; 3/30/49, 16.0; 6/29/49, 26.3; 7/27/49, 28.4; 8/26/49, 27.8; 12/6/49, 22.9; 3/30/50, 18.7; 11/9/50, 24.6; 4/3/51, 15.9; 11/20/51, 22.2; 4/3/52, 12.9.

13N/5E-16E1—Reference point—hole in pump base, elevation 75.9 feet, 0.1 mile south of Bear River Drive, 0.85 mile west of Placer Road. 11/26/47, 16.5; 3/22/48, 18.2; 11/4/48, 19.9; 3/30/49, 14.3; 12/6/49, 21.4.

13N/5E-17D1—Reference point—top of concrete base, elevation 71.2 feet, 0.15 mile east of Brewer Road, 0.2 mile north of Bear River Drive. 11/26/47, 18.3; 3/22/48, 19.7; 11/4/48, 22.3; 3/30/49, 18.9; 12/6/49, 25.1; 3/30/50, 22.2; 11/9/50, 27.2; 4/3/51, 18.9; 11/20/51, 25.6; 4/3/52, 15.6.

13N/5E-17J2—Reference point—hole in pump base, elevation 70 feet, 0.4 mile south of Bear River Drive, 1.0 mile west of Placer Road. 11/4/48, 19.3; 3/30/49, 13.4; 12/6/49, 21.1.

13N/5E-17R1—Reference point—hole in pump base, elevation 70 feet, 0.7 mile south of Bear River Drive, 0.8 mile east of Brewer Road. 11/4/48, 24.9; 3/30/49, 19.2; 12/6/49, 27.6; 3/30/50, 22.9; 11/9/50, 30.4; 4/4/51, 20.8; 11/20/51, 27.0; 4/3/52, 22.3.

13N/5E-18B1—Reference point—top of casing, elevation 70.8 feet, 1.5 miles east of Pleasant Grove Road, 0.25 mile north of Bear River Drive. 12/3/47, 23.3; 3/8/48, 27.4; 3/30/48, 21.1; 11/4/48, 25.1; 3/30/49, 20.6; 12/6/49, 28.0.

13N/5E-18B2—Reference point—hole in top of pump base, elevation 69.3 feet. North side of Bear River Drive, 0.3 mile west of Brewer Road. 12/17/47, 21.3; 3/22/48, 20.3; 3/30/48, 19.5; 5/14/48, 17.1; 11/4/48, 23.3; 1/26/49, 21.0; 3/30/49, 19.0; 11/30/49, 26.4.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Mode by Division of Water Resources
(Depths to water in feet measured from reference point)

13N 5E-18C1—Reference point—top of casing, elevation 69.6 feet, 0.25 mile north of Bear River Drive, 0.7 mile west of Brewer Road. 12/3/47, 22.5; 3/30/48, 20.3; 11/4/48, 24.0; 3/31/49, 19.8.

13N 5E-18F1—Reference point—top of casing, elevation 60.8 feet, South side of Bear River Drive, 0.6 mile west of Brewer Road. 12/3/47, 14.3; 3/8/48, 15.2; 3/30/48, 12.1; 5/14/48, 14.0; 11/4/48, 20.3; 3/31/49, 15.9; 5/25/49, 21.3; 8/3/49, 31.1; 12/6/49, 23.4.

13N 5E-18R1—Reference point—hole in casing, elevation 69 feet, West side of Brewer Road, 0.75 mile south of Bear River Drive. 12/17/47, 24.2; 3/22/48, 23.7; 3/30/48, 23.0; 5/8/48, 21.4; 11/5/48, 28.4; 3/30/49, 23.5; 11/30/49, 32.8; 3/30/50, 28.0; 11/20/51, 31.4; 4/3/52, 25.7.

13N 5E-19C1—Reference point—bottom of pump base, elevation 71.6 feet, 0.75 mile south of Bear River Drive, 1.2 miles east of Pleasant Grove Road. 12/8/47, 27.7; 3/10/48, 27.0; 3/31/48, 26.0; 5/8/48, 24.5; 11/5/48, 30.0; 1/26/49, 27.4; 4/1/49, 25.2.

13N 5E-19N1—Reference point—top of casing, elevation 68.3 feet, North side of Kempton Road, 1.1 miles east of Pleasant Grove Road. 12/8/47, 24.8; 3/9/48, 25.9; 3/31/48, 23.6; 5/8/48, 22.2; 11/5/48, 28.6; 1/26/49, 25.9; 4/1/49, 24.0; 5/25/49, 42.0; 6/29/49, 54.2; 7/27/49, 45.0; 8/26/49, 58.0; 11/30/49, 31.1; 3/30/50, 27.3; 11/9/50, 34.3; 4/3/51, 26.8; 4/3/52, 22.4.

13N 5E-19P1—Reference point—top of casing, elevation 70.0 feet, North side of Kempton Road, 1.4 miles east of Pleasant Grove Road. 12/8/47, 25.5; 3/9/48, 25.5; 3/31/48, 24.1; 5/8/48, 23.7; 11/5/48, 29.6; 1/26/49, 27.0; 4/1/49, 25.1; 11/30/49, 32.3.

13N 5E-19R1—Reference point—top of casing, elevation 72.5 feet, 100 feet north of Kempton Road, 0.05 mile west of Brewer Road. 12/17/47, 26.6; 3/9/48, 26.8; 11/5/48, 30.5; 4/1/49, 25.9; 11/30/49, 33.3; 3/30/50, 29.7; 11/9/50, 37.1; 4/3/51, 28.5; 11/20/51, 35.7; 4/3/52, 28.5.

13N 5E-28A1—Reference point—slot in concrete base, elevation 80 feet, South side of Kempton Road, 1.8 miles east of Brewer Road. 11/5/48, 28.2; 4/4/49, 22.4; 5/12/49, 25.1; 7/1/49, 29.5; 7/29/49, 31.4; 8/25/49, 32.8; 9/29/49, 31.1; 11/10/49, 29.4; 11/30/49, 28.7; 2/15/50, 26.3; 3/14/50, 25.9; 3/30/50, 25.3; 4/5/50, 25.2; 5/8/50, 27.5; 6/7/50, 31.5; 7/7/50, 34.2; 8/1/50, 36.5; 9/6/50, 38.0; 10/3/50, 34.0; 11/9/50, 31.5; 11/14/50, 31.2; 1/4/51, 25.8; 2/7/51, 26.0; 3/27/51, 24.3; 5/9/51, 24.8; 11/15/51, 31.3; 11/20/51, 31.1; 2/28/52, 25.4; 3/31/52, 24.0; 4/3/52, 24.0.

13N 5E-28C1—Reference point—top of casing, elevation 76 feet, South side of Kempton Road, 1.3 miles east of Brewer Road. 12/17/47, 22.0; 3/9/48, 21.4; 11/5/48, 29.5; 4/4/49, 24.4; 11/10/49, 32.7; 11/30/49, 31.7; 3/30/50, 27.7; 11/9/50, 34.9; 3/27/51, 27.2; 11/20/51, 33.8; 4/3/52, 26.4.

13N 5E-23N1—Reference point—top of casing, elevation 80.7 feet, North side of Waltz Road, 1.25 miles east of Brewer Road. 11/5/48, 29.8; 1/26/49, 26.6; 4/1/49, 25.0; 11/10/49, 33.8; 3/15/50, 28.7; 3/30/50, 28.2; 4/5/50, 28.1; 9/5/50, 43.9; 10/3/50, 39.0; 11/10/50, 35.7; 11/14/50, 35.3; 12/14/50, 32.6; 1/4/51, 32.2; 3/23/51, 28.7; 11/15/51, 36.8; 11/21/51, 36.3; 3/31/52, 29.7; 4/3/52, 29.1.

13N 5E-23R1—Reference point—top of casing, elevation 84.7 feet, 0.1 mile north of Waltz Road, 2.0 miles east of Brewer Road. 11/5/48, 27.1; 4/4/49, 22.0; 9/29/49, 30.3; 11/9/49, 28.1; 2/15/50, 25.2; 3/15/50, 24.7; 4/5/50, 24.1; 5/9/50, 25.1; 6/7/50, 28.0; 7/7/50, 30.2; 8/1/50, 32.2; 9/5/50, 35.4; 10/3/50, 31.2; 11/14/50, 30.0; 12/14/50, 27.7; 1/4/51, 27.2; 3/23/51, 24.8; 5/9/51, 25.7; 6/5/51, 33.1; 7/16/51, 38.0; 8/22/51, 40.6; 9/26/51, 36.8; 11/15/51, 32.9; 2/28/52, 27.3; 3/31/52, 26.3.

13N 5E-29Q1—Reference point—top of casing, elevation 75.8 feet, North side of Waltz Road, 0.6 mile east of Brewer Road. 4/5/50, 28.5.

13N 5E-30A1—Reference point—top of casing, elevation 68 feet, Southwest of corner of Kempton and Brewer Roads. 4/1/49, 27.2.

13N 5E-30C1—Reference point—top of casing, elevation 70.3 feet, South side of Kempton Road, 0.6 mile west of Brewer Road. 12/8/47, 25.9; 3/9/48, 26.3; 3/31/48, 24.5; 11/5/48, 29.9; 4/1/49, 25.3; 11/30/49, 32.6.

13N 5E-30J1—Reference point—hole in pump base, elevation 69 feet, West side of Brewer Road, 0.3 mile north of Waltz Road. 3/22/49, 25.8.

13N 5E-30R1—Reference point—top of casing, elevation 70 feet, Northwest corner of Brewer and Waltz Roads. 11/5/48, 29.5; 4/4/49, 24.8; 11/9/49, 33.2; 11/30/49, 33.4; 2/15/50, 29.5; 3/14/50, 29.0; 3/30/50, 28.3; 4/5/50, 28.2; 11/10/50, 36.1; 11/15/51, 34.7; 11/21/51, 34.7; 3/31/52, 28.7; 4/3/52, 28.5.

13N 5E-31G1—Reference point—top of casing, elevation 69 feet, North side of Hicks Road, 0.35 mile west of Brewer Road. 12/16/47, 22.6; 3/9/48, 21.7; 3/31/48, 21.1; 11/5/48, 27.3; 1/26/49, 24.3; 4/4/49, 22.3; 11/10/49, 30.9; 11/30/49, 30.4; 2/16/50, 27.5; 3/14/50, 26.8; 3/30/50, 26.1; 11/3/50, 33.5; 11/10/50, 33.5; 4/3/52, 26.6.

13N 5E-32C1—Reference point—top of casing, elevation 74 feet, South side of Waltz Road, 0.35 mile east of Brewer Road. 2/25/49, 29.6; 4/1/49, 25.6; 5/12/49, 30.1; 6/27/49, 36.2; 7/29/49, 39.8; 8/25/49, 41.4; 9/29/49, 37.1; 11/9/49, 33.8; 2/15/50, 30.2; 3/15/50, 29.5; 4/5/50, 29.0; 5/9/50, 30.5; 6/7/50, 35.7; 7/7/50, 40.3; 8/1/50, 43.2; 9/5/50, 45.3; 10/3/50, 40.6; 11/14/50, 37.1; 12/14/50, 34.8; 1/4/51, 34.4; 3/23/51, 27.9; 5/9/51, 33.1; 6/5/51, 36.7; 7/11/51, 39.5; 8/22/51, 42.2; 9/26/51, 38.9; 11/15/51, 35.8; 2/28/52, 31.1; 3/31/52, 29.9.

13N 5E-33L1—Reference point—top of casing, elevation 80.1 feet, 0.35 mile north of Cornelius Avenue, 1.3 miles east of Brewer Road. 12/22/48, 27.5; 3/18/49, 25.3; 11/10/49, 34.3; 4/6/50, 28.2; 5/8/50, 28.9; 11/13/50, 35.0; 3/27/51, 29.1; 11/15/51, 37.8; 4/7/52, 30.6.

13N 5E-33P1—Reference point—top of casing, elevation 79.3 feet, 100 feet north of Cornelius Avenue, 1.3 miles east of Brewer Road. 12/22/48, 26.0; 3/18/49, 24.2; 11/10/49, 32.2; 4/6/50, 27.3; 11/13/50, 34.5; 3/27/51, 28.9; 11/15/51, 37.0; 4/7/52, 30.3.

14N 2E-2D2—Reference point—top of casing, elevation 39 feet, 0.15 mile south of Bogue Road, 0.6 mile east of Schlag Road. 12/15/47, 5.3; 3/8/48, 6.4; 11/12/48, 5.2; 3/21/49, 1.8; 11/29/49, 5.4; 3/24/50, 4.3; 11/2/50, 3.9; 3/28/51, 3.5; 11/16/51, 4.2; 4/1/52, 4.0.

14N 2E-10F1—Reference point—top of casing, elevation 35 feet, West side of Schlag Road, 0.55 mile north of Oswald Road. 11/27/29, 9.8; 10/6/30, 9.0; 12/12/31, 9.0; 11/30/32, 9.6; 11/10/34, 9.6; 11/28/36, 9.6; 1/25/39, 10.1; 1/13/41, 5.0.

14N 2E-10L1—Reference point—top of casing, elevation 37 feet, West side of Schlag Road, 0.5 mile north of Oswald Road. 12/20/33, 12.2; 11/10/34, 12.7; 11/11/36, 12.6; 11/24/37, 12.8.

14N 2E-10R1—Reference point—top of casing, elevation 30 feet, North side of Oswald Road, 0.45 mile east of Schlag Road. 11/6/47, 8.9; 12/15/48, 10.5; 12/9/49, 10.6; 11/10/50, 9.4; 12/8/51, 3.4.

14N 2E-12H1—Reference point—top of pipe in base, elevation 41 feet, 150 feet west of Township Road, 0.6 mile north of Oswald Road. 12/15/47, 9.5; 3/9/48, 10.6; 11/12/48, 9.7; 3/21/49, 8.2; 11/29/49, 10.6.

14N 2E-13A1—Reference point—top of casing, elevation 42.1 feet, 0.05 mile south of Oswald Road, 0.1 mile west of Township Road. 12/15/47, 8.9; 3/8/48, 10.3; 11/12/48, 6.1; 3/21/49, 7.0; 11/29/49, 8.4.

14N 2E-13C1—Reference point—top of casing, elevation 39 feet, 100 feet south of Oswald Road, 0.7 mile west of Township Road. 12/15/47, 5.5; 3/8/48, 6.6; 11/12/48, 4.7; 3/21/49, 3.1; 11/29/49, 6.0.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet meosured from reference point)

14N/2E-13R1—Reference point—top of casing, elevation 37 feet, 0.1 mile west of Township Road, 0.4 mile south of Pierce Road. 12/15/47, 10.9; 3/8/48, 11.7; 10/8/48, 8.0; 11/12/48, 9.5; 1/18/49, 11.0; 3/21/49, 8.5; 6/6/49, 10.4; 6/30/49, 6.7; 7/27/49, 5.4; 8/25/49, 5.5; 11/29/49, 11.1; 3/24/50, 10.9; 11/2/50, 10.2; 3/28/51, 9.0; 11/16/51, 11.2; 4/1/52, 6.5.

14N/2E-14E1—Reference point—top of casing, elevation 34 feet, 0.4 mile south of Oswald Road, 0.4 mile west of Boulton Road. 12/15/47, 5.5; 3/8/48, 6.6; 11/12/48, 4.7; 3/21/49, 3.1; 11/29/49, 6.0.

14N/2E-14J1—Reference point—top of stone casing, elevation 36 feet, 0.1 mile south of Pierce Road, 0.3 mile east of Boulton Road. 12/15/47, 4.7; 3/8/48, 6.0; 10/8/48, 2.2; 11/12/48, 3.9.

14N/2E-26R1—Reference point—top of casing, elevation 33 feet, 0.2 mile north of O'Banion Road, 1.1 miles west of Township Road. 12/11/47, 7.4; 3/10/48, 7.6; 11/8/48, 6.4; 3/24/49, 3.9; 12/2/49, 7.7.

14N/3E-1H1—Reference point—top of casing, elevation 54 feet, 0.20 mile west of Feather River Boulevard, 1.70 miles north of Ella Avenue. 11/12/47, 21.2; 3/5/48, 20.0; 5/8/48, 15.8; 10/7/48, 23.8; 11/11/48, 22.3; 1/27/49, 20.9; 3/22/49, 17.6; 6/1/49, 25.2; 7/3/49, 25.5; 8/26/49, 25.5; 12/1/49, 23.5; 3/28/50, 17.2; 11/21/51, 22.7; 4/5/52, 10.8.

14N/3E-1R1—Reference point—top of casing, elevation 53 feet, 0.20 mile west of Feather River Boulevard, 1.20 miles north of Ella Avenue. 11/12/47, 20.5; 3/5/48, 20.2; 11/11/48, 20.1; 3/22/49, 17.9; 12/1/49, 23.5.

14N/3E-2G1—Reference point—hole in base of pump, elevation 49 feet, 0.36 mile north of Stewart Road, 0.45 mile east of Garden Highway. 11/11/47, 32.3; 3/24/48, 24.0; 10/6/48, 27.7; 11/15/48, 24.4; 3/17/49, 21.4; 11/30/49, 29.8.

14N/3E-2Q1—Reference point—hole in base of pump, elevation 53.9 feet, 0.07 mile south of Stewart Road, 0.10 mile east of Garden Highway. 11/10/47, 26.8; 3/4/48, 33.9; 11/15/48, 28.8; 3/17/49, 21.7; 11/30/49, 23.2; 3/27/50, 21.4; 11/3/50, 26.7; 3/29/51, 17.9; 11/20/51, 27.2.

14N/3E-3A1—Reference point—hole in side of pump, elevation 50 feet, 0.19 mile south of Bogue Road, 0.25 mile east of Highway 24. 11/10/47, 36.1; 3/23/48, 35.5; 10/6/48, 36.3; 11/15/48, 31.0; 3/7/49, 29.3; 11/30/49, 35.0; 3/27/50, 30.5; 11/3/50, 33.5; 3/28/51, 27.2; 11/16/51, 32.2.

14N/3E-3C2—Reference point—hole in base of pump, elevation 53.1 feet, 0.05 mile south of Bogue Road, 0.11 mile west of State Highway 24. 3/12/48, 43.8; 10/6/48, 35.6; 11/11/48, 33.9; 1/18/49, 32.8; 3/7/49, 32.1; 6/1/49, 37.6; 6/28/49, 45.0; 7/27/49, 47.5; 8/25/49, 42.3; 12/1/49, 35.4.

14N/3E-3C3—Reference point—bottom of pump base, elevation 53.1 feet, 0.27 mile south of Bogue Road, 0.06 mile west of State Highway 24. 3/29/48, 36.4; 11/15/48, 33.9; 3/7/49, 32.7; 11/30/49, 35.0.

14N/3E-3F1—Reference point—top of casing, elevation 51.3 feet, 0.2 mile west of State Highway 24, 0.45 mile south of Bogue Road. 11/18/47, 31.6; 3/23/48, 39.2; 10/6/48, 34.0; 11/11/48, 32.8; 3/17/49, 30.9; 11/30/49, 34.4.

14N/3E-3G1—Reference point—hole in pump base, elevation 52 feet, 0.17 mile east of State Highway 24, 0.54 mile south of Bogue Road. 3/4/48, 37.5; 11/16/48, 32.8; 3/17/49, 29.7; 11/30/49, 32.9.

14N/3E-3N1—Reference point—top of casing, elevation 55.4 feet, 0.09 mile south of Stewart Road, 0.40 mile west of State Highway 24. 11/10/47, 38.7; 3/4/48, 41.5; 11/15/48, 39.7; 3/17/49, 37.1; 11/30/49, 43.7.

14N/3E-3N2—Reference point—hole in base of pump, elevation 48 feet, South side of Stewart Road, 0.30 mile west of State Highway 24. 3/12/48, 40.4; 11/15/48, 34.7.

14N/3E-3P1—Reference point—top of pit, elevation 50 feet, 0.10 mile north of Reed Road, 0.17 mile west of State Highway 24. 11/26/29, 28.3; 9/27/30, 32.4; 12/12/31, 33.8; 12/1/32, 32.4; 12/15/33, 33.4; 11/10/34, 34.1; 11/25/36, 28.4; 11/24/37, 26.2; 1/26/39, 20.4; 1/13/41, 24.0; 11/6/47, 33.8; 12/15/48, 34.2; 12/9/49, 36.0; 11/10/50, 39.1.

14N/3E-3R2—Reference point—slot in base, elevation 51.3 feet, 0.19 mile south of Stewart Road, 0.35 mile east of Garden Highway. 11/10/47, 31.1; 11/15/48, 28.4; 3/17/49, 25.2; 11/30/49, 30.7.

14N/3E-4E3—Reference point—top of casing, elevation 47 feet, 0.05 mile south of Star Road, 0.20 mile east of Grove Avenue. 12/16/47, 30.6; 3/24/48, 31.7; 11/12/48, 33.3; 3/18/49, 30.0; 11/29/49, 35.8.

14N/3E-4G1—Reference point—hole in pump base, elevation 50.1 feet, 0.20 mile east of Walton Avenue, 0.48 mile south of Bogue Road. 11/18/47, 33.8; 3/12/48, 35.4; 10/6/48, 37.0; 11/11/48, 35.1; 3/18/49, 33.1; 11/30/49, 37.1.

14N/3E-4Q1—Reference point—hole in base of pump, elevation 47 feet, 0.10 mile north of Reed Road, 0.04 mile east of Walton Avenue. 11/10/47, 32.9; 3/4/48, 34.0; 3/12/48, 36.7; 3/29/48, 32.3; 11/15/48, 33.9; 3/18/49, 31.2; 11/29/49, 35.6; 3/27/50, 33.2; 11/3/50, 38.5; 3/28/51, 32.9; 11/16/51, 36.2.

14N/3E-5A2—Reference point—top of concrete pit, elevation 49 feet, West side of Grove Avenue, 0.15 mile south of Bogue Road. 12/16/47, 29.9; 3/9/48, 32.7; 10/7/48, 34.8; 11/12/48, 32.5; 3/18/49, 29.0; 11/29/49, 34.0.

14N/3E-5C1—Reference point—hole in base of pump, elevation 50 feet, 0.07 mile south of Bogue Road, 0.50 mile east of George Washington Boulevard. 12/16/48, 30.4; 3/9/48, 28.8; 10/7/48, 31.2; 11/12/48, 29.0; 3/18/49, 26.1; 6/1/49, 32.8; 7/27/49, 41.8; 8/25/49, 39.0; 11/29/49, 30.2; 3/27/50, 27.1; 11/3/50, 33.5; 3/28/51, 23.6; 4/1/52, 23.8.

14N/3E-5D1—Reference point—invert of pipe in base, elevation 48.1 feet, South side of Bogue Road, 0.15 mile east of George Washington Boulevard. 12/20/47, 23.4; 3/5/48, 25.3; 10/4/48, 26.6; 11/18/48, 24.8; 3/29/49, 22.0.

14N/3E-5K1—Reference point—hole in base of pump, elevation 46 feet, 0.14 mile north of Stewart Road, 0.47 mile west of Grove Avenue. 3/9/48, 27.3; 3/30/48, 28.4; 11/12/48, 31.0; 12/9/49, 31.7.

14N/3E-6G1—Reference point—slot in concrete base, elevation 45 feet, 0.45 mile west of George Washington Boulevard, 0.38 mile south of Bogue Road. 12/16/47, 13.9; 3/9/48, 14.7; 11/12/48, 14.6; 12/9/49, 15.0.

14N/3E-6M1—Reference point—hole in base of pump, elevation 40 feet, 0.50 mile north of Reed Road, 0.06 mile east of Township Road. 12/15/47, 10.8; 3/24/48, 13.2; 10/8/48, 7.3; 11/12/48, 9.3; 1/18/49, 10.9; 3/21/49, 9.2; 6/6/49, 6.1; 6/28/49, 6.7; 7/27/49, 6.6; 8/25/49, 6.0; 11/29/49, 10.1; 3/24/50, 9.9; 11/2/50, 10.0; 3/28/51, 8.7; 11/16/51, 9.2; 4/1/52, 7.9.

14N/3E-7A1—Reference point—hole in base of pump, elevation 45 feet, 0.12 mile south of Reed Road, 0.25 mile west of George Washington Boulevard. 12/17/47, 19.5; 3/9/48, 20.2; 11/12/48, 20.6; 3/21/49, 18.6; 11/29/49, 21.3.

14N/3E-7M1—Reference point—top of casing under pump, elevation 42 feet, 0.10 mile east of Township Road, 0.52 mile north of Oswald Avenue. 12/15/47, 11.2; 3/9/48, 12.3; 11/12/48, 11.8; 3/21/49, 10.2; 11/29/49, 11.2; 3/24/50, 10.8; 11/2/50, 11.8; 3/28/51, 9.0; 11/16/51, 11.1; 4/2/52, 10.1.

14N/3E-8B1—Reference point—hole in base of pump, elevation 45 feet, South side of Reed Road, 0.52 mile west of Walton Avenue. 12/17/47, 26.3; 3/9/48, 25.6; 11/12/48, 30.2; 3/21/49, 25.0; 11/29/49, 31.1; 3/27/50, 26.1; 11/3/50, 35.3; 3/28/51, 24.3; 11/16/51, 31.6; 4/2/52, 27.7.

14N/3E-8D1—Reference point—hole in base of pump, elevation 46.6 feet, South side of Reed Road, 0.15 mile east of George Washington Boulevard. 12/17/47, 23.2; 3/9/48, 23.5; 3/21/49, 21.6.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet measured from reference point)

14N 3E-8J1—Reference point—hole in base of pump, elevation 45 feet, 0.03 mile west of Grove Avenue, 0.45 mile north of Oswald Avenue, 12/16/47, 27.8; 3/4/48, 29.0; 11/12/48, 30.8; 3/18/49, 27.3; 11/29/49, 33.1; 3/27/50, 29.4; 11/3/50, 36.2; 3/28/51, 29.1; 11/19/51, 33.8; 4/2/52, 23.8.

14N 3E-8K1—Reference point—hole in base of pump, elevation 45 feet, 0.40 mile west of Grove Avenue, 0.35 mile north of Oswald Road, 12/16/47, 26.9; 3/24/48, 28.3; 11/12/48, 30.9; 3/18/49, 26.8; 11/29/49, 32.1.

14N 3E-8M3—Reference point—top of casing, elevation 45 feet, 0.20 mile east of George Washington Boulevard, 0.50 mile north of Oswald Road, 12/17/47, 22.7; 3/9/48, 21.1; 10/7/48, 28.0; 11/12/48, 25.6; 1/18/49, 23.1; 3/21/49, 21.8; 6/1/49, 25.0; 6/30/49, 26.3; 7/27/49, 34.5; 8/25/49, 31.5; 11/29/49, 26.7.

14N 3E-8N1—Reference point—top of casing, elevation 44.8 feet, North side of Oswald Avenue, 0.15 mile east of George Washington Boulevard, 12/16/47, 21.5; 3/9/48, 16.4; 3/12/48, 21.8; 11/12/48, 23.8; 3/21/49, 20.7; 11/29/49, 21.9; 3/24/50, 21.4; 11/2/50, 29.3; 3/28/51, 18.9; 11/19/51, 25.5; 4/2/52, 13.5.

14N 3E-9A2—Reference point—top of concrete pit, south edge, elevation 40 feet, 0.1 mile south of Reed Road, 0.35 mile east of Walton Avenue, 11/19/47, 32.0; 3/4/48, 32.3; 5/12/48, 31.1; 11/15/48, 32.1; 11/18/49, 32.1; 3/18/49, 31.0; 11/30/49, 35.2.

14N 3E-9D1—Reference point—hole in base of pump, elevation 46 feet, 0.10 mile south of Reed Road, 0.45 mile west of Walton Road, 12/16/47, 31.4; 3/9/48, 33.8.

14N 3E-9K1—Reference point—top of casing, elevation 45 feet, South side of Barry Road, 0.25 mile east of Walton Avenue, 11/8/47, 33.2; 3/4/48, 34.9; 3/12/48, 34.1; 3/29/48, 32.5; 10/6/48, 35.6; 11/15/48, 34.3; 3/17/49, 32.0; 11/30/49, 35.8.

14N 3E-9Q1—Reference point—hole in base of pump, elevation 42 feet, North side of Oswald Road, 0.25 mile east of Walton Avenue, 3/12/48, 29.0; 11/15/48, 23.4; 3/17/49, 21.3.

14N 3E-10B1—Reference point—top of casing, elevation 50 feet, 0.17 mile east of State Highway 24, 0.33 mile north of Barry Road, 11/19/47, 29.4; 10/6/48, 31.3; 11/30/49, 31.2; 11/3/50, 33.5; 11/20/51, 31.7.

14N 3E-10B2—Reference point—top of casing, elevation 49 feet, 0.32 mile south of Stewart Road, 0.18 mile east of State Highway 24, 11/19/47, 29.4; 3/4/48, 32.0; 10/6/48, 31.3; 11/15/48, 31.5; 3/7/49, 26.3; 11/30/49, 31.2; 3/27/50, 28.4; 11/3/50, 33.5; 3/29/51, 24.8; 11/20/51, 31.7.

14N 3E-10F1—Reference point—top of casing at bottom of pit, elevation 27 feet, 0.70 mile west of State Highway 24, 0.80 mile north of Barry Road, 11/18/47, 35.1; 3/4/48, 34.1; 3/12/48, 33.9; 11/15/48, 34.8; 3/17/49, 31.7; 11/29/49, 36.6.

14N 3E-10N1—Reference point—top of concrete base, elevation 18.6 feet, 0.08 mile north of Oswald Avenue, 0.36 mile west of State Highway 24, 11/8/47, 30.1; 3/12/48, 32.1; 3/29/48, 29.1; 5/12/48, 27.0; 10/6/48, 32.2; 11/15/48, 31.3; 1/18/49, 29.4; 3/17/49, 28.5; 11/30/49, 32.2; 3/29/50, 30.0; 11/3/50, 33.9; 3/29/51, 28.6; 11/20/51, 32.3.

14N 3E-11D2—Reference point—top of casing, elevation 49 feet, 0.10 mile north of Barry Road, 0.63 mile east of State Highway 24, 11/19/47, 27.3; 3/4/48, 30.6; 3/29/48, 31.3; 5/12/48, 23.4; 10/6/48, 34.1; 11/16/48, 27.7; 11/18/49, 25.8; 3/17/49, 24.4; 6/1/49, 31.6; 6/28/49, 39.2; 8/3/49, 38.9; 8/25/49, 31.8; 11/30/49, 29.1.

14N 3E-11F2—Reference point—hole in base of pump, elevation 51.7 feet, 0.17 mile north of Barry Road, 0.95 mile east of State Highway 24, 11/10/47, 27.1; 3/23/48, 27.8; 11/16/48, 21.2; 3/17/49, 20.7; 11/30/49, 26.1; 3/27/50, 19.6; 11/3/50, 26.1; 3/29/51, 16.0; 11/20/51, 25.0.

14N 3E-12F1—Reference point—top of casing, elevation 52 feet, 0.65 mile north of Ella Road, 0.50 mile east of Feather River Boulevard, 3/28/50, 17.0; 11/6/50, 23.6; 3/30/51, 18.4; 4/5/52, 20.6.

14N 3E-12M1—Reference point—hole in base of pump, elevation 50 feet, 0.22 mile north of Ella Avenue, 0.84 mile west of Feather River Boulevard, 11/12/47, 20.4; 3/6/48, 20.5; 11/15/48, 20.2; 3/22/49, 16.8; 12/1/49, 22.1; 3/28/50, 17.6; 11/6/50, 72.1; 11/21/51, 20.8; 4/5/52, 9.5.

14N 3E-12Q1—Reference point—hole in base of pump, elevation 53.6 feet, 0.23 mile north of Ella Avenue, 0.29 mile west of Feather River Boulevard, 11/11/49, 21.7; 3/5/48, 23.0; 5/8/48, 19.5.

14N 3E-13B1—Reference point—top of casing, elevation 50.9 feet, 0.17 mile south of Ella Avenue, 0.44 mile west of Feather River Boulevard, 11/12/47, 20.7; 3/5/48, 22.8; 11/11/48, 20.2; 3/2/49, 18.0; 12/1/49, 22.1; 3/28/50, 21.7; 11/6/50, 21.8; 3/30/51, 13.0; 11/20/51, 21.8; 4/5/52, 12.1.

14N 3E-13N1—Reference point—hole in base of pump, elevation 48.3 feet, 0.11 mile north of Plumas Road, 0.81 mile west of Feather River Boulevard, 3/6/48, 24.1; 5/8/48, 16.0; 11/11/48, 19.8; 1/27/49, 18.4; 3/21/49, 16.9; 12/1/49, 21.1; 3/29/50, 17.4; 11/6/50, 20.9; 4/5/52, 10.0.

14N 3E-14E1—Reference point—hole in base of pump, elevation 47 feet, 0.20 mile west of Garden Highway, 0.75 mile north of Messick Road, 11/18/47, 25.3; 3/23/48, 22.1; 11/15/48, 22.2; 3/17/49, 19.6; 11/29/49, 22.4.

14N 3E-14E2—Reference point—top of casing, elevation 47 feet, 0.11 mile west of Garden Highway, 0.75 mile north of Messick Road, 11/10/47, 20.6; 3/5/48, 23.7; 5/12/48, 13.9; 10/6/48, 21.6; 11/15/48, 20.2; 1/27/49, 19.2; 3/17/49, 17.1; 6/1/49, 19.5; 6/30/49, 26.7; 7/27/49, 28.0; 8/25/49, 25.7; 11/29/49, 23.3; 3/29/50, 16.4; 11/3/50, 23.3; 3/29/51, 12.7; 11/20/51, 20.8.

14N 3E-14N1—Reference point—hole in base of pump, elevation 46 feet, 0.27 mile north of Messick Road, 0.13 mile east of Garden Highway, 11/18/47, 19.1; 3/5/48, 27.7; 11/15/48, 19.4; 3/17/49, 16.6; 11/29/49, 21.6.

14N 3E-14R1—Reference point—hole in base of pump, elevation 49.4 feet, 1.07 miles west of Feather River Boulevard, 0.67 mile north of Broadway, 11/11/47, 24.3; 3/6/48, 25.8; 11/11/48, 20.9; 3/21/49, 17.9; 12/1/49, 22.1; 3/29/50, 17.9; 11/6/50, 22.3; 3/30/51, 13.4; 11/20/51, 21.1; 4/5/52, 10.9.

14N 3E-15A2—Reference point—slot in base of pump, elevation 47 feet, 0.57 mile south of Barry Road, 0.41 mile east of State Highway 24, 11/19/47, 27.6; 3/23/48, 27.8; 11/15/48, 29.7; 3/17/49, 24.8; 11/29/49, 28.8.

14N 3E-15B1—Reference point—top of casing, elevation 47 feet, 0.18 mile south of Oswald Avenue, 0.04 mile east of State Highway 24, 11/8/47, 39.0; 3/5/48, 33.8; 3/12/48, 32.5; 11/15/48, 28.5; 3/17/49, 35.1; 11/29/49, 33.2.

14N 3E-15B2—Reference point—top of casing, elevation 48 feet, 1.0 mile north of Messick Road, 0.17 mile east of State Highway 24, 11/18/47, 26.9.

14N 3E-15E1—Reference point—hole in base of pump, elevation 17.2 feet, 0.48 mile south of Oswald Road, 0.43 mile west of State Highway 24, 3/23/48, 27.9; 10/6/48, 29.0; 11/15/48, 27.0; 3/17/49, 25.9; 11/30/49, 29.4.

14N 3E-15P1—Reference point—top of casing, elevation 45 feet, 0.38 mile north of Messick Road, 0.02 mile west of State Highway 24, 3/23/48, 29.2; 11/15/48, 17.2; 3/17/49, 25.9; 11/29/49, 28.5.

14N 3E-16C1—Reference point—hole in base of pump, elevation 48.9 feet, 0.10 mile west of Walton Avenue, 0.22 mile south of Oswald Road, 12/16/47, 32.3; 3/20/48, 30.6; 3/26/48, 29.9; 3/30/48, 29.9; 5/12/48, 28.1; 11/15/48, 31.8; 3/18/49, 29.6; 11/29/49, 34.7.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet measured from reference point)

14N/3E-16E1—Reference point—top of casing, elevation 47.7 feet, 0.25 mile east of Carlson Road, 0.40 mile south of Oswald Road. 12/16/47, 27.1; 3/20/48, 29.0; 10/7/48, 30.2; 11/15/48, 28.9; 3/18/49, 26.8; 11/29/49; 35.8; 3/27/50, 28.6; 11/3/50, 32.6; 3/29/51, 30.2; 11/19/51, 30.6; 4/2/52, 22.2.

14N/3E-16J1—Reference point—top of casing, elevation 46.4 feet, 0.77 mile west of State Highway 24, 0.64 mile south of Oswald Avenue. 11/7/47, 28.4; 3/5/48, 25.2; 3/12/48, 25.3; 10/6/48, 28.2; 11/15/48, 26.8; 1/27/49, 26.1; 3/17/49, 25.4; 3/29/50, 26.6; 11/3/50, 24.2; 3/29/51, 25.1.

14N/3E-17B1—Reference point—top of "I" beam pump support, elevation 44 feet, 0.35 mile west of Carlson Road, 0.06 mile south of Oswald Road. 12/16/47, 31.9; 3/9/48, 24.2; 3/12/48, 24.7; 11/12/48, 26.9; 3/18/49, 24.0; 11/29/49, 29.0.

14N/3E-17Q1—Reference point—top of casing under pump, elevation 42.5 feet, 0.30 mile west of Carlson Road, 0.25 mile north of Best Road. 12/16/47, 22.7; 3/8/48, 23.5; 3/12/48, 23.2; 10/7/48, 26.3; 11/15/48, 24.9; 1/27/49, 23.9; 3/18/49, 23.1; 11/29/49, 29.7.

14N/3E-17R1—Reference point—top of casing, elevation 45.9 feet, West side of Carlson Road, 0.23 mile north of Best Road. 3/30/48, 24.5; 11/15/48, 27.3; 3/18/49, 25.8.

14N/3E-18D1—Reference point—top of casing, elevation 43 feet, Southeast corner of Oswald Avenue and Township Road. 11/26/29, 9.3; 10/6/30, 7.2; 12/12/31, 11.0; 11/30/32, 10.3; 12/20/33, 12.5; 11/10/34, 10.1; 11/28/36, 8.7; 11/24/37, 8.6; 1/25/39, 8.5; 1/13/41, 1.3; 11/6/47, 6.9; 12/15/48, 7.9; 12/9/49, 7.9; 11/10/50, 7.7; 12/8/51, 5.8.

14N/3E-18F1—Reference point—top of casing, elevation 40 feet, 0.41 mile south of Oswald Avenue, 0.23 mile east of Township Road. 12/15/47, 11.3; 3/8/48, 6.1; 10/8/48, 5.1; 11/12/48, 5.1; 3/2/49, 5.0; 11/29/49, 5.8; 3/27/50, 5.2; 11/2/50, 6.7; 3/28/51, 4.8; 11/16/51, 6.7; 4/2/52, 5.0.

14N/3E-18H3—Reference point—top of concrete pit, elevation 41 feet, West side George Washington Boulevard, 0.44 mile south of Oswald Avenue. 12/16/47, 19.6; 3/8/48, 18.2; 10/7/48, 20.9; 11/12/48, 20.1; 3/21/49, 18.0; 11/29/49, 20.6.

14N/3E-18R1—Reference point—top of casing, elevation 40 feet, 0.10 mile north of Best Road, 0.26 mile west of George Washington Boulevard. 12/15/47, 16.9; 3/8/48, 17.1; 11/12/48, 18.5; 3/21/49, 16.8; 11/29/49, 19.6.

14N/3E-19L1—Reference point—hole in pump base, elevation 37 feet, 0.50 mile west of George Washington Boulevard, 0.69 mile south of Best Boad. 12/5/47, 10.9; 3/8/48, 11.6; 10/8/48, 15.8; 11/12/48, 13.8; 3/18/49, 12.7; 11/29/49, 14.9; 3/27/50, 13.1; 11/2/50, 15.8; 3/28/51, 10.6; 11/16/51, 14.5; 4/2/52, 6.0.

14N/3E-19P1—Reference point—top of pipe in base, elevation 38 feet, 0.50 mile west of George Washington Boulevard, 0.83 mile north of Best Road. 12/11/47, 13.2; 3/24/48, 14.0; 11/8/48, 13.7; 3/24/49, 12.2; 12/2/49, 14.6.

14N/3E-20A2—Reference point—hole in casing, elevation 44.5 feet, 0.10 mile south of Best Road, east side of George Washington Boulevard. 12/16/47, 22.7; 3/8/48, 21.6; 11/15/48, 25.3; 3/18/49, 24.0; 11/29/49, 26.9; 3/27/50, 25.4; 11/3/50, 32.6; 3/28/51, 25.2; 11/19/51, 26.4; 4/2/52, 18.4.

14N/3E-20E1—Reference point—top of casing, elevation 40 feet, 0.27 mile south of Best Road, 0.20 mile east of George Washington Boulevard. 12/16/47, 17.9; 3/8/48, 20.0; 3/29/48, 18.0; 11/12/48, 20.1; 3/18/49, 18.3; 11/29/49, 21.7.

14N/3E-20F1—Reference point—top of casing, elevation 40 feet, 0.49 mile east of George Washington Boulevard, 0.51 mile north of Hutchinson Road. 12/16/47, 20.8; 3/8/48, 23.7; 3/12/48, 23.6; 10/7/48, 24.0; 11/15/48, 23.1; 3/18/49, 21.4; 11/29/49, 24.8; 3/27/50, 22.6; 11/2/50, 26.4; 3/28/51, 20.6; 11/19/51, 24.2; 4/2/52, 15.7.

14N/3E-20Q1—Reference point—top of concrete pit, elevation 42 feet, 0.54 mile west of George Washington Boulevard, 0.14 mile north of Hutchinson Road. 12/13/47, 20.1; 3/10/48, 21.3; 3/12/48, 21.5; 11/8/48, 24.9; 3/23/49, 20.5; 12/5/49, 24.0; 3/24/50, 21.5; 11/7/50, 26.7; 3/28/51, 21.8; 11/15/51, 22.7; 4/3/52, 14.8.

14N/3E-21M1—Reference point—top of casing, elevation 44.3 feet, 0.46 mile north of Hutchinson Road, west side of Carlson Road. 12/16/47, 21.8; 3/8/48, 23.0; 3/20/48, 23.4; 3/26/48, 22.2; 3/30/48, 21.7; 10/7/48, 24.2; 11/15/48, 24.0; 3/18/49, 23.2; 11/29/49, 25.7.

14N/3E-21Q1—Reference point—hole in pump base, elevation 42 feet, North side of Hutchinson Road, 0.48 mile west of State Highway 24. 11/15/47, 21.9; 3/8/48, 23.9; 3/12/48, 27.4; 3/26/48, 22.0; 3/29/48, 21.9; 5/12/48, 21.2; 11/9/48, 25.0; 1/18/49, 24.0; 3/23/49, 22.8; 6/1/49, 21.8; 6/28/49, 30.4; 8/3/49, 20.1; 8/25/49, 28.6; 12/6/49, 26.0.

14N/3E-22B2—Reference point—bottom of pump base, elevation 48.3 feet, North side of Messick Road, 0.50 mile west of Garden Highway. 11/7/47, 25.9; 3/5/48, 26.1; 3/12/48, 26.6; 3/29/48, 25.2; 10/6/48, 28.5; 11/15/48, 25.8; 3/17/49, 24.4; 11/30/49, 27.6; 3/29/50, 25.2; 11/3/50, 28.0; 3/29/51, 22.3; 11/20/51, 26.3.

14N/3E-22E2—Reference point—bottom of pump base, elevation 47.8 feet, South of Messick Road, 0.1 mile east of State Highway 24. 11/7/47, 26.6; 3/5/48, 26.2; 3/12/48, 27.8; 11/15/48, 25.3; 3/17/49, 23.8; 11/29/49, 27.5.

14N/3E-22H1—Reference point—top of casing, elevation 47.2 feet, 0.03 mile west of Garden Highway, 0.16 mile south of Messick Road. 3/5/48, 22.1; 10/6/48, 19.8; 11/15/48, 20.7.

14N/3E-22R1—Reference point—hole in concrete base, elevation 45.2 feet, West side Garden Highway, 0.15 mile north of Hutchinson Road. 11/15/47, 20.9; 3/8/48, 26.4; 3/29/48, 19.0; 5/12/48, 16.5; 11/10/48, 20.7; 1/24/49, 19.9; 3/23/49, 17.9; 12/6/49, 22.4.

14N/3E-23D2—Reference point—top of concrete base, elevation 48.1 feet, 0.2 mile east of Garden Highway, 0.03 mile south of Messick Road. 11/7/47, 20.6; 3/23/48, 21.1; 10/6/48, 23.3; 11/15/48, 22.2; 3/17/49, 20.9; 11/29/49, 23.0; 3/29/50, 18.8; 11/3/50, 22.9; 3/29/51, 16.3; 11/20/51, 22.3.

14N/3E-24B1—Reference point—hole in pump base, elevation 50.8 feet, 0.01 mile south of Plumas Road, 0.26 mile west of Feather River Boulevard. 11/11/47, 23.1; 3/6/48, 22.6; 5/8/48, 20.7; 10/7/48, 24.2; 11/11/48, 22.0; 3/21/49, 19.9; 6/1/49, 24.6; 7/3/49, 31.0; 7/28/49, 28.8; 8/26/49, 30.0; 12/1/49, 23.4; 3/29/50, 22.2; 11/6/50, 24.5; 3/30/51, 14.4; 11/20/51, 23.9; 4/5/52, 14.6.

14N/3E-24G1—Reference point—top of casing at pit bottom, elevation 39.4 feet, 0.10 mile north of Broadway, 0.31 mile east of Feather River Boulevard. 11/11/47, 14.2; 3/6/48, 12.1, 11/11/48, 12.0; 3/21/49, 9.4; 12/1/49, 13.4.

14N/3E-25B2—Reference point—hole in side of pump, elevation 47 feet, South of Anderson Road, 0.31 mile west of Feather River Boulevard. 11/17/47, 22.5; 3/8/48, 19.7; 5/8/48, 17.3; 11/10/48, 20.1; 1/24/49, 18.9; 3/23/49, 17.6; 12/2/49, 21.3.

14N/3E-25C1—Reference point—top of casing, elevation 49.5 feet, 0.15 mile south of Anderson Road, 0.71 mile west of Feather River Boulevard. 11/17/47, 22.3; 3/8/48, 19.8; 11/10/48, 22.0; 3/23/49, 19.8; 12/2/49, 22.7; 3/29/50, 18.6; 11/6/50, 22.6; 3/30/51, 15.9; 11/6/51, 21.5; 4/1/52, 15.4.

14N/3E-25K2—Reference point—top of casing, elevation 46.1 feet, 0.01 mile south of Country Club Road, 0.26 mile west of Feather River Boulevard. 11/17/47, 17.8; 3/8/48, 18.5; 3/23/49, 15.6; 12/2/49, 19.1.

14N/3E-26M2—Reference point—hole in base of pump, elevation 44 feet, 0.32 mile north of O'Banion Road, 0.22 mile east of Garden Highway. 11/14/47, 21.0; 3/8/48, 23.4; 5/6/48, 14.4; 6/1/48, 14.7; 7/3/48, 52.4 (operating); 11/10/48, 20.9; 3/23/49, 16.8; 12/6/49, 22.4.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet measured from reference point)

14N/3E-27D1—Reference point—top of casing, elevation 42 feet. East side of State Highway 24, 0.10 mile south of Hutchinson Road. 11/15/47, 21.7; 3/8/48, 22.0; 3/12/48, 28.4; 5/12/48, 20.8; 11/9/48, 24.2; 3/23/49, 21.8; 12/6/49, 25.4; 3/29/50, 23.2; 11/7/50, 26.1; 3/29/51, 19.9; 11/15/51, 26.4; 4/3/52, 13.5.

14N/3E-27J1—Reference point—hole in base of pump, elevation 43 feet. West side of Garden Highway, 0.36 mile north of O'Banion Road. 11/14/47, 21.4; 3/8/48, 30.7; 5/5/48, 15.0; 11/10/48, 20.6; 3/23/49, 17.1; 6/1/49, 21.5; 8/30/49, 26.6; 12/6/49, 22.1; 3/29/50, 17.6; 11/7/50, 22.3; 3/29/51, 13.8; 11/15/51, 21.1; 4/3/52, 9.0.

14N/3E-27M2—Reference point—hole in base of pump, elevation 41 feet, 0.06 mile east of State Highway 24, 0.33 mile north of O'Banion Road. 11/15/47, 22.3; 3/8/48, 24.1; 11/9/48, 23.1; 3/23/49, 20.6; 12/6/49, 24.8.

14N/3E-28G2—Reference point—top of casing, elevation 41 feet, 0.28 mile west of State Highway 24, 0.45 mile south of Hutchinson Road. 1/16/48, 21.4.

14N/3E-28M1—Reference point—top of wooden platform under pump, elevation 43.6 feet, 0.31 mile north of O'Banion Road, 0.15 mile east of Carlson Road. 12/13/47, 21.6; 3/9/48, 25.4; 3/12/48, 25.6; 11/8/48, 25.6; 3/24/49, 22.3; 12/5/49, 26.6.

14N/3E-28R1—Reference point—top of casing, elevation 40 feet, 0.16 mile west of State Highway 24, 0.16 mile north of O'Banion Road. 11/14/47, 21.3; 3/24/48, 21.9; 11/9/48, 23.8; 3/23/49, 20.4; 12/6/49, 30.3; 3/29/50, 22.5; 11/2/50, 26.7; 3/29/51, 19.5.

14N/3E-29A1—Reference point—hole in base of pump, elevation 43.5 feet, 0.16 mile west of Carlson Road, 0.24 mile south of Hutchinson Road. 12/13/47, 22.6; 3/10/48, 24.0; 3/12/48, 24.6; 11/8/48, 25.1; 3/24/49, 22.2; 12/5/49, 26.3.

14N/3E-29L1—Reference point—top of casing, elevation 41 feet, 0.48 mile east of George Washington Boulevard, 0.27 mile north of O'Banion Road. 12/13/47, 20.0; 3/9/48, 20.0; 11/8/48, 21.3; 3/24/49, 18.9; 5/31/49, 28.1; 6/30/49, 31.3; 8/1/49, 32.0; 12/5/49, 22.4.

14N/3E-29R1—Reference point—hole in pump base, elevation 43.5 feet. West side of Carlson Road, 0.19 mile north of O'Banion Road. 5/21/48, 22.1; 11/8/48, 25.6; 3/24/49, 22.5; 12/5/49, 26.4; 3/29/50, 23.5; 11/7/50, 28.0; 3/29/51, 21.6; 11/15/51, 26.9; 4/3/52, 16.0.

14N/3E-30E1—Reference point—top of casing, elevation 36 feet, 0.22 mile east of Township Road, 0.40 mile south of Hutchinson Road. 12/11/47, 12.1; 3/10/48, 8.6; 3/12/48, 8.5; 11/8/48, 8.3; 3/24/49, 6.4; 12/2/49, 9.1.

14N/3E-30H1—Reference point—top of casing, elevation 38 feet, 0.28 mile south of Hutchinson Road, 0.03 mile west of George Washington Boulevard. 12/11/47, 14.9; 3/10/48, 14.6; 3/12/48, 14.5; 11/8/48, 16.1; 3/24/49, 14.0; 12/2/49, 17.5.

14N/3E-30M1—Reference point—top of concrete pit (west wall), elevation 37 feet, 0.38 mile north of O'Banion Road, 0.03 mile east of Township Road. 12/11/47, 8.5; 3/10/48, 9.6; 3/12/48, 9.6; 11/8/48, 9.3; 3/24/49, 6.0; 12/2/49, 9.0.

14N/3E-31B1—Reference point—top of casing, elevation 38 feet, 0.06 mile south of O'Banion Road, 0.36 mile west of George Washington Boulevard. 12/11/47, 12.6; 3/10/48, 13.1; 3/12/48, 13.1; 3/29/48, 12.9; 11/8/48, 12.2; 1/24/49, 13.1; 3/24/49, 11.4; 12/2/49, 13.4; 3/29/50, 12.0; 11/7/50, 15.3; 3/29/51, 10.7; 11/15/51, 14.3; 4/3/52, 7.7.

14N/3E-31L1—Reference point—top of casing, elevation 35 feet, 0.24 mile east of Township Road, 0.66 mile south of O'Banion Road. 12/11/47, 12.3; 3/10/48, 7.9; 3/12/48, 7.9; 11/8/48, 9.5; 3/25/49, 8.7.

14N/3E-31R1—Reference point—top of casing, elevation 36 feet, 0.12 mile west of George Washington Boulevard, 0.78 mile south of O'Banion Road. 12/12/47, 15.9; 3/10/48, 16.3; 3/12/48, 16.1; 11/8/48, 14.2; 3/24/49, 13.5; 12/5/49, 16.3.

14N/3E-32D1—Reference point—hole in base of pump, elevation 40 feet, 0.11 mile south of O'Banion Road, 0.09 mile east of George Washington Boulevard. 12/2/47, 16.7; 3/10/48, 17.5; 3/12/48, 17.4; 5/12/48, 16.2; 11/8/48, 16.7; 3/24/49, 14.8; 6/30/49, 20.8; 8/25/49, 19.2; 12/5/49, 17.9.

14N/3E-33D3—Reference point—hole in base of pump, elevation 40 feet, 0.18 mile south of O'Banion Road, 0.03 mile west of Burch Road. 12/12/47, 26.1; 3/9/48, 21.2; 3/12/48, 20.8; 3/29/48, 19.7; 5/29/48, 18.2; 11/8/48, 12.7; 1/19/49, 20.6; 3/24/49, 19.0; 6/1/49, 21.7; 6/28/49, 44.2; 7/27/49, 28.4; 8/25/49, 23.6.

14N/3E-33M2—Reference point—top of 2" x 4" plank over earth pit, elevation 27.8, 0.67 mile south of O'Banion Road, 0.15 mile west of Burch Road. 12/12/47, 15.8; 3/24/48, 16.9.

14N/3E-34C1—Reference point—top of casing, elevation 39 feet, 0.21 mile east of State Highway 24, south side of O'Banion Road. 11/14/47, 20.4; 3/8/48, 24.2; 3/29/48, 21.4; 5/12/48, 19.4; 11/9/48, 23.5; 1/19/49, 21.7; 3/23/49, 20.6; 12/6/49, 25.3.

14N/3E-34L1—Reference point—hole in side of pump, elevation 40 feet, 0.43 mile east of State Highway 24, 0.51 mile south of O'Banion Road. 11/14/47, 26.9; 3/8/48, 24.5; 11/10/48, 28.4; 3/25/49, 22.7; 12/6/49, 21.7.

14N/3E-35Q1—Reference point—hole in side of pump, elevation 43 feet, 0.35 mile east of Garden Highway, 0.57 mile north of Tudor Road. 11/14/47, 21.2; 3/8/48, 17.2; 11/10/48, 17.3; 3/23/49, 11.4; 12/6/49, 18.9.

14N/3E-36C1—Reference point—top of casing, elevation 50 feet, 0.51 mile south of Country Club Road, 0.72 mile east of Feather River Boulevard. 11/17/47, 17.7; 3/9/48, 16.7; 5/8/48, 9.2; 11/10/48, 18.2; 1/24/49, 17.6; 3/23/49, 11.8; 12/2/49, 18.6; 3/29/50, 10.7; 11/6/50, 18.0; 3/30/51, 11.0; 11/16/51, 16.2; 4/1/52, 6.4.

14N/4E-2F1—Reference point—top of casing outside shed, elevation 67.8 feet, 0.1 mile west of Virginia Road, 0.3 mile south of junction of Earle and Spenceville Roads. 12/4/47, 20.8; 3/18/48, 19.6; 11/22/48, 23.4; 3/21/49, 22.3.

14N/4E-2K1—Reference point—top of casing under pump, elevation 65.9 feet, 200 feet east of Virginia Road, 0.7 mile south of Spenceville Road. 12/4/47, 17.2; 5/18/48, 16.7; 11/22/48, 21.0; 11/23/49, 26.8.

14N/4E-2R1—Reference point—top of casing under pump, elevation 68.9 feet, 250 feet north of Earle Road, 0.2 mile east of junction of Virginia Road and Spenceville Roads. 12/3/47, 21.5; 3/18/48, 21.3; 11/19/48, 25.9; 3/21/49, 24.2; 11/23/49, 32.3.

14N/4E-4A1—Reference point—hole in side of pump, elevation 65 feet, 0.9 mile north of Hale Road, 1.0 mile east of U. S. Highway 99E. 12/1/47, 29.1; 3/18/48, 27.4; 11/19/48, 31.3; 3/23/49, 29.2; 11/23/49, 35.0; 3/27/50, 32.3; 11/3/50, 36.2; 4/5/51, 30.8; 11/21/51, 37.2; 4/4/52, 32.1.

14N/4E-4C1—Reference point—vertical hole in side of pump, elevation 63 feet, 0.6 mile east of U. S. Highway 99E, 0.9 mile north of Hale Road. 11/19/48, 28.4; 3/23/49, 26.1; 11/23/49, 31.6.

14N/4E-4M1—Reference point—top of hole in pump base, elevation 60 feet, 0.2 mile west of U. S. Highway 99E, 0.7 mile north of McGowan Road. 12/1/47, 21.3; 3/17/48, 19.9; 11/19/48, 23.9; 3/21/49, 21.7; 12/7/49, 26.7; 3/27/50, 24.5; 11/3/50, 28.5; 4/5/51, 24.6; 11/21/51, 33.7; 4/2/52, 26.2.

14N/4E-5A1—Reference point—top of casing under pump, elevation 60 feet, 0.05 mile west of U. S. Highway 99E, 1.3 miles north of McGowan Road. 12/1/47, 23.2; 3/17/48, 21.4.

14N/4E-5C1—Reference point—top tin, casing under pump, elevation 58 feet, 1.3 miles north of McGowan Road, 0.5 mile west of U. S. Highway 99E. 12/1/47, 22.8; 3/15/48, 22.1.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet meosured from reference point)

14N/4E-5J1—Reference point—top of casing under pump, elevation 62 feet, 0.3 mile west of U. S. Highway 99E, 0.8 mile north of McGowan Road. 12/1/47, 20.8; 3/15/48, 19.7.

14N/4E-5L1—Reference point—top of casing, elevation 60 feet, 0.4 mile west of U. S. Highway 99E, 1.9 miles north of McGowan Road. 12/1/47, 22.1; 3/15/48, 21.5; 11/19/48, 24.1; 3/21/49, 23.0; 12/7/49, 26.5; 4/3/52, 23.8.

14N/4E-7A1—Reference point—top of casing, 2.5 feet above ground, elevation 55 feet, 0.15 mile west of Arboga Road, 0.80 mile north of Ella Road. 11/12/47, 22.3; 3/15/48, 20.9; 5/14/48, 22.0; 10/17/48, 27.2; 11/11/48, 23.0; 3/21/49, 21.0; 12/1/49, 24.6; 3/29/50, 22.7; 11/6/50, 26.2; 3/30/51, 20.7; 11/20/51, 25.4; 4/5/52, 20.6.

14N/4E-7A2—Reference point, top of casing, elevation 58 feet, 264 feet west of Arboga Road, 0.81 mile north of Ella Road. 3/5/48, 21.5; 5/14/48, 21.6; 3/21/49, 19.5; 12/1/49, 25.0; 3/29/50, 21.2; 11/6/50, 27.9.

14N/4E-7D1—Reference point—top of casing at bottom of 9-foot pit, elevation 52 feet, 500 feet east of Feather River Boulevard, 0.85 mile north of Ella Road. 11/12/47, 12.3; 3/5/48, 11.0; 10/7/48, 13.8; 11/11/48, 11.5; 3/22/49, 10.5; 12/1/49, 15.2.

14N/4E-7F1—Reference point—top of discharge flange, elevation 53 feet, 0.4 mile east of Feather River Boulevard, 0.7 mile north of Ella Avenue. 11/12/47, 16.1; 3/5/48, 19.0; 11/11/48, 19.7; 3/22/49, 17.4; 12/1/49, 20.5.

14N/4E-8C1—Reference point—top of casing, concrete box, elevation 57 feet, 0.9 mile west of U. S. Highway 99E, 0.4 mile north of McGowan Road. 12/1/47, 28.2.

14N/4E-9B1—Reference point—top of casing, elevation 62 feet, 200 feet west of U. S. Highway 99E, 0.3 mile north of McGowan Road 12/2/47, 28.6; 3/17/48, 27.3; 11/19/48, 30.6; 3/21/49, 28.5; 11/23/49, 33.9.

14N/4E-9F1—Reference point—hole in pump base, elevation 60 feet, 50 feet north of McGowan Road, 0.7 mile west of U. S. Highway 99E. 11/19/48, 28.2; 1/25/49, 27.0; 3/18/49, 25.5; 11/23/49, 31.5; 3/28/50, 28.2; 11/3/50, 33.3; 4/5/51, 28.1.

14N/4E-9L1—Reference point—top of casing under pump, elevation 61 feet, 0.3 mile south of McGowan Road, 0.8 mile west of U. S. Highway 99E. 12/2/47, 23.7; 3/17/48, 21.4.

14N/4E-9Q1—Reference point—top of casing, elevation 52 feet, 0.7 mile west of U. S. Highway 99E, 0.3 mile south of McGowan Road. 12/2/47, 20.9; 3/17/48, 10.4; 11/19/48, 13.5; 3/18/49, 10.0; 11/23/49, 16.9; 4/2/52, 9.5.

14N/4E-10H2—Reference point—top of concrete pit, north edge, elevation 63 feet, 1.1 miles east of U. S. Highway 99E, 0.6 mile north of Ostrom Road. 12/3/47, 23.9; 3/18/48, 23.5; 11/19/48, 27.6; 3/21/49, 25.1; 11/23/49, 32.5; 3/22/50, 28.2; 11/3/50, 33.8; 4/5/51, 28.4; 11/23/51, 24.2; 4/4/52, 17.2.

14N/4E-10L1—Reference point—top of casing under pump, elevation 60 feet, 0.1 mile east of U. S. Highway 99E, 0.4 mile north of Slaughter House Road. 12/3/47, 16.9; 3/17/48, 15.4.

14N/4E-10M1—Reference point—top of casing 2 feet above ground line, elevation 58 feet, 0.2 mile west of U. S. Highway 99E, 0.4 mile north of Slaughter House Road. 11/19/48, 16.4.

14N/4E-10R1—Reference point—top of casing under pump, elevation 62 feet, 50 feet north of Ostrom Road, 0.5 mile east of U. S. Highway 99E. 12/3/47, 23.7; 3/18/48, 22.3; 11/19/48, 27.7; 11/23/49, 31.3.

14N/4E-11C1—Reference point—top of casing, elevation 68.6 feet, 2.0 miles east of U. S. Highway 99E, 0.7 mile south of Virginia Road. 11/18/48, 24.7.

14N/4E-11C2—Reference point—top of casing, elevation 68 feet, 1.9 miles east of U. S. Highway 99E, 0.7 mile south of Virginia Road. 11/18/48, 26.1; 3/21/49, 24.2; 11/23/49, 31.6.

14N/4E-11H1—Reference point—top of casing, elevation 72 feet, 1.0 mile west of Bradshaw Road, 0.6 mile north of Ostrom Road. 11/18/48, 29.4; 3/21/49, 27.7; 11/24/49, 35.9; 3/27/50, 33.2; 11/2/50, 38.6; 4/5/51, 34.6; 11/23/51, 40.6; 4/4/52, 37.2.

14N/4E-11J1—Reference point—top of casing, elevation 69.8 feet, 0.4 mile north of Ostrom Road, 1.1 miles west of Bradshaw Road. 11/18/48, 30.1; 3/21/49, 28.3; 11/23/49, 36.4.

14N/4E-11Q1—Reference point—top of casing, elevation 71 feet, 50 feet north of Ostrom Road, 1.5 miles west of Bradshaw Road. 11/18/48, 30.0; 11/23/49, 34.8.

14N/4E-12A1—Reference point—hole in pump base, elevation 75 feet, 100 feet west of Bradshaw Road, 1.0 mile north of Ostrom Road. 11/18/48, 31.4; 1/18/48, 28.8; 3/29/49, 28.1; 11/23/49, 36.6; 3/30/50, 33.6; 11/2/50, 40.5; 4/5/51, 43.2; 4/4/52, 37.1.

14N/4E-12B1—Reference point—hole in pump base, elevation 72 feet, 0.4 mile west of Bradshaw Road, 1.0 mile north of Ostrom Road. 11/18/48, 29.0; 4/5/51, 34.7.

14N/4E-12E1—Reference point—top of casing, elevation 70 feet, 0.7 mile north of Ostrom Road, 100 feet east of Virginia Road. 10/7/48, 29.55; 11/18/48, 28.9; 1/18/49, 28.0; 3/21/49, 27.15; 11/23/49, 35.4.

14N/4E-12R1—Reference point—top of casing, elevation 78 feet, 100 feet northwest of the intersection of Bradshaw and Ostrom Roads. 10/7/48, 35.0; 11/18/48, 33.0; 3/18/49, 30.8; 11/23/49, 39.8; 3/22/50, 36.7; 11/2/50, 44.2; 4/5/51, 39.0; 11/23/51, 47.4; 4/3/52, 40.8.

14N/4E-13A1—Reference point—top of casing, elevation 79.4 feet, 50 feet west of Bradshaw Road, 0.2 mile south of Ostrom Road. 3/24/48, 29.8; 10/7/48, 37.4; 11/18/48, 35.1; 1/18/48, 33.8; 3/18/49, 32.8; 11/23/49, 41.8; 3/27/50, 38.4.

14N/4E-13B1—Reference point—top of casing, elevation 75.5 feet, 0.3 mile west of Bradshaw Road, 100 feet south of Ostrom Road. 11/18/46, 31.6.

14N/4E-13C1—Reference point—top of casing, elevation 73.5 feet, 100 feet south of Ostrom Road, 0.6 mile west of Bradshaw Road. 10/7/48, 30.6; 11/18/48, 29.0; 1/18/49, 28.0; 3/18/49, 27.0; 11/23/49, 34.9; 3/27/50, 32.0; 11/2/50, 38.4; 4/5/51, 33.4; 11/23/51, 39.8; 4/3/52, 35.1.

14N/4E-13Q1—Reference point—top of casing under pump, elevation 71 feet, 0.9 mile south of Ostrom Road, 0.5 mile east of Virginia Road. 12/3/47, 30.4; 3/18/48, 29.1; 10/7/48, 34.7; 11/18/48, 33.6; 3/18/49, 31.6; 11/23/49, 39.0; 3/27/50, 36.7; 11/3/50, 41.8; 4/5/51, 37.9.

14N/4E-13R1—Reference point—top of casing, elevation 80 feet, 50 feet west of Bradshaw Road, 1 mile south of Ostrom Road. 11/18/48, 39.1; 3/18/49, 36.5; 11/24/49, 57.7.

14N/4E-14C1—Reference point—top of casing, elevation 70 feet, 20 feet south of Ostrom Road, 0.8 mile east of U. S. Highway 99E. 10/7/48, 30.7; 11/18/48, 29.0; 1/18/49, 28.0; 3/18/49, 29.1; 11/24/49, 33.9; 3/27/50, 31.5; 11/2/50, 36.2; 4/5/51, 31.6; 11/23/51, 38.4; 4/4/52, 33.6.

14N/4E-14J1—Reference point—top of casing, elevation 62 feet, 200 feet west of Virginia Road, 0.5 mile south of Ostrom Road. 12/3/47, 23.8; 3/18/48, 22.6; 10/7/48, 27.5; 11/18/48, 27.0; 3/18/49, 25.4.

14N/4E-14R1—Reference point—top of casing, elevation 70 feet, 260 feet west of Virginia Road, 0.4 mile north of U. S. Highway 99E. 3/18/49, 30.4.

14N/4E-15C1—Reference point—hole in pump base, elevation 64.6 feet, 200 feet south of Slaughter House Road, 0.4 mile west of U. S. Highway 99E. 12/2/47, 23.9; 3/17/48, 22.6; 10/7/48, 30.5; 11/19/48, 25.9; 3/18/49, 23.3; 11/23/49, 29.6; 3/28/50, 26.5; 11/3/50, 31.0; 4/5/51, 26.0; 11/21/51, 33.1; 4/2/52, 28.9.

14N/4E-15C2—Reference point—top of casing under pump, elevation 65 feet, 500 feet south of Slaughter House Road, 0.3 mile west of U. S. Highway 99E. 12/2/47, 23.1; 3/17/48, 20.8.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet measured from reference point)

14N 4E-15C3—Reference point—top of casing, 1 foot below ground, elevation 62.7 feet, 250 feet north of Slaughter House Road, 0.2 mile west of U. S. Highway 99E. 11/22/29, 16.4; 9/18/30, 15.9; 12/11/31, 16.4; 12/10/32, 15.7; 12/21/33, 11.0; 11/23/34, 10.7; 11/22/37, 15.8; 11/27/39, 12.1; 12/21/40, 15.3; 11/7/47, 23.2; 12/16/48, 24.3; 12/7/49, 28.2; 11/10/50, 29.7; 12/5/51, 31.3.

14N 4E-15C4—Reference point—top of 1-inch pipe to jet, elevation 65.2 feet, 0.1 mile north of Slaughter House Road, 0.3 mile west of U. S. Highway 99E. 11/19/48, 26.6; 3/18/49, 24.1; 11/23/49, 30.3.

14N 4E-15D1—Reference point—top of casing, elevation 55.9 feet, 200 feet southwest of Slaughter House Road, 0.7 mile due west of U. S. Highway 99E. 12/2/47, 15.8; 3/17/48, 14.1; 11/19/48, 17.5.

14N 4E-15L1—Reference point—top of casing under pump, elevation 66 feet, 0.8 mile west of U. S. Highway 99E, 0.4 mile south of Slaughter House Road. 12/2/47, 25.6; 3/17/48, 24.4; 10/7/48, 29.5; 11/19/48, 27.6; 1/25/49, 26.6; 3/18/49, 25.2; 5/25/49, 33.1; 6/29/49, 34.5; 7/29/49, 35.5; 11/23/49, 31.4; 3/28/50, 28.4; 11/3/50, 32.8; 4/5/51, 28.2; 11/21/51, 37.0; 4/2/52, 29.0.

14N 4E-16M1—Reference point—top of casing, elevation 55 feet, 1.3 miles south of McGowan Road, 0.4 mile east of Western Pacific Railroad tracks. 12/3/47, 22.5; 3/18/48, 20.3; 11/19/48, 20.9; 3/13/49, 18.4.

14N 4E-17C1—Reference point—top of casing under pump, elevation 55 feet, 0.5 mile south of McGowan Road, 100 feet west of Western Pacific Railroad. 12/2/47, 23.9; 3/18/48, 20.6; 11/19/48, 23.6; 3/18/49, 21.1; 11/22/49, 25.3; 3/28/50, 22.8; 11/3/50, 26.7; 4/5/51, 20.8.

14N 4E-17D1—Reference point—hole in side of casing, elevation 54 feet, 0.5 mile south of McGowan Road, 0.3 mile west of Western Pacific Railroad. 3/18/49, 21.0; 3/28/50, 22.5.

14N 4E-17D2—Reference point—top of casing under pump, elevation 54 feet, 0.5 mile south of McGowan Road, 0.3 mile west of Western Pacific Railroad. 12/1/47, 22.3.

14N 4E-17P1—Reference point—top of casing under pump, elevation 58.7 feet, 500 feet west of Western Pacific Railroad, 1.4 miles south of McGowan Road. 12/3/47, 23.2; 3/18/48, 21.8; 5/14/48, 23.2; 11/19/48, 24.4; 3/18/49, 21.9; 11/23/49, 25.8; 3/28/50, 23.0; 11/31/50, 26.6; 4/5/51, 20.9; 4/3/52, 23.2.

14N 4E-18C1—Reference point—hole in top of casing, elevation 53.1 feet, 200 feet south of Ella Road, 0.4 mile east of Feather River Boulevard. 11/11/47, 20.9; 3/5/48, 19.7; 10/7/48, 27.5; 11/11/48, 19.5; 1/27/49, 18.7; 3/21/49, 17.8; 12/1/49, 20.4; 3/28/50, 19.1; 11/6/50, 23.5; 3/30/51, 15.1; 11/20/51, 23.3; 4/5/52, 15.7.

14N 4E-18H1—Reference point—bottom of pump, elevation 54.1 feet, 400 feet west of Arboga Road, 0.5 mile south of Ella Road. 11/11/47, 21.2; 3/5/48, 19.8; 10/7/48, 24.9; 11/11/48, 21.0; 3/21/49, 19.6; 12/1/49, 21.6.

14N 4E-18J1—Reference point—top of suction flange, elevation 45.6 feet, 400 feet west of Arboga Road, 0.6 mile south of Ella Road. 11/11/47, 17.6; 3/5/48, 14.2; 11/11/48, 16.3; 3/21/49, 14.8; 12/1/49, 22.0.

14N 4E-19E1—Reference point—top of casing, 4 feet below ground in pit, elevation 52 feet, 0.2 mile east of Feather River Boulevard, 0.1 mile north of Broadway. 11/8/29, 8.0; 9/26/30, 8.7; 12/11/31, 8.6; 12/31/32, 8.6; 12/21/33, 8.9; 11/20/34, 9.1; 11/27/36, 9.1; 11/21/37, 11.1; 1/30/39, 6.6; 12/21/40, 8.1.

14N 4E-19L1—Reference point—top of casing, 0.6 foot above ground, elevation 18 feet, 0.1 mile east of Feather River Boulevard, 0.1 mile south of Broadway. 11/7/47, 20.6; 12/16/48, 20.7; 12/9/49, 21.8; 11/10/50, 23.6; 12/5/51, 21.2.

14N 4E-19P1—Reference point—top of casing, top of concrete floor, elevation 50.1 feet, 0.3 mile south of Broadway, 0.5 mile east of Feather River Boulevard. 11/17/47, 33.6; 3/9/48, 18.4; 11/10/48, 19.7; 3/23/49, 17.5; 12/2/49, 21.4; 3/29/50, 18.9; 11/6/50, 22.3; 3/30/51, 18.7; 11/16/51, 22.1; 4/1/52, 9.5.

14N 4E-20D1—Reference point—top of casing under pump, elevation 53 feet, 200 feet north of Broadway, 0.6 mile west of Arboga Road. 12/3/47, 24.9; 3/18/48, 23.3.

14N 4E-20E1—Reference point—pump base hole, elevation 54.3 feet, 150 feet north of Broadway, 1.0 mile east of Feather River Boulevard. 11/11/48, 20.9; 3/21/49, 18.2.

14N 4E-20M1—Reference point—bottom of pump mount, blocked up from concrete, elevation 52.2 feet, 50 feet south of Broadway, 0.95 mile east of Feather River Boulevard. 11/11/47, 22.4; 3/6/48, 20.0; 10/7/48, 22.8; 11/11/48, 21.5; 1/24/29, 20.6; 3/21/49, 19.7; 12/1/49, 23.0; 3/29/50, 20.9; 11/6/50, 23.1; 11/20/51, 23.3; 4/5/52, 17.4.

14N 4E-20M2—Reference point—hole in side of pump, elevation 52.8 feet, 400 feet south of Broadway, 1.0 mile east of Feather River Boulevard. 11/11/47, 18.7; 3/6/48, 20.0; 10/7/48, 21.7; 11/11/48, 19.5; 3/2/49, 16.9; 12/1/49, 21.2; 3/29/50, 18.5; 11/6/50, 22.1; 3/30/51, 18.0; 11/20/51, 21.7; 4/5/52, 16.1.

14N 4E-22F1—Reference point—hole in top of pump base, elevation 60 feet, 100 feet west of Forty Mile Road, 1.35 miles south of Slaughter House Road. 12/1/47, 22.6; 3/1/48, 21.3; 3/31/48, 20.8; 10/7/48, 25.6; 11/8/48, 24.0; 1/25/49, 23.0; 3/18/49, 21.5; 11/23/49, 27.7.

14N 4E-22F2—Reference point—hole in base of pump, elevation 58.4 feet, 200 feet west of Forty Mile Road, 1.2 miles south of Slaughter House Road. 12/2/47, 18.7; 3/17/48, 17.4.

14N 4E-22F3—Reference point—access pipe in concrete base, elevation 61.9 feet, 150 feet west of Forty Mile Road, 1.3 miles south of Slaughter House Road. 12/2/47, 23.6; 3/17/48, 22.2; 11/19/48, 24.9; 3/18/49, 21.9; 11/23/49, 27.0; 3/28/50, 25.6; 11/2/50, 30.1; 4/5/51, 28.9; 11/21/51, 32.4; 4/2/52, 25.5.

14N 4E-22M1—Reference point—top of casing, elevation 61.8 feet, 0.4 mile west of Forty Mile Road, 1.25 miles north of Plumas School. 12/1/47, 21.7; 3/1/48, 20.5; 10/7/48, 25.1; 11/8/48, 23.5; 3/25/49, 20.5; 11/23/49, 26.4; 3/28/50, 23.1; 11/3/50, 28.1; 12/3/51, 28.1; 4/1/52, 23.9.

14N 4E-22P1—Reference point—top of concrete curb around open pit well, elevation 64.9 feet, 50 feet west of Forty Mile Road, 1.2 miles north of Plumas School. 11/21/47, 26.9.

14N 4E-23A1—Reference point—top of casing, elevation 60 feet, 300 feet southwest of U. S. Highway 99E, 1.5 miles southeast of Slaughter House Road. 12/3/47, 31.7; 3/18/48, 30.2; 11/18/48, 33.8; 3/18/49, 32.2; 11/23/49, 38.2; 3/29/50, 36.5; 11/3/50, 40.4; 11/21/51, 43.4; 4/2/52, 41.0.

14N 4E-23B1—Reference point—top of casing, elevation 70 feet, 0.07 mile southwest of U. S. Highway 99E, 0.38 mile northwest of Virginia Road. 12/3/47, 30.7; 3/18/48, 29.5.

14N 4E-23G1—Reference point—top of pump base, elevation 70 feet, 0.70 mile west of U. S. Highway 99E, at a point 2.02 miles southeast of Slaughter House Road. 12/1/47, 30.9; 10/7/48, 33.2; 11/8/48, 32.9; 3/29/49, 30.9; 11/25/49, 37.2.

14N 4E-23Q1—Reference point—top of casing, elevation 72 feet, 1.98 miles south of Slaughter House Road, 1.05 miles east of Forty Mile Road. 11/21/47, 32.6; 3/3/48, 29.2.

14N 4E-23R1—Reference point—top of casing, elevation 67 feet, 1.98 miles south of Slaughter House Road, 1.48 miles east of Forty Mile Road. 11/21/47, 30.5; 3/31/47, 29.7; 11/11/48, 33.0; 3/29/49, 30.6; 11/25/49, 36.1.

14N 4E-24B1—Reference point—top of pump base, elevation 75 feet, 0.80 mile east of Virginia Road, 1 mile south of Ostrom Road. 3/18/49, 28.3.

14N 4E-24H1—Reference point—top of pump base, elevation 85 feet, 1.3 miles south of Ostrom Road, 0.14 mile west of Bradshaw Road. 11/18/48, 36.9; 3/18/49, 34.0; 11/23/49, 42.9; 3/27/50, 39.8; 11/2/50, 45.8; 4/5/51, 41.3; 11/30/51, 51.7; 4/3/52, 43.7.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet measured from reference point)

14N/4E-24M1—Reference point—top of casing, elevation 70 feet, 0.05 mile southwest of U. S. Highway 99E, 0.38 mile southeast of Virginia Road. 11/21/47, 22.5; 3/2/48, 28.7; 11/11/48, 31.1; 3/23/49, 28.3; 11/25/49, 34.5.

14N/4E-24P1—Reference point—top of pump base, elevation 70 feet. West side of U. S. Highway 99E, 0.68 mile southeast of Virginia Road. 11/21/47, 32.7; 3/2/48, 30.5; 11/9/48, 33.7; 1/25/49, 31.9; 3/23/49, 30.5; 5/25/49, 40.3; 7/1/49, 44.8; 11/25/49, 38.5; 3/28/50, 35.1; 11/3/50, 40.6; 4/4/51, 35.8; 12/6/51, 39.6; 4/2/52, 41.9.

14N/4E-25R1—Reference point—top of casing, elevation 74 feet, 0.53 mile northwest of Dairy Road, 0.67 mile southwest of U. S. Highway 99E. 12/2/47, 29.4; 3/2/48, 27.6; 10/7/48, 32.8; 11/11/48, 31.2; 3/29/49, 28.0; 11/23/49, 34.7.

14N/4E-26A1—Reference point—hole in base of pump, elevation 65 feet, 1.03 miles southeast of Virginia Road, 0.98 mile west of U. S. Highway 99E. 11/11/48, 33.2; 3/29/49, 30.2.

14N/4E-26C1—Reference point—top of casing, elevation 66 feet, 1.45 mile north of Levee Road, 0.95 mile east of Forty Mile Road. 12/1/47, 18.2; 3/3/48, 16.7; 11/11/48, 19.7; 3/29/49, 17.5; 11/25/49, 22.4; 3/29/50, 20.9; 11/8/50, 24.8; 4/4/51, 20.8; 5/5/51, 23.5; 4/2/52, 23.0.

14N/4E-27D1—Reference point—top of casing, elevation 60 feet, 1.20 miles north of Levee Road, 0.40 mile west of Forty Mile Road. 11/21/47, 24.8.

14N/4E-27L1—Reference point—pipe in base, elevation 64.1 feet, 2.60 miles south of Slaughter House Road, west side of Forty Mile Road. 12/1/47, 24.8; 3/1/48, 23.4; 3/29/48, 23.5; 10/7/48, 30.0; 11/8/48, 28.1; 1/25/49, 26.7; 3/25/49, 25.6; 11/23/49, 29.6; 3/28/50, 28.0; 11/3/50, 32.5; 11/30/51, 23.0; 4/1/52, 28.5.

14N/4E-27R1—Reference point—top of casing, elevation 60 feet, 2.85 miles south of Slaughter House Road, 0.52 mile east of Forty Mile Road. 12/2/47, 30.3; 3/1/48, 28.7; 11/8/48, 31.7; 3/25/49, 28.8; 11/23/49, 33.6.

14N/4E-28N1—Reference point—top of casing, elevation 49 feet, 2.05 miles south of Slaughter House Road, 1.50 miles west of Forty Mile Road. 11/8/29, 10.5; 9/26/30, 10.4; 12/11/31, 11.0; 12/5/32, 11.1; 12/21/33, 11.2; 11/20/34, 11.5; 11/27/36, 11.9; 11/24/37, 12.0; 11/30/39, 9.2; 12/21/40, 10.9; 11/7/47, 13.1; 12/16/48, 13.8; 12/9/49, 15.9; 11/10/50, 15.0; 12/5/51, 15.9.

14N/4E-28R1—Reference point—pipe in base of pump, elevation 60.2 feet, 0.55 mile north of Levee Road, 0.68 mile west of Forty Mile Road. 12/2/47, 25.2; 3/1/48, 24.1; 11/8/48, 25.6; 3/25/49, 23.6; 11/23/49, 27.4; 3/28/50, 25.6; 11/3/50, 29.1; 4/4/51, 21.7; 11/30/51, 34.1; 4/1/52, 24.6.

14N/4E-30E1—Reference point—hole in base of pump, elevation 48.6 feet, 0.11 mile east of Feather River Boulevard, 0.25 mile south of Anderson Road. 11/17/47, 23.5; 3/9/48, 19.3; 11/10/48, 20.3; 3/23/49, 18.1; 12/2/49, 21.8.

14N/4E-30F1—Reference point—top of casing, elevation 45 feet, 0.15 mile north of Country Club Road, 0.46 mile east of Feather River Boulevard. 11/17/47, 16.9; 3/9/48, 16.9; 11/10/48, 17.9.

14N/4E-30K1—Reference point—top of casing, elevation 45.0 feet, South side of Country Club Boulevard, 0.51 mile east of Feather River Boulevard. 11/17/47, 14.5; 3/8/48, 14.5; 5/8/48, 12.0; 11/10/48, 15.4; 1/29/49, 14.4; 3/23/49, 12.1; 6/1/49, 22.6; 6/29/49, 24.0; 7/28/49, 25.7; 8/26/49, 30.1; 3/29/50, 13.5; 11/6/50, 17.2; 3/30/51, 12.2; 11/16/51, 16.8; 4/1/52, 12.2.

14N/4E-31E1—Reference point—top of casing, elevation 38.5 feet, 0.06 mile east of Feather River Boulevard, 0.80 mile south of Country Club Road. 11/10/48, 11.9; 3/22/49, 8.9; 12/2/49, 11.8.

14N/4E-32L1—Reference point—top of casing, elevation 45 feet, 1.0 mile south of Country Club Avenue, 1.24 miles east of Feather River Boulevard. 11/17/47, 18.0; 3/9/48, 18.2; 11/10/48, 17.3; 3/29/49, 15.4; 12/2/49, 19.3.

14N/4E-33K1—Reference point—top of casing, elevation 51 feet, 1.50 mile west of Forty Mile Road, 0.55 mile north of Levee Road. 12/1/47, 19.7; 11/8/48, 20.6; 3/25/49, 18.0.

14N/4E-33M1—Reference point—top of casing, elevation 51 feet, 3.73 miles south of Slaughter House Road, 0.21 mile east of Western Pacific Railroad. 11/17/47, 14.3; 3/9/48, 13.1; 5/5/48, 9.1; 5/31/48, 9.1; 11/10/48, 13.9; 1/24/49, 13.8; 3/22/49, 10.8; 6/1/49, 10.8; 6/29/49, 12.8; 7/28/49, 14.2; 8/26/49, 15.8; 12/2/49, 15.3; 3/29/50, 9.7; 11/6/50, 14.7; 11/16/51, 13.7; 4/1/52, 5.5.

14N/4E-34C1—Reference point—top of concrete pit, elevation 63.4 feet, 3.05 miles south of Slaughter House Road, 0.05 mile west of Forty Mile Road. 12/1/47, 27.8; 3/1/48, 26.5; 5/5/48, 25.1; 6/3/48, 26.8; 6/24/48, 32.2 (operating); 7/8/48, 29.2 (operating).

14N/4E-35N1—Reference point—slot in base, elevation 62 feet. West side of Forty Mile Road, 0.60 mile northwest of Dairy Road. 11/28/47, 25.7; 3/1/48, 24.4; 3/21/48, 24.2; 3/29/48, 23.8; 5/5/48, 22.5; 5/13/48, 61.5 (operating); 11/8/48, 27.5; 1/26/49, 25.6; 3/25/49, 24.0; 11/23/49, 30.3; 3/28/50, 27.3; 11/6/50, 32.1; 4/4/51, 26.3; 11/30/51, 33.1; 4/1/52, 27.4.

14N/4E-36G1—Reference point—top of casing, elevation 70 feet, 0.20 mile northwest of U. S. Highway 99E. 12/2/47, 30.5; 3/2/48, 28.5; 3/29/48, 28.0; 10/7/48, 33.6; 11/11/48, 32.4; 1/25/49, 31.8; 3/25/49, 29.0; 11/23/49, 36.7; 3/28/50, 32.6; 11/8/50, 37.6; 4/4/51, 30.8; 12/3/51, 41.0.

14N/5E-5A1—Reference point—top of casing, elevation 90.2 feet, 400 feet south of Spenceville Road, 1.0 mile west of South Beale Road. 12/5/49, 39.1; 11/2/50, 46.9; 4/5/51, 41.9; 4/4/52, 41.5.

14N/5E-6B1—Reference point—top of 12-inch casing, elevation 78.5 feet, 150 feet south of Spenceville Road, 2.25 miles west of South Beale Road. 11/28/48, 26.0; 1/18/49, 25.2; 3/21/49, 24.9; 11/24/49, 32.4; 3/27/40, 30.3; 11/2/50, 37.6; 4/5/51, 32.8; 11/30/51, 37.6; 4/4/52, 34.6.

14N/5E-6D1—Reference point—top of 8-inch casing, elevation 76.4 feet, 600 feet south of Spenceville Road, 1.75 miles east of Virginia Road. 12/24/47, 22.4; 3/24/48, 22.3; 3/21/49, 23.7; 11/24/49, 33.7.

14N/5E-6D2—Reference point—top of 6-inch casing, elevation 73.6 feet, 800 feet south of Spenceville Road, 1.75 miles east of Virginia Road. 11/18/48, 23.9.

14N/5E-8A1—Reference point—top of 16-inch casing, elevation 90 feet, 0.40 mile northwest of South Beale Road at a point 0.70 mile northeast of Ostrom Road. 11/18/48, 24.7.

14N/5E-8D1—Reference point—top of casing, elevation 82 feet, 1.0 mile north of Ostrom Road, 1.0 mile east of Bradshaw Road. 3/18/49, 31.2.

14N/5E-8R1—Reference point—top of 14-inch casing, elevation 89.6 feet, 0.15 mile northeast of intersection of Ostrom Road and South Beale Road. 11/18/48, 30.5; 3/18/49, 30.1; 11/23/49, 39.7; 4/5/52, 39.2.

14N/5E-15D1—Reference point—top of casing, elevation 111 feet, 500 feet east of Ostrom Road, 0.25 mile south of Ostrom Road. 12/9/49, 42.3; 11/2/50, 46.4; 12/8/51, 47.3.

14N/5E-16C1—Reference point—top of brick casing, elevation 99 feet, 100 feet south of Ostrom Road, 100 feet west of Jasper Lane. 11/22/29, 26.3; 9/8/30, 25.5; 12/11/31, 27.5; 12/10/32, 26.7; 12/21/33, 27.6; 11/20/34, 27.8; 11/23/36, 26.4; 11/22/37, 25.6; 1/27/39, 25.5; 1/13/41, 30.0; 11/7/47, 30.0; 12/23/47, 29.7; 3/24/48, 30.0; 10/7/48, 31.2; 11/18/48, 31.2; 12/16/48, 31.9; 1/18/49, 31.7; 3/18/49, 31.2.

14N/5E-16C2—Reference point—top of casing, elevation 100 feet, 40 feet west of Jasper Lane, 40 feet south of Ostrom Road. 12/5/51, 41.9.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet measured from reference point)

14N 5E-17B1—Reference point—top of 12-inch casing, elevation 85.7 feet, 100 feet south of Ostrom Road, 0.30 mile west of South Beale Road. 12/23/47, 28.0; 3/24/48, 24.7; 10/7/48, 31.3; 11/18/48, 30.7; 3/18/49, 29.8; 11/23/49, 40.7; 4/3/52, 40.1.

14N 5E-17B2—Reference point—top of 16-inch casing, elevation 90.4 feet, Northwest side of South Beale Road, 1,000 feet southwest of Ostrom Road intersection. 11/19/48, 34.6; 3/18/49, 33.4; 11/23/49, 42.6.

14N 5E-17D1—Reference point—top of 12 inch casing, elevation 86.8 feet, 600 feet south of Ostrom Road, 0.80 mile west of South Beale Road. 11/18/48, 37.1; 1/18/49, 36.0; 3/18/49, 35.2; 11/23/49, 48.3.

14N 5E-18A1—Reference point—top of casing, elevation 87.0 feet, 750 feet south of Ostrom Road, 0.80 mile west of South Beale Road. 12/23/47, 33.7; 3/24/48, 32.9; 10/7/48, 39.0; 11/18/48, 37.5; 1/18/49, 36.4; 3/18/49, 35.6; 11/23/49, 45.1; 3/27/50, 41.8; 11/2/50, 50.1; 4/5/51, 44.4; 11/23/51, 50.5; 1/3/52, 45.8.

14N 5E-18B1—Reference point—top of 12-inch casing, elevation 78.1 feet, South side of Ostrom Road, 0.35 mile east of Bradshaw Road. 12/23/47, 25.7; 3/2/48, 28.5; 10/7/48, 33.5; 11/18/48, 31.7; 3/18/49, 28.0; 5/25/49, 36.6; 6/29/49, 40.4; 8/1/49, 42.7; 8/30/49, 51.2; 11/23/49, 39.7.

14N 5E-21R1—Reference point—top of casing, elevation 93 feet, 200 feet northeast of Jasper Lane at a point 1.9 miles south of Ostrom Road. 11/25/47, 21.5.

14N 5E-26P1—Reference point—top of concrete crib, elevation 119.7 feet, 0.25 mile southeast of Wheatland-Spenceville Road at a point 0.85 mile northeast of Jasper Lane. 11/25/47, 28.5; 3/6/48, 28.2; 11/9/48, 28.8; 3/23/49, 27.5; 12/9/49, 31.0; 3/29/50, 29.9; 11/8/50, 33.7; 4/5/51, 29.9.

14N 5E-27K1—Reference point—top of concrete crib, elevation 84.7 feet, 0.25 mile northeast of Jasper Lane at a point 0.85 mile northwest of Wheatland-Spenceville Road. 11/25/47, 12.0; 3/6/48, 11.8; 11/9/48, 13.2; 3/23/49, 11.3; 6/29/49, 12.7; 7/28/49, 13.3; 8/30/49, 13.9; 11/28/49, 16.8.

14N 5E-27L1—Reference point—top of 14 inch casing at bottom of pit, elevation 81.2 feet, 900 feet northeast of Jasper Lane at a point 1.1 miles northwest of Wheatland-Spenceville Road. 27L2 replaces 27L1 after 4/4/51. 11/25/47, 6.7; 3/6/48, 6.3; 11/9/48, 7.9; 3/23/49, 6.0; 11/28/49, 9.1; 3/29/50, 7.1; 11/8/50, 12.2; 4/4/51, 5.4.

14N 5E-27L2—Reference point—top of casing, elevation 92 feet, 900 feet northeast of Jasper Lane at a point 1.1 miles northwest of Wheatland-Spenceville Road. 11/21/51, 32.2; 4/2/52, 27.5.

14N 5E-28M1—Reference point—top of casing pit, elevation 86.5 feet, 1.0 mile southwest of Jasper Lane at a point 1.15 miles northwest of Wheatland-Spenceville Road. 11/26/47, 25.7; 3/6/48, 24.6; 11/9/48, 26.9; 3/29/49, 24.5; 11/28/49, 30.4; 3/29/50, 27.7; 11/28/49, 30.4; 3/29/50, 27.7; 11/8/50, 34.0; 1/1/51, 29.0; 11/21/51, 31.2; 4/2/52, 28.2.

14N 5E-30J1—Reference point—top of 11-inch casing, elevation 81.8 feet, 0.30 mile northeast of U. S. Highway 99E at a point 1.8 miles northwest of Wheatland Road. 11/25/47, 38.8; 11/9/48, 32.8; 3/29/49, 29.1; 12/8/49, 36.0.

14N 5E-30Q1—Reference point—top of 16-inch casing, elevation 76.6 feet, 100 feet southwest of Oakley Lane, 0.10 miles northwest of Dairy Road. 11/24/47, 30.4; 3/5/48, 28.6; 3/29/48, 27.9; 5/8/48, 27.0; 11/11/48, 32.5; 1/25/49, 31.0; 3/23/49, 29.5; 11/23/49, 35.9; 3/28/50, 35.7; 11/8/50; 39.5; 4/4/51, 34.5; 12/6/51, 39.0; 1/2/52, 36.1.

14N 5E-31B1—Reference point—hole in casing, elevation 76.8 feet, 150 feet northwest of Dairy Road, 500 feet southwest of Oakley Lane. 11/22/47, 28.1; 3/5/48, 27.1; 11/11/48, 30.2; 3/25/49, 26.8; 11/25/49, 33.6.

14N 5E-31J1—Reference point—top of 8-inch casing at bottom of pit, elevation 59.8 feet, 100 feet southwest of Oakley Lane, 0.45 mile southeast of Dairy Road. 11/22/47, 11.2; 3/5/48, 9.5; 11/11/48, 13.1; 3/25/49, 9.3; 11/28/49, 16.1.

14N 5E-32F1—Reference point—top of 14-inch casing, elevation 71.0 feet, Southwest of U. S. Highway 99E, 0.35 mile southeast of Dairy Road. 11/22/47, 17.1; 3/5/48, 16.6; 3/29/48, 15.6; 11/11/48, 19.4; 1/26/49, 18.0; 3/24/49, 16.0; 11/23/49, 22.5.

14N 5E-32M1—Reference point—top of 12-inch casing, elevation 67.2 feet, 0.25 mile northeast of Oakley Lane, 0.60 mile southeast of Dairy Road. 11/22/47, 14.7; 3/5/48, 13.6; 11/11/48, 16.2; 3/23/49, 12.5; 11/28/49, 19.7.

14N 5E-32N1—Reference point—top of casing at bottom of pit, elevation 63.2 feet, Southwest side of Oakley Lane, 0.70 miles southeast of Dairy Road. 11/20/47, 11.7; 3/5/48, 10.7; 11/11/48, 13.3; 3/25/49, 9.3; 11/23/49, 17.2; 3/29/50, 12.7; 11/8/50, 18.5; 4/4/51, 9.9; 12/3/51, 17.6; 4/2/52, 8.5.

14N 5E-32R1—Reference point—top of concrete base, elevation 73.8 feet, 400 feet southwest of U. S. Highway 99E at a point 0.55 mile northwest of Wheatland Road. 12/24/47, 16.9; 3/5/48, 15.7; 11/11/48, 17.5; 3/30/49, 15.0; 5/3/49, 16.9; 6/2/49, 19.8; 7/2/49, 21.1; 8/31/49, 24.0; 11/28/49, 20.3.

14N 5E-32R2—Reference point—top of 14-inch casing, elevation 74.8 feet, 100 feet southwest of U. S. Highway 99E, 0.55 mile northwest of Wheatland Road. 11/24/47, 17.3; 3/5/48, 16.2; 11/11/48, 18.5; 3/30/49, 15.2; 6/2/49, 24.9; 7/2/49, 27.6; 8/31/49, 28.0; 11/24/49, 21.1; 3/29/50, 18.0; 11/8/50, 23.1; 4/4/51, 15.1; 11/21/51, 23.2; 4/2/52, 13.0.

14N 5E-33K1—Reference point—bottom of slot in casing, elevation 78.3 feet, 0.40 mile northwest of Wheatland-Spenceville Road at a point 0.45 mile northeast of U. S. Highway 99E. 11/25/47, 14.0; 3/6/48, 13.3; 11/9/48, 15.5; 3/23/49, 11.4; 11/28/49, 17.6; 3/29/50, 13.9; 11/8/50, 19.5; 11/21/51, 19.5; 4/2/52, 10.4.

14N 5E-33M1—Reference point—top of casing at bottom of pit, elevation 65.8 feet, 0.15 mile northeast of U. S. Highway 99E at a point 0.55 mile northwest of Wheatland Road. 11/25/47, 6.0; 3/6/48, 5.6; 12/6/48, 6.8.

14N 5E-33Q1—Reference point—top of concrete well curb, elevation 86 feet, Northwest of the northeast corner of town of Wheatland, 1,000 feet north of school house east side. 11/22/29, 22.2; 9/18/30, 23.6; 12/11/31, 23.3; 12/10/32, 22.4; 12/21/33, 22.7; 11/20/34, 23.5; 11/23/36, 23.4; 11/22/37, 22.0; 1/27/39, 20.8; 1/2/40, 20.4; 11/7/47, 27.0; 12/16/48, 26.3; 12/9/49, 29.0; 11/8/50, 31.3; 12/5/51, 28.8.

14N 5E-34F1—Reference point—top of casing, elevation 90.2 feet, 500 feet northwest of Wheatland-Spenceville Road, 0.25 mile southwest of Jasper Lane. 11/25/47, 19.0; 3/6/48, 18.1; 11/9/48, 20.2; 3/23/49, 17.4; 11/28/49, 22.5.

14N 5E-34H1—Reference point—base of pump, elevation 99.7 feet, 600 feet southeast of Wheatland-Spenceville Road, 1,000 feet northeast of Jasper Lane. 11/25/47, 20.6; 3/6/48, 20.4; 11/9/48, 21.2; 3/23/49, 19.8; 11/28/49, 23.4.

15N 1E-12A1—Reference point—hole in pump base, elevation 150 feet, 1.05 miles north of South Butte Road, 2.1 miles west of Irwin Avenue. 12/2/48, 83.0 (operating).

15N 1E-12H1—Reference point—hole in pump base, elevation 80 feet, 0.75 mile north of South Butte Road, 2.1 miles west of Irwin Avenue. 12/2/48, 13.2.

15N 1E-3A1—Reference point—hole in pump base, elevation 57 feet, 0.1 mile north of South Butte Road, 2.1 miles west of Irwin Avenue. 12/22/49, 25.1; 3/4/48, 21.8; 3/29/49, 19.4; 11/15/49, 24.0; 3/23/50, 13.3; 11/2/50, 27.2; 4/3/52, 27.1.

15N 1E-13B1—Reference point—hole in cement pipe base, elevation 55 feet, 0.15 mile north of South Butte Road, 2.3 miles west of Irwin Avenue. 12/2/48, 31.8; 11/2/50, 33.2; 3/26/51, 63.8 (operating).

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Divisian of Water Resources
(Depths to woter in feet meosured from reference point)

15N/1E-14F1—Reference point—bottom of 2" x 4" board under pump, elevation 54 feet. South side of South Butte Road, 0.3 mile east of Sutter Bypass east levee. 12/22/47, 18.5; 3/4/48, 18.3; 5/4/48, 15.5; 6/2/48, 15.8; 7/3/48, 16.6; 8/3/48, 17.7; 9/1/48, 17.9; 12/2/48, 18.9; 12/8/49, 19.0; 3/23/50, 10.9; 11/2/50, 19.6.

15N/1E-14F2—Reference point—top of concrete pit, elevation 47 feet, 0.05 mile south of South Butte Road, 0.2 mile east of Sutter Bypass east levee. 11/27/29, 16.8; 10/6/30, 15.0; 12/16/31, 14.8; 12/8/32, 15.0; 12/15/33, 15.1; 11/2/34, 14.8; 11/23/34, 14.3; 11/27/36, 14.4; 11/15/37, 15.6; 1/25/39, 14.8; 1/11/41, 10.7; 11/4/47, 15.4; 12/13/48, 15.7; 12/8/49, 16.1; 11/10/50, 16.8; 12/7/51, 14.3.

15N/2E-1A1—Reference point—top of concrete pit, elevation 58.0 feet, 100 feet south of Nuestro Road, 0.15 mile west of Township Road. 12/19/47, 11.9; 3/3/48, 12.7; 12/1/48, 12.5; 1/20/49, 12.2; 3/16/49, 12.2; 6/28/49, 10.2; 7/27/49, 9.4; 11/11/49, 13.2; 3/23/50, 13.2; 11/6/50, 13.5; 4/3/51, 9.7; 11/14/51, 12.1; 4/3/52, 6.5.

15N/2E-1C1—Reference point—top of casing, elevation 58.2 feet, 0.1 mile south of Nuestro Road, 0.65 mile west of Township Road. 12/19/47, 10.3; 12/2/48, 11.7; 11/11/49, 11.5.

15N/2E-1H1—Reference point—top of concrete pit, elevation 57.7 feet, 150 feet west of Township Road, 0.35 mile south of Nuestro Road. 12/22/47, 13.3; 3/3/48, 13.6; 12/1/48, 14.0; 3/16/49, 13.7; 11/11/49, 14.6.

15N/2E-2C1—Reference point—top of wooden platform under pump, elevation 60.4 feet, 50 feet west of East Butte Road, 0.15 mile north of Nuestro Road. 12/19/47, 11.8; 3/3/48, 11.8; 12/2/48, 9.5; 3/16/49, 8.0; 11/10/49, 6.5; 3/22/50, 9.4; 11/2/50, 6.8; 4/4/51, 8.6; 11/14/51, 8.1; 4/3/52, 6.3.

15N/2E-2H1—Reference point—top of casing, elevation 57.6 feet, 0.3 mile south of Nuestro Road, 1.1 miles west of Township Road. 12/19/47, 10.4; 3/3/48, 11.3; 12/2/48, 10.0; 3/16/49, 9.0; 11/11/49, 9.2; 3/23/50, 10.1; 11/2/50, 9.1; 4/4/51, 9.7; 11/14/51, 9.0; 4/3/52, 7.9.

15N/2E-3K1—Reference point—top of casing, elevation 57 feet, 0.1 mile east of Mallott Road, 0.8 mile north of Butte House Road. 12/22/47, 10.7; 3/4/48, 11.8; 12/2/48, 10.0; 11/16/49, 9.5.

15N/2E-4Q1—Reference point—top of casing, elevation 86 feet, 0.15 mile east of Acacia Avenue, 0.3 mile north of Butte House Road. 12/22/47, 35.7; 3/4/48, 36.2; 12/2/48, 35.6; 3/29/49, 36.0; 11/16/49, 36.6.

15N/2E-4R1—Reference point—base of pump, elevation 74 feet, 0.3 mile east of Acacia Avenue, 0.35 mile north of Butte House Road. 12/22/47, 34.2; 12/2/48, 35.0; 11/16/49, 37.0; 3/23/50, 36.0; 11/2/50, 38.0; 4/5/51, 34.0; 11/15/51, 37.0; 4/3/52, 31.0.

15N/2E-8J1—Reference point—hole in pump base, elevation 75 feet, 0.2 mile west of Irwin Avenue, 0.45 mile north of South Butte Road. 5/4/48, 33.6; 12/2/48, 34.7; 12/8/49, 34.8; 3/23/50, 34.2; 11/15/51, 35.8; 4/3/52, 34.7.

15N/2E-8Q1—Reference point—hole in pump base, elevation 62 feet, 250 feet north of South Butte Road, 0.25 mile west of Irwin Avenue. 12/22/47, 29.4; 12/2/48, 29.3; 3/29/49, 27.8; 11/15/49, 29.6; 3/23/50, 27.7; 11/2/50, 30.6; 4/5/51, 30.6; 11/15/51, 30.3; 4/3/52, 24.5.

15N/2E-10F1—Reference point—top of casing, elevation 56 feet, 0.1 mile south of Butte House Road, 0.2 mile west of Mallott Road. 12/22/47, 21.2; 3/5/48, 19.1; 3/29/49, 20.0; 11/16/49, 20.5; 3/23/50, 21.4; 11/2/50, 20.5; 3/26/51, 20.1; 11/15/51, 20.1; 4/2/52, 15.5.

15N/2E-11C1—Reference point—top of casing, elevation 53.6 feet, 200 feet north of Butte House Road, 0.15 mile west of East Butte Road. 12/22/47, 9.0; 3/3/48, 10.6; 12/2/48, 7.7; 3/16/49, 9.1; 11/10/49, 7.4; 3/23/50, 8.2; 11/2/50, 7.6; 4/4/51, 9.1; 11/14/51, 6.9; 4/3/52, 7.2.

15N/2E-11N1—Reference point—top of casing, elevation 50 feet, 50 feet west of Humphrey Road, 0.55 mile south of Butte House Road. 12/22/47, 9.9; 3/5/48, 10.8; 9/27/48, 5.1; 11/17/48, 8.9; 3/28/49, 9.1.

15N/2E-12A1—Reference point—top of casing, elevation 55.8 feet, 100 feet southwest of intersection of Township and Pease Roads. 12/21/47, 5.8; 3/3/48, 16.8; 12/1/48, 15.0; 3/16/49, 13.6; 11/11/49, 14.8.

15N/2E-12K1—Reference point—base of pump, elevation 53.8 feet, 100 feet north of Butte House Road, 0.45 mile west of Township Road. 12/22/47, 13.2; 3/3/48, 12.4; 12/2/48, 11.9; 1/20/49, 13.3; 3/17/49, 11.5; 11/10/49, 11.3; 3/23/50, 11.1; 11/1/50, 11.3; 4/4/51, 9.2; 11/14/51, 10.0; 4/3/52, 5.2.

15N/2E-12R1—Reference point—top of casing, elevation 52 feet, 0.1 mile west of Township Road, 0.3 mile south of Butte House Road. 12/19/47, 6.2; 3/24/48, 7.2; 11/18/48, 7.0; 3/28/49, 6.0; 11/23/49, 6.4.

15N/2E-13E1—Reference point—top of wooden planks under pump, elevation 50 feet, 0.3 mile south of Fortuna Road, 0.9 mile west of Township Road. 12/22/47, 7.8; 3/5/48, 9.5; 11/18/48, 11.3; 3/28/49, 7.5; 11/23/49, 9.4.

15N/2E-13J2—Reference point—top of casing at bottom of pit, elevation 46 feet, 250 feet west of Township Road, 0.4 mile north of State Highway 20. 12/19/47, 8.1; 3/5/48, 9.1; 9/27/48, 9.3; 11/18/48, 9.0; 3/28/49, 8.1; 5/26/49, 8.0; 6/28/49, 10.7; 7/27/49, 11.3; 8/26/49, 10.5; 11/23/49, 9.8; 3/23/50, 8.0; 3/27/51, 6.8; 11/14/51, 7.9; 4/1/52, 4.4.

15N/2E-14A1—Reference point—top of brick casing, elevation 51.7 feet, 200 feet south of Fortuna Road, 1 mile west of Township Road. 12/22/47, 10.8; 3/3/48, 10.2; 12/2/48, 10.1; 3/16/49, 9.2; 11/11/49, 9.3; 3/23/50, 9.7; 11/2/50, 9.6; 4/4/51, 7.4; 11/14/51, 7.9; 4/3/52, 5.8.

15N/2E-15C1—Reference point—top of casing at bottom of pit, elevation 39 feet, 200 feet south of South Butte Road, 0.85 mile east of Acacia Road. 12/23/47, 4.0; 3/4/48, 4.5; 12/2/48, 3.3; 12/8/49, 2.4.

15N/2E-15D1—Reference point—top of casing in pit, elevation 44 feet, South side of South Butte Road, 0.5 mile east of Acacia Avenue. 12/23/47, 5.4; 3/4/48, 6.2; 12/2/48, 6.2; 3/29/49, 6.1; 11/16/49, 4.4; 3/23/50, 4.7; 11/2/50, 4.1; 4/1/51, 4.3; 11/15/51, 3.6; 4/2/52, 1.1.

15N/2E-15R1—Reference point—top of casing, elevation 48 feet, 150 feet west of Humphrey Road, 0.1 mile north of State Highway 20. 12/22/47, 9.3; 3/5/48, 10.4; 9/27/48, 3.8; 11/17/48, 5.9; 3/28/49, 4.5; 11/23/49, 5.7; 3/24/50, 5.5; 10/31/50, 4.7; 3/26/51, 3.1; 11/15/51, 4.1; 4/1/52, 2.6.

15N/2E-16E1—Reference point—slot in casing, elevation 56 feet, 200 feet west of Third Avenue, 0.25 mile south of South Butte Road. 12/22/47, 21.4; 3/4/48, 22.2; 12/2/48, 21.15; 3/29/49, 20.7; 11/16/49, 20.0.

15N/2E-17E1—Reference point—slot in casing, elevation 46 feet, 0.3 mile south of South Butte Road, 0.7 mile west of Irwin Avenue. 12/22/47, 14.1; 3/4/48, 14.1; 12/2/48, 14.2; 3/29/49, 12.1; 11/15/49, 14.9; 3/23/50, 12.9; 11/2/50, 15.8; 3/26/51, 35.2 (operating); 11/15/51, 21.0; 4/3/52, 8.9.

15N/2E-21C1—Reference point—top of casing in pit, elevation 38 feet, South west corner of Acacia Road and State Highway 20. 12/22/47, 1.6; 3/4/48, 2.6; 12/2/48, 1.8; 3/29/49, 0.8; 11/16/49, 0.3; 3/24/50, 0.5; 11/2/50, —0.7; 3/26/51, —1.0; 11/15/51, 0.0; 4/2/52, —2.7.

15N/2E-22B1—Reference point—top of casing, elevation 46 feet, 0.2 mile south of State Highway 20, 0.3 mile west of Humphrey Road. 12/23/47, 10.2; 3/4/48, 11.2; 12/2/48, 9.5; 3/24/49, 4.9; 11/16/49, 8.9; 3/23/50, 9.5; 11/2/50, 9.1; 3/26/51, 8.5; 11/15/51, 8.3; 4/2/52, 6.8.

15N/2E-22R1—Reference point—top of casing, elevation 45 feet, 200 feet north of Franklin Road, 0.15 mile west of Humphrey Road. 12/22/47, 8.9; 3/5/48, 9.5; 9/27/48, 6.0; 11/17/48, 8.0; 3/28/49, 4.1.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet measured from reference point)

15N 2E-23B1—Reference point—top of casing, elevation 45 feet, 100 feet south of State Highway 20, 0.75 mile east of Humphrey Road. 12/22/47, 6.8; 3/5/48, 7.8; 11/17/48, 6.2; 3/28/49, 5.9; 11/23/49, 6.4; 3/24/50, 6.7; 10/31/50, 7.1; 3/26/51, 5.0; 11/15/51, 5.2; 4/1/52, 2.8.

15N 2E-24B1—Reference point—hole in pump base, elevation 51 feet, 300 feet south of State Highway 20, 0.3 mile west of Township Road. 12/22/47, 13.7; 3/5/48, 14.4; 9/27/48, 12.4; 11/17/48, 13.5; 3/28/49, 13.5; 11/23/49, 8.1; 3/24/50, 13.8; 10/31/50, 14.6; 3/27/51, 11.0; 11/11/51, 12.9; 4/1/52, 7.0.

15N 2E-24N1—Reference point—top of concrete foundation, elevation 47 feet, 0.1 mile north of Franklin Road, 0.8 mile west of Township Road. 11/27/29, 14.0; 10/6/30, 13.0; 12/15/31, 14.0; 11/30/32, 13.0; 12/14/33, 13.9; 11/10/34, 13.6; 11/28/36, 11.2; 11/24/37, 10.9; 1/25/39, 10.3; 1/11/41, 5.6; 11/4/47, 9.4; 12/14/48, 10.9; 12/8/49, 10.4; 11/10/50, 10.4; 12/7/51, 6.6.

15N 2E-25A1—Reference point—top of concrete pit, elevation 48 feet, 0.05 mile south of Franklin Road, 0.2 mile west of Township Road. 12/22/47, 13.4; 3/5/48, 14.6; 11/17/48, 13.5; 3/28/49, 12.2; 11/23/49, 13.5; 3/24/50, 13.1; 10/31/50, 13.4; 3/27/51, 10.7; 11/14/51, 12.0; 4/1/52, 6.9.

15N 2E-25N1—Reference point—top of casing, elevation 49 feet, 0.1 mile north of Lincoln Road, 0.85 mile west of Township Road. 12/22/47, 11.8; 3/5/48, 13.0; 11/17/48, 11.1; 3/28/49, 10.6; 11/23/49, 10.8.

15N 2E-26B1—Reference point—top of concrete pipe casing, elevation 46 feet, 50 feet south of Franklin Road, 0.6 mile east of Humphrey Road. 12/22/47, 7.3; 3/5/48, 8.2; 9/27/48, 3.0; 11/17/48, 6.0; 3/28/49, 5.5; 11/23/49, 6.4; 3/24/50, 6.9; 10/31/50, 5.6; 3/27/51, 5.3; 11/15/51, 5.2; 4/1/52, 4.1.

15N 2E-26E1—Reference point—top of wooden box casing, elevation 42 feet, 250 feet east of Humphrey Road, 0.45 mile south of Franklin Road. 12/22/47, 9.8; 3/5/48, 9.8; 11/17/48, 8.2; 3/28/49, 6.6; 11/23/49, 7.0; 3/24/50, 8.1; well destroyed.

15N 2E-28D1—Reference point—top of casing, elevation 41 feet, 500 feet south of Franklin Road, 0.1 mile west of Wadsworth Canal west levee. 12/22/47, 7.1; 3/4/48, 8.2; 12/2/48, 7.0; 3/29/49, 5.5; 11/16/49, 5.9; 3/23/50, 7.7.

15N 2E-28D2—Reference point—top of casing in pit, elevation 38 feet, 500 feet south of Franklin Road, 0.2 mile west of Wadsworth Canal west levee. 11/2/50, 2.5; 3/26/51, 11.6 (operating); 11/15/51, 2.4; 4/3/52, —0.8.

15N 2E-34D1—Reference point—top of casing, elevation 41 feet, Southeast of intersection of Lincoln and Clements roads. 12/22/47, 7.5; 3/4/48, 8.1; 12/2/48, 7.0; 11/15/49, 5.1.

15N 2E-35B1—Reference point—top of casing in pit, elevation 35 feet, 0.1 mile south of Lincoln Road, 1.4 miles west of Township Road. 12/22/47, 1.6; 3/5/48, 2.6; 10/4/48, 0.5; 11/17/48, 1.5; 3/28/49, —0.6.

15N 2E-35D1—Reference point—hole in pump base, elevation 42 feet, 0.1 mile south of Lincoln Road, 1.8 miles west of Township Road. 12/23/47, 8.7; 3/6/48, 9.5; 11/17/48, 8.1; 3/28/49, 6.2; 11/23/49, 8.3; 3/24/50, 6.8; 11/1/50, 7.2; 3/27/51, 6.8; 11/11/51, 6.2; 4/1/52, 1.7.

15N 2E-35Q1—Reference point—top of casing, elevation 41.6 feet, 0.1 mile north of Bogue Road, 1.3 miles west of Township Road. 12/22/47, 5.0; 3/5/48, 6.1; 10/4/48, 4.7; 11/17/48, 4.4; 3/29/49, 3.0; 11/25/49, 4.1; 3/24/50, 4.1; 11/1/50, 3.3; 3/27/51, 2.9; 11/14/51, 2.5.

15N 2E-36A1—Reference point—top of casing, elevation 46 feet, 100 feet south of Lincoln Road, 0.1 mile west of Township Road. 12/22/47, 12.3; 3/5/48, 13.3; 10/4/48, 10.6; 11/12/48, 11.6; 3/28/49, 11.6; 6/28/49, 6.7; 7/27/49, 7.4; 8/25/49, 7.9; 11/23/49, 11.2; 3/24/50, 11.3; 11/1/50, 10.9; 3/27/51, 9.4; 11/11/51, 10.2; 4/2/52, 6.3.

15N 2E-36H1—Reference point—top of plank in pit, elevation 40 feet, 0.15 mile west of Township Road, 0.45 mile south of Lincoln Road. 12/22/47, 6.3; 3/5/47, 7.5; 11/17/48, 4.1; 3/29/49, 5.0.

15N 2E-36P1—Reference point—top of casing, elevation 43.7 feet, 0.15 mile north of Bogue Road, 0.65 mile west of Township Road. 12/22/47, 7.6; 3/5/48, 8.9; 11/17/48, 6.0; 3/29/49, 3.6; 11/25/49, 5.8; 3/24/50, 6.8.

15N 3E-1C1—Reference point—top of 16-inch casing, elevation 63 feet, 0.3 mile east of State Highway 24, 1.0 mile south of Ellis Road. 11/6/47, 14.5; 3/17/48, 14.0; 11/30/48, 14.9; 1/26/49, 14.2; 3/17/49, 13.0; 11/17/49, 15.7; 3/21/50, 13.1; 11/6/50, 15.9; 3/29/51, 9.9; 11/27/51, 14.6; 4/6/52, 7.5.

15N 3E-1D1—Reference point—hole in pump base, elevation 64 feet, 0.1 mile east of State Highway 24, 0.75 mile south of Ellis Road. 11/6/47, 19.5; 3/20/48, 16.1; 11/30/48, 17.0; 3/17/49, 15.0; 11/16/49, 18.8.

15N 3E-2A1—Reference point—top of 16-inch casing, elevation 64 feet, 0.3 mile west of State Highway 24, 0.85 mile south of Ellis Road. 11/6/47, 25.1; 3/20/48, 18.9; 11/30/48, 21.6; 11/16/49, 22.3; 3/31/50, 16.3; 11/6/50, 22.1.

15N 3E-2A2—Reference point—top of 14-inch casing, elevation 63 feet, 0.25 mile west of State Highway 24, 1.05 miles south of Ellis Road. 11/6/47, 20.4; 11/30/48, 14.7; 3/17/49, 16.9; 11/17/49, 19.0.

15N 3E-2A3—Reference point—hole in base of pump, elevation 65 feet, 0.05 mile west of State Highway 24, 0.5 mile south of Ellis Road. 11/6/47, 18.4; 3/20/48, 18.2; 12/2/48, 17.7; 3/17/49, 15.5; 11/16/49, 19.8.

15N 3E-2B2—Reference point—hole in base of pump, elevation 64 feet, 0.35 mile west of State Highway 24, 0.75 mile south of Ellis Road. 11/6/47, 21.2; 11/30/48, 17.2; 3/17/49, 16.2; 11/16/49, 22.0; 3/29/51, 12.9.

15N 3E-2C1—Reference point—hole in base of pump, elevation 65 feet, 0.85 mile west of State Highway 24, 0.9 mile south of Ellis Road. 11/6/47, 24.5; 3/20/48, 23.5; 11/30/48, 23.3; 3/17/49, 20.4; 11/17/49, 25.3; 3/21/50, 19.2; 11/6/50, 24.3; 3/29/51, 15.1; 11/16/51, 23.5; 4/6/52, 10.2.

15N 3E-2H1—Reference point—bottom of pump base, elevation 63 feet, 0.3 mile west of State Highway 24, 1.25 miles south of Ellis Road. 11/6/47, 20.6; 3/17/48, 19.0; 5/7/48, 17.3; 11/30/48, 19.6; 3/17/49, 17.8; 11/17/49, 21.3.

15N 3E-2J1—Reference point—top of 16-inch casing, elevation 63 feet, 0.1 mile west of State Highway 24, 1.6 miles south of Ellis Road. 11/6/47, 17.8; 3/17/48, 16.8; 5/7/48, 14.8; 11/30/48, 17.4; 1/26/49, 16.7; 3/17/49, 15.5; 11/17/49, 18.4.

15N 3E-3D2—Reference point—top of casing, elevation 63.7 feet, 250 feet south of Eager Road, 0.1 mile west of U.S. Highway 99E. 11/4/47, 25.8.

15N 3E-3G1—Reference point—hole in base of pump, elevation 62 feet, 0.2 mile south of Rednall Road, 0.3 mile east of U.S. Highway 99E. 11/5/47, 28.6; 3/17/48, 28.1; 5/12/48, 23.6; 11/29/48, 28.5; 3/17/49, 25.7; 11/14/49, 30.6; 3/22/50, 24.9; 11/6/50, 29.6; 4/3/51, 21.2; 11/14/51, 27.7; 4/3/52, 19.1.

15N 3E-4C1—Reference point—top of casing, elevation 60.9 feet, 0.20 mile south of Eager Road, 0.65 mile west of Onstott Road. 12/19/47, 23.2; 3/2/48, 27.5; 12/1/48, 22.7; 3/17/49, 21.2; 11/11/49, 25.8; 4/3/51, 18.4.

15N 3E-4C2—Reference point—hole in pump base, elevation 61.5 feet, 0.25 mile south of Eager Road, 0.50 mile west of Onstott Road. 5/4/48, 22.9; 6/3/48, 22.0; 9/1/48, 30.3; 9/30/48, 27.2; 11/29/48, 23.7; 1/20/49, 23.2; 3/17/49, 22.5; 11/11/49, 27.1; 3/22/50, 23.7; 11/1/50, 27.5; 11/14/51, 23.7; 4/3/52, 11.9.

15N 3E-4H1—Reference point—top of concrete base, bottom of pit, elevation 47.2 feet, 0.1 mile west of Onstott Road, 0.6 mile south of Eager Road. 11/4/47, 17.9; 11/20/48, 15.5; 3/17/49, 12.4; 11/14/49, 16.0.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet measured from reference point)

15N/3E-4J1—Reference point—top of casing, bottom of pit, elevation 47.7 feet, 0.15 mile west of Onstott Road, 0.85 mile south of Eager Road. 11/4/47, 17.6; 11/29/48, 16.0; 3/17/49, 13.0; 11/14/49, 18.4; 11/14/50, 23.0.

15N/3E-4N1—Reference point—top of casing, elevation 59.4 feet, 0.1 mile north of Pease Road, 0.5 mile east of Terra Buena Road. 12/21/47, 27.1; 3/24/48, 27.1; 12/1/48, 27.6; 3/16/49, 26.5; 5/26/49, 27.0; 6/30/49, 34.0; 11/11/49, 29.6; 3/23/50, 25.9; 11/6/50, 30.7; 4/4/51, 22.6; 11/14/51, 26.8.

15N/3E-5B2—Reference point—hole in base of pump, elevation 62.5 feet, 0.15 mile south and 150 feet east of a point on Eager Road at intersection of Larkin Road. 12/19/47, 21.8; 3/2/48, 22.1; 12/1/48, 20.7; 1/20/49, 20.2; 3/17/49, 19.5; 11/11/49, 23.0.

15N/3E-5D2—Reference point—hole in base of pump, elevation 59.8 feet, 50 feet south of Nuestro Road, 0.4 mile west of Terra Buena Road. 12/19/47, 18.7; 3/24/48, 20.6; 12/1/48, 18.0; 3/16/49, 17.3; 11/11/49, 19.9; 3/23/50, 15.1; 11/6/50, 22.0; 4/3/51, 12.3; 11/14/51, 18.2; 4/3/52, 7.4.

15N/3E-5G1—Reference point—hole in base of pump, elevation 59.5 feet, 0.25 mile east of Terra Buena Road, 0.5 mile north of Pease Road. 12/19/47, 18.9; 3/3/48, 24.2; 12/1/48, 23.0; 3/16/49, 22.0; 11/11/49, 24.7.

15N/3E-6B1—Reference point—top of 2" x 6" bridge over concrete pit, elevation 59.8 feet, 200 feet east of Broadway, 0.15 mile west of Nuestro Road. 12/19/47, 16.8; 3/24/48, 17.4; 12/1/48, 16.1; 3/16/49, 13.7; 11/11/49, 18.2.

15N/3E-6C1—Reference point—top of 2" x 6" bridge over concrete pit, elevation 58.8 feet, 400 feet north of Nuestro Road, 0.2 mile east of Township Road. 12/19/47, 14.2; 3/3/48, 14.3; 12/1/48, 14.9; 3/16/49, 12.2; 5/26/49, 13.8; 6/28/49, 15.4; 7/27/49, 17.3; 8/25/49, 16.5; 11/11/49, 16.3.

15N/3E-6Q1—Reference point—slot in concrete base, elevation 56.4 feet, 0.2 mile north of Pease Road, 0.4 mile east of Township Road. 12/21/47, 17.8; 3/3/48, 17.6; 12/1/48, 18.2; 3/16/49, 17.0; 11/11/49, 18.7; 3/23/50, 21.9; 11/1/50, 20.8; 4/4/51, 12.9; 11/14/51, 17.4; 4/3/52, 7.5.

15N/3E-7H2—Reference point—top of casing, elevation 57.0 feet, 0.5 mile north of Butte House Road, 0.55 mile west of Terra Buena Road. 12/21/47, 23.9; 3/24/48, 23.6; 12/1/48, 24.8; 3/16/49, 22.5; 11/11/49, 26.1.

15N/3E-7P1—Reference point—hole in base of pump, elevation 55.4 feet, 500 feet south of Butte House Road, 0.35 mile east of Township Road. 12/21/47, 19.8; 3/3/48, 20.8; 12/1/48, 21.0; 3/16/49, 19.5; 11/10/49, 22.1.

15N/3E-7Q1—Reference point—hole in base of pump, elevation 56 feet, 150 feet south of Butte House Road, 0.45 mile east of Township Road. 12/19/47, 20.7; 3/24/48, 20.9; 11/18/48, 22.1; 3/28/49, 19.8; 11/23/49, 22.9; 3/23/50, 19.8; 10/31/50, 24.4; 3/27/51, 17.9; 11/14/51, 21.2; 4/1/52, 9.8.

15N/3E-7R1—Reference point—top of discharge pipe, elevation 55.8 feet, 0.1 mile north of Butte House Road, 0.7 mile west of Terra Buena Road. 12/21/47, 23.8; 3/3/48, 22.5; 12/1/48, 24.8; 3/16/49, 22.5; 11/11/49, 26.2; 3/23/50, 19.6; 11/1/50, 23.3; 4/4/51, 19.4; 11/14/51, 24.1; 4/3/52, 12.2.

15N/3E-8C1—Reference point—bottom of pump base, elevation 57.5 feet, 50 feet south of Pease Road, 0.15 mile west of Terra Buena Road. 12/22/47, 23.9; 3/3/48, 24.7; 12/1/48, 24.2; 1/20/49, 23.0; 3/16/49, 22.2; 11/11/49, 25.0; 3/23/50, 21.5; 11/1/50, 28.0; 4/4/51, 17.4; 11/14/51, 23.6; 4/3/52, 11.2.

15N/3E-8J4—Reference point—top of casing, elevation 56.8 feet, 200 feet west of Elmer Avenue, 0.7 mile north of Butte House Road. 12/22/47, 27.9; 3/3/48, 26.9; 3/16/49, 26.0; 11/11/49, 30.7.

15N/3E-9A1—Reference point—top of concrete floor, elevation 59.8 feet, 300 feet south of Pease Road, 0.1 mile west of Onstott Road. 11/4/47, 37.9; 5/12/48, 27.1; 6/1/48, 26.5; 6/30/48, 48.8 operating; 8/2/48, 45.0; 9/30/48, 33.2; 10/21/48, 31.8; 11/30/48, 29.3; 1/20/49, 27.4; 3/17/49, 26.4; 11/14/49, 31.3; 3/22/50, 22.2; 11/1/50, 31.0; 4/4/51, 24.1; 11/14/51, 27.3; 4/3/52, 19.7.

15N/3E-9C1—Reference point—top of casing, elevation 58.1 feet, 0.1 mile south of Pease Road, 0.55 mile west of Onstott Road. 11/4/47, 40.6; 3/17/48, 27.6; 11/29/48, 27.4; 3/17/49, 25.5; 11/14/49, 29.5.

15N/3E-9G1—Reference point—top of pneumatic gage hole, elevation 61.0 feet, 50 feet east of Stabler Lane, 0.45 mile south of Pease Road. 11/4/47, 32.8; 3/17/48, 34.2; 11/29/48, 32.5; 3/17/49, 29.4; 11/14/49, 34.8.

15N/3E-9N1—Reference point—bottom of pump base, elevation 57.6 feet, 100 feet east of Blevin Road, 0.55 mile north of Butte House Road. 12/22/47, 29.8; 3/3/48, 31.6; 12/1/48, 31.0; 3/16/49, 28.0; 11/11/49, 33.3.

15N/3E-9P3—Reference point—top of 12-inch casing, elevation 55 feet, 0.30 mile east of Blevin Road, 0.60 mile north of Butte House Road. 11/18/47, 27.7; 11/18/48, 28.2; 3/23/49, 26.6.

15N/3E-9R2—Reference point—bottom of pump base, elevation 200 feet, West of Onstott Road, 1.4 miles north of Butte House Road. 11/18/47, 35.0; 3/17/48, 35.5; 11/19/48, 36.4; 3/23/49, 32.0; 11/22/49, 37.9; 3/23/50, 34.0; 11/13/51, 34.4; 4/1/52, 32.6.

15N/3E-10G1—Reference point—hole in pump base, elevation 60 feet, 0.05 mile west of U. S. Highway 99E, 0.50 mile south of Pease Road. 11/19/47, 30.2; 3/17/48, 28.3; 11/19/48, 34.6; 3/23/49, 26.6; 11/22/49, 33.4; 3/23/50, 24.3; 11/30/50, 30.8; 3/27/51, 20.9; 11/14/51, 36.1; 4/1/52, 20.3.

15N/3E-11B1—Reference point—top of concrete base, elevation 60 feet, 0.80 mile west of State Highway 24, 2.50 miles south of Ellis Road. 11/7/49, 21.5; 3/7/48, 21.1; 5/19/48, 18.1; 11/30/48, 21.6; 3/17/49, 19.2; 11/17/49, 23.1; 3/21/50, 19.2; 11/6/50, 23.0; 3/29/51, 16.5; 11/16/51, 22.3; 4/6/52, 12.1.

15N/3E-11H1—Reference point—top of casing, elevation 61 feet, 0.45 mile west of State Highway 24, 2.70 miles south of Ellis Road. 11/6/47, 18.5; 3/17/48, 16.8; 11/30/48, 17.8; 3/17/49, 15.6; 11/17/49, 18.2.

15N/3E-11H2—Reference point—top of casing, elevation 61 feet, 0.40 mile west of State Highway 24, 2.70 miles south of Ellis Road. 11/6/47, 16.9; 3/17/48, 16.4; 11/30/48, 16.7; 3/17/49, 13.5; 11/17/49, 17.7.

15N/3E-14M1—Reference point—top of casing, elevation 57 feet, 0.35 mile east of U. S. Highway 99E at a point 0.70 mile north of State Highway 20. 11/19/47, 24.2; 3/17/48, 22.2. Well destroyed.

15N/3E-15B2—Reference point—hole in pump base, elevation 59 feet, 0.05 mile west of U. S. Highway 99E, 1.0 mile north of State Highway 20. 11/19/47, 31.4; 3/17/48, 30.2; 5/12/48, 26.7; 9/27/48, 31.1; 11/19/48, 33.6; 3/23/49, 28.8; 11/22/49, 32.9; 3/23/50, 28.4; 10/30/50, 32.0; 3/27/51, 30.8; 4/1/52, 24.1.

15N/3E-15E2—Reference point—base of pump, elevation 58.6 feet, 400 feet east of Onstott Road, 0.30 mile north of Butte House Road. 11/18/47, 35.3; 3/4/48, 34.8; 3/15/48, 34.8; 11/19/48, 41.8; 3/23/49, 32.7; 11/22/49, 39.3; 3/23/50, 34.6; 11/30/50, 38.7; 3/27/51, 33.9; 3/13/51, 36.1; 4/1/52, 29.7.

15N/3E-16C1—Reference point—hole in pump base, elevation 56 feet, 0.25 mile east of Blevin Road, 0.50 mile north of Butte House Road. 11/19/47, 33.6; 3/17/48, 33.6; 5/13/48, 30.8; 11/19/48, 39.0; 3/23/49, 32.2; 11/29/49, 36.4; 11/3/50, 36.6.

15N/3E-16L1—Reference point—concrete rim of pit, elevation 56 feet, 300 feet east of Tharp Road, 0.1 mile south of Butte House Road. 11/18/47, 34.8; 3/15/48, 34.8; 11/18/48, 37.9; 3/23/49, 32.0; 11/23/49, 36.1; 3/23/50, 33.6; 10/31/50, 38.2; 3/27/51, 31.4; 11/14/51, 35.2; 4/1/52, 24.5.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet measured from reference point)

15N 3E-16R2—Reference point—top of casing, elevation 57.1 feet, 300 feet east of Blevin Road, 0.35 mile north of Butte House Road. 12/19/47, 31.0; 3/24/48, 32.9; 9/27/48, 34.5; 11/18/48, 31.7; 3/28/49, 28.9; 11/23/49, 32.7; 3/23/50, 29.7; 11/23/49, 32.7; 3/23/50, 29.7; 10/30/50, 35.2; 3/27/51, 27.2; 11/11/51, 31.9; 4/1/52, 24.8.

15N 3E-17C1—Reference point—top of casing at bottom of pit, elevation 16.8 feet, 200 feet east of Hooper Road, 0.05 mile north of Butte House Road. 12/19/47, 17.5; 3/6/48, 16.0; 9/27/48, 20.9; 11/18/48, 19.0; 3/28/49, 16.0; 11/23/49, 19.3; 3/23/50, 24.8; 10/30/50, 20.7; 3/27/51, 13.5.

15N 3E-17P2—Reference point—top of flanged coupling at bottom of pit, elevation 41.0 feet, 0.05 mile north of State Highway 20, 0.25 mile east of Hooper Road. 12/19/47, 15.1; 3/6/48, 14.6; 9/27/48, 19.6; 11/18/48, 16.9; 3/28/49, 12.8. Well destroyed.

15N 3E-18R1—Reference point—top of casing, elevation 53 feet, 0.1 mile north of State Highway 20, 0.1 mile west of George Washington Boulevard. 12/19/47, 23.3; 3/6/48, 22.8; 11/18/48, 25.6; 3/28/49, 21.9; 11/23/49, 26.2; 10/31/50, 28.2; 3/27/51, 19.7; 11/11/51, 25.3; 4/1/52, 12.7.

15N 3E-19B1—Reference point—2" x 4" on top of concrete pit, elevation 57.3 feet, 0.21 mile south of State Highway 20, 0.54 mile east of Township Road. 12/21/47, 29.2; 3/3/48, 27.6; 12/1/48, 30.0; 1/20/49, 28.7; 3/16/49, 27.0; 11/11/49, 32.3; 3/23/50, 27.5; 11/1/50, 22.4; 4/4/51, 25.6; 11/14/51, 30.6.

15N 3E-20E1—Reference point—top of casing, elevation 37.5 feet, 0.48 mile west of El Margarita Road, 0.53 mile south of State Highway 20. 12/19/47, 9.6; 3/6/48, 9.5; 9/27/48, 13.8; 11/18/48, 11.7; 3/28/49, 8.4; 11/25/49, 11.3.

15N 3E-20G1—Reference point—hole in base of pump, elevation 52 feet, 0.25 mile east of El Margarita Road, 0.50 mile south of State Highway 20. 12/19/47, 30.8; 3/6/48, 31.0; 3/28/49, 28.7; 11/25/49, 29.1; 10/31/50, 36.6; 11/14/51; 39.4; 4/1/52, 23.6.

15N 3E-20R1—Reference point—top of casing, elevation 53.4 feet, 0.20 mile west of Harding Road, 0.05 mile north of Franklin Road. 12/19/47, 29.9; 3/24/48, 30.8; 11/18/48, 33.2; 3/28/49, 28.0; 5/26/49, 33.5; 6/28/49, 35.4; 7/27/49, 38.4; 8/25/49, 38.7; 11/25/49, 33.4; 3/27/50, 30.1; 10/31/50, 35.3; 3/27/51, 28.9; 11/14/51, 36.6; 1/1/52, 25.3.

15N 3E-21C1—Reference point—hole in concrete base, elevation 54 feet, 0.40 mile east of Harding Road, 0.12 mile south of State Highway 20. 3/17/48, 32.8; 11/18/48, 32.5; 3/23/49, 29.2; 11/25/49, 31.4.

15N 3E-21D1—Reference point—hole in concrete base, elevation 55.6 feet, 0.05 mile south of State Highway 20, 0.24 mile east Harding Road. 12/19/47, 30.8; 3/24/48, 31.2; 5/12/48, 31.1; 9/22/48, 37.1; 11/18/48, 32.8; 3/28/49, 28.8; 5/26/49, 37.8; 6/30/49, 45.0; 8/25/49, 41.8; 11/25/49, 31.1.

15N 3E-21F1—Reference point—hole in concrete base, elevation 55 feet, 0.28 mile east of Harding Road, 0.38 mile south of State Highway 20. 11/17/47, 34.3; 3/17/48, 34.8; 11/18/48, 39.3; 3/23/49, 31.5; 11/25/49, 38.9; 10/31/50, 39.0; 3/27/51, 32.5; 11/11/51, 37.3; 4/1/52, 28.4.

15N 3E-21L2—Reference point—top of casing, elevation 55.0 feet, 0.04 mile west of Walton Road, 0.61 mile south of State Highway 20. 12/19/47, 32.2; 3/24/48, 32.7; 11/18/48, 31.5; 3/28/49, 30.3; 11/25/49, 35.9.

15N 3E-21P2—Reference point—slot in casing, elevation 51.3 feet, 0.18 mile north of Franklin Road, 0.48 mile east of Harding Road. 11/18/47, 33.3; 3/15/48, 34.8; 11/18/48, 34.8; 3/23/49, 31.0; 11/25/49, 35.4.

15N 3E-21Q1—Reference point—top of pit, elevation 53 feet, North side of Franklin Road, 0.25 mile east of Walton Road. 1/4/41, 24.5; 11/4/47, 33.6; 12/15/48, 33.5; 12/8/49, 36.1; 11/17/50, 38.4; 12/7/51, 35.8.

15N 3E-21R1—Reference point—top of casing, elevation 53.3 feet, 0.1 mile west of Onstott Road, 0.13 mile north of Franklin Road. 11/17/47, 31.1; 3/17/48, 31.4; 3/29/48, 30.4; 5/12/48, 30.7; 9/27/48, 35.1; 11/18/48, 32.7; 3/23/49, 29.5; 11/25/49, 35.1; 3/27/50, 31.4; 10/31/50, 36.2; 3/27/51, 30.7; 11/13/51, 34.5; 1/1/52, 26.7.

15N 3E-22D1—Reference point—hole in base of pump, elevation 54.8 feet, 0.05 mile east of Onstott Road, 0.17 mile south of State Highway 20. 11/17/47, 31.2; 3/17/48, 31.5; 9/27/48, 34.2; 11/19/48, 32.2; 3/23/49, 29.2; 11/25/49, 34.7.

15N 3E-24N1—Reference point—top of casing, elevation 48.6 feet, 0.38 mile southwest of Western Pacific Railroad crossing of Yuba River, 0.50 mile west of U. S. Highway 99E. 11/14/47, 10.0; 3/19/48, 8.6; 11/23/48, 11.0; 3/24/49, 6.8; 11/22/49, 13.8; 3/28/50, 24.0; 11/20/51, 31.3; 4/2/52, 12.6.

15N 3E-24N2—Reference point—top of casing, elevation 70.9 feet, 0.35 mile southwest of Western Pacific Railroad crossing of Yuba River, 0.50 mile north of U. S. Highway 99E. 11/14/47, 31.5; 3/19/48, 29.9; 11/23/48, 31.7.

15N 3E-24Q1—Reference point—pipe in base, elevation 64.8 feet, 0.04 mile south of Riverside Boulevard, 0.04 mile west of Western Pacific Railroad. 11/12/47, 27.2; 3/19/48, 27.4; 11/22/48, 31.4; 3/24/49, 24.8; 12/13/49, 31.0.

15N 3E-25C1—Reference point—top of casing, elevation 53.4 feet, 0.15 mile west of Riverside Boulevard, 0.55 mile south of Western Pacific Railroad crossing on Yuba River. 11/14/47, 14.6; 3/19/48, 13.2; 3/30/48, 12.5; 11/23/48, 15.0; 3/24/49, 11.2; 11/22/49, 15.1.

15N 3E-25F1—Reference point—top of casing, elevation 61.0 feet, 0.85 mile south of Western Pacific Railroad crossing on Yuba River, 0.27 mile west of Riverside Boulevard. 11/12/47, 24.4; 3/19/48, 23.3; 11/23/48, 25.1; 3/24/49, 21.6; 11/22/49, 26.5; 3/28/50, 20.8; 11/9/50, 25.6; 3/28/51, 15.1; 11/20/51, 24.0; 4/3/52, 15.3.

15N 3E-25H1—Reference point—base of pump, elevation 59.9 feet, South side of Walnut Avenue, 0.15 mile southwest of Garden Avenue. 11/12/47, 22.3; 3/19/48, 22.5; 10/4/48, 24.2; 11/22/48, 23.2; 3/24/49, 19.5; 11/18/49, 23.8.

15N 3E-25H2—Reference point—hole in base of pump, elevation 57.1 feet, West side of Garden Avenue, 0.15 mile south of Walnut Avenue. 11/14/47, 19.3; 11/22/48, 20.8; 3/24/49, 18.0; 11/18/49, 21.5.

15N 3E-25K1—Reference point—hole in base of pump, elevation 61.5 feet, 0.11 mile east of Riverside Boulevard, 0.86 mile north of Feather River Boulevard. 11/12/47, 24.8; 3/19/48, 23.1; 11/23/48, 24.8.

15N 3E-25K2—Reference point—top of casing, elevation 48.0 feet, 0.15 mile east of Riverside Boulevard, 0.82 mile north of Feather River Boulevard. 11/12/47, 10.9; 3/19/48, 9.3; 3/30/48, 8.7; 10/4/48, 21.2; 11/22/48, 19.5; 3/24/49, 16.7; 11/22/49, 21.0.

15N 3E-26M1—Reference point—top of casing, elevation 52 feet, 0.31 mile north of Lincoln Road, 0.24 mile east of Garden Highway. 11/14/47, 23.8; 3/17/48, 23.6; 3/2/48, 20.8; 10/4/48, 26.8; 11/19/48, 24.7; 3/23/49, 21.8; 6/29/49, 29.8; 7/31/49, 32.8; 8/25/49, 31.4; 11/28/49, 25.9; 3/27/50, 21.1; 11/1/50, 26.1; 3/27/51, 23.2; 11/13/51, 28.0; 4/1/52, 17.0.

15N 3E-27C1—Reference point—hole in base of pump, elevation 53 feet, 0.10 mile west of Clark Avenue, 0.14 mile south of Franklin Road. 11/17/47, 29.7; 3/17/48, 29.9; 11/19/48, 31.6; 3/23/49, 30.5.

15N 3E-28B3—Reference point—top of pit, elevation 53 feet, 0.25 mile east of Walton Road, south side of Franklin Road. 11/27/29, 23.8; 9/27/30, 27.8; 12/15/31, 28.8; 12/1/32, 28.4; 12/14/33, 30.5; 11/10/34, 31.3; 11/25/36, 21.5; 11/24/37, 23.6; 1/26/39, 18.3.

15N 3E-28C1—Reference point—top of casing, elevation 54.2 feet, 0.18 mile west of Walton Road, 0.07 mile south of Franklin Road. 12/19/47, 33.1; 3/24/48, 33.4; 5/12/48, 31.3; 9/27/48, 36.4; 11/18/48, 36.6; 3/28/49, 31.5; 11/25/49, 37.1.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet measured from reference point)

15N/3E-28G1—Reference point—top of casing, elevation 54.3 feet. 0.09 mile east of Walton Road, 0.37 mile south of Franklin Road. 11/17/47, 33.7; 3/15/48, 33.5; 11/18/48, 36.4; 3/23/49, 32.0; 11/25/49, 36.6; 3/27/50, 34.3; 10/31/50, 39.6; 3/27/51, 33.2; 11/13/51, 37.4; 4/1/52, 28.5.

15N/3E-28Q1—Reference point—base of pump, elevation 52.9 feet, 0.10 mile north of Lincoln Road, 0.18 mile east of Walton Road. 11/17/47, 32.0; 3/15/48, 32.0; 3/29/48, 31.4; 10/4/48, 35.2; 11/18/48, 34.8; 3/23/49, 31.0; 11/28/49, 36.6.

15N/3E-29D1—Reference point—bottom of flange coupling in pit, elevation 40.2 feet, west side of Butte Avenue, 0.14 mile south of Franklin Road. 12/19/47, 13.3; 3/5/48, 14.2; 11/18/48, 17.9; 3/28/49, 13.0; 12/13/49, 17.3; 3/27/50, 14.9; 11/1/50, 19.7; 3/27/51, 11.1; 11/14/51, 19.0; 4/1/52, 16.7.

15N/3E-29N1—Reference point—top of casing, in pit, elevation 36.9 feet, 0.14 mile north of Lincoln Road, 0.13 mile east of George Washington Boulevard. 12/19/47, 10.4; 3/5/48, 10.6; 11/18/48, 12.0; 3/28/49, 9.1; 11/23/49, 14.3; 3/27/50, 9.6; 11/1/50, 14.9; 3/27/51, 7.6; 11/14/51, 15.3; 4/1/52, 14.0.

15N/3E-29R2—Reference point—top of pump base, elevation 51.9 feet, 0.57 mile west of Walton Avenue, 0.03 mile north of Lincoln Road. 12/19/47, 31.6; 3/24/48, 31.1; 10/4/48, 34.7; 11/18/48, 33.2; 11/25/49, 34.8.

15N/3E-30Q1—Reference point—top of discharge pipe, elevation 47 feet. North side Lincoln Road, 0.40 mile west of George Washington Boulevard. 12/22/47, 20.3; 3/5/48, 20.5; 10/4/48, 21.6; 11/17/48, 20.7; 3/28/49, 18.9; 11/23/49, 21.3.

15N/3E-32N1—Reference point—top of casing, elevation 48.4 feet, 0.05 mile north of Bogue Road, 0.20 mile east of George Washington Boulevard. 12/20/47, 23.7; 3/5/48, 27.9; 11/17/48, 25.4; 3/29/49, 23.5; 11/25/49, 24.3; 3/27/50, 22.9; 11/1/50, 30.5; 3/27/51, 20.4; 11/14/51, 27.6; 4/1/52, 15.8.

15N/3E-33D1—Reference point—hole in base of pump, elevation 51 feet, 0.08 mile south of Lincoln Road, 0.32 mile west of Walton Road. 5/4/48, 30.0; 6/1/48, 29.4; 11/18/48, 34.7; 3/29/49, 29.5; 11/25/49, 35.0; 3/27/50, 32.3; 11/1/50, 37.7; 3/27/51, 31.3; 11/14/51, 35.5; 4/1/52, 29.0.

15N/3E-33F1—Reference point—hole in base of pump, elevation 52.0 feet, 0.10 mile west of Walton Road, 0.27 mile south of Lincoln Road. 12/20/47, 29.7; 3/5/48, 34.5; 5/4/48, 28.3; 5/12/48, 29.2; 6/1/48, 28.2; 11/18/48, 35.0; 3/29/49, 31.8; 11/25/49, 33.7; 3/27/50, 30.5; 11/1/50, 36.0; 3/27/51, 29.9; 11/14/51, 36.3; 4/1/52, 26.0.

15N/3E-33K1—Reference point—hole in base of pump, elevation 52.1 feet. East side of Walton Road, 0.54 mile south of Lincoln Road. 3/12/48, 36.1; 5/6/48, 31.3; 6/1/48, 30.9; 11/11/48, 36.5.

15N/3E-33K2—Reference point—hole in base of pump, elevation 49 feet, 0.20 mile east of Walton Road, 0.73 mile south of Lincoln Road. 11/17/47, 35.6; 3/15/48, 35.6; 11/25/49, 35.9.

15N/3E-33N2—Reference point—hole in base of pump, elevation 48.4 feet, 0.32 mile west of Walton Road, 0.06 mile north of Bogue Road. 12/20/47, 27.9; 3/5/48, 33.8; 11/18/48, 30.0; 3/29/49, 26.7; 11/25/49, 31.4; 3/27/50, 20.6; 11/1/50, 34.4; 11/14/51, 32.9; 4/1/52, 23.8.

16N/3E-33P1—Reference point—top of concrete pit, elevation 50.5 feet. West side of Walton Road, 0.15 mile north of Bogue Road. 11/10/47, 30.3; 3/23/48, 32.7; 11/11/48, 32.1; 1/18/49, 29.8; 3/7/49, 29.0; 11/29/49, 33.2; 3/27/50, 30.6; 11/3/50, 35.7; 11/16/51, 33.3.

15N/3E-33C2—Reference point—hole in base of pump, elevation 48.6 feet, 0.20 mile north of Bogue Road, 0.10 mile east of Walton Avenue. 3/16/48, 34.0; 11/11/48, 31.6; 3/7/49, 29.1; 12/1/49, 33.4.

15N/3E-34L1—Reference point—top of casing, elevation 50 feet, 0.52 mile south of Lincoln Road, 0.96 mile east of Walton Road. 11/14/47, 31.3; 3/15/48, 33.9; 5/5/48, 29.2; 6/1/48, 29.2; 7/3/48, 57.0 (operating); 8/3/48, 48.1; 9/30/48, 37.8; 10/4/48, 41.5; 11/19/48, 37.7; 3/23/49, 31.0; 5/31/49, 33.7; 8/31/49, 38.6; 11/28/49, 36.8; 3/27/50, 31.5; 11/1/50, 35.7; 3/28/51, 30.3; 11/13/51, 33.9; 4/1/52, 32.0.

15N/3E-34N1—Reference point—top of casing, elevation 39.5 feet, 0.05 mile west of Phillips Road, 0.15 mile north of Bogue Road. 3/12/48, 21.2; 11/11/48, 37.0; 3/7/49, 34.2; 12/1/49, 36.5.

15N/3E-35E1—Reference point—top of casing, elevation 50 feet, 0.37 mile east of Garden Highway, 0.44 mile south of Lincoln Road. 11/14/47, 22.1; 3/17/48, 21.2; 11/23/48, 22.5; 3/23/49, 20.5; 11/28/49, 21.1; 3/27/50, 20.8.

15N/4E-3A1—Reference point—top of casing, elevation 95.0 feet 0.31 mile east of Hallwood Road, south side of Walnut Road. 11/25/47, 16.6; 3/3/48, 19.8; 4/1/48, 19.1; 11/29/48, 17.0; 3/22/49, 18.8; 11/18/49, 17.7.

15N/4E-3B1—Reference point—top of casing, elevation 95.4 feet, 0.47 mile south of Walnut Road, 0.03 mile west of Hallwood Road. 11/25/47, 23.5; 3/3/48, 26.2; 11/29/48, 24.0; 1/27/49, 25.2; 3/22/49, 23.9; 11/16/49, 23.7.

15N/4E-3D1—Reference point—top of casing, elevation 93.4 feet, 0.45 mile west of Hallwood Road, 0.01 mile south of Walnut Road. 11/25/47, 18.8; 3/3/48, 21.9; 4/1/48, 21.8; 11/29/48, 20.0; 1/27/49, 22.2; 3/22/49, 20.1; 11/18/49, 19.4.

15N/4E-3D2—Reference point—top of casing, elevation 90 feet, 0.56 mile west of Hallwood Road, southeast of curve in Walnut Road. 11/29/48, 22.2; 3/23/49, 22.0.

15N/4E-4A1—Reference point—top of casing, elevation 90.4 feet, South side of Walnut Road, 0.85 mile along Walnut Road from intersection with State Highway 20. 11/25/47, 19.9; 3/3/48, 20.9; 11/29/48, 19.8; 3/22/49, 19.0; 11/18/49, 19.2.

15N/4E-4C1—Reference point—top of casing, elevation 88.7 feet, 0.05 mile south of Walnut Road, 0.41 mile along Walnut Road from intersection with State Highway 20. 11/25/47, 19.4; 3/3/48, 21.1; 4/1/48, 20.4; 11/29/48, 20.4; 3/22/49, 18.8; 11/18/49, 20.0.

15N/4E-4D1—Reference point—hole in pump base, elevation 85 feet, 0.03 mile southeast of intersection of State Highway 20 and Walnut Road. 11/29/48, 26.1; 1/27/49, 26.0; 3/22/49, 23.2; 12/9/49, 27.1.

15N/4E-4E1—Reference point—top of 10-inch casing inside shed, elevation 87.5 feet, 0.17 mile east of State Highway 20, 0.38 mile south along State Highway 20 from intersection of Walnut Road. 11/25/47, 21.9; 3/2/48, 22.8; 4/1/48, 22.4; 11/26/48, 22.8; 1/27/49, 23.2; 3/22/49, 21.0; 11/18/49, 22.5; 3/23/50, 21.5; 10/31/50, 22.2; 3/30/51, 20.5; 11/14/51, 22.3.

15N/4E-4H1—Reference point—top of tin casing at suction line, elevation 85 feet, 0.9 mile east of State Highway 20, 0.5 mile south of Walnut Road. 11/28/47, 20.2; 3/2/48, 20.8; 4/1/48, 21.7; 3/22/49, 20.5; 11/18/49, 20.8.

15N/4E-4N1—Reference point—top of casing, elevation 85.6 feet, 0.55 mile east of State Highway 20, 0.82 mile south of intersection of State Highway 20 and Walnut Road. 11/25/47, 24.3; 3/2/48, 24.3; 4/1/48, 23.5; 11/26/48, 24.6; 3/22/49, 22.6; 12/9/49, 25.2.

15N/4E-4N2—Reference point—top of casing, elevation 85.3 feet, 0.61 mile east of State Highway 20, 0.91 mile south along State Highway 20 from intersection with Walnut Road. 11/25/47, 23.9; 3/2/48, 23.9; 3/22/49, 22.0.

15N/4E-4P1—Reference point—top of casing, elevation 86.5 feet, 0.72 mile east of State Highway 20, 0.73 mile south along State Highway 20 from intersection with Walnut Road. 11/25/47, 70.4; 3/2/48, 25.6.

15N/4E-4R1—Reference point—hole in side of pump, elevation 85.7 feet, 0.81 mile northwest of Dantoni Packing Shed on Dantoni Road, southeast of Yuba River. 11/24/47, 26.3; 3/4/48, 25.0; 3/31/48, 27.3; 10/4/48, 25.4; 11/24/48, 25.4; 1/17/49, 25.2; 3/16/49, 24.0; 5/24/49, 26.3; 6/29/49, 28.7; 7/28/49, 27.8; 8/26/49, 27.9; 11/21/49, 26.2; 3/23/50, 24.1; 10/31/50, 26.5; 4/2/51, 21.4; 11/21/51, 25.6; 4/5/52, 20.4.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet measured from reference point)

15N/4E-5D1—Reference point—top of tin casing, elevation 65 feet, 0.17 mile northwest of Kimball Lane at curve, 1.0 mile along Kimball Lane from intersection with Nigger Jack Slough Road. 11/26/47, 7.2; 3/1/48, 8.8; 11/30/48, 8.2; 3/23/49, 8.5; 12/9/49, 8.5.

15N/4E-6C1—Reference point—top of suction pipe flange, elevation 65 feet, 0.10 mile north of intersection of Kimball Lane and Nigger Jack Slough Road on west side of Nigger Jack Slough Road. 11/7/47, 8.3; 12/2/48, 6.0; 3/18/49, 4.5; 11/17/49, 5.1.

15N/4E-7J1—Reference point—top of casing, elevation 68 feet. North side of State Highway 20, 1.65 miles along State Highway 20 from Yuba Street. 11/19/47, 15.9; 3/19/48, 15.9; 11/21/48, 16.3; 3/28/48, 15.0; 11/17/49, 16.0; 3/28/50, 15.8; 11/2/50, 15.7; 3/28/51, 10.5; 11/16/51, 16.2; 4/2/52, 10.2.

15N/4E-7M1—Reference point—hole in base of pump, elevation 61 feet, 0.80 mile north of 15th Street, west side of Nigger Jack Slough Road. 11/19/47, 19.4; 3/19/48, 18.8; 10/5/48, 19.1; 11/22/48, 19.7; 3/28/49, 17.5; 11/17/49, 19.8; 3/28/50, 16.9.

15N/4E-8D1—Reference point—top of casing outside milk house, elevation 65 feet, 0.46 mile east of Nigger Jack Slough Road, 0.25 mile northwest of State Highway 20. 11/25/47, 15.4; 3/2/48, 16.1; 11/30/48, 15.9; 3/22/49, 14.7; 11/21/49, 15.1; 3/23/50, 14.3; 10/31/50, 15.0; 3/30/51, 14.7; 11/14/51, 15.8; 4/5/52, 12.6.

15N/4E-8M1—Reference point—top of casing, elevation 74 feet, 0.20 mile east of State Highway 20, 1.68 miles from intersection with Yuba Street. 11/25/47, 23.1; 3/2/48, 22.7; 11/26/48, 23.1; 3/22/49, 22.2; 12/9/49, 24.7.

15N/4E-8R1—Reference point—base of pump, elevation 80.3 feet, 1.58 miles north of intersection of Dantoni and Hammond Roads on south bank of Yuba River. 11/19/47, 26.7; 3/2/48, 26.7; 3/31/48, 25.7; 5/5/48, 23.3; 6/1/48, 23.2; 10/4/48, 26.8; 11/21/48, 26.9; 3/16/49, 25.4; 11/21/49, 27.7; 3/23/50, 25.0; 10/31/50, 27.7; 4/2/51, 22.2; 11/21/51, 26.9; 4/5/52, 23.4.

15N/4E-9G1—Reference point—top of casing, elevation 84.6 feet, 0.70 mile northwest of Dantoni Road, 0.10 mile southwest along road from Dantoni Packing Shed. 11/24/47, 29.6; 3/3/48, 24.9; 3/4/48, 25.1; 10/4/48, 25.9; 11/24/48, 25.5; 1/17/49, 24.9; 3/16/49, 23.7; 11/21/49, 26.0; 3/23/50, 23.2; 10/31/50, 25.9; 4/2/51, 21.1; 11/21/51, 25.0; 4/5/52, 20.3.

15N/4E-9R1—Reference point—hole in side of pump, elevation 77.2 feet, 0.23 mile northwest of Dantoni Road, 0.40 mile southwest along road from Dantoni Packing Shed. 11/24/47, 19.2; 3/1/48, 20.9; 3/3/48, 21.0; 11/24/48, 20.1; 3/16/49, 20.2; 11/21/49, 21.1.

15N/4E-10F1—Reference point—hole in base of pump, elevation 80.5 feet, 0.23 mile northwest of Dantoni Road, 0.20 mile northeast along road from Dantoni Packing Shed. 11/24/47, 21.5; 3/1/48, 19.8; 3/31/48, 25.7; 10/4/48, 20.9; 11/24/48, 20.6; 3/16/49, 19.7; 11/21/49, 21.5.

15N/4E-10L2—Reference point—pipe in concrete base, elevation 87.8 feet, 0.12 mile southeast from Dantoni Road, opposite Dantoni Packing Shed. 11/21/47, 26.2; 3/3/48, 31.0; 3/4/48, 26.9; 5/6/48, 25.0; 10/8/48, 27.4; 11/21/48, 27.3; 1/17/49, 26.8; 3/16/49, 26.1; 3/24/49, 31.0; 6/29/49, 29.5; 7/28/49, 30.3; 8/30/49, 30.5; 11/21/49, 28.6.

15N/4E-10N1—Reference point—hole in casing, elevation 84.1 feet, 0.16 mile southeast of Dantoni Road, 0.30 mile southwest along road from Dantoni Packing Shed. 11/24/47, 28.6; 3/1/48, 26.0; 3/31/48, 26.6; 5/6/48, 24.2; 10/4/48, 26.2; 11/24/48, 26.5; 3/16/49, 25.8; 11/21/49, 28.0; 12/7/49, 27.8; 3/23/50, 26.6; 10/31/50, 28.2; 4/2/51, 20.7; 11/21/51, 26.9; 4/5/52, 23.0.

15N/4E-11C1—Reference point—top of casing, elevation 90 feet, 1.60 miles north of Hammonton Road at a point 0.55 mile southwest along Hammonton Road from Brophy Road. 5/13/48, 25.0; 6/1/48, 24.7; 10/1/48, 27.5; 11/23/48, 27.5; 1/17/49, 26.9; 3/16/49, 26.5; 11/21/49, 28.8; 3/23/50, 25.4; 3/30/51, 18.8; 11/1/51, 27.1; 4/4/52, 18.4.

15N/4E-11G1—Reference point—hole in pump base, elevation 85 feet, 1.17 miles north of Hammonton Road at a point 0.35 mile southwest along Hammonton Road from Brophy Road. 5/13/48, 25.3; 6/1/48, 24.9; 9/1/48, 29.5; 10/1/48, 26.2; 11/23/48, 26.1, 1/17/49, 26.1; 3/16/49, 25.4; 4/12/49, 24.1; 5/24/49, 28.5; 6/29/49, 29.4; 7/28/49, 28.5; 8/26/49, 28.4; 11/21/49, 23.6; well destroyed.

15N/4E-11K1—Reference point—hole in top of pump base, elevation 83 feet, 0.29 mile west of Brophy Road, 0.90 mile north of Brophy School. 5/13/48, 18.1; 10/1/48, 20.1; 11/23/48, 19.4; 3/16/49, 18.4.

15N/4E-12P1—Reference point—hole in pump base, elevation 82.3 feet, 0.57 mile north of Brophy School, 0.29 mile east of Brophy Road. 11/24/47, 24.3; 3/1/48, 25.9; 3/31/48, 23.8; 11/23/48, 27.5; 11/21/49, 26.7; 12/5/49, 26.6; 3/24/50, 22.4; 11/2/50, 27.6; 4/4/52, 19.4.

15N/4E-13B1—Reference point—top of casing, elevation 84 feet, South side of Hammonton Road, 0.4 mile northeast from intersection with Brophy Road. 12/24/47, 22.9; 3/23/48, 22.6; 11/23/48, 25.7; 3/21/49, 22.1; 12/5/49, 26.2; 3/23/50, 22.7; 11/2/50, 27.7; 4/2/51, 18.7; 11/21/51, 26.4; 4/4/52, 20.4.

15N/4E-14B1—Reference point—top of casing, elevation 80.5 feet, 0.21 mile north of Hammonton Road, 0.20 mile southwest from intersection with Brophy Road. 11/26/47, 16.1; 3/1/48, 16.4; 3/31/48, 16.4; 11/24/48, 17.8; 3/17/49, 16.3; 11/22/49, 16.4; 3/30/51, 4.6; 11/20/51, 17.0; 4/4/52, 4.7.

15N/4E-14N1—Reference point—hole in pump base, elevation 79 feet, 0.11 mile south of Hammonton Road, 0.85 mile southwest from intersection with Brophy Road. 5/6/48, 24.0; 6/3/48, 26.7; 3/17/49, 25.7; 11/21/49, 30.3.

15N/4E-14N2—Reference point—top of casing, elevation 78.8 feet, North side of Hammonton Road, 0.87 mile southwest from intersection with Brophy Road. 11/26/47, 22.7; 5/6/48, 21.8; 10/1/48, 26.4; 10/8/48, 25.8; 11/24/48, 24.9; 1/17/49, 23.9; 3/16/49, 23.3; 5/24/49, 31.3; 6/29/49, 33.5; 7/28/49, 35.3; 8/26/49, 30.8; 11/22/49, 27.7; 3/23/50, 24.3; 11/10/50, 28.7; 3/30/51, 18.5; 11/20/51, 27.9; 4/4/52, 20.3.

15N/4E-14P1—Reference point—hole in pump base, elevation 82 feet, 0.52 mile west of Brophy Road, 0.23 mile south of Hammonton Road. 5/6/48, 25.2; 6/3/48, 28.7; 3/17/49, 26.9; 8/2/49, 40.6; 11/21/49, 30.7.

15N/4E-15A1—Reference point—pipe in concrete base, elevation 78.5 feet, 1.02 miles west of Brophy Road, 0.86 mile north of Hammonton Road. 11/26/47, 18.3; 3/2/48, 17.1; 3/31/48, 18.5; 10/8/48, 20.2; 11/24/48, 19.6; 1/7/49, 19.0; 3/16/49, 18.4; 11/21/49, 21.0; 3/23/50, 19.1; 11/10/50, 22.0; 4/2/51, 11.1; 11/21/51, 20.3; 4/4/52, 12.2.

15N/4E-15L1—Reference point—top of concrete pit, elevation 81.5 feet, 0.15 mile east of Griffith Avenue, 0.66 mile north of Hammonton Road. 11/26/47, 27.0; 3/2/48, 29.8.

15N/4E-16A1—Reference point—hole in side of pump base, elevation 79.5 feet, North side of Dantoni Road, 0.73 mile along road from Dantoni Packing Shed. 11/7/47, 22.5; 3/2/48, 23.2; 3/31/48, 22.7; 10/4/48, 23.7; 10/8/48, 23.7; 11/24/48, 23.7; 1/17/49, 23.2; 3/16/49, 23.0; 11/21/49, 25.1.

15N/4E-16K1—Reference point—base of pump, elevation 81.0 feet, 0.03 mile west of Dantoni Road, 1.43 miles along road from intersection with Hammonton Road. 11/22/47, 26.8; 3/2/48, 28.2; 3/31/48, 27.9; 10/4/48, 30.0; 10/8/48, 29.9; 11/24/48, 29.2; 3/16/49, 28.4; 11/22/49, 31.2; 11/10/50, 30.5; 4/2/51, 21.5; 11/21/51, 29.5; 4/5/52, 22.0.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet measured from reference point)

15N/4E-16N2—Reference point—hole in pump base, elevation 74.5 feet, 0.28 mile northwest of Dantoni Road, 0.76 mile along road from intersection with Hammonton Road. 11/19/47, 23.9; 3/2/48, 23.3; 3/31/48, 23.1; 5/6/48, 22.3; 6/1/48, 21.8; 10/4/48, 24.5; 11/24/48, 24.2; 3/16/49, 23.6.

15N/4E-16P1—Reference point—base of pump, elevation 76.9 feet, 0.23 mile west of Dantoni Road, 1.31 miles along road from intersection with Hammonton Road. 11/5/47, 24.7; 3/2/48, 24.1; 5/13/48, 24.2; 6/1/48, 22.3; 10/4/48, 25.8; 10/8/48, 25.7; 11/24/48, 24.7; 3/16/49, 24.4; 11/21/49, 28.2.

15N/4E-17M1—Reference point—top of casing, elevation 74.2 feet, 0.76 mile measured perpendicular north of Simpson Lane at a point 0.82 mile from 7th St. Bridge. 11/11/47, 26.4; 3/19/48, 25.8; 3/30/48, 25.5; 11/5/48, 27.0; 11/22/48, 32.8; 3/24/49, 25.2; 11/17/49, 27.3; 3/28/50, 24.7; 11/2/50, 28.2; 3/28/51, 17.9; 11/16/51, 25.8; 4/2/52, 15.9.

15N/4E-17N1—Reference point—top of casing, elevation 74.5 feet, 0.35 mile measured perpendicular north of Simpson Lane at a point 1.27 miles from intersection with Yuba Street. 11/11/47, 26.0; 3/19/48, 25.4; 3/30/48, 25.3; 11/22/48, 26.6; 3/24/49, 25.2; 11/17/49, 27.6.

15N/4E-18G1—Reference point—top of casing, elevation 71 feet, 0.13 mile east of State Highway 20 at a point 0.90 mile from intersection with Yuba Street. 11/19/47, 27.7; 3/19/48, 26.2; 11/21/48, 28.5; 3/28/49, 24.5; 11/17/49, 28.1; 11/2/50, 26.2; 3/28/51, 22.3; 11/16/51, 28.1; 4/2/52, 21.6.

15N/4E-18Q1—Reference point—base of pump at edge, elevation 68.7 feet, 0.36 mile measured perpendicular north of Simpson Lane at a point 0.75 mile from intersection with Yuba Street. 11/12/47, 23.7; 3/18/48, 22.5; 11/22/48, 24.3; 3/24/49, 22.0; 11/17/49, 25.5; 11/16/51, 27.7.

15N/4E-19H1—Reference point—surface of concrete block, elevation 67.0 feet, 0.13 mile measured perpendicular south of Simpson Lane at a point 1.04 miles from intersection with Yuba Street. 11/11/47, 23.5; 3/19/48, 22.6; 10/5/48, 29.0; 11/22/48, 26.5; 3/24/49, 20.7; 11/17/49, 25.0; 11/2/50, 25.3; 3/28/51, 13.7.

15N/4E-19J1—Reference point—hole in pump base, elevation 71.8 feet, 0.43 mile south of Simpson Lane at a point 1.12 miles from intersection with Yuba Street. 11/11/47, 27.4; 3/19/48, 27.3; 3/24/49, 26.8; 11/18/49, 30.0; 3/28/50, 27.5; 11/3/50, 30.3; 3/28/51, 18.5; 11/16/51, 26.5; 4/2/52, 17.6.

15N/4E-19N1—Reference point—top of casing, elevation 59.9 feet. South bank of Levee Road, 0.35 mile east of U. S. Highway 99E bridge over Yuba River. 11/10/47, 20.0; 3/17/48, 19.0; 3/24/49, 17.0; 11/18/49, 21.4.

15N/4E-19P1—Reference point—top of casing, elevation 64.0 feet, 0.04 mile south of levee between Avondale and Southern Pacific Railroad. 11/11/47, 22.7; 3/17/48, 22.6; 3/30/48, 21.1; 11/22/48, 33.7; 3/24/49, 21.0; 12/13/49, 25.2.

15N/4E-20F1—Reference point—hole in pump base, elevation 72.5 feet, 0.20 mile due west from intersection of Hammonton and Dantoni Roads. 11/11/47, 25.7; 3/17/48, 26.0; 5/3/48, 24.7; 6/2/48, 25.4; 11/22/48, 26.2; 3/24/49, 26.5; 11/17/49, 29.6; 3/28/50, 27.3; 11/16/51, 25.1; 4/2/52, 23.6.

15N/4E-20L1—Reference point—top of casing, elevation 66 feet, 0.41 mile north of Hammonton Road at a point 0.55 mile along Hammonton Road from intersection with U. S. Highway 99E. 11/11/47, 14.3; 3/17/48, 15.0; 11/22/48, 13.3; 11/18/49, 22.4; 11/3/50, 22.7; 3/28/51, 12.6.

15N/4E-20N1—Reference point—top of casing, elevation 57.8 feet, 0.40 mile north of Hammonton Road at a point 0.41 mile along Hammonton Road from intersection with U. S. Highway 99E. 11/11/47, 13.6; 3/17/48, 13.9; 10/4/48, 24.4; 11/22/48, 19.3; 3/24/49, 13.5; 11/18/49, 16.1; 3/28/50, 14.3.

15N/4E-20N2—Reference point—top of casing, 8.5 feet below top of concrete pit, elevation 53.4 feet, 0.22 mile north of Hammonton Road at a point 0.45 mile along Hammonton Road from intersection with U. S. Highway 99E. 11/11/47, 12.6; 3/17/48, 12.9; 3/24/49, 6.0; 11/18/49, 8.6.

15N/4E-20N3—Reference point—top of casing, elevation 58.9 feet, 0.31 mile north of Hammonton Road at a point 0.50 mile along Hammonton Road from intersection with U. S. Highway 99E. 4/8/47, 14.7; 3/17/48, 15.3; 3/30/48, 14.5; 11/12/48, 22.2; 3/24/49, 15.9; 11/18/49, 17.3.

15N/4E-20P1—Reference point—top of concrete pit, east wall, elevation 67.5 feet, 0.14 mile due west of intersection of Hammonton and Linda Roads. 12/10/47, 22.5; 3/1/48, 22.5; 11/22/48, 23.3; 3/17/49, 22.9; 11/22/49, 24.6; 3/24/50, 23.2; 11/2/50, 25.7; 11/15/51, 20.7.

15N/4E-20R1—Reference point—top of casing, elevation 67.4 feet. North side of Linda Road, 0.41 mile east of Hammonton Road. 12/12/47, 22.2; 3/1/48, 21.3; 11/22/48, 23.6; 11/22/49, 25.2.

15N/4E-21F1—Reference point—base of wooden block supporting pump, south side, elevation 70.4, 0.10 mile north of Hammonton Road, 0.68 mile west of Griffith Avenue. 11/26/47, 23.6; 3/1/48, 23.6; 10/8/48, 25.7; 11/24/48, 24.8; 3/16/49, 23.5; 6/29/49, 29.2; 8/26/49, 31.0; 11/21/49, 28.8; 3/23/50, 25.3; 11/2/50, 30.0; 3/30/51, 19.1; 11/20/51, 30.8; 4/5/52, 21.9.

15N/4E-21R2—Reference point—hole in pump base, elevation 75.1 feet. West side of Griffith Avenue, 0.05 mile north of North Beale Road. 11/26/47, 27.1; 10/8/48, 29.4; 11/22/48, 29.2; 3/17/49, 27.8; 11/21/49, 32.3; 3/24/50, 29.9; 11/3/50, 34.3; 3/30/51, 26.3; 11/21/51, 33.7; 4/3/52, 26.9.

15N/4E-22B1—Reference point—top of casing, elevation 73.6 feet. North side of Hammonton Road, 0.75 mile along road from intersection with Griffith Avenue. 11/26/47, 20.6; 3/1/48, 20.1; 3/31/48, 20.0; 5/6/48, 19.6; 10/1/48, 23.3; 10/8/48, 23.1; 11/24/48, 22.4; 1/17/49, 21.9; 3/16/49, 21.3; 5/24/49, 24.9; 7/1/49, 31.1; 8/3/49, 28.9; 8/26/49, 28.1; 11/21/49, 25.3; 3/23/50, 22.7; 11/2/50, 27.2; 3/30/51, 15.2; 11/20/51, 24.9; 4/4/52, 27.1.

15N/4E-22K1—Reference point—top of casing, elevation 86.9 feet, 0.40 mile north of North Beale Road, 0.76 mile east of Griffith Road. 12/10/47, 27.7; 3/1/48, 34.7; 10/8/48, 36.6; 11/22/48, 36.9; 3/17/49, 36.5; 11/22/49, 40.0.

15N/4E-22L1—Reference point—top of casing, elevation 74 feet, 0.39 mile east of Griffith Road, 0.26 mile north of North Beale Road. 11/22/29, 25.7; 9/16/30, 25.3; 12/14/31, 27.3; 12/9/32, 27.6.

15N/4E-22P1—Reference point—top of concrete foundation, elevation 72 feet, 0.32 mile east of Griffith Road, 0.15 mile north of North Beale Road. 11/5/47, 23.6; 12/10/48, 26.3; 12/9/49, 29.5; 11/10/50, 31.5; 12/5/51, 30.7.

15N/4E-22P2—Reference point—top of brick lining of well, elevation 73 feet, 0.31 mile east of Griffith Road, 0.15 mile north of North Beale Road. 12/14/33, 29.6; 11/20/34, 30.4; 11/28/36, 27.9; 11/22/37, 27.6; 1/27/39, 25.1; 1/9/41, 22.0.

15N/4E-23A1—Reference point—crack between wood blocks, southeast corner, elevation 84.2 feet. West side of Brophy Road, 0.96 mile north of North Beale Road. 11/26/47, 24.5; 3/1/48, 24.1; 3/31/48, 24.0; 5/6/48, 23.4; 6/3/48, 38.0; 10/1/48, 28.1; 10/8/48, 27.5; 11/23/48, 26.5; 1/17/49, 25.7; 3/16/49, 25.3; 6/1/49, 34.6; 7/3/49, 39.5 (operating); 8/2/49, 39.5 (operating); 11/22/49, 31.0; 3/23/50, 26.7; 11/2/50, 31.2; 3/30/51, 23.8; 11/21/51, 30.8; 4/4/52, 25.1.

15N/4E-23P1—Reference point—top of casing, elevation 77.2 feet, 0.04 mile north of North Beale Road, 0.65 mile east of Brophy Road. 12/10/47, 27.1; 3/1/48, 27.6; 3/31/48, 24.9; 10/8/48, 27.3; 11/22/48, 27.4; 3/17/49, 27.0; 11/22/49, 30.3; 11/2/50, 32.5.

15N/4E-23R1—Reference point—top of wooden platform under pitcher pump, elevation 79.1 feet, 0.05 mile northwest of intersection of North Beale and Brophy Roads. 12/10/47, 24.2; 3/1/48, 24.2.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet measured from reference point)

15N 4E-24C1—Reference point—top of casing, elevation 83 feet, 0.19 mile east of Brophy Road, 0.99 mile north of North Beale Road. 5-5-48, 25.1; 6-3-48, 28.6; 11-23-48, 28.1; 1-17-49, 27.4; 3-16-49, 27.0; 7-3-49, 16.0 (operating); 8-2-49, 52.0 (operating); 12-5-49, 30.8; 3-24-50, 29.1; 11-2-50, 33.3; 4-2-51, 28.3; 11-21-51, 38.1; 4-4-52, 35.9.

15N 4E-25L1—Reference point—hole in pump base, elevation 78 feet, 0.49 mile east of Brophy Road, 0.51 mile south of North Beale Road. 10-6-49, 30.0; 11-23-48, 29.5; 3-21-49, 28.6; 12-5-49, 33.7; 3-27-50, 32.1; 11-2-50, 37.2; 4-4-51, 34.5; 11-21-51, 40.0; 4-5-52, 36.7.

15N 4E-26J1—Reference point—hole in base of pump, elevation 76 feet, 0.70 mile south of North Beale Road due south of Brophy Road. 11-23-48, 28.8; 3-17-49, 28.5; 11-23-49, 31.9; 12-5-49, 32.6.

15N 4E-27E2—Reference point—top of concrete north wall, elevation 71.0 feet, 0.23 mile east of Griffith Road, 0.40 mile south of North Beale Road. 12/10-47, 23.1; 3/1/48, 22.3; 3-31-48, 22.4; 10-8-48, 25.5; 11-22-48, 25.4; 3-17-49, 24.5; 11-22-49, 28.5; 4-4-52, 25.3.

15N 4E-28D1—Reference point—hole in pump base, elevation 77.7 feet, 0.04 mile south of North Beale Road, 0.17 mile east of intersection of North Beale and Linda Roads. 11/26/47, 32.3; 3-1-48, 31.5; 11-22-48, 34.1; 3/26-49, 32.5; 11/21-49, 36.9; 3-24-50, 34.3; 11-2/50, 38.9; 3/30/51, 37.5 (operating); 11-21-51, 39.1; 4-3/52, 31.5.

15N 4E-29E1—Reference point—top of casing, elevation 61 feet, 0.23 mile northeast of U. S. Highway 99E, 0.20 mile southeast of Hammonton Road. 12-10-47, 20.9; 3/1/48, 20.6.

15N 4E-29F2—Reference point—top of 4" x 4" bridge over pit, elevation 64 feet, 0.26 mile south of North Beale Road, 0.62 mile west of intersection of North Beale and Linda Roads. 12/10/47, 22.4; 3/1/48, 20.9.

15N 4E-29P1—Reference point—top of 4" x 6" mud sill of shed, elevation 63.6 feet, 0.03 mile north of Earle Road, 0.04 mile east of Southern Pacific Railroad. 12/10/47, 21.5; 3/1/48, 22.7; 10-8-48, 25.0; 11-22-48, 24.2.

15N 4E-30B2—Reference point—hole in base of pump, elevation 62.7 feet, Northeast side of Avondale Avenue, 0.05 mile northwest of North Beale Road. 11/10-47, 21.3; 3/17/48, 20.3; 10-4-48, 23.7; 11-22-48, 22.2; 3-24-49, 19.0; 12/13/49, 23.4; 3-28-50, 20.5; 11-2-50, 24.6.

15N 4E-30D1—Reference point—base of pump, north side, elevation 59.1 feet, 0.03 mile south of U. S. Highway 99E at first turn south of Rancho Motel. 11-10-47, 20.4; 3-17/48, 20.5; 3-30-48, 18.8; 5-5-48, 16.0; 6-2-48, 16.6; 7-1-48, 39.2 (operating); 11-22-48, 21.6; 3-24-49, 18.0; 5-24/49, 20.8; 6-29-49, 24.3; 8-26-49, 25.1; 11-22-49, 24.8; 3-28/50, 17.0; 11-2-50, 22.3; 3-28-51, 10.2; 10-20-51, 21.8.

15N 4E-30E2—Reference point—base of pump, elevation 56.8 feet, Southwest side of Garden Avenue, 0.38 mile southeast of Walnut Avenue. 11-12-47, 18.9; 3-19-48, 17.8; 10-4-48, 22.1; 11-22-48, 21.0; 3-21-49, 16.8; 11-18-49, 21.2.

15N E-30L1—Reference point—top of pump base, elevation 56.0 feet, 0.04 mile southwest of Garden Avenue, 0.25 mile northwest of Feather River Boulevard. 11-11-47, 18.2; 3-19-48, 16.8; 11-22-18, 18.8; 3-21-49, 16.0; 11-18-49, 21.2.

15N 4E-30L2—Reference point—hole in pump base, elevation 56.5 feet, 0.03 mile northwest of Feather River Boulevard, 0.08 mile southwest of Garden Avenue. 11-12-47, 18.2; 3-19-48, 17.3; 3-30-48, 17.0; 3-24-49, 16.7; 12-13-49, 20.7; 3-28-50, 7.0; 11-2-50, 21.7; 3-28-51, 10.2; 11/20-51, 18.2; 4-1-52, 9.8.

15N 4E-31K1—Reference point—hole in pump base, elevation 63.1 feet, 0.56 mile south of Earle Road, 0.33 mile west of Arboga Road. 12-10-47, 21.8; 3-2-48, 21.4; 3-30-48, 20.9; 11-22-48, 23.1; 3-17-49, 21.6; 11-23-49, 22.7.

15N 4E-31Q1—Reference point—hole in side of pump, elevation 57 feet, 0.34 mile west of Arboga Road, 2.20 miles north of Ella Road. 11-12-47, 23.0; 3/5/48, 21.4.

15N 4E-32D1—Reference point—hole in pump base, elevation 61.6 feet, 0.10 mile west of intersection of U. S. Highway 99E and Earle Road, 0.03 mile south of Earle Road. 12-10/47, 31.2; 3/2/48, 22.7; 3/30-48, 22.3; 11/22/48, 24.5; 3/18/49, 23.1; 11/23-49, 26.1; 11-2/50, 28.5.

15N 4E-32D2—Reference point—top of casing, elevation 62 feet, South side Pasado Avenue 0.13 mile west of U. S. Highway 99E. 3/19/48, 22.4; 11/22/48, 27.6; 3/28/50, 27.1.

15N 4E-32F1—Reference point—top of wood frame in concrete floor under pump, elevation 62.2 feet, 0.18 mile west of U. S. Highway 99E at a point 0.53 mile south of intersection with Earle Road. 12/10/47, 21.8; 3/2/48, 22.2; 3/30-48, 20.8; 5-14/48, 20.9; 11/22/48, 23.7; 11/23/49, 25.1.

15N 4E-32L1—Reference point—top of concrete under pump, elevation 64 feet, 0.06 mile east of Olivehurst Avenue at a point 0.03 mile from intersection with U. S. Highway 99E. 12/1/47, 30.7; 3/17/48, 22.8.

15N 4E-32M1—Reference point—top of casing, elevation 60 feet, 0.40 mile due west of intersection of Olivehurst Avenue and U. S. Highway 99E. 12/1/47, 22.1; 3/17/48, 22.3; 11/19/48, 24.4; 3/21-49, 23.5.

15N 4E-33D1—Reference point—top of casing, elevation 70.5 feet, 0.10 mile south of Earle Road, 0.80 mile east of intersection with U. S. Highway 99E. 12/10/47, 28.2; 3/1/48, 26.7; 11/22/49, 33.1.

15N 4E-33D2—Reference point—top of concrete pit, north wall, elevation 70.2 feet, 0.10 mile south of Earle Road, 0.85 mile west of Griffith Avenue. 12/10/47, 28.1; 3/2/48, 26.6; 3/31/48, 26.6; 10-8/48, 31.6; 11/22/48, 30.5; 3/17/49, 28.2; 11-22/49, 33.8; 3/24/50, 30.8; 4-4/52, 31.8.

15N 4E-33H1—Reference point—top of casing, elevation 64.0 feet, 0.05 mile west of Griffith Avenue, 0.46 mile south of Earle Road. 12/4/47, 26.8; 3/18/48, 25.5; 11-19/48, 29.3; 3/23/49, 27.5; 11-23/49, 32.6; 3/27/50, 30.3; 11-2/50, 34.9; 7/5/51, 29.5; 11/30/51, 34.9; 4/4/52, 30.3.

15N 4E-33R1—Reference point—top of casing, elevation 65 feet, 1.51 miles north of McGowan Road, 1 mile due east of U. S. Highway 99E. 12-1/47, 26.8; 3/8/48, 29.6; 11/19/48, 33.9; 3/23-49, 31.6; 11-23/49, 38.0.

15N 4E-34D1—Reference point—top of wooden floor of pump house, elevation 69.4 feet, South side of Earle Road, 0.10 mile east of Griffith Avenue. 12/10/47, 22.7; 10-8/48, 26.5; 11/22/48, 25.6; 3/17/49, 24.8; 11/22-49, 29.0; 3/30/51, 26.8; 11-21-51, 31.2; 4/4/52, 26.1.

15N 4E-35E1—Reference point—top of 6" x 6" sill, south wall, elevation 68.7 feet, 0.15 mile east of curve in Earle Road, 1.32 miles south of North Beale Road. 12/10-47, 23.4; 3/1/48, 13.8; 3-31-48, 13.6; 10-8/48, 26.1; 11-22-48, 26.5; 3/17-49, 26.1; 11/22/49, 30.2; 3-24-50, 29.8; 11-2-50, 32.4; 3/30-51, 30.4; 11-21-51, 35.2; 4-4-52, 32.6.

15N 4E-35Q1—Reference point—top of casing, elevation 72.2 feet, North side of Spenceville Road, 0.26 mile east of intersection with Earle Road. 12-4/47, 21.8; 3/18/48, 21.6; 11-18-48, 25.3; 3/23/49, 23.9.

15N 5E-19C1—Reference point—top of brick curb, elevation 86 feet, 1.20 miles south of Hammonton Road at a point 1.50 miles from intersection of Brophy Road. 11-22-29, 24.3; 9-6-30, 24.1; 12-14-31, 26.2; 12-9/32, 25.7; 12-11/33, 25.9; 11-20/34, 26.6; 11/28-36, 25.4; 1-9-41, 3.0; 11-6-47, 24.6; 12-10-48, 24.6; 12-7-49, 27.3; 11/10/50, 26.9.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Meosurements Mode by Division of Woter Resources
(Depths to water in feet meosured from reference point)

15N/5E-19L1—Reference point—top of concrete crib, elevation 86 feet, 1.77 miles south of Hammonton Road at a point 1.40 miles from intersection of Brophy Road. 11/22/29, 25.8; 9/26/30, 25.5; 12/14/31, 26.5; 12/9/32, 26.7; 12/14/33, 27.4; 11/20/34, 27.6; 11/28/36, 26.2; 11/23/37, 27.1; 1/9/41, 3.0; 11/6/47, 30.9; 12/10/48, 33.4; 12/7/49, 37.0; 11/10/50, 39.6; 12/5/51, 69.7.

15N/5E-31R1—Reference point—top of casing, elevation 79.2 feet. North side of Spenceville Road, 2.43 miles east of intersection with Virginia Road. 12/24/47, 22.1; 3/24/48, 22.0; 11/18/48, 26.7; 1/18/48, 24.9; 3/21/49, 24.2; 12/5/49, 32.2; 3/27/50, 30.3; 11/2/50, 38.4; 4/2/51, 33.2; 4/4/52, 36.5.

15N/5E-32J1—Reference point—top of casing, elevation 91 feet, 0.26 mile north of Spenceville Road, 3.43 miles east of intersection with Virginia Road. 12/24/47, 33.9; 3/24/48, 33.7; 11/18/48, 36.0; 3/21/49, 36.1; 12/5/49, 43.5; 3/27/50, 42.1; 11/2/50, 50.6; 4/2/51, 45.6; 11/21/51, 48.6.

16N/2E-1B1—Reference point—top of casing, elevation 76.2 feet, 350 feet south of Pennington Road, 0.3 mile west of Township Road. 12/22/47, 10.1; 3/1/48, 10.4; 12/8/48, 9.6; 3/29/49, 8.0; 11/8/49, 9.4; 3/21/50, 8.8; 11/2/50, 9.7 3/27/51, 8.6; 11/13/51, 9.2; 4/2/52, 8.1.

16N/2E-1J1—Reference point—hole in pump flange, elevation 72.1 feet, 0.2 mile west of Township Road, 0.5 mile south of Pennington Road. 12/23/47, 7.2; 3/1/48, 7.4; 12/18/48, 6.9; 1/20/49, 6.5; 3/21/49, 4.0; 11/9/49, 6.6.

16N/2E-2A1—Reference point—top of concrete floor, elevation 74.2 feet, 300 feet south of Pennington Road, 0.15 mile west of Schroeder Road. 12/22/47, 8.1; 3/1/48, 8.6; 12/8/48, 7.7; 3/20/49, 6.1; 11/8/49, 6.1; 3/21/50, 7.3; 11/2/50, 6.9; 3/23/51, 7.2; 11/13/51, 7.3; 4/2/52, 6.6.

16N/2E-2J1—Reference point—top of casing, elevation 73.6 feet, 300 feet west of Schroeder Road, 0.75 mile south of Pennington Road. 12/23/47, 8.8; 3/1/48, 9.2; 12/8/48, 8.7; 3/21/49, 5.7; 11/9/49, 6.1.

16N/2E-3K1—Reference point—top of casing, elevation 71.0 feet, 0.50 mile south of Pennington Road, 0.50 mile west of Krehe Road. 11/26/29, 8.4; 10/21/30, 8.7; 12/16/31, 8.1; 12/9/32, 8.4; 12/13/33, 7.0; 11/21/34, 7.8; 11/27/36, 7.5; 12/1/37, 7.1; 1/25/39, 6.8; 1/10/41, 3.5; 11/4/47, 2.7; 12/14/48, 6.2; 11/8/49, 5.6; 11/10/50, 6.7; 11/26/51, 6.1.

16N/2E-4B1—Reference point—top of casing, elevation 73.7 feet, 0.30 mile south of Pennington Road, 1.27 miles west of Krehe Road. 12/22/47, 9.9; 3/2/48, 10.1; 12/3/48, 10.0; 3/30/49, 8.2; 11/15/49, 8.6.

16N/2E-5B1—Reference point—bottom of flange above discharge pipe, elevation 74.8 feet, 0.15 mile south of Pennington Road, 2.3 miles west of Krehe Road. 12/22/41, 6.8; 3/2/48, 6.7; 12/3/48, 9.2; 3/30/49, 10.0; 11/16/49, 8.0.

16N/2E-5L1—Reference point—top of casing, elevation 87.8 feet, 0.55 mile south-southeast of 90 degree turn in Pennington Road, 2.5 miles west of Krehe Road. 12/22/47, 12.8; 3/2/48, 12.8; 12/3/48, 13.6; 3/30/49, 12.0; 11/15/49, 14.0; 3/24/50, 12.8; 11/2/50, 16.1; 3/27/51, 12.9.

16N/2E-12J1—Reference point—top of casing, elevation 71.8 feet, 0.25 mile west of Township Road, 0.15 mile north of Paseo Avenue. 12/23/47, 8.5; 3/1/48, 8.6; 12/8/48, 8.4; 3/21/49, 4.0; 11/9/49, 8.0; 3/22/50, 7.3; 11/3/50, 8.0; 4/3/51, 7.1; 11/14/51, 7.8; 4/2/52, 7.0.

16N/2E-13G2—Reference point—top of casing, elevation 64.6 feet, 0.3 mile west of Township Road, 0.7 mile north of Clark Road. 12/23/47, 7.0; 3/1/48, 3.6; 12/8/48, 3.2; 3/21/49, —1.5; 11/10/49, 5.8; 3/22/50, 7.4.

16N/2E-24D1—Reference point—top of casing, elevation 66.4 feet, 100 feet south of Clark Road, 0.8 mile west of Township Road. 12/23/47, 8.9; 3/1/48, 8.0; 12/8/48, 7.7; 1/20/49, 8.5; 3/21/49, 6.1; 11/10/49, 4.5; 3/22/50, 8.2; 11/3/50, 8.1; 4/3/51, 36.2 (operating); 11/14/51, 8.2; 4/2/52, 6.6.

16N/2E-25P1—Reference point—top of casing, elevation 62.1 feet, 100 feet north of Sanders Road, 1.0 mile west of Broadway. 12/19/47, 9.7; 3/3/48, 10.5; 12/2/48, 9.2; 1/20/49, 10.0; 3/16/49, 8.8; 11/10/49, 7.7; 3/22/50, 9.2; 11/6/50, 8.2; 4/4/51, 8.6; 11/14/51, 8.3; 4/3/52, 6.9.

16N/2E-26K1—Reference point—top of casing, elevation 66.4 feet, 500 feet east of East Butte Road, 0.25 mile north of Sanders Road. 12/19/47, 14.7; 3/3/48, 14.5; 12/2/48, 13.5; 3/16/49, 13.3; 11/10/49, 10.8; 3/22/50, 11.9; 11/2/50, 12.8; 4/4/51, 11.9; 11/14/51, 12.4; 4/3/52, 9.2.

16N/2E-35B1—Reference point—top of casing, elevation 64 feet, 800 feet east of East Butte Road, 0.25 mile south of Sanders Road. 11/26/29, 12.0; 10/21/30, 11.5; 12/16/31, 13.0; 12/8/32, 12.1; 11/21/34, 12.2; 11/24/36, 12.7; 12/1/37, 11.0; 1/25/39, 12.0; 1/11/41, 6.7; 11/4/47, 1.0; 12/14/48, 12.1; 11/11/49, 10.3; 11/10/50, 11.1; 11/26/51, 11.6.

16N/2E-35C2—Reference point—top of casing (10 feet above ground), elevation 65 feet, 300 feet west of East Butte Road, 0.1 mile south of Sanders Road. 12/13/33, 16.3; 11/21/34, 16.9; 12/1/37, 14.5; 1/25/39, 16.2; 1/11/41, 9.8.

16N/3E-1E1—Reference point—top of casing at bottom of pit, ground elevation 80 feet, 0.1 mile east of State Highway 24, 0.6 mile north of Ramirez Road. 11/3/47, 12.5; 3/23/48, 9.4; 12/6/48, 11.2; 3/21/49, 9.4; 11/15/49, 13.4.

16N/3E-1E2—Reference point—base of pump, elevation 80 feet, 0.20 mile east of State Highway 24, 0.6 mile north of Ramirez Road. 11/3/47, 22.3; 3/23/48, 19.2; 12/6/48, 20.6; 3/21/49, 19.0; 11/15/49, 23.1; 3/21/50, 17.0; 11/7/50, 24.5; 3/29/51, 15.2; 11/15/51, 21.7; 4/6/52, 10.7.

16N/3E-1M1—Reference point—top of casing, elevation 78 feet, 500 feet east of State Highway 24, 0.3 mile north of Ramirez Road. 11/4/47, 21.2; 3/23/48, 18.5.

16N/3E-1P2—Reference point—base of pump, elevation 78 feet, 300 feet north of Ramirez Road, 0.60 mile east of State Highway 24. 11/4/47, 18.4; 3/23/48, 15.1; 12/2/48, 15.8; 3/21/49, 15.0; 11/15/49, 18.2; 3/2/50, 19.7; 3/29/51, 11.6; 11/15/51, 17.7; 4/6/52, 5.6.

16N/3E-2C1—Reference point—top of casing, elevation 80 feet, 0.60 mile west of State Highway 24, 0.70 mile north of Ramirez Road. 11/3/47, 21.6; 3/23/48, 18.0; 12/6/48, 20.5; 3/21/49, 18.5; 11/15/49, 22.6; 3/21/50, 16.2; 11/7/50, 22.4; 3/29/51, 14.0; 11/15/51, 21.0; 4/6/52, 10.3.

16N/3E-2J1—Reference point—top of casing, elevation 79 feet, 0.17 mile west of State Highway 24, 0.32 mile north of Ramirez Road. 6/1/48, 16.5; 6/30/48, 20.0; 7/21/48, 34.9; 9/1/48, 21.2; 9/30/48, 20.6; 12/3/48, 17.9; 3/21/49, 16.1.

16N/3E-4L1—Reference point—top of casing, elevation 75 feet, 30 feet west of Sheldon Road, 0.25 mile south of Archer Road. 11/10/47, 10.4; 3/20/48, 13.4; 12/3/48, 10.9; 3/8/49, 13.0; 11/9/49, 9.2.

16N/3E-4M1—Reference point—top of casing, elevation 79.2 feet, 50 feet east of Sinnard Road, 0.15 mile south of Archer Road. 12/23/47, 11.3; 3/1/48, 11.9; 12/3/48, 10.7; 3/21/49, 9.4; 11/9/49, 9.9.

16N/3E-4N1—Reference point—top of casing, elevation 76.9 feet, 100 feet south of Coleman Avenue, 0.05 mile west of Sinnard Road. 12/23/47, 9.9; 3/1/48, 10.8; 12/3/48, 9.2.

16N/3E-5A1—Reference point—top of casing, elevation 78.6 feet, 400 feet south of Pennington Road, 0.4 mile east of Larkin Road. 12/23/47, 10.7; 3/1/48, 11.0; 12/8/48, 10.5; 3/30/49, 9.0; 11/8/49, 10.1; 3/22/50, 8.1; 11/2/50, 11.1; 3/27/51, 8.3; 11/14/51, 10.6; 4/2/52, 7.5.

16N/3E-5P1—Reference point—hole in pump base, elevation 74.0 feet, 0.15 mile west of Larkin Road, 1.0 mile north of Paseo Road. 5/4/48, 8.9; 6/2/48, 8.7; 6/30/48, 49.9 (operating); 12/4/48, 11.5; 3/21/49, 5.4; 4/3/51, 7.7.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet measured from reference point)

16N 3E-6A1—Reference point—top of casing, elevation 77.9 feet. South side of Pennington Road, 0.8 mile east of Township Road. 12/22/47, 12.1; 3/1/48, 11.4; 5/13/48, 10.0; 12/8/48, 12.3; 1/21/49, 11.4; 3/30/49, 8.0; 11/8/49, 12.6; 3/22/50, 8.6; 11/2/50, 13.6; 3/27/51, 7.5; 11/13/51, 12.8; 4/2/52, 5.2.

16N 3E-7D2—Reference point—top of casing, elevation 73.5 feet, 0.1 mile east of Township Road, 0.65 mile north of Paseo Avenue. 12/23/47, 10.1; 3/1/48, 9.8; 12/8/48, 9.5; 3/21/49, 3.6; 11/9/49, 9.2; 3/22/50, 8.0; 11/3/50, 10.0; 4/3/51, 7.4; 11/14/51, 8.7; 4/2/52, 7.0.

16N 3E-8C1—Reference point—top of curb, elevation 74.1 feet, 0.2 mile west of Larkin Road, 0.75 mile north of Paseo Avenue. 12/23/47, 8.9; 3/1/48, 9.1; 12/4/48, 9.1; 3/21/49, 5.4; 11/9/49, 6.9; 3/22/50, 5.5; 11/3/50, 9.9; 4/3/51, 6.3; 11/14/51, 8.9; 4/2/52, 2.9.

16N 3E-8P1—Reference point—top of casing, elevation 72.0 feet, 200 feet north of Paseo Avenue, 0.15 mile west of Larkin Road. 12/23/47, 8.8; 3/1/48, 9.0; 12/4/48, 8.7; 3/21/49, 5.5; 11/9/49, 7.3.

16N 3E-8R1—Reference point—top of casing, elevation 71 feet, 160 feet north of Paseo Avenue, 400 feet east of U. S. Highway 99E. 1/10/41, 3.1; 11/5/47, 7.6; 12/5/47, 9.2; 12/13/48, 9.3; 11/9/49, 7.1; 3/22/50, 8.7; 11/10/50, 9.4; 4/2/51, 7.2; 11/26/51, 7.8.

16N 3E-8R2—Reference point—top of casing, elevation 71 feet, 100 feet north of Paseo Avenue, 300 feet east of U. S. Highway 99E. 1/23/29, 8.8; 9/27/30, 8.3; 12/16/31, 9.3; 12/9/32, 9.3; 12/13/33, 8.9; 11/21/34, 7.3; 1/24/36, 8.4; 12/1/37, 7.3; 1/26/39, 10.3.

16N 3E-9A1—Reference point—top of casing, elevation 72 feet, 1,500 feet north of Bishop Road, 100 feet east of Levee. 11/10/47, 14.9; 3/20/48, 17.1; 12/3/48, 16.0; 3/8/49, 17.4; 11/9/49, 13.7; 3/22/50, 10.0; 11/3/50, 13.8; 4/2/51, 11.0; 11/14/51, 14.5; 4/3/52, 11.7.

16N 3E-9M1—Reference point—top of casing, elevation 71 feet, 400 feet east of Simard Road, 0.3 mile north of Paseo Avenue. 3/20/48, 11.5; 12/3/48, 10.8; 3/8/49, 11.3; 11/9/49, 8.7; 3/22/50, 9.1; 11/3/50, 9.0; 4/2/51, 7.3; 11/14/51, 8.8; 4/3/52, 5.9.

16N 3E-9Q1—Reference point—top of casing, elevation 75 feet, 60 feet west of Kent Avenue, 150 feet north of Paseo Avenue. 11/10/47, 16.1; 3/20/48, 19.1; 5/13/48, 13.1; 12/3/48, 18.6; 3/8/49, 18.2; 11/8/49, 17.2.

16N 3E-11C1—Reference point—base of pump, elevation 79 feet, 0.50 mile west of State Highway 24 on Ramirez Road extension. 11/4/47, 21.2; 3/23/48, 18.9; 5/7/48, 16.6; 12/3/48, 19.9; 1/26/49, 19.4; 3/21/49, 19.0; 11/15/49, 22.1; 3/21/50, 18.1; 11/7/50, 22.6; 3/29/51, 14.4; 11/15/51, 20.8; 4/6/52, 10.6.

16N 3E-11E1—Reference point—top of casing, elevation 78 feet, 0.75 mile west of State Highway 24, 0.45 mile south of Ramirez Road. 11/5/47, 21.2; 3/23/48, 18.3; 12/3/48, 20.7; 3/21/49, 17.6; 11/15/49, 21.6.

16N 3E-11F1—Reference point—top of casing, elevation 77 feet, 0.50 mile west of State Highway 24, 0.35 mile south of Ramirez Road. 11/5/47, 20.6; 3/23/48, 18.6; 12/3/48, 19.1; 3/21/49, 17.0; 11/15/49, 21.1.

16N 3E-11F2—Reference point—base of pump, elevation 76 feet, 0.50 mile west of State Highway 24, 0.30 mile south of Ramirez Road. 11/5/47, 19.8; 3/23/48, 17.5; 12/3/48, 19.2; 3/21/49, 15.2; 11/15/49, 20.3.

16N 3E-11K1—Reference point—base of pump, elevation 76 feet, 0.20 mile west of State Highway 24, 0.70 mile south of Ramirez Road. 11/5/47, 19.8; 3/23/48, 20.6; 12/3/48, 18.0; 3/18/49, 16.5; 11/15/49, 19.4.

16N 3E-11L1—Reference point—top of casing, elevation 76 feet, 0.40 mile west of State Highway 24, 0.7 mile south of Ramirez Road. 11/5/47, 18.0; 3/23/48, 16.2; 12/3/48, 16.4; 3/18/49, 14.6; 11/15/49, 17.8.

16N 3E-11Q1—Reference point—top of casing, elevation 75 feet, 750 feet west of State Highway 24, 0.9 mile south of Ramirez Road. 11/5/47, 10.1; 12/3/48, 9.5; 3/18/49, 7.0; 11/15/49, 10.0.

16N 3E-12B1—Reference point—top of casing, elevation 79 feet, 20 feet south of Ramirez Road, 0.70 mile east of State Highway 24. 11/4/47, 16.4; 3/23/48, 14.5; 5/7/48, 13.1; 12/2/48, 14.5; 1/25/49, 14.2; 3/21/49, 13.0; 11/15/49, 16.7.

16N 3E-12B2—Reference point—top of casing, elevation 79 feet, 750 feet south of Ramirez Road, 0.75 mile east of State Highway 24. 11/4/47, 9.4; 3/23/48, 7.4; 12/2/48, 7.2; 3/21/49, 5.6; 11/15/49, 8.6.

16N/3E-12E1—Reference point—top of casing at bottom of pit, elevation 76 feet, 0.3 mile east of State Highway 24, 0.6 mile south of Ramirez Road. 11/5/47, 10.2; 3/23/48, 7.6; 12/6/48, 9.5; 3/18/49, 7.5; 11/15/49, 10.3; 3/21/50, 15.3; 11/7/50, 20.6*; 3/29/51, 11.9; 11/15/51, 18.2*; 4/6/52, 6.4*.

16N/3E-12L2—Reference point—top of casing, elevation 76 feet, 0.6 mile east of State Highway 24, 0.6 mile south of Ramirez Road. 11/7/47, 11.3; 3/23/48, 9.2; 12/6/48, 5.4; 3/18/49, 8.0; 11/15/49, 10.1.

16N/3E-13G1—Reference point—top of casing, elevation 72 feet, 2,600 feet north of Magnon Way, 4,300 feet east of State Highway 24. 11/7/47, 14.6; 3/25/48, 13.8; 12/10/48, 13.7; 11/16/49, 14.7; 3/21/50, 13.6; 11/7/50, 18.1; 3/29/51, 9.1; 4/6/52, 5.5.

16N/3E-14B1—Reference point—top of casing, elevation 75 feet, 500 feet west of State Highway 24, 1.2 miles south of Ramirez Road. 11/5/47, 9.2; 3/23/48, 8.1; 5/7/48, 5.8; 12/3/48, 7.8; 3/18/49, 6.1; 11/15/49, 9.3; 3/21/50, 10.0; 11/7/50, 10.3; 3/29/51, 1.7; 11/15/51, 7.9; 4/6/52, 3.7.

16N/3E-14C1—Reference point—top of casing, elevation 74 feet, 1.2 miles south of Ramirez Road, 0.4 mile west of State Highway 24. 11/5/47, 9.75; 3/25/48, 9.1; 12/3/48, 6.8; 3/18/48, 6.8; 11/15/49, 9.9.

16N/3E-14D1—Reference point—top of casing, elevation 72 feet, 1.2 miles south of Ramirez Road, 0.5 mile west of State Highway 24. 11/5/47, 9.9; 3/23/48, 10.7; 5/7/48, 5.8; 12/3/48, 8.9; 1/26/49, 7.9; 3/18/49, 7.0; 11/15/49, 10.2; 3/21/50, 13.9; 11/7/50, 11.2; 3/29/51, 9.4; 11/15/51, 15.8.

16N/3E-14J1—Reference point—hole in front of base of pump, elevation 71 feet, 600 feet north of Magnolia Way, 950 feet east of State Highway 24. 11/8/47, 16.1; 3/25/48, 14.8; 12/3/48, 15.3; 3/18/49, 13.1; 11/16/49, 16.5.

16N/3E-14L1—Reference point—top of casing at bottom of 12-foot pit, elevation 59 feet, 0.5 mile west of State Highway 24, 1.5 miles south of Ramirez Road. 11/8/47, 6.7; 3/25/48, 5.1; 12/3/48, 5.3; 3/18/49, 5.1; 11/16/49, 7.3; 3/21/50, 3.2; 11/7/50, 7.8; 3/29/51, 12.0*; 11/15/51, 18.8*; 4/6/52, 6.0.

16N/3E-16M1—Reference point—top of concrete block, elevation 70 feet, 900 feet south of Cutting Avenue, 300 feet east of U. S. Highway 99E. 11/10/47, 7.65; 3/20/48, 11.7; 12/3/48, 8.9.

16N/3E-17C1—Reference point—top of flange under pump, elevation 72.4 feet, 400 feet east of Larkin Road, 0.8 mile north of Clark Road. 12/23/47, 8.7; 3/1/48, 8.8; 12/4/48, 7.7, 3/21/49, 6.5; 11/9/49, 7.8; 3/22/50, 7.6; 11/3/50, 8.9; 4/3/51, 7.5; 11/14/51, 8.2; 4/2/52, 6.9.

16N/3E-17Q1—Reference point—top of concrete pit, elevation 70.5 feet, 0.2 mile east of Larkin Road, 500 feet north of Clark Road. 12/23/47, 9.3; 3/2/48, 10.1; 5/4/48, 8.0; 6/1/48, 7.0; 12/1/48, 9.4; 1/20/49, 9.8; 3/21/49, 7.5; 5/26/49, 7.0; 6/30/49, 5.6; 7/31/49, 6.2; 8/31/49, 6.5; 11/10/49, 8.7; 3/22/50, 8.9; 11/3/50, 8.8; 4/3/51, 6.8; 11/14/51, 7.9; 4/3/52, 5.4.

* Top of pit.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Meosurements Made by Division of Water Resources
(Depths to water in feet measured from reference point)

16N/3E-18C1—Reference point—top of casing, elevation 68.3 feet, 100 feet south of Pasco Avenue, 100 feet west of Broadway. 12/23/47, 6.4; 3/1/48, 6.3; 12/4/48, 8.3; 1/20/49, 6.2; 3/21/49, 4.1.

16N/3E-19C1—Reference point—top of casing, elevation 66.8 feet, 250 feet west of Broadway, 0.1 mile south of Clark Road. 12/23/47, 7.1; 3/2/48, 7.2; 12/4/48, 6.8; 3/21/49, 4.7; 11/10/49, 5.5; 3/22/50, 8.6; 11/3/50, 6.3; 4/3/51, 6.4; 11/14/51, 6.7; 4/2/52, 5.7.

16N/3E-20E1—Reference point—slot in concrete base, elevation 69.8 feet, 200 feet west of Marden Avenue, 0.2 mile south of Clark Road. 12/23/47, 10.4; 3/24/48, 11.3; 12/4/48, 10.2; 3/21/49, 8.1; 5/26/49, 7.5; 6/28/49, 7.8; 7/27/49, 9.3; 8/25/49, 8.7; 11/10/49, 9.7; 3/22/50, 10.0; 11/3/50, 9.3; 4/3/51, 9.6; 11/14/51, 10.3; 4/2/52, 9.2.

16N/3E-21D1—Reference point—hole in base of pump, elevation 70 feet, 200 feet south of Clark Road, 0.6 mile east of Larkin Road. 12/23/47, 10.7; 3/2/48, 11.4; 12/3/48, 10.3; 11/8/49, 10.3; 3/22/50, 9.6; 11/3/50, 10.3; 4/3/51, 6.4; 11/4/51, 9.2; 4/3/52, 4.0.

16N/3E-21J1—Reference point—top of casing, elevation 68.0 feet, 0.4 mile east of U. S. Highway 99E, 0.3 mile north of Encinal Road. 11/10/47, 17.9; 3/20/48, 16.4; 5/13/48, 13.3; 12/3/48, 17.5; 1/21/49, 17.0; 3/8/49, 16.8; 11/10/49, 18.6; 3/22/50, 17.2; 4/3/51, 10.5; 11/14/51, 16.5; 4/3/52, 5.2.

16N/3E-21P2—Reference point—top of casing, elevation 65.9 feet, West side of Southern Pacific Railroad Right of Way, 0.1 mile north of Encinal Road. 12/23/47, 14.5; 3/2/48, 15.3; 12/3/48, 14.1; 3/21/49, 13.0; 11/10/49, 15.3.

16N/3E-23C1—Reference point—top of casing, elevation 71 feet, 0.25 mile west of State Highway 24 at a point 0.4 mile south of Magnolia Way intersection. 11/8/47, 17.2; 3/25/48, 15.9; 5/19/48, 13.9; 12/2/48, 15.9; 1/26/49, 15.5; 3/8/49, 13.0.

16N/3E-23J1—Reference point—top of casing, elevation 70 feet, 0.1 mile east of State Highway 24, 0.3 mile north of Woodruff Lane. 11/8/47, 14.3; 3/25/48, 13.1; 5/19/48, 11.9; 12/2/48, 14.6; 3/18/49, 13.0; 11/16/49, 15.1.

16N/3E-23R3—Reference point—center of pump shaft, elevation 70 feet, 200 feet north of Woodruff Lane, 0.3 mile east of State Highway 24. 11/8/47, 14.0; 3/25/48, 13.0; 12/2/48, 13.0; 3/18/49, 11.5; 11/16/49, 13.9.

16N/3E-24A1—Reference point—top of casing, elevation 70 feet, 0.2 mile south of Magnolia Way extended 1.1 miles east of State Highway 24. 11/7/47, 13.8; 3/25/48, 13.5; 12/2/48, 13.7; 1/26/49, 14.4; 3/18/49, 11.1; 11/16/49, 14.5; 3/21/50, 12.1; 11/6/50, 15.8; 3/29/51, 9.4; 11/15/51, 15.1; 4/6/52, 6.0.

16N/3E-24C1—Reference point—top of casing, elevation 70 feet, 0.4 mile south of Magnolia Way, 0.75 mile east of State Highway 24. 11/7/47, 12.3; 3/25/48, 11.7; 12/10/48, 12.1; 3/18/49, 9.8; 11/16/49, 13.2.

16N/3E-24Q1—Reference point—top of casing in pit, elevation 66 feet, North of Woodruff Lane, 1.05 miles east of State Highway 24. 11/7/47, 4.2; 3/25/48, 4.2; 5/19/48, 2.9; 11/30/48, 4.6; 11/16/49, 11.8; 3/21/50, 8.8; 11/6/50, 12.8; 3/29/51, 6.9; 11/15/51, 17.3; 9/6/52, 5.0.

16N/3E-24R2—Reference point—hole in pump base, elevation 69 feet, 0.1 mile north of Woodruff Lane, 0.1 mile east of State Highway 24. 6/2/48, 11.8; 7/1/48, 15.2; 7/21/48, 15.5; 8/1/48, 18.1; 9/2/48, 17.3.

16N/3E-26F1—Reference point—hole in pump base, elevation 69 feet, 0.45 mile west of State Highway 24, at a point 0.3 mile south of Woodruff Lane intersection. 11/15/47, 18.0; 5/3/48, 12.3; 6/1/48, 13.2; 11/30/48, 18.2; 12/13/48, 18.1; 1/26/49, 15.5; 3/18/49, 14.1; 12/9/49, 18.7; 3/21/50, 14.0; 11/6/50, 17.8; 11/10/50, 18.6; 3/29/51, 10.1; 11/15/51, 17.4; 12/7/51, 14.7; 4/6/52, 5.9.

16N/3E-26F2—Reference point—top of concrete pit, elevation 68 feet, 0.5 mile west of State Highway 24, at a point 0.3 mile south of Woodruff Lane intersection. 11/26/29, 15.9; 9/25/30, 15.6; 12/16/31, 16.7; 12/6/32, 16.8; 12/14/33, 16.5; 11/23/34, 16.9; 11/24/36, 15.8; well destroyed.

16N/3E-26G1—Reference point—hole in pump base, elevation 68 feet, 0.25 mile west of State Highway 24 at a point 0.3 mile south of Woodruff Lane intersection. 5/7/48, 12.2; 6/30/48, 52.6 (operating); 11/30/48, 13.6.

16N/3E-26G2—Reference point—top of casing, elevation 68 feet, 0.15 mile west of State Highway 24, at a point 0.3 mile south of Woodruff Lane intersection. 12/1/37, 11.0; 1/27/39, 9.4; 1/10/41, 6.5.

16N/3E-27E1—Reference point—top of casing, elevation 66 feet, 0.1 mile north of Morse Road, 0.4 mile east of U. S. Highway 99E. 3/17/48, 21.9; 11/29/48, 23.7; 3/17/49, 20.0; 5/26/49, 20.5; 6/28/49, 24.5; 7/27/49, 25.1; 8/25/49, 26.2; 11/14/49, 25.2.

16N/3E-28C1—Reference point—top of concrete pit, elevation 65 feet, 0.05 mile south of Encinal Road, 0.1 mile west of U. S. Highway 99E. 3/17/48, 14.2; 11/29/48, 14.6; 3/17/49, 13.7; 11/14/49, 15.5.

16N/3E-28E1—Reference point—top of casing, elevation 65 feet, 0.25 mile south of Encinal Avenue, 0.35 mile west of U. S. Highway 99E. 11/4/47, 17.5.

16N/3E-28N1—Reference point—top of casing, elevation 64.6 feet, 200 feet north of Sanders Road, 0.6 mile east of Larkin Road. 12/19/47, 17.2; 11/29/48, 17.5; 3/17/49, 15.8; 11/10/49, 18.6; 3/22/50, 15.9; 11/3/50, 18.9; 4/3/51, 11.2; 11/14/51, 16.6; 4/3/52, 7.6.

16N/3E-29B1—Reference point—top of concrete pit, elevation 66.8 feet, South side of Encinal Road, 0.2 mile east of Larkin Road. 12/23/47, 12.8; 3/2/48, 13.6; 5/13/48, 11.5; 12/4/48, 13.0; 1/19/49, 13.0.

16N/3E-29N1—Reference point—top of concrete pit, elevation 65.8 feet, 0.25 mile west of Sacramento Northern Railroad tracks, 0.25 mile north of Sanders Road. 12/19/47, 15.3; 3/2/48, 15.2; 12/1/48, 14.3; 3/16/49, 14.0; 1/10/49, 14.7; 3/22/50, 13.2; 11/3/50, 14.5; 4/3/51, 9.6; 11/14/51, 12.4; 4/3/52, 7.3.

16N/3E-29R1—Reference point—hole in pump base, elevation 62 feet, 150 feet north of Sanders Road, 0.4 mile east of Larkin Road. 5/4/48, 17.3; 6/1/48, 16.1; 11/29/48, 19.6.

16N/3E-30A2—Reference point—top of casing, elevation 68.8 feet, 0.1 mile south of Encinal Road, 0.35 mile east of Broadway. 12/23/47, 12.1; 3/2/48, 12.8; 12/4/48, 11.9; 3/21/49, 11.4; 11/10/49, 11.0.

16N/3E-30F1—Reference point—top of pit wall, elevation 64.3 feet, 0.1 mile west of Broadway, 0.45 mile south of Encinal Road. 12/23/47, 11.1; 3/2/48, 11.6; 12/4/48, 10.8; 1/19/49, 10.7; 3/21/49, 9.0; 11/10/49, 10.5; 3/22/50, 10.1; 11/3/50, 10.7; 4/3/51, 9.2; 11/14/51, 10.8; 4/3/52, 6.7.

16N/3E-30L1—Reference point—top of casing next to pump, elevation 62.5 feet, 0.4 mile north of Sanders Road, 400 feet west of Broadway. 12/19/47, 8.9; 3/2/48, 9.5; 12/1/48, 8.7; 3/16/49, 8.8; 11/10/49, 7.8.

16N/3E-30R1—Reference point—top of casing next to pump, elevation 62.5 feet, 500 feet north of Sanders Road, 0.5 mile west of Sacramento Northern Railroad. 12/19/47, 12.9; 3/2/48, 12.6.

16N/3E-31D1—Reference point—top of casing under pump, elevation 60.4 feet, 500 feet south of Sanders Road, 0.2 mile west of Broadway Road. 12/19/47, 9.1; 3/3/48, 9.7; 3/16/49, 9.5.

16N/3E-31K2—Reference point—top of tin cover under pump, elevation 63.2 feet, 0.2 mile east of Broadway Road, 0.5 mile south of Sanders Road. 12/19/47, 13.7; 3/3/48, 14.1; 12/1/48, 17.3; 3/16/49, 16.4; 11/11/49, 18.3; 3/22/50, 15.2; 11/6/50, 19.3; 4/3/51, 12.1; 11/14/51, 16.6; 4/3/52, 17.0.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet measured from reference point)

16N 3E-32A2—Reference point—pump base hole, elevation 64.9 feet, 200 feet south of Sanders Road, 0.6 mile east of Sacramento Northern Railroad. 1/6/48, 19.5; 3/2/48, 19.7; 11/29/48, 21.0; 3/17/49, 17.0; 11/10/49, 19.8.

16N 3E-32B2—Reference point—top of 2" x 14" bridge over earth pit, elevation 64.4 feet, 200 feet south of Sanders Road, 0.3 mile east of Sacramento Northern Railroad. 12/19/47, 15.9; 3/2/48, 17.25; 12/1/48, 16.2; 3/17/49, 15.0; 11/10/49, 17.7.

16N 3E-32C2—Reference point—top of casing under pump, elevation 64.4 feet, 0.2 mile south of Sanders Road, 200 feet west of Sacramento Northern Railroad. 12/19/47, 18.1; 3/2/48, 18.7; 12/1/48, 16.9; 3/17/49, 16.1; 11/11/49, 18.5; 3/22/50, 15.9; 11/3/50, 18.2; 4/3/51, 11.3; 11/14/51, 16.1; 4/3/52, 6.4.

16N 3E-32G2—Reference point—hole in pump base, elevation 62.8 feet, 0.5 mile south of Sanders Road, 0.3 mile east of Sacramento Northern Railroad. 12/19/47, 18.9; 3/2/48, 20.2; 12/1/48, 16.9; 3/17/49, 16.8; 11/11/49, 19.8.

16N 3E-33D1—Reference point—top of concrete base, elevation 61.2 feet, 100 feet south of Sanders Road at a point 0.55 mile west of U. S. Highway 99E. 11/4/47, 17.2; 11/29/48, 19.2; 1/20/49, 17.2; 3/17/49, 16.8; 5/26/49, 17.1; 6/28/49, 19.3; 7/27/49, 26.15; 8/25/49, 25.9; 11/14/49, 20.0.

16N 3E-33E1—Reference point—top of concrete base under pump, elevation 64.1 feet, 0.3 mile south of Sanders Road at a point 0.8 mile west of U. S. Highway 99E. 11/4/47, 17.6; 3/17/48, 21.3; 5/13/48, 15.6; 11/29/48, 17.3; 11/14/49, 18.7; 3/22/50, 16.0; 11/6/50, 19.1; 4/3/51, 11.6; 4/3/52, 7.6.

16N 3E-33J2—Reference point—edge of pump base, elevation 66 feet, 150 feet west of U. S. Highway 99E at a point 0.45 mile north of Eager Road. 5/12/48, 20.3; 11/29/48, 27.0; 1/20/49, 23.0; 3/17/49, 22.0; 11/14/49, 27.3; 3/22/50, 22.0; 11/6/50, 25.4; 4/3/51, 17.2.

16N 3E-33P1—Reference point—hole beneath pump base, elevation 61.9 feet, 250 feet north of Eager Road at a point 0.6 mile west of U. S. Highway 99E. 1/9/48, 22.9; 11/22/48, 22.6; 3/17/49, 22.5; 11/14/49, 25.5.

16N 3E-35G1—Reference point—top of volute plug, elevation 67 feet, 400 feet north of Ellis Road at a point 0.5 mile west of State Highway 24. 11/6/47, 17.1; 1/26/49, 14.7; 3/18/49, 18.0; 11/16/49, 22.3.

16N 3E-35J1—Reference point—top of casing, elevation 70 feet, 100 feet south of Ellis Road at a point 0.2 mile west of State Highway 24. 11/6/47, 18.7; 3/29/48, 17.7; 11/30/48, 19.0; 3/17/49, 17.0; 11/16/49, 20.2.

16N 3E-35L1—Reference point—top of air gage hole, elevation 65 feet, 0.2 mile south of Ellis Road at a point 0.7 mile west of State Highway 24. 11/6/47, 20.2; 3/20/48, 20.1; 11/30/48, 20.9; 3/17/49, 20.1; 11/16/49, 22.9; 3/21/50, 17.4; 11/6/50, 22.9; 3/29/51, 19.5; 11/15/51, 23.5; 4/6/52, 10.1.

16N 3E-36G1—Reference point—top of concrete base under pump, elevation 64 feet, 300 feet north of Bills Road at a point 0.5 mile east of State Highway 24. 11/5/47, 11.7; 3/29/48, 11.4; 5/7/48, 10.0; 11/30/48, 12.2; 3/18/49, 9.6; 11/16/49, 12.1; 3/21/50, 11.1; 11/6/50, 12.7; 3/29/51, 6.7; 11/15/51, 11.8; 4/6/52, 4.6.

16N 4E-4L1—Reference point—top of concrete cribbing, elevation 96 feet, 0.15 mile west of La Porte Road, 0.30 mile north of Ramirez Road. 11/19/47, 22.4; 3/15/48, 22.8; 12/1/48, 23.1; 3/23/49, 24.0; 3/22/50, 24.9; 10/31/50, 26.7; 3/28/51, 23.5.

16N 4E-4N1—Reference point—top of casing, elevation 94 feet, 10.0 feet north of Ramirez Road, 0.05 mile east of Loma Rica Road. 3/15/48, 10.8.

16N 4E-5G1—Reference point—top of concrete cribbing, elevation 91 feet, 0.15 mile north of Ramirez Road, 0.5 mile west of Loma Rica Road. 11/19/47, 19.4; 3/15/48, 19.4; 12/1/48, 20.9; 3/23/49, 18.0; 12/9/49, 22.5; 3/22/50, 20.6; 10/31/50, 24.9; 3/28/51, 19.2; 11/14/51, 23.4; 4/6/52, 23.4.

16N 4E-6H1—Reference point—base of pump, elevation 85 feet, 0.50 mile north of Ramirez Road, 1.0 mile west of Loma Rica Road. 11/4/47, 17.8; 11/18/47, 17.2; 3/15/48, 17.6; 3/23/48, 17.4; 12/1/48, 18.1; 12/2/48, 19.0; 1/26/49, 17.1; 3/21/49, 16.2; 11/15/49, 20.7; 3/22/50, 17.6; 3/29/51, 16.7.

16N 4E-6J1—Reference point—top of casing, elevation 86 feet, 0.25 mile north of Ramirez Road, 1.0 mile west of Loma Rica Road. 11/4/47, 19.4; 11/19/47, 19.2; 3/15/48, 19.2; 3/23/48, 19.2; 12/1/48, 19.4; 12/2/48, 20.0; 3/21/49, 18.1; 11/15/49, 22.6; 3/21/50, 20.0; 3/22/50, 20.0; 11/7/50, 23.8; 11/15/51, 22.7; 4/6/52, 16.5.

16N 4E-6N1—Reference point—top of casing, elevation 80 feet, 30 feet north of Ramirez Road, 1.1 miles east of State Highway 24. 11/4/47, 16.9; 3/23/48, 15.5; well destroyed.

16N 4E-7B1—Reference point—top of casing, elevation 82 feet, 200 feet south of Ramirez Road, 1.5 miles west of Loma Rica Road. 11/4/47, 16.6; 3/23/48, 15.5; 12/2/48, 17.0; 3/21/49, 16.1; 11/15/49, 18.6.

16N 4E-8A1—Reference point—hole in pump base, elevation 91 feet, 150 feet south of Ramirez Road, 0.15 mile west of Loma Rica Road. 11/19/47, 18.8; 3/15/48, 20.0; 5/7/48, 17.5; 3/23/49, 17.8; 6/7/49, 40.5; 7/3/49, 37.3; 8/2/49, 37.6; 11/15/49, 22.0; 3/22/50, 19.8; 10/31/51, 18.9; 11/14/51, 23.0; 11/27/51, 22.6; 4/6/52, 18.0.

16N 4E-8A2—Reference point—top of casing, elevation 94 feet. South side of Ramirez Road, 0.15 mile west of Loma Rica Road. 11/26/29, 18.4; 9/25/30, 17.6; 12/14/31, 19.5; 12/6/32, 19.2; 12/14/33, 19.6; 11/23/34, 19.8; 11/24/36, 18.1; 11/23/37, 17.8; 11/27/39, 15.7; 1/9/41, 16.8; 11/5/47, 18.1; 12/13/48, 21.0; 12/9/49, 22.1; 11/10/50, 23.6.

16N 4E-9J1—Reference point—top of casing, elevation 95 feet, 200 feet west of Bangor Road, 0.6 mile south of Ramirez Road. 11/19/47, 23.2; 3/15/48, 23.4; 12/1/48, 24.0; 3/23/49, 21.8; 11/15/49, 26.6.

16N 4E-10E1—Reference point—top of casing at bottom of pit, elevation 80 feet, 400 feet east of Bangor Road, 0.35 mile south of Ramirez Road. 3/15/48, 2.4; 12/1/48, 3.4; 3/23/49, 2.6.

16N 4E-16A1—Reference point—hole in 4" x 4" board support, elevation 90 feet, 0.1 mile east of Bangor Road, 1.1 mile south of Ramirez Road. 11/19/47, 19.8; 3/15/48, 20.5; 5/7/48, 19.6; 12/1/48, 20.0; 3/23/49, 20.0; 11/17/49, 23.6; 3/23/50, 21.9; 10/31/50, 25.3; 3/28/51, 21.4; 11/14/51, 24.7; 4/6/52, 20.6.

16N 4E-16E1—Reference point—hole in pump base, elevation 81 feet, 100 feet east of Loma Rica Road, 1.25 miles south of Ramirez Road. 11/19/47, 13.0; 3/15/48, 9.3; 12/1/48, 13.6; 3/23/49, 11.8; 11/17/49, 16.5; 3/23/50, 14.5; 3/28/51, 13.1; 11/14/51, 14.6; 4/6/52, 10.8.

16N 4E-21M1—Reference point—top of casing, elevation 75 feet, 0.1 mile east of Loma Rica Road, 0.15 mile south of Bangor Road. 11/19/47, 5.6; 3/15/48, 6.5; 12/1/48, 6.2; 3/23/49, 4.0.

16N 4E-25M1—Reference point—top of concrete floor at bottom of pit, elevation 89 feet, 0.1 mile south of State Highway 20, 1.50 miles east of Loma Rica Road. 11/26/47, 2.8; 3/3/48, 5.0.

16N 4E-26F1—Reference point—top of casing, elevation 91 feet, 0.20 mile north of State Highway 20, 0.85 mile east of Loma Rica Road. 11/26/47, 16.5; 3/3/48, 17.4; 11/29/48, 16.9; 3/23/49, 17.2; 11/18/49, 17.8.

16N 4E-27F1—Reference point—bottom of 90° elbow on suction pipe, elevation 93.6 feet, 600 feet north of Woodruff Lane, 0.20 mile west of Loma Rica Road. 11/26/47, 7.3; 11/18/49, 8.4.

16N 4E-27M1—Reference point—top of casing, elevation 89 feet, 150 feet south of Woodruff Lane, 0.2 mile west of State Highway 20. 12/6/32, 6.4; 12/14/33, 6.9; 11/23/34, 6.9; 11/28/36, 5.6; 11/23/37, 11.6 (operating); 1/9/41, 2.7.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet measured from reference point)

16N/4E-27N1—Reference point—top of casing, elevation 89.9 feet, 500 feet north of State Highway 20, 0.30 mile south of Woodruff Lane. 11/27/29, 10.9; 9/25/30, 8.3; 12/14/31, 11.3; 1/9/41, 4.8; 11/5/47, 7.5; 11/26/47, 4.9; 3/3/48, 13.7; 11/29/48, 11.2; 12/13/48, 12.0; 3/23/49, 11.0; 11/18/49, 10.2; 12/9/49, 11.7; 3/23/50, 12.5; 10/31/50, 8.8; 3/30/51, 10.7; 11/14/51, 10.5; 11/27/51, 11.8; 4/6/52, 8.2.

16N/4E-28B1—Reference point—top of casing, elevation 89.4 feet, 0.25 mile north of Woodruff Lane, 0.60 mile east of Kimball Lane. 11/26/47, 13.3; 3/3/48, 16.1; 11/29/48, 13.7; 3/23/49, 12.2; 11/18/49, 12.8.

16N/4E-28E1—Reference point—top of 90° elbow, elevation 80.9 feet, 0.20 mile north of Woodruff Lane, 0.15 mile east of Kimball Lane. 11/26/47, 9.7; 3/3/48, 10.8; 11/29/48, 10.2; 3/23/49, 7.0; 11/18/49, 9.5; 3/23/50, 10.0; 10/31/50, 8.2; 3/30/51, 9.7; 11/14/51, 9.1; 4/6/52, 7.9.

16N/4E-29B1—Reference point—top of casing, elevation 78.1 feet, 500 feet west of Mathews Lane, 0.35 mile north of Woodruff Lane. 11/26/47, 8.7; 3/3/48, 9.6; 5/7/48, 8.1; 11/29/48, 9.3; 3/23/49, 7.2; 11/17/49, 9.5; 10/31/50, 9.0.

16N/4E-33B1—Reference point—top of casing, elevation 83 feet, 200 feet north of West Hallwood Road, 0.6 mile west of State Highway 20. 11/26/47, 7.7; 3/3/48, 10.6; 11/30/48, 8.5; 3/23/49, 13.0; 11/15/49, 7.9.

16N/4E-33J1—Reference point—top of casing, elevation 88.7 feet, 200 feet east of State Highway 20, 0.45 mile south of West Hallwood Road. 11/26/47, 11.8; 3/3/48, 14.9; 3/23/49, 13.0; 11/18/49, 11.8.

16N/4E-33K1—Reference point—top of casing, elevation 84.0 feet, 200 feet northwest of State Highway 20, 0.70 mile south of West Hallwood Road. 11/26/47, 9.2; 3/8/48, 12.1; 11/30/48, 10.5; 3/23/49, 9.7; 11/18/49, 9.7.

16N/4E-33N1—Reference point—top of casing cap, elevation 80.1 feet, 200 feet northwest of State Highway 20, 1.3 miles south of West Hallwood Road. 11/26/47, 8.3; 3/4/48, 11.5; 11/30/48, 10.6; 3/23/49, 9.2; 11/18/49, 10.0; 3/23/50, 10.2; 10/31/50, 9.3; 3/30/51, 9.1; 11/14/51, 10.0; 4/5/52, 7.4.

16N/4E-34B1—Reference point—top of casing, elevation 96.8 feet, 100 feet north of West Hallwood Road, 200 feet east of levee. 11/25/47, 14.4; 3/3/48, 20.5; 11/29/48, 19.5; 3/22/49, 15.8; 11/18/49, 14.6.

16N/4E-34D1—Reference point—top of casing, elevation 91.9 feet, 600 feet west of State Highway 20, 0.20 mile north of West Hallwood Road. 11/26/47, 12.7; 3/3/48, 16.1; 11/30/48, 13.8; 3/23/49, 13.5; 11/18/49, 13.0.

16N/4E-34L1—Reference point—top of casing 2.5 feet above ground, elevation 98.5 feet, 0.4 mile north of Walnut Road, 200 feet west of Hallwood Road. 10/25/47, 17.5; 3/3/48, 21.7; 11/29/48, 18.7; 3/22/49, 19.9; 11/18/49, 18.3.

16N/4E-34Q1—Reference point—top of casing under pump, elevation 95.3 feet, 400 feet north of Walnut Road, 400 feet east of Hallwood Road. 11/25/47, 16.7; 3/3/48, 21.1; 11/29/48, 17.7; 3/22/49, 19.3; 11/18/49, 16.7; 3/23/50, 19.7; 10/31/50, 16.6; 3/30/51, 17.6; 11/14/51, 17.1; 4/6/52, 15.1.

16N/4E-35M1—Reference point—top of casing under pump, elevation 101.1 feet, 0.6 mile east of Hallwood Road, 0.5 mile north of Walnut Road. 11/25/47, 15.3; 3/3/48, 17.9; 4/1/48, 18.1; 3/23/49, 16.8; 11/18/49, 16.6.

17N/1E-25J1—Reference point—hole in base of pump, elevation 77 feet, 100 feet south of North Butte Road, 0.4 mile west of 90° turn (NW.) in North Butte Road. 3/25/48, 18.9; 12/3/48, 19.7; 3/30/49, 16.7; 11/15/49, 22.0; 3/24/50, 16.6; 11/2/50, 21.6; 3/27/51, 21.2; 11/13/51, 23.8.

17N/2E-22R1—Reference point—top of casing, elevation 79.5 feet, 0.07 mile northwest of intersection of Krehe and Lucerne Roads. 12/22/47, 7.7; 3/2/48, 8.3; 11/15/49, 7.4.

17N/2E-24N1—Reference point—top of casing, elevation 81.1 feet, 100 feet north of Lucerne Road, 0.95 mile west of Township Road. 12/22/47, 7.4; 3/1/48, 8.2; 12/8/48, 8.0; 1/21/49, 7.5; 3/30/49, 4.5; 11/8/49, 6.5.

17N/2E-29M1—Reference point—hole in pump base, elevation 79.6 feet, 0.1 mile east of Crane Road, 0.3 mile north of Bigelow Road. 12/22/47, 14.6; 12/3/48, 16.1; 3/30/49, 12.6; 11/15/49, 16.1; 3/24/50, 13.5; 3/27/51, 12.6.

17N/2E-29Q1—Reference point—top of casing, elevation 77.9 feet, 0.1 mile, east-northeast of 90° turn in Bigelow Road, at a point 0.5 mile east of Crane Road. 12/23/47, 13.9; 3/2/48, 15.1; 12/3/48, 15.5; 3/30/49, 12.0; 11/15/49, 14.3.

17N/2E-30N1—Reference point—top of casing, elevation 83 feet, 0.15 mile south of Pennington Road at a point 0.1 mile west of Pennington School. 3/25/48, 22.9; 12/3/48, 24.1; 3/30/49, 21.3; 11/15/49, 25.2.

17N/2E-31A1—Reference point—top of casing, elevation 85 feet, 100 feet north of Pennington Road at a point 0.1 mile west of Bigelow and Pennington Roads intersection. 3/25/48, 23.5; 12/3/48, 24.7; 3/30/49, 22.8; 11/15/49, 25.5; 3/24/50, 23.0; 11/2/50, 26.7; 3/27/51, 21.8; 11/13/51, 28.3; 4/2/52, 20.2.

17N/2E-33J1—Reference point—top of casing, elevation 71.3 feet, 0.35 mile north of Pennington Road, 1.05 miles west of Krehe Road. 12/23/47, 6.4; 3/2/48, 6.5; 12/13/48, 6.2; 3/30/49, 4.0; 11/15/49, 3.7.

17N/2E-34A1—Reference point—top of casing, elevation 74.6 feet, East side of Krehe Road, 0.9 mile north of Pennington Road. 12/22/47, 6.8; 3/1/48, 7.2; 12/8/48, 6.8; 1/21/49, 6.6; 3/30/49, 5.0; 11/8/49, 4.2; 3/21/50, 6.7; 11/2/50, 4.9; 3/27/51, 12.7 (operating); 11/13/51, 6.2; 4/2/52, 5.8.

17N/2E-34Q1—Reference point—top of outer casing, elevation 71.8 feet, North side of Pennington Road, 0.5 mile west of Krehe Road. 12/22/47, 6.4; 3/2/48, 7.1; 12/3/48, 7.0; 3/30/49, 5.0; 11/15/49, 5.7; 3/24/50, 5.5; 11/2/50, 5.5; 3/27/51, 6.6; 11/13/51, 6.1; 4/2/52, 5.4.

17N/2E-35A1—Reference point—top of casing, elevation 75.2 feet, 50 feet west of Schroeder Road, 0.95 mile north of Pennington Road. 12/22/47, 4.7; 3/1/48, 5.7; 12/8/48, 5.5; 3/30/49, 4.0; 5/26/49, 3.8; 6/28/49, 4.2; 7/27/49, 3.4; 8/25/49, 3.5; 11/8/49, 4.4; 3/21/50, 6.0; 11/2/50, 5.9; 3/27/51, 5.0; 11/13/51, 6.2; 4/2/52, 5.5.

17N/2E-36H1—Reference point—top of casing, elevation 76 feet, 300 feet west of Township Road, 0.6 mile north of Pennington Road. 3/26/48, 7.0; 12/8/48, 7.9.

17N/3E-22R1—Reference point—top of casing, elevation 86 feet, 0.25 mile north of Laurel Road at a point 0.48 mile west of intersection with Thame Road. 10/29/47, 23.3; 3/22/48, 26.0; 12/10/48, 21.9; 3/8/49, 21.2; 11/14/49, 23.3; 3/21/50, 22.2; 11/7/50, 23.4; 3/28/51, 16.8; 11/15/51, 22.1; 4/6/52, 13.6.

17N/3E-23P1—Reference point—hole in concrete base, elevation 87 feet, 0.37 mile north of Laurel Road, due north of intersection with Thame Road. 10/29/47, 22.7; 12/10/48, 20.5; 3/8/49, 20.0; 11/14/49, 22.9.

17N/3E-25G1—Reference point—hole in base of pump, elevation 85 feet, 2.57 miles north of Ramirez Road, 0.53 mile east of State Highway 24. 10/29/47, 22.9; 3/22/48, 19.1; 12/10/48, 19.4; 3/8/49, 18.8; 11/14/49, 21.6; 3/21/50, 18.1; 11/7/50, 21.7; 3/28/51, 46.0 (operating); 11/15/51, 23.4; 4/6/52, 9.3.

17N/3E-25M1—Reference point—hole in base of pump, elevation 80 feet, 2.27 miles north of Ramirez Road, 0.15 mile east of State Highway 24. 10/29/47, 22.6; 3/22/48, 19.8; 12/10/48, 20.8.

17N/3E-25N1—Reference point—hole in base of pump, elevation 84 feet, 1.97 miles north of Ramirez Road, 0.24 mile east of State Highway 24. 3/22/48, 20.7; 12/10/48, 19.3; 3/8/49, 18.0; 11/14/49, 21.8.

TABLE 1—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Division of Water Resources
(Depths to water in feet measured from reference point)

17N/3E-25Q1—Reference point—hole in base of pump, elevation 84 feet, 2.27 miles north of Ramirez Road, 0.75 mile east of State Highway 24. 10/31/47, 18.7; 3/22/48, 18.7; 12/10/48, 17.7; 3/8/49, 15.3; 11/14/49, 20.2.

17N/3E-26A2—Reference point—hole in base of pump, elevation 85 feet, 0.04 mile south of Laurel Road, 0.10 mile west of State Highway 24. 10/28/47, 22.8; 3/28/48, 21.9; 12/10/48, 21.1; 1/26/49, 20.5; 3/8/49, 20.1; 11/14/49, 23.7; 3/21/50, 21.1; 11/7/50, 22.8; 3/28/51, 14.6; 11/15/51, 27.6; 4/6/52, 11.1.

17N/3E-26B1—Reference point—flange of suction line, elevation 87 feet, 0.07 mile north of Laurel Road, 0.28 mile west of State Highway 24. 10/29/47, 15.5; 3/22/48, 11.9; 5/7/48, 9.7; 12/10/48, 13.5; 3/8/49, 12.5; 11/14/49, 15.5.

17N/3E-26H1—Reference point—hole in base of pump, elevation 85 feet, 0.25 mile south of Laurel Road, 0.22 mile west of State Highway 24. 10/29/47, 24.1; 12/10/48, 22.6; 11/14/49, 23.7.

17N/3E-26R1—Reference point—hole in base of pump, elevation 84 feet, 0.10 mile west of State Highway 24, 0.65 mile south of Laurel Road. 10/29/47, 20.0; 3/22/48, 20.8; 12/10/48, 18.8; 3/8/49, 18.0; 11/14/49, 21.0.

17N/3E-28P1—Reference point—top of flange on suction pipe, elevation 82 feet, 0.18 mile east of Cooley Road, 1.10 miles north of intersection of Meteer Road. 10/31/47, 5.8; 3/20/48, 7.4; 5/30/48, 4.7; 12/8/48, 4.9; 3/8/49, 7.0; 11/8/49, 5.5; 3/22/50, 5.1; 11/3/50, 7.0; 3/27/51, 3.1; 11/14/51, 6.5; 4/3/52, 2.2.

17N/3E-29C1—Reference point—top of casing, elevation 82.4 feet, 0.21 mile west of Larkin Road, 0.04 mile north of Riviera Road. 12/22/47, 8.9; 3/1/48, 9.4; 12/8/48, 9.7; 3/30/49, 5.9; 11/8/49, 8.2; 3/21/50, 6.3; 11/2/50, 8.8; 3/27/51, 5.8; 11/13/51, 8.8; 4/2/52, 4.5.

17N/3E-29H1—Reference point—top of casing, elevation 77.7 feet, South side Riviera Road, 0.52 mile east of Larkin Road. 12/23/47, 5.0; 3/1/48, 5.6; 5/12/48, 3.5; 11/8/49, 4.7.

17N/3E-30F1—Reference point—top of casing, elevation 80.6 feet, South side Riviera Road, 0.35 mile east of Township Road. 11/26/29, 4.7; 9/27/30, 3.3; 12/16/31, 6.2; 12/9/32, 5.4; 12/13/33, 5.6; 11/21/34, 5.4; 11/23/37, 3.7; 1/26/39, 6.4; 1/10/49, 3.1; 11/4/47, 7.8; 12/5/47, 8.0; 12/22/47, 8.2; 3/1/48, 8.5; 12/8/48, 8.6; 12/13/48, 9.3; 11/8/49, 7.6; 3/30/49, 5.4; 3/21/50, 3.5.

17N/3E-30G1—Reference point—top of casing, elevation 81 feet, South Side of Riviera Road, 0.23 mile west of U. S. Highway 99E. 11/10/50, 8.6; 11/26/51, 8.7.

17N/3E-30N1—Reference point—top of pumphouse floor, elevation 73.0 feet, 0.08 mile east of Township Road, 1.25 miles north of Pennington Road. 12/22/47, 4.1; 3/1/48, 4.4; 5/13/48, 3.1; 12/8/48, 4.0; 1/21/49, 4.0; 3/30/49, 1.5; 5/26/49, 7.0; 6/28/49, 7.0; 7/27/49, 7.5; 8/25/49, 8.5; 11/8/49, 3.7; 3/21/50, 6.5; 11/2/50, 8.9; 3/27/51, 6.6; 11/13/51, 8.4; 4/2/52, 1.0.

17N/3E-31A2—Reference point—hole in base of pump, elevation 82 feet, 1.01 miles west of Township Road, 0.85 mile north of Pennington Road. 12/8/48, 10.0; 3/30/49, 6.6.

17N/3E-31M1—Reference point—top of casing, elevation 75 feet, 0.24 mile east of Township Road, 0.32 mile north of Pennington Road. 3/26/48, 7.1; 12/8/48, 9.1.

17N/3E-32B1—Reference point—top of casing, elevation 81.5 feet, 0.09 mile east of Larkin Road, 1 mile south of Riviera Road. 12/23/47, 12.2; 3/1/48, 12.4; 12/8/48, 11.7; 3/30/49, 8.1; 1/8/49, 13.3; 3/22/50, 7.8; 3/27/51, 6.5; 11/13/51, 9.8; 4/2/52, 4.7.

17N/3E-33Q1—Reference point—top of casing, elevation 80 feet, North side of Pennington Road, 0.50 mile east of Meteer Road. 11/10/47, 12.2; 3/20/48, 16.7; 12/3/48, 13.1; 3/8/49, 16.6; 11/9/49, 10.7; 3/22/50, 14.0; 11/3/50, 11.4; 4/2/51, 11.3; 11/14/51, 12.4; 4/3/52, 8.8.

17N/3E-35H1—Reference point—top of casing, elevation 82 feet, 0.05 mile west of State Highway 24, 1.57 miles north of Ramirez Road. 10/29/47, 21.5; 3/22/48, 19.0; 10/10/48, 19.7; 3/8/49, 19.0; 11/15/49, 22.2.

17N/3E-35H2—Reference point—hole in base of pump, elevation 82 feet, 1.67 miles north of Ramirez Road, west side of State Highway 24. 10/29/47, 23.4; 3/22/48, 21.0; 5/7/48, 17.2; 12/10/48, 19.9; 3/8/49, 19.0; 11/15/49, 22.3; 3/21/50, 18.2; 11/7/50, 22.9; 3/28/51, 14.2; 11/15/51, 22.3; 4/6/52, 10.1.

17N/3E-36B1—Reference point—top of casing, elevation 84 feet, 0.70 mile east of State Highway 24, 1.87 miles north of Ramirez Road. 10/31/47, 17.9; 3/22/48, 17.6; 12/10/48, 17.0; 3/8/49, 15.5; 11/14/49, 19.6.

17N/3E-36B2—Reference point—hole in base of pump, elevation 84 feet, 0.55 mile east of State Highway 24, 1.9 miles north of Ramirez Road. 10/31/47, 23.7; 3/22/48, 17.3; 5/7/48, 17.0; 12/10/48, 17.6; 1/26/49, 17.1; 3/8/49, 16.3; 11/14/49, 19.9; 3/21/50, 16.6; 11/7/50, 20.2; 3/28/51, 12.3; 11/15/51, 18.6; 4/6/52, 7.4.

17N/3E-36E1—Reference point—slot in base, elevation 83 feet, 0.2 mile east of State Highway 24, 1.55 miles north of Ramirez Road. 10/31/47, 20.3; 3/22/48, 18.4; 3/8/49, 17.7; 11/15/49, 20.8.

17N/4E-22H1—Reference point—top of casing, elevation 116 feet, 0.2 mile east of La Porte Road bridge across Middle Honcut Creek. 2/25/48, 16.1; 3/15/48, 15.3; 11/17/49, 18.3; 3/28/51, 12.1; 11/14/51, 18.6; 4/6/52, 10.2.

17N/4E-27E1—Reference point—top of concrete pit cribbing, elevation 105 feet, 0.30 mile west of La Porte Road bridge across South Honcut Creek. 11/19/47, 29.9; 3/15/48, 33.2; 11/30/48, 30.0; 3/23/49, 24.2.

17N/4E-27F1—Reference point—top of casing, elevation 106 feet, West side La Porte Road, south bank of South Honcut Creek. 11/18/47, 24.8; 3/30/48, 24.2; 5/12/48, 24.2; 11/30/48, 24.9; 3/23/49, 23.1; 11/17/49, 28.0; 3/22/50, 24.9; 10/3/50, 30.2; 3/28/51, 24.1; 11/14/51, 30.3; 4/6/52, 23.8.

17N/4E-29L1—Reference point—hole in pump base, elevation 80 feet, 1.02 miles west of Southern Pacific Railroad tracks, 0.30 mile south of South Honcut Creek. 12/1/48, 21.2; 3/23/49, 19.5; 11/17/49, 26.1; 3/22/50, 22.3; 10/31/50, 30.0; 3/28/51, 21.6; 11/27/51, 14.6; 4/6/52, 5.0.

17N/4E-33D1—Reference point—top of casing, elevation 96 feet, West side Southern Pacific Railroad tracks, 1.08 miles north along tracks from intersection with Ramirez Road. 11/18/47, 24.1; 3/15/48, 24.8; 12/1/48, 25.2; 3/23/49, 27.6; 11/17/49, 27.6; 3/22/50, 27.0; 10/31/50, 28.0; 3/28/51, 25.1; 11/14/51, 28.1; 4/6/52, 24.3.

17N/4E-35C1—Reference point—hole in pump base, elevation 122 feet, South side Iowa City Road, 1.20 miles east of La Porte Road. 3/15/48, 26.7; 11/17/49, 28.5; 3/28/51, 28.5; 11/14/51, 33.1; 4/6/52, 30.1.

TABLE 2

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by S. T. Harding
(Depths to water in feet meosured from reference point)

13N/2E-1 (Harding 43)—Reference point—top of pump house floor, elevation 35 feet, 1,800 feet north of east quarter corner of section. 9/20/31, 16.5; 12/2/32, 15.7.

13N/3E-2 (Harding 139)—Reference point—top of casing, elevation 43 feet, 30 feet north of east and west center line, 1,700 feet east of Garden Highway. 10/16/31, 22.7; 11/29/32, 18.0.

13N/3E-3 (Harding 76)—Reference point—top of casing, elevation 40 feet, 200 feet south and 1,400 feet east of center of section. 10/13/31, 21.3; 11/29/32, 19.2.

13N/3E-4 (Harding 141A)—Reference point—top of casing, elevation 39 feet, 800 feet south and 50 feet west of northeast corner of section. 10/9/31, 22.1; 12/2/32, 20.0.

13N/3E-4 (Harding 70)—Reference point—top of casing, elevation 40 feet, 20 feet west of Sawtelle Avenue at southeast corner of section. 10/8/31, 23.0; 12/2/32, 20.0.

13N/3E-5 (Harding 140)—Reference point—top of pit, elevation 36 feet, 550 feet south and 200 feet west of north quarter corner of section. 10/9/31, 23.0; 12/2/32, 20.7.

13N/3E-5 (Harding 141)—Reference point—top of casing, elevation 34 feet, 200 feet west and 300 feet north of east quarter corner of section. 10/9/31, 20.5; 12/2/32, 18.0.

13N/3E-7 (Harding 73)—Reference point—top of casing, elevation 33 feet, 1,300 feet east of west quarter corner of section. 10/8/31, 12.0; 12/2/32, 13.0.

13N/3E-9 (Harding 72)—Reference point—top of wall of pit, elevation 35 feet, 500 feet south of north quarter corner of section. 10/8/31, 18.5; 12/2/32, 13.1.

13N/3E-10 (Harding 69)—Reference point—top of wall of wooden pit, elevation 38 feet, 500 feet north and 500 feet south of northeast corner of section. 10/8/31, 17.0; 12/2/32, 17.1.

13N/3E-11 (Harding 75)—Reference point—top of wall of pit, elevation 40 feet, 2,000 feet south and 600 feet west of northeast corner of section. 10/8/31, 17.5; 12/7/32, 15.6.

13N/3E-13 (Harding 74)—Reference point—top of wall of pit, elevation 38 feet, 100 feet east and 1,000 feet north of southwest corner of section. 10/8/31, 16.8; 12/7/32, 17.1.

13N/3E-14 (Harding 64)—Reference point—top of wall of pit, elevation 35 feet, 500 feet north of intersection of Wilson Road and Garden Highway. 10/6/31, 15.5; 12/2/32, 15.2.

13N/3E-15 (Harding 63)—Reference point—top of casing, elevation 35 feet, West side of Southern Pacific Railroad, ¼ mile north of Wilson Road. 10/6/31, 15.0; 12/2/32, 13.8.

13N/3E-16 (Harding 62)—Reference point—top of casing, elevation 36 feet, 500 feet north of southeast corner of section. 10/6/31, 17.0; 12/2/32, 16.4.

13N/3E-16 (Harding 71)—Reference point—top of casing, elevation 31 feet, 1,300 feet east and 2,700 feet south of northwest corner of section. 10/8/31, 12.0; 12/2/32, 11.3.

13N/3E-23 (Harding 60)—Reference point—top of concrete pit wall, elevation 35 feet, 100 feet east of Garden Highway, 2,200 feet south of north quarter corner of section. 10/6/31, 15.5; 12/2/32, 12.5.

13N/3E-23 (Harding 61)—Reference point—top of casing, elevation 36 feet, 500 feet east and 200 feet south of northwest corner of section. 10/6/31, 16.4; 12/2/32, 15.2.

14N/2E-4 (Harding 51)—Reference point—top of casing, elevation 37 feet, 300 feet west and 200 feet south of northeast corner of section. 9/26/31, 8.3; 11/30/32, 6.6.

14N/2E-36 (Harding 47)—Reference point—top of casing, elevation 34 feet, 500 feet south of north quarter corner of section. 9/23/31, 12.0; 12/2/32, 11.6.

14N/2E-36 (Harding 42)—Reference point—top of casing, elevation 35 feet. At east quarter corner of section. 9/20/31, 14.0; 12/2/32, 13.2.

14N/3E-1 (Harding 99)—Reference point—top of casing, elevation 53 feet, 200 feet west of Feather River Boulevard and 1.5 miles south of Alicia Station. 10/16/31, 12.0; 12/5/32, 12.3.

14N/3E-2 (Harding 54)—Reference point—top of casing below ground, elevation 48 feet, 5,200 feet east of Southern Pacific Railroad and 1,500 feet north of latitude 39° 05′. 9/26/31, 21.3; 11/29/32, 18.5.

14N/3E-2 (Harding 79)—Reference point—top of casing, elevation 48 feet, 1,400 feet east and 700 feet south of northwest corner of section. 10/13/31, 19.5; 11/29/32, 16.0.

14N/3E-3 (Harding 66)—Reference point—top of casing, elevation 51 feet, 700 feet west of Southern Pacific Railroad, 1,700 feet south of north line of section. 10/7/31, 35.3; 12/1/32, 33.0.

14N/3E-4 (Harding 57)—Reference point—top of concrete pit, elevation 51 feet, 1,150 feet east and 800 feet south of north quarter corner of section. 9/28/31, 36.3; 11/30/32, 35.3.

14N/3E-4 (Harding 56)—Reference point—top of concrete pit, elevation 48 feet, 600 feet east and 360 feet south of west quarter corner of section. 9/27/31, 33.9; 11/30/32, 32.0.

14N/3E-8 (Harding 118)—Reference point—top of casing, elevation 44 feet, 1,500 feet north and 200 feet east of southwest corner of section. 9/28/31, 25.1; 11/30/32, 23.6.

14N/3E-9 (Harding 123)—Reference point—top of pit, elevation 46 feet, 300 feet east and 200 feet north of south quarter corner of section. 9/30/31, 32.5; 11/30/32, 31.0.

14N/3E-10 (Harding 116)—Reference point—top of pit, elevation 50 feet, 300 feet north of east and west center line, 550 feet west of Southern Pacific Railroad. 10/1/31, 36.0; 12/1/32, 32.6.

14N/3E-10 (Harding 115)—Reference point—top of casing, elevation 52 feet, 700 feet south and 200 feet west of northeast corner of section. 10/1/31, 33.8; 11/29/32, 29.0.

14N/3E-11 (Harding 55)—Reference point—top of casing, elevation 53 feet, 4,400 feet east of Southern Pacific Railroad, 100 feet south of latitude 39° 05′. 9/5/31, 30.1; 10/17/31, 29.0.

14N/3E-13 (Harding 100)—Reference point—top of wall of pit, elevation 50 feet, West of Feather River Boulevard, 500 feet north of Pearson Station. 10/16/31, 10.0; 12/5/32, 10.1.

14N/3E-15 (Harding 67)—Reference point—top of concrete pit, elevation 47 feet, 800 feet east and 150 feet south of northwest corner of section. 10/7/31, 32.7; 12/1/32, 29.2.

14N/3E-15 (Harding 124)—Reference point—top of concrete pit, elevation 48 feet, 1,600 feet south of north line and 200 feet east of Southern Pacific Railroad. 10/8/31, 30.8; 12/1/32, 25.2.

14N/3E-15 (Harding 122)—Reference point—top of concrete pit, elevation 45 feet, 2,150 feet north and 600 feet east of southwest corner of section. 10/17/31, 29.4; 12/1/32, 24.0.

14N/3E-16 (Harding 58)—Reference point—bottom of 6 x 6 strut across top of pit, elevation 45 feet, 750 feet north and 40 feet west of southwest corner of section. 9/29/31, 25.8; 11/30/32, 25.6.

14N/3E-16 (Harding 120)—Reference point—top of concrete pit, elevation 45 feet, 1,350 feet east and 200 feet north of south quarter corner of section. 10/17/31, 27.7; 12/1/32, 25.4.

14N/3E-17 (Harding 119)—Reference point—top of casing, elevation 42 feet, 1,500 feet north and 100 feet east of southwest corner of section. 10/3/31, 21.5; 11/30/32, 20.0.

14N/3E-18 (Harding 45)—Reference point—top of wall of concrete pit, elevation 39 feet, 1,100 feet east and 2,000 feet south of northwest corner of section. 9/21/31, 14.5; 11/30/32, 14.4.

14N/3E-19 (Harding 46)—Reference point—top of pit wall, elevation 38 feet, 1,800 feet east and 900 feet south of northwest corner of section. 9/21/31, 16.0; 11/30/32, 15.0.

14N/3E-20 (Harding 123A)—Reference point—top of casing, elevation 42 feet, 2,000 feet north and 130 feet west of southeast corner of section. 10/3/31, 29.7; 12/1/32, 26.4.

TABLE 2—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by S. T. Harding
(Depths to water in feet measured from reference point)

14N/3E-22 (Harding 68)—Reference point—top of concrete pit, elevation 45 feet, 1,100 feet south of north line of section and 350 feet west of Garden Highway. 10/8/31, 23.4; 11/29/32, 19.7.

14N/3E-23 (Harding 107)—Reference point—top of pit wall, elevation 50 feet. West end of Country Club Road on center line of section. 10/16/31, 20.5; 12/9/32, 19.7.

14N/3E-23 (Harding 129)—Reference point—top of casing, elevation 46 feet, 100 feet east of Garden Highway and 1,650 feet north of latitude 39° 32' 30". 10/13/31, 25.2.

14N/3E-27 (Harding 131)—Reference point—top of casing, elevation 42 feet, 700 feet east of Southern Pacific Railroad and 300 feet north of south line of section. 10/16/31, 25.0; 11/29/32, 21.7.

14N/3E-27 (Harding 130)—Reference point—top of casing, elevation 44 feet, 2,000 feet south of latitude 39° 32' 30" and 400 feet west of Garden Highway. 10/13/31, 25.2; 11/29/32, 21.2.

14N/3E-28 (Harding 128)—Reference point—top of concrete pit, elevation 40 feet, 500 feet east and 1,600 feet north of southwest corner of section. 10/12/31, 29.8; 12/1/32, 27.0.

14N/3E-28 (Harding 127)—Reference point—top of casing, elevation 42 feet, 150 feet west and 25 feet south of northwest corner of section. 10/12/31, 30.3; 12/1/32, 27.4.

14N/3E-29 (Harding 126)—Reference point—top of planks across top of pit, elevation 41 feet, 1,200 feet west and 1,600 feet south of northeast corner of section. 10/10/31, 29.0; 12/1/32, 26.7.

14N/3E-29 (Harding 125)—Reference point—top of concrete casing, elevation 42 feet, 750 feet north and 300 feet west of south quarter corner of section. 9/5/31, 29.2; 10/9/31, 28.3; 12/2/32, 25.5.

14N/3E-30 (Harding 77)—Reference point—top of casing, elevation 39 feet, 1,500 feet south and 250 feet west of northeast corner of section. 10/13/31, 23.1; 12/2/32, 20.7.

14N/3E-31 (Harding 44)—Reference point—top of concrete pit, elevation 37 feet, 1,000 feet west and 200 feet south of northeast corner of section. 9/20/31, 21.5; 12/2/32, 16.5.

14N/3E-32 (Harding 133)—Reference point—top of casing, elevation 36 feet, 2,000 feet north and 200 feet east of southwest corner of section. 10/14/31, 23.3; 12/2/32, 20.7.

14N/3E-32 (Harding 132)—Reference point—top of casing, elevation 37 feet, 250 feet south and 150 feet west of center of section. 10/14/31, 25.0; 11/29/32, 21.0.

14N/3E-33 (Harding 134)—Reference point—top of tile at hand pump, elevation 43 feet, 200 feet south and 1,410 feet east of northwest corner of section. 10/14/31, 27.6; 12/1/32, 24.8.

14N/3E-34 (Harding 135)—Reference point—top of pit, elevation 41 feet, 300 feet east and 40 feet south of northwest corner of section. 10/14/31, 27.8; 12/1/32, 24.9.

14N/3E-35 (Harding 138)—Reference point—top of wood pit, elevation 42 feet, 100 feet west of levee, 500 feet north of south line of section. 10/16/31, 18.3; 11/29/32, 17.5.

14N/3E-35 (Harding 137)—Reference point—top of casing, elevation 43 feet, 100 feet east of Garden Highway, 100 feet north of south line of section. 10/16/31, 25.4; 11/29/32, 22.1.

14N/3E-35 (Harding 136)—Reference point—top of wooden pit, elevation 42 feet, 200 feet east of Garden Highway, 1,100 feet north of south line of section. 10/16/31, 24.8; 11/29/32, 22.0.

14N/4E-8 (Harding 101)—Reference point—top of pit wall, elevation 56 feet, 700 feet west and 700 feet south of west quarter corner of section. 10/16/31, 12.0; 12/3/32, 12.8.

14N/4E-8 (Harding 103)—Reference point—top of casing, elevation 63 feet, 200 feet southeast of northwest corner of section. 10/16/31, 18.0; 12/3/32, 18.8.

14N/4E-19 (Harding 104)—Reference point—top of casing, elevation 49 feet. Immediately north of center of section. 10/16/31, 14.0; 12/3/32, 13.5.

14N/4E-31 (Harding 98)—Reference point—top of casing, elevation 59 feet, 50 feet east of bend in River Road, ½ mile above Alicia. 10/16/31, 18.0; 12/3/32, 17.0.

15N/2E-1 (Harding 18)—Reference point—top of casing, elevation 56 feet, 1,000 feet south and 180 feet west of northeast corner of section. 9/7/31, 11.8; 10/17/31, 11.3; 12/8/32, 10.2.

15N/2E-12 (Harding 17)—Reference point—top of casing in pit, elevation 51 feet, 1,600 feet south and 400 feet west of northeast corner of section. 9/7/31, 8.1; 10/17/31, 9.3; 12/8/32, 10.1.

15N/2E-12 (Harding 114)—Reference point—top of casing, elevation 54 feet, 200 feet south of Butte House Road on north side of east and west center line of section. 10/1/31, 8.5; 12/8/32, 11.9.

15N/2E-13 (Harding 35)—Reference point—top of highest horizontal flange on suction, elevation 51 feet, 1,800 feet west and 200 feet north of east quarter corner of section. 9/18/31, 14.5; 12/8/32, 14.6.

15N/2E-13 (Harding 113)—Reference point—top of casing, elevation 50 feet, 1,000 feet east and 500 feet north of west quarter corner of section. 10/1/31, 8.0; 12/8/32, 9.7.

15N/2E-26 (Harding 111)—Reference point—top of casing, elevation 44 feet, 2,000 feet west and 50 feet south of northeast corner of section. 10/1/31, 7.0; 11/30/32, 7.7.

15N/2E-28 (Harding 112)—Reference point—top of casing, elevation 43 feet, 500 feet west of east quarter corner of section. 10/1/31, 9.0; 11/30/32, 7.9.

15N/2E-35 (Harding 53)—Reference point—top of casing, elevation 38 feet, 0.25 mile west and 300 feet north of southeast corner of section. 9/26/31, 5.0; 11/30/32, 5.4.

15N/3E-1 (Harding 87)—Reference point—top of casing, elevation 64 feet. East side of State Highway 24, 0.5 mile north of Walnut Avenue. 10/15/31, 14.5; 12/5/32, 13.8.

15N/3E-1 (Harding 85)—Reference point—top of casing, elevation 66 feet, 200 feet north of Walnut Avenue, 0.25 mile west of State Highway 24. 10/15/31, 19.5; 12/5/32, 15.8.

15N/3E-1 (Harding 84)—Reference point—top of walls of pit, elevation 61 feet, 700 feet east of State Highway 24 and 1 mile north of railroad crossing. 10/15/31, 6.0.

15N/3E-1 (Harding 84A)—Reference point—top of casing, elevation 61 feet, 300 feet east of State Highway 24 and 1 mile north of railroad crossing. 12/5/32, 5.0.

15N/3E-2 (Harding 86)—Reference point—top of casing, elevation 68 feet, 500 feet north of west end of Walnut Avenue. 10/15/31, 25.5; 12/5/32, 24.1.

15N/3E-2 (Harding 109)—Reference point—top of casing, elevation 62 feet. West end of first road to left on State Highway 24 after crossing bridge ¼ mile north of cemetery. 10/20/31, 21.5; 12/5/32, 21.0.

15N/3E-2 (Harding 108)—Reference point—top of wall of pit, elevation 61 feet, 0.60 mile west of State Highway 24, on first left road after crossing bridge, ¼ mile north of cemetery. 10/20/31, 19.0; 12/5/32, 18.3.

15N/3E-3 (Harding 4)—Reference point—top of casing, elevation 61 feet, 250 feet south and 240 feet east of northwest corner of section. 8/31/31, 22.7; 10/17/31, 23.4.

15N/3E-4 (Harding 15)—Reference point—top of concrete pit, elevation 60 feet, 1,900 feet north and 900 feet west of southeast corner of section. 9/4/31, 25.5; 10/17/31, 25.5; 12/7/32, 23.7.

15N/3E-5 (Harding 14)—Reference point—2 inches above top of concrete pit, elevation 59 feet. On east line 1,800 feet north of southeast corner of section. 9/3/31, 24.5; 10/17/31, 24.5; 12/7/32, 22.8.

TABLE 2—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by S. T. Harding
(Depths to water in feet measured from reference point)

15N/3E-6 (Harding 16)—Reference point— top of casing, elevation 60 feet, 1,320 feet west and 1,200 feet north of southeast corner of section. 9/7/31, 18.2; 12/8/32, 17.1.

15N/3E-9 (Harding 22)—Reference point—top of concrete pit, elevation 58 feet, 1,000 feet south and 500 feet east of west quarter corner of section. 9/10/31, 28.1; 10/17/31, 27.9; 12/8/32, 25.7.

15N/3E-10 (Harding 19)—Reference point—top of concrete pit, elevation 63 feet. Near north quarter of section. 9/8/31, 30.7; 10/17/31, 30.5; 12/7/32, 28.0.

15N/3E-11 (Harding 82)—Reference point—top of casing, elevation 57 feet. Under Southern Pacific Railroad trestle 2 miles north of Yuba City. 10/20/31, 16.5; 12/6/32, 16.3.

15N/3E-13 (Harding 110)—Reference point—top of casing, elevation 62 feet, 50 feet east of road which runs north and south behind Marysville High School and 0.4 mile south of north end of road. 10/20/31, 12.0; 12/5/32, 12.6.

15N/3E-14 (Harding 83)—Reference point—top of wall of pit, elevation 56 feet, 400 feet east and 200 feet south of west quarter corner of section. 10/13/31, 21.5.

15N/3E-15 (Harding 21)—Reference point—top of concrete pit, elevation 60 feet, 500 feet west of highway and 100 feet south of north line of section. 9/8/31, 29.3; 10/17/31, 29.1; 12/7/32, 27.2.

15N/3E-16 (Harding 23)—Reference point—top of concrete pit, elevation 58 feet, 750 feet south and 850 feet west of northeast corner of section. 9/10/31, 30.2; 10/17/31, 29.7; 12/7/32, 27.7.

15N/3E-17 (Harding 29)—Reference point—top of concrete pit, elevation 56 feet, 1,100 feet east of Live Oak drain, south of Sacramento Northern Railroad. 9/19/31, 25.0; 12/8/32, 22.5.

15N/3E-19 (Harding 37)—Reference point—floor of pit, 8 feet deep, elevation 50 feet, 660 feet east and 500 feet south of northwest corner of section. 9/18/31, 16.0; 10/17/31, 17.5; 11/28/32, 16.9.

15N/3E-19 (Harding 36)—Reference point—top of concrete pit wall, elevation 50 feet, 1,320 feet north and 300 feet east of southwest corner of section. 9/18/31, 18.0; 12/1/32, 17.0.

15N/3E-20 (Harding 20)—Reference point—top of concrete pit, elevation 57 feet, 850 feet west and 40 feet south of northeast corner of section. 9/8/31, 31.4; 10/17/31, 31.0; 12/1/32, 28.6.

15N/3E-20 (Harding 28)—Reference point—floor of pump house or top of pit, elevation 56 feet, 220 feet east and 250 feet north of south quarter corner of section. 9/18/31, 32.1.

15N/3E-21 (Harding 24)—Reference point—top of casing, elevation 55 feet, 1,100 feet west and 400 feet south of northeast corner of section. 9/10/31, 28.1; 10/17/31, 28.5.

15N/3E-23 (Harding 27)—Reference point—top of casing, elevation 57 feet. In Yuba City, back of blacksmith shop, 150 feet south of Sutter Hotel. 9/17/31, 22.2; 11/29/32, 21.1.

15N/3E-26 (Harding 48)—Reference point—top of concrete pit, elevation 54 feet, 3,800 feet east and 700 feet south of northwest corner of section. 9/—/31, 26.5; 11/29/32, 26.0.

15N/3E-26 (Harding 80)—Reference point—top of casing, elevation 50 feet, 2,000 feet east of northwest corner of section. 10/13/31, 20.5.

15N/3E-26 (Harding 81)—Reference point—top of casing, elevation 55 feet, 100 feet west of toe of levee, 3,500 feet south of Yuba City south limit. 10/13/31, 23.5; 11/29/32, 25.5.

15N/3E-27 (Harding 25)—Reference point—top of casing, elevation 55 feet, 500 feet west and 300 feet south of north quarter corner of section. 8/17/31, 30.2; 12/1/32, 28.5.

15N/3E-27 (Harding 49)—Reference point—top of concrete pit, elevation 51 feet, 1,000 feet west and 1,300 feet north of south quarter corner of section. 9/1/31, 32.2; 11/30/32, 32.4.

15N/3E-28 (Harding 26)—Reference point—top of wood pit, elevation 53 feet. South side of highway, 1,100 feet west of northeast corner of section. 4/—/13, 17.0; 9/17/31, 31.4; 12/1/32, 28.4.

15N/3E-29 (Harding 31)—Reference point—top of concrete pit, elevation 50 feet, 150 feet north and 50 feet west of southeast corner of section. 9/22/31, 32.4; 11/30/32, 29.4.

15N/3E-29 (Harding 30)—Reference point—top of concrete pit, elevation 49 feet, 660 feet east and 660 feet north of southwest corner of section. 9/20/31, 25.2; 11/30/32, 22.6.

15N/3E-30 (Harding 39)—Reference point—top of frame of wooden pit, elevation 52 feet, 1,320 feet south of north quarter corner on east bank of Live Oak drain. 9/19/31, 22.5.

15N/3E-31 (Harding 40)—Reference point—top of wall of concrete pit, elevation 45 feet, 1,800 feet east and 200 feet north of southwest corner of section. 9/19/31, 17.5; 11/30/32, 17.3.

15N/3E-31 (Harding 38)—Reference point—top of wall of concrete pit, elevation 47 feet, 200 feet west and 200 feet south of northeast corner of section. 9/19/31, 22.0; 11/30/32, 21.8.

15N/3E-32 (Harding 32)—Reference point—top of concrete pit, elevation 50 feet, 600 feet east and 500 feet north of south quarter corner of section. 9/22/31, 32.7; 12/1/32, 29.1.

15N/3E-33 (Harding 33)—Reference point—top of concrete pit, elevation 50 feet, 1,150 feet east and 250 feet south of northwest corner of section. 9/23/31, 33.3; 11/30/32, 30.6.

15N/3E-34 (Harding 50)—Reference point—top of concrete pit, elevation 52 feet, 1,600 feet north and 400 feet east of south quarter corner of section. 9/—/31, 34.6; 12/1/32, 32.7.

15N/4E-32 (Harding 102)—Reference point—top of wall of pit, elevation 61 feet, 50 feet east of west line of section, 500 feet south of railroad crossing. 10/16/31, 17.0; 12/3/32, 18.0.

16N/3E-2 (Harding 95)—Reference point—top of casing, elevation 80 feet, 100 feet north of Ramirez Road, 0.50 mile east of State Highway 24. 10/15/31, 17.5.

16N/3E-11 (Harding 96)—Reference point—top of casing, elevation 76 feet. At west end of road running west from State Highway 24, 0.8 mile north of Magnolia Avenue. 10/15/31, 19.5; 12/6/32, 17.9.

16N/3E-14 (Harding 97)—Reference point—top of wall of pit, elevation 75 feet, 500 feet west of State Highway 24, 400 feet south of La Finca Lane. 10/15/31, 15.0; 12/6/32, 14.9.

16N/3E-19 (Harding 12)—Reference point—top of casing, elevation 67 feet, 1,260 feet east and 200 feet north of north quarter of section. 9/2/31, 10.1; 12/7/32, 10.1.

*16N/3E-21 (Harding 10)—Reference point—top of wood pit, west side, elevation 68 feet. Near southeast corner of section, 0.5 mile east of Southern Pacific Railroad. 9/2/31, 23.8; 10/17/31, 22.9; 12/7/32, 20.8.

16N/3E-24 (Harding 90)—Reference point—top of casing, elevation 70 feet. North of Woodruff Road, 1 mile east of State Highway 24. 10/15/31, 10.0; 12/6/32, 11.5.

16N/3E-27 (Harding 78)—Reference point—top of casing, elevation 69 feet, 500 feet north of east and west center line of section at toe of levee. 10/13/31, 25.0; 12/7/32, 22.4.

16N/3E-28 (Harding 8)—Reference point—top of concrete pit, west side, elevation 64 feet, 1,300 feet west of U. S. Highway 99E, 250 feet north of south line of section. 9/2/31, 21.8; 10/17/31, 20.6; 12/7/32, 19.1.

16N/3E-28 (Harding 9)—Reference point—top of casing, elevation 66 feet, 1,000 feet south of north line of section and 300 feet east of Southern Pacific Railroad. 9/2/31, 19.0; 10/17/31, 19.2; 12/7/32, 17.7.

16N/3E-29 (Harding 2)—Reference point—top of concrete pit, elevation 66 feet, 100 feet west and 120 feet south of northeast quarter of northwest quarter of section. 8/13/31, 13.5; 10/17/31, 13.2; 12/7/32, 12.6.

TABLE 2—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Meosurements Made by S. T. Hording
(Depths to water in feet meosured from reference point)

16N 3E-29 (Harding 1)—Reference point—top of casing, elevation 65 feet, 1,880 feet north and 660 feet west of east quarter corner of section. 8/31/31, 15.5; 10/17/31, 14.8; 12/7/32, 13.7.

16N 3E-29 (Harding 6)—Reference point—top of casing, elevation 65 feet, 750 feet east and 1,100 feet north of south quarter corner of section. 8/31/31, 18.4; 10/17/31, 18.0; 12/7/32, 16.3.

16N 3E-29 (Harding 91)—Reference point—top of casing, elevation 71 feet. At cross roads at east end of Woodruff Road. 10/15/31, 6.5; 12/6/32, 6.0.

16N 3E-30 (Harding 11)—Reference point—top of casing, elevation 66 feet, 1,750 feet east and 500 feet north of southwest corner of section. 9/2/31, 10.1; 12/7/32, 12.0.

16N 3E-31 (Harding 34)—Reference point—top of timber frame, elevation 61 feet, 1,300 feet east and 300 feet north of south quarter corner of section. 9/17/31, 18.0; 10/17/31, 20.0; 12/7/32, 17.8.

16N 3E-32 (Harding 13)—Reference point—top of concrete pit, elevation 64 feet, 1,350 feet south and 300 feet east of north quarter corner of section. 9/2/31, 19.1; 10/17/31, 18.6; 12/7/32, 17.5.

16N 3E-32 (Harding 3)—Reference point—top of wood pit, west side, elevation 60 feet, 600 feet north and 300 feet east of south quarter corner of section. 8/31/31, 19.3; 10/17/31, 18.9; 12/7/32, 17.0.

16N 3E-33 (Harding 5)—Reference point—top of casing, elevation 64 feet, 3,300 feet west of U. S. Highway 99E, 200 feet south of north line of section. 8/31/31, 24.9; 10/17/31, 19.1; 12/7/32, 17.5.

16N 3E-33 (Harding 7)—Reference point—top of concrete base, elevation 60 feet, 1,100 feet east and 400 feet north of southwest corner of section. 9/1/31, 20.6; 12/7/32, 18.8.

16N 3E-35 (Harding 89)—Reference point—top of wall of pit, elevation 66 feet, 1,000 feet west of angle in Oroville Highway, 0.5 mile north of Ellis Road. 10/15/31, 18.0; 12/6/32, 16.4.

16N 3E-35 (Harding 88)—Reference point—top of wall of pit, elevation 65 feet, 0.75 mile north of Walnut Avenue, 0.50 mile west of Oroville Highway. 10/15/31, 20.0; 12/6/32, 19.1.

16N 3E-36 (Harding 92)—Reference point—top of wall of pit, elevation 65 feet, 600 feet south of Ellis Road, 500 feet west of Western Pacific Railroad. 10/15/31, 7.5; 12/5/32, 8.5.

TABLE 3

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Sutter County Farm Advisor
(Depths to water in feet and/or inches measured from reference point)

13N/3E-2C1—Reference point—air gage. 1/19/32, 18.2; 2/24/32, 17.5; 3/2/32, 17.9; 4/18/32, 19.0; 5/23/32, 17.1; 6/15/32, 20.4; 7/18/32, 23.0; 9/8/32, 19.8; 10/25/32, 19.0; 11/15/32, 19.3; 12/23/32, 19.0; 2/3/33, 18.5; 3/3/33, 18.6; 4/11/33, 21.4; 5/2/33, 19.8; 6/28/33, 24.2; 8/1/33, 35.0; 9/14/33, 32.0; 10/17/33, 31.0; 3/22/34, 27.0; 9/18/34, 31.5; 11/9/34, 30.0; 12/27/34, 29.3; 1/22/35, 27.8; 3/22/35, 26.3; 4/19/35, 23.7; 5/27/35, 22.7; 7/2/35, 57.8 (operating); 10/31/35, 28.4; 12/26/35, 27.6; 1/3/36, 26.0; 2/25/36, 22.0; 4/11/36, 23.0; 6/15/36, 29.0; 7/24/36, 33.0; 8/20/36, 28.0; 9/24/36, 27.8; 10/27/36, 27.8; 12/28/36, 27.0; 2/9/37, 26.0; 4/5/37, 20.0; 5/13/37, 20.0.

13N/3E-5E2—Reference point—top of pit. 5/16/31, 20′ 8″; 7/11/31, 24′ ¾″; 8/31/31, 21′ 7½″; 9/23/31, 21′ 7″; 10/16/31, 21′ ½″; 11/17/31, 20′ 7″; 12/17/31, 19′ 11″; 1/19/32, 18′ 11″; 2/24/32, 18′ 3¾″; 3/22/32, 17′ 11½″; 4/19/32, 18′ 5½″; 5/23/32, 19′ 6″; 6/23/32, 19′ 2″; 9/13/32, 19′ 11½″; 10/18/32, 19′ 10″; 11/30/32, 19′ 7″; 12/27/32, 19′ 6″; 2/6/33, 19′ 2″; 3/5/33, 18′ 10½″; 4/10/33, 19′ ¾″; 5/17/33, 20′ 5½″; 8/1/33, 22′ 4¾″; 9/14/33, 21′ 5¾″; 3/16/34, 19′ 5½″; 11/9/34, 20′ 7″; 12/11/34, 20′ 0″; 2/15/35, 17′ 7″; 3/22/35, 18.0; 4/19/35, 17.5; 5/24/35, 17.6; 7/2/35, 24.8 (operating); 8/21/35, 18.7; 9/25/35, 18.5; 10/31/35, 18.5; 12/26/35, 18.1; 1/24/36, 17.7; 2/25/36, 16.6; 4/14/36, 15.2; 4/22/36, 16.7; 8/18/36, 16.9; 9/28/36, 16.9; 10/21/36, 16.4; 12/28/36, 15.8; 2/9/37, 15.3.

13N/3E-24G1—Reference point—air gage. 5/6/31, 19.9; 7/15/31, 22.2; 8/28/31, 19.9; 9/22/31, 21.1; 10/14/31, 19.9; 11/17/31, 19.9; 12/17/31, 19.7; 1/2/32, 17.2; 1/19/32, 16.5; 2/25/32, 15.8; 3/2/32, 17.6; 4/26/32, 15.1; 6/22/32, 16.9; 7/18/32, 19.9; 9/8/32, 18.8; 10/18/32, 18.1; 11/15/32, 18.8; 12/22/32, 18.1; 2/3/33, 17.6; 3/3/33, 17.4; 4/11/33, 21.1; 5/2/33, 17.6; 6/28/33, 34.9 (operating); 8/1/33, 22.2; 9/14/33, 19.5; 10/17/33, 18.3; 3/22/34, 28.0; 6/29/34, 21.6; 9/18/34, 19.9; 11/9/34, 19.7; 12/27/34, 18.8; 1/22/35, 16.5; 3/22/35, 16.5; 4/19/35, 13.0; 5/27/35, 12.4; 7/2/35, 36.1 (operating); 8/19/35, 16.5; 9/25/35, 19.5; 10/31/35, 17.6; 12/26/35, 17.6; 1/30/36, 15.3; 2/25/36, 10.9; 4/6/36, 11.9; 8/10/36, 19.5; 9/3/36, 19.9; 9/24/36, 14.9; 10/27/36, 18.8; 12/28/36, 18.8; 2/9/37, 12.4; 4/5/37, 7.1; 5/19/37, 7.8; 9/13/37, 14.1; 12/30/37, 9.7; 2/24/36, 4.7; 3/23/38, 3.8; 4/25/38, 3.7; 6/3/38, 4.8; 6/21/38, 8.9; 7/22/38, 12.2; 9/8/38, 12.3; 2/25/39, 12.5; 4/10/39, 13.8; 8/2/39, 17.6; 10/11/39, 15.8; 11/29/39, 15.4; 2/8/40, 11.5; 3/22/40, 7.8; 5/20/40, 7.9; 8/24/40, 15.0.

13N/4E-13F3—Reference point—hole in pump base. 12/1/32, 18′ 6¾″; 1/12/33, 17′ 9½″; 2/3/33, 17′ 4½″; 3/10/33, 16′ 9½″; 4/3/33, 18′ 2″; 5/23/33, 20′ 8½″; 10/23/33, 22′ 1½″; 3/20/34, 23′ 3½″; 6/27/34, 30′ 6″; 9/26/34, 24′ 6″; 12/10/34, 20′ 11″; 2/14/35, 18′ 5″; 3/25/35, 17′ 4½″; 4/30/35, 15′ 6¾″; 5/28/35, 19′ 2″; 8/18/35, 26′ 3½″; 9/26/35, 20′ 7½″; 1/15/36, 16.7; 3/28/36, 14.2; 3/27/36, 20.6; 8/10/36, 25.3; 8/20/36, 22.6; 9/23/36, 21.0; 10/27/36, 19.4; 1/2/37, 16.7; 2/10/37, 15.6; 4/8/37, 11.6; 11/27/37, 17.0; 3/16/38, 11.0; 4/27/38, 10.7; 5/31/38, 14.0; 7/21/38, 32.2*; 9/8/38, 18.1; 12/29/38, 15.6; 2/16/39, 15.3; 6/15/39, 34.9; 10/12/39, 22.7; 12/6/39, 20.9; 2/19/40, 17.1; 3/27/40, 15.1; 5/15/40, 15.3; 8/6/40, 28.7.

13N/4E-13R2—Reference point—top of casing. 1/12/33; 16′ 3″; 2/3/33, 14′ 8¼″; 3/10/33, 15′ 0″; 4/3/33, 16′ 4½″; 5/23/33, 18′ 1″; 6/28/33, 26′ 3″*; 8/9/33, 25′ 1¾″; 9/15/33, 22′ 8″. Following measurements from new well, reference point—hole in side of pump, 3/20/34, 22′ 3½″; 12/10/34, 18′ 8″; 2/14/35, 16′ 3½″; 3/25/35, 14′ 11½″; 4/30/35, 13′ 5¼″; 5/28/35, 14′ 10″; 7/3/35, 22′ 4½″; 1/25/36, 11.2; 2/28/36, 16.2; 8/10/36, 20.7; 8/20/36, 19.0; 9/23/36, 19.6; 10/27/36, 15.4; 1/2/37, 13.4; 2/10/37, 11.9; 4/8/37, 7.6; 5/26/37, 9.7; 11/27/37, 13.6; 3/16/38, 6.9; 4/27/38, 6.6; 5/31/38, 7.8; 12/29/38, 11.6; 2/16/39, 9.2; 12/6/39, 16.5; 2/19/40, 13.3; 3/27/40, 11.3; 5/15/40, 9.7; 8/6/40, 21.5; 5/19/41, 6.4.

* Nearby well pumping.

13N/4E-14D1—Reference point—air gage. 2/14/33, 12.01; 3/8/33, 12.01; 4/5/33, 39.63 (operating); 6/27/33, 15.00.

13N/4E-15R1—Reference point—air gage. 2/14/33, 18.94; 3/8/33, 18.25; 4/5/33, 43.2 (operating); 5/23/33, 23.56; 6/26/33, 32.8; 9/26/33, 24.0; 10/23/33, 28.18; 3/20/34, 23.56; 6/27/34, 31.65; 9/26/34, 30.49; 12/10/34, 25.11; 2/14/35, 22.15; 3/25/35, 20.79; 4/30/35, 18.94; 5/28/35, 18.94; 6/24/35, 27.03; 8/6/35, 31.65; 9/26/35, 25.18; 1/15/36, 21.25; 2/28/36, 18.25; 3/29/36, 28.18; 7/23/36, 30.5; 8/20/36, 30.5; 9/23/36, 31.65; 10/27/36, 28.41; 1/2/37, 23.56; 2/10/37, 21.25; 5/26/37, 16.63; 7/21/37, 26.4.

13N/5E-7L1—Reference point—top of casing. 12/1/32, 22′ 2″; 2/3/33, 20′ 10½″.

13N/5E-16D1—Reference point—top of casing. 12/1/32, 1′ 3¾″; 1/12/33, 1′ ½″; 2/3/33, 0′ 10½″; 3/10/33, 0′ 6½″; 4/5/33, 0′ 6″; 5/23/33, 1′ 4″; 6/27/33, 2′ 8½″; 8/9/33, 7′ 1″; 9/15/33, 5′ 0″; 10/23/33, 4′ 8½″; 3/20/34, 1′ 4″; 6/27/34, 4′ 6½″; 9/26/34, 6′ ½″; 12/10/34, 4′ 4″; 2/14/34, 1′ 10¾″; 3/25/35, 0′ 2½″; 4/30/35, 0′ 9½″; 5/28/35, —0′ 1¾″; 7/3/35, 1′ 9″; 8/6/35, 3′ 0″; 9/26/35, 2′ 7″; 1/15/36, 13.0; 2/28/36, 9.1; 3/27/36, 9.3; 7/30/36, 14.3; 8/20/36, 13.7; 9/23/36, 13.3; 10/27/36, 13.1; 1/2/37, 12.7; 2/10/37, 11.3; 4/8/37, 6.5; 5/26/37, 9.1; 7/21/37, 14.7; 3/16/38, 5.1; 4/27/38, 6.4; 7/21/38, 12.5; 9/8/38, 13.5; 12/29/38, 11.5; 2/16/39, 11.4; 4/27/39, 14.4; 6/15/39, 15.9; 10/12/39, 17.5; 12/6/39, 15.6; 2/9/40, 12.9; 3/27/40, 9.8; 5/15/40, 8.7; 8/6/40, 16.8; 5/19/41, 6.7; 7/28/41, 14.2.

13N/5E-18C1—Reference point—hole in top of pump base. 12/1/32, 17′ 4½″; 1/12/33, 16′ 7″; 2/3/33, 16′ 2″; 3/10/33, 15′ 7″; 4/3/33, 18′ 4½″; 5/23/33, 19′ 9″; 6/28/33, 25′ 1″; 9/15/33, 22′ 6″; 10/23/33, 21′ 4″; 6/27/34, 30′ 3″; 9/26/34, 23′ 7½″; 12/10/34, 20′ ¼″; 2/14/35, 17′ 11½″; 3/25/35, 15′ 7½″; 4/30/35, 14′ 1½″; 5/28/35, 16′ 2″; 6/24/35, 21′ 4″; 8/6/35, 26′ 5½″; 9/26/35, 18′ 8½″; 8/10/36, 22.05; 8/20/36, 22.2; 9/23/36, 20.9; 10/27/36, 15.0; 1/2/37, 14.3; 2/16/37, 13.04; 4/8/37, 8.2; 5/26/37, 12.9; 11/27/37, 14.6; 3/16/38, 8.0; 4/27/38, 8.2; 5/31/38, 10.2; 7/21/38, 20.3; 9/8/38, 16.4; 12/29/38, 13.2; 5/19/41, 8.2; 7/28/41, 19.7.

15N/3E-7M2—Reference point—top of casing. 7/15/31, 17′ 6½″; 8/27/31, 17′ 11″; 9/17/31, 17′ 6″; 10/26/31, 16′ 11″; 11/19/31, 16′ 6½″; 12/16/31, 16′ ¾″; 4/18/32, 14′ 8½″; 2/23/32, 14′ 2″; 3/23/32, 14′ 2½″; 4/15/32, 14′ 6½″; 5/18/32, 14′ 7½″; 6/2/32, 15′ 3½″; 7/13/32, 15′ 9½″; 9/12/32, 16′ 2½″; 10/17/32, 17′ 11″; 11/30/32, 16′ 4″; 12/29/32, 16′ 3¾″; 1/26/33, 16′ 5½″; 3/3/33, 16′ 2¾″; 4/7/33, 16′ 5″; 5/12/33, 16′ 9½″; 6/20/33, 18′ 3″; 7/31/33, 18′ 6½″; 9/13/33, 17′ 2″; 10/17/33, 16′ 9½″; 11/8/33, 16′ 11½″; 3/12/34, 16′ 3″; 6/26/34, 17′ 8″; 11/2/34, 18′ 5½″; 1/28/35, 17′ 5″; 3/14/35, 16′ 3″; 4/18/35, 15′ 5½″; 5/23/35, 15′ 1¾″; 6/25/35, 16′ 0″; 7/27/35, 17′ 0″; 10/25/35, 15.2; 12/19/35, 15.2; 1/23/36, 14.8; 2/27/36, 13.2; 3/31/36, 11.7; 7/9/36, 12.0; 8/18/36, 12.8; 9/17/36, 12.5; 10/20/36, 13.3; 12/28/36, 13.2; 2/16/37, 12.2; 3/29/37, 9.4; 5/3/37, 8.8; 7/16/37, 10.7; 9/28/37, 12.2; 12/4/37, 14.2; 4/15/38, 4.6; 5/26/38, 6.6; 7/14/38, 8.5; 9/20/38, 10.3; 10/28/38, 9.5; 12/24/38, 10.5; 1/31/39, 10.6; 3/3/39, 10.9; 4/13/39, 11.6; 8/1/39, 14.7; 9/27/39, 14.6; 11/8/39, 14.2; 1/18/40, 13.2; 3/20/40, 9.6; 5/16/40, 7.9; 8/2/40, 11.2; 10/17/40, 12.7; 9/20/41, 10.3.

15N/3E-31A1—Reference point—top of pit plus 4-inch timber. 5/12/31, 21′ 10¾″; 6/26/31, 22′ 10¾″; 7/28/31, 24′ 0″; 8/31/31, 24′ 11″; 9/23/31, 24′ ¾″; 10/20/31, 23′ 8½″; 11/8/31, 23′ 1″; 12/17/31, 22′ 9½″; 1/19/32, 22′ 2″; 2/23/32, 21′ 4″; 3/22/32, 20′ 11½″; 4/18/32, 21′ 4½″; 5/23/32, 21′ 2″; 6/21/32, 21′ 5½″; 7/19/32, 22′ 4″; 9/13/32, 22′ 11″; 10/18/32, 22′ 6¾″; 11/22/32, 22′ 2½″; 12/27/32, 21′ 10″; 1/30/33, 21′ 3″; 4/10/33, 21′ 5″; 5/17/33, 22′ 2½″; 6/29/33, 23′ ¾″; 7/25/33, 24′ 5″; 10/18/33, 23′ 7½″; 12/8/33, 23′ 7½″; 3/13/34; 22′ 3½″; 6/26/34, 23′ 11″; 10/2/34, 24′ 7″; 11/5/34, 24′ ¾″; 12/11/34, 23′ 7½″; 2/15/35, 22′ 5″; 3/19/35, 21′ 11″; 4/19/35, 21′ 2″; 5/23/35, 20′ 5½″;

TABLE 3—Continued

DEPTHS TO GROUND WATER AT MEASUREMENT WELLS IN SUTTER-YUBA AREA

Measurements Made by Sutter Caunty Farm Advisar
(Depths to water in feet and/ar inches measured fram reference point)

6/27/35, 21′ 2″; 7/30/35, 22′ 6″; 9/21/35, 23′ 1¾″; 10/25/35, 21.9; 12/20/35, 21.1; 1/23/36, 17.2; 2/25/36, 20.1; 4/14/36, 19.1; 7/22/36, 20.1; 8/18/36, 20.7; 9/17/36, 20.2; 10/21/36, 20.2; 12/28/36, 19.7.

16N/3E-30A1—Reference point—top of casing, 6 inches above ground level. 6/27/31, 11′ 10″; 7/28/31, 12′ 2″; 8/27/31, 12′ 3½″; 9/17/31, 12′ 6″; 10/26/31, 12′ 9″; 11/17/31, 13′ ½″; 12/16/31, 13′ 1½″; 1/18/32, 10′ ¼″; 2/18/32, 9′ 11″; 3/18/32, 10′ 1½″; 5/15/32, 10′ 10½″; 6/30/32, 10′ 6½″; 7/13/32, 10′ 9½″; 9/8/32, 11′ 10″; 10/17/32, 12′ 4¾″; 11/22/32, 12′ 8½″; 12/21/32, 13′ 2″; 1/26/33, 13′ 2½″; 3/3/33, 13′ 7¼″; 4/7/33, 12′ 11″; 5/11/33, 12′ 8½″; 6/20/33, 12′ 11″; 7/31/33, 12′ 11″; 9/13/33, 13′ 6½″; 10/17/33, 13′ 10″; 12/8/33, 14′ 4″; 3/12/34, 12′ 7½″; 6/26/34, 11′ 9″; 7/31/34, 12′ 1½″; 9/27/34, 12′ 6½″; 11/2/34, 13′ 4″; 12/11/34, 13′ 7¾″; 1/28/35, 11′ 4¼″; 3/14/35, 9′ 2″; 4/18/35, 9′ 6¼″; 5/22/35, 10′ 5″; 6/25/35, 10′ 8″; 7/29/35, 10′ 11½″; 9/19/35, 12′ 2″; 10/23/35, 11.9; 12/19/35, 12.6; 1/22/36, 11.2; 2/27/36, 7.5; 3/31/36, 9.1; 5/15/36, 9.7; 6/12/36, 10.2; 7/9/36, 10.7; 8/18/36, 11.7; 9/17/36, 12.1; 10/20/36, 12.2; 12/22/36, 12.7; 2/16/37, 9.1; 3/29/37, 6.6; 5/3/37, 8.6; 7/16/37, 10.1; 12/4/37, 10.2; 5/17/38, 7.9; 7/14/38, 9.5; 9/15/38, 11.2; 10/26/38, 11.8; 12/24/38, 12.4; 1/31/39, 12.6; 3/3/39, 12.7; 4/13/39, 13.1; 6/3/39, 12.1; 8/1/39, 12.5; 9/22/39, 11.6.

16N/3E-30C1—Reference point—top of casing, 4 inches above ground. 5/22/31, 11′ 8½″; 6/25/31, 11′ 7″; 7/29/31, 12′ 0″; 8/27/31, 11′ 9″; 9/17/31, 11′ 7½″; 10/21/31, 11′ ½″; 11/19/31, 10′ 7½″; 12/23/31, 10′ 2″; 1/18/32, 8′ 7″; 2/23/32, 8′ 4½″; 3/19/32, 8′ 4½″; 4/15/32, 8′ 11¾″; 5/17/32, 9′ 1″; 6/21/32, 8′ 9½″; 7/13/32, 9′ 1″; 9/12/32, 9′ 2⅝″; 10/17/32, 9′ 4½″; 11/30/32, 10′ 2½″; 12/29/32, 10′ 6½″; 1/26/33, 10′ 9¼″; 3/3/33, 10′ 6½″; 4/7/33, 10′ 10″; 5/12/33, 10′ 9½″; 6/20/33, 9′ 10″; 7/31/33, 9′ 7½″; 9/13/33, 9′ 3″; 10/17/33, 9′ 6″; 12/8/33, 10′ 4½″; 3/12/34, 10′ 0″; 6/26/34, 11′ 8½″; 9/27/34, 11′ 9″; 11/2/34, 12′ 9″; 12/11/34, 11′ 11½″; 1/28/35, 10′ 10¾″; 3/4/35, 9′ 8½″; 4/18/35, 9′ 4″; 5/23/35, 9′ 8″; 6/25/35, 10′ 5″; 7/29/35, 11′ 5½″; 9/21/35, 11′ 2½″; 10/25/35, 10′ 10¾″; 12/19/35, 11.1; 1/23/36, 10.7; 2/27/36, 9.5; 3/31/36, 8.3; 7/9/36, 9.4; 8/18/36, 9.8; 9/17/36, 9.6; 10/20/36, 9.7; 12/28/36, 10.3; 2/16/37, 6.5; 3/29/37, 6.9; 5/3/37, 8.5; 7/16/37, 8.6; 9/28/37, 8.2; 12/4/37, 8.6; 1/25/38, 6.5; 4/14/38, 3.2; 5/26/38, 6.3; 7/14/38, 6.9; 9/20/38, 8.5; 10/26/38, 8.0; 12/24/38, 8.7; 1/31/39, 8.9; 3/3/39, 9.2; 4/13/39, 10.3; 8/1/39, 11.2; 9/22/39, 12.1; 11/8/39, 10.6; 1/18/40, 10.2; 3/20/40, 6.5; 5/16/40, 6.7; 8/2/40, 9.7; 10/17/40, 10.3.

16N/3E-32G5—Reference point—top of casing, 1 foot 6 inches above ground surface. 6/25/31, 22′ 5″; 7/28/31, 26′ 2½″; 8/27/31, 24′ 6½″; 9/17/31, 20′ 5½″; 10/19/31, 18′ 11″; 11/19/31, 18′ 6″; 12/16/31, 18′ 2¾″; 1/2/32, 17′ 8½″; 1/18/32, 17′ 0″; 2/18/32, 15′ 9″; 3/18/32, 12′ 8½″; 4/15/32, 19′ 6″; 5/17/32, 15′ 1½″; 6/23/32, 23′ 10½″*; 7/13/32, 18′ 1″; 9/8/32, 18′, 2½″; 10/17/32, 17′ 10½″; 11/22/32, 17′ 8″; 12/29/32, 17′ 5″; 1/26/33, 17′ 3½″; 3/3/33, 18′ 1½″; 4/7/33, 25′ 4″ (operating); 5/11/33, 17′ 9½″; 6/20/33, 22′ 5½″; 7/31/33, 28′ 10″ (operating); 9/13/33, 21′ 10½″; 10/17/33, 21′ 0″; 11/18/33, 19′ 2½″; 3/12/34, 18′ 2″. Reference point—top of casing, ground level. 6/26/34, 24′ 5″; 7/31/34, 25′ 7″; 9/27/34, 23′ 9¾″; 11/2/34, 19′ 5″; 12/11/34, 18′ 5½″; 1/28/35, 16′ 10″; 3/14/35, 14′ 4½″; 4/18/35, 14′ ½″; 5/22/35, 12′ 2½″; 7/3/35, 16′ 5½″; 7/29/35, 20′ 0″; 8/27/35, 17′ 1″; 9/19/35, 19′ 17″; 1/22/36, 15.4; 2/27/36, 12.9; 3/31/36, 13.4; 7/9/36, 18.5; 8/18/36, 18.8; 9/17/36, 19.5; 10/23/36, 16.4; 12/22/36, 15.3; 2/16/37, 13.8; 3/29/37, 11.2; 5/3/37, 10.7; 7/16/37, 15.3; 12/4/37, 15.0; 1/25/38, 12.2; 2/25/38, 5.1; 4/14/38, 3.5; 5/26/38, 5.7; 7/14/38, 12.8; 9/15/38, 13.2; 10/26/38, 12.8.

Estimated Cost of Browns Valley Distribution System	170
Estimated Cost of Camp Far West Dam and Reservoir	170
Estimated Cost of Bear River Canal	171
Estimated Cost of East Central Zone Siphon, Conduit, and Distribution System	171
Estimated Cost of South Side Zone Conduit and Distribution System	172
Estimated Cost of Coon Creek Dam and Reservoir	173
Estimated Cost of Coon Creek Diversion, Conduit, and Distribution System	174

ESTIMATED COST OF PEACH BOWL PROJECT

(Based on prices prevailing in April, 1952)

Pumping plant capacity: 135 second-feet
Gross seasonal diversion: 24,000 acre-feet
Maximum monthly demand: (July) 6,450 acre-feet, 105 second-feet

Acreage served: Presently irrigated lands, 4,500 acres; irrigated lands to be developed, 2,500 acres

Item	Quantity	Unit price	Cost	
Capital Costs				
Pumping Plant				
Pumps, motors, and electrical equipment	3 each	$14,330	$43,000	
Discharge pipe and footings	3 each	5,700	17,100	
Sump and trash racks		lump sum	7,100	
Structure		lump sum	14,400	
Discharge structure and sand trap		lump sum	3,400	$85,000
Subtotal				$85,000
Administration and engineering, 10%				$8,500
Contingencies, 15%				12,800
Interest during construction				1,600
TOTAL				$107,900
Conveyance System				
Excavation	137,800 cu. yd.	$0.30	$41,400	
Trimming	195,900 sq. yd.	0.25	49,000	
Lining, concrete	10,900 cu. yd.	35.00	381,500	
Turnouts, 100 second-feet	14 each	1,100	15,400	
50 second-feet	20 each	830	16,600	
Crossings, 100 second-feet				
Railroad	1 each	5,800	5,800	
County road	1 each	3,200	3,200	
Crossings, 50 second-feet				
County road	4 each	2,300	9,200	
Farm road	6 each	1,400	8,400	
Right of way				
Orchard lands	52 acres	1,500	78,000	
Open lands	44 acres	750	33,000	$641,500
Subtotal				$641,500
Administration and engineering, 10%				$64,200
Contingencies, 15%				96,200
Interest during construction				12,000
TOTAL				$813,900

Item	Quantity	Unit price	Cost	
Capital Costs—Continued				
Distribution System				
Presently irrigated lands	4,500 acres	$70.00	$315,000

Operation and maintenance				8,500
TOTAL				$196,200

ESTIMATED COST OF COON CREEK DIVERSION, CONDUIT, AND DISTRIBUTION SYSTEM

(Based on prices prevailing in April, 1952)

Capacity of conduit: 100 second-feet
Length of conduit: 7.8 miles
Canal lined for first 0.5 mile

Distribution system: Unlined canals and ditches
Acreage served: 12,000 acres

Item	Quantity	Unit price	Cost	
Capital Costs				
Diversion Structure				
Stripping	320 cu.yd.	$0.50	$200	
Embankment	900 cu.yd.	0.50	400	
Timber, flashboards	1.2 MBM	250.00	300	
Crane for removing flashboards		lump sum	1,000	$1,900
Levee				
Stripping	1,500 cu.yd.	0.50	800	
Embankment	2,000 cu.yd.	0.50	1,000	
Concrete headwall and wing walls	22 cu.yd.	60.00	1,300	
Reinforcing steel	2,200 lbs.	0.15	300	
Headgate, 4' x 5'		lump sum	500	3,900
Conduit				
Excavation	72,810 cu.yd.	0.50	36,400	
Compacted fill	32,740 cu.yd.	0.50	16,400	
Trimming	101,830 sq.yd.	0.30	30,500	
Concrete				
Shotcrete	5,330 sq.yd.	3.50	18,700

ACKNOWLEDGMENTS

The author wishes to acknowledge his gratitude to Dr. Jerome J. Wright for guidance and assistance in this work, and to Drs. Eugene S. Simpson and William B. Bull for their helpful advice in its editorial criticism.

Special thanks are due to my fellow student, Dr. Errol I. Montgomery, for his technical help and friendly interest; and to Robert L. Lunch, who contributed constructive criticism as to the form and continuity of this report.

The author expresses his appreciation to Fred E. Kasline, State Oil and Gas Supervisor, California Division of Oil and Gas, for authorizing the use of information in the Division's files, and to Ralph M. Barger, Deputy Supervisor of the California Division of Oil and Gas, for supplying water quality and shut-in pressure data from gas wells located in the Sacramento Valley. Serge Reynolds, Consulting Geologist, provided electric-logs which could not be obtained through other channels and shared with the author his considerable knowledge of the sub-surface geology of the Sacramento Valley. Ted Bear, Consulting Geologist, also deserves thanks for supplying important geophysical information.

The author is grateful to Lowell E. Redwine, Research Geologist with Union Oil Company, for his critical review of the preliminary cross-sections used in this report and for sharing his authoritative knowledge of the post-Eocene stratigraphy.

ABSTRACT

A mound of saline water exists in continental sediments between two fresh water rivers in the Sutter Basin of the Sacramento Valley, California. This saline water has moved from the marine sediments, at depth, upward along the Sutter Basin Fault and then through 2,000 feet of alluvium.

The hydraulic head required to move the connate water is supplied by the high topographic position of the Cretaceous sediments carried up by the Sutter Buttes intrusives and exposed at the surface some 250 to 400 feet above the valley floor. Around the Buttes the marine sediments have been flushed with fresh water to depths of over 2,000 feet. The displaced saline connate water has moved south where it intercepts the Sutter Basin Fault.

The geologic section consists of about 5,500 feet of Cretaceous and Eocene marine sediments which have been deposited atop the basement complex (the western extension of the Sierra Nevada fault block) and capped by 2,000 feet of post-Eocene alluvium.

Chemical analyses of the ground water indicate sodium chloride water is being introduced from depth, and as the rising connate water moves northerly into the

orchard area it changes to a calcium-magnesium chloride type water.

INTRODUCTION

Purpose of the Investigation

When a mound of saline ground water exists between two fresh water rivers in alluvial sediments 2,000 feet thick, there must be an explanation. Two principal theories have been offered to account for the saline ground water mound that exists in the South Central portion of the Sutter Basin in California. Wilcox (1948) was the first to propose that the saline water was rising from depth. Wolfe (1958) advanced the theory that the saline water resulted from residual evaporites.

It is the thesis of this investigator that the salinity of the mound is due to the hydraulic head between the elevation of the Kione Sands, at their outcrop (recharge area) in the Sutter Buttes, and the elevation of the top of the saline ground water mound in the Sutter Basin. Fresh water has infiltrated and flushed the Kione Sands to depths of approximately 2,000 feet. The displaced marine connate water has moved south and rises along the Sutter Basin Fault, thence through the overlying alluvial sediments to the surface of the basin. A number of other geologic features are involved in the process.

The physical evidence to support the hypothesis was obtained through a study of the subsurface geology, the

hydraulic continuity of the strata and structures and the chemistry of the water.

Maps display the strata, ground water hydrology and chemistry to support the statements that underly this thesis.

Location and Extent of the Area

The saline ground water mound with which this study is concerned lies north of the town of Robbins, California, in the middle of the Sacramento Valley, between the Sacramento and Feather Rivers. Under the saline ground water mound are approximately 2,000 feet of alluvial and non-marine basin sediments. The base of the fresh water that overlies the saline mound lowers in all directions from its center. The salinity of the ground water mound appears to increase with depth.

The area, generally known as the Sutter Basin, is bounded on the west by the Sacramento River, and by the Sutter Bypass on the east. It extends from the alluvial fans of the Sutter Buttes, some 30 miles southeast, to the confluence of the Sacramento and Feather Rivers. The basin lies wholly in Sutter County, California and consists of 114,500 acres of flat, topographical, low, poorly drained land.

To properly evaluate the ground water conditions of the Sutter Basin, the area of investigation was extended to include 1,026 square miles of land lying in all or part of

Township 10 North to Township 16 North, and Range 1 West to Range 4 East, Mount Diablo Base & Meridian. This includes parts of Colusa, Sacramento, Sutter, Yolo and Yuba Counties (Fig. 1).

Previous Investigations

The Division of Soil Management and Irrigation of the United States Department of Agriculture conducted a series of studies in cooperation with the Sutter Mutual Water Company during 1931, 1932, 1933, 1946 and 1947. These studies showed that the amount of dissolved solids in water drained from lands in the southern half of the Sutter Basin greatly exceeded the amount brought onto the land in irrigation water. The salt output during the study periods, expressed as proportion of the input, is reported to have ranged between 248 and 655 percent, with the average about 407 percent. It should be pointed out that all irrigation water for this area is diverted from the Sacramento River. The water table of the basin is controlled by extensive drainage ditches; the drain water is pumped out of the system back into the Sacramento River.

The investigator for the U. S. Department of Agriculture (Wilcox, 1948) concluded that the increase in salt content of the drainage water was due to rising connate water and said (pg. 48):

FIGURE 1 MAP OF CALIFORNIA SHOWING AREA OF INVESTIGATION

> Analyses show that the underground water is moderately to very saline, the lowest concentration observed being several times that of the input irrigation water. Also, all of the wells show a strong artesian pressure. Water in the domestic wells stands at or near the soil surface while the deep wells flow. It appears probable, therefore, that due to the upward pressure, substantial quantities of underground water are intercepted and carried off by the drains.

In September, 1952 the California State Water Resources Board published Bulletin No. 6, "Sutter-Yuba Counties Investigation." In this Bulletin reference is made to the Sutter Basin studies of the U. S. Department of Agriculture and indicates it is in agreement with the report as to the origin of these high chloride waters. Bulletin 6 states (pg. 35):

> The opinion was expressed in a report on the foregoing 1946 salt balance study that the salt in the drainage water was probably derived from saline waters underlying the area. Preliminary studies made by the Division of Water Resources similarly indicated that the chloride salinity in many of the wells was due to admixture of deep-seated brines with native fresh ground waters. There is evidence that such brines may underlie aquifers of good quality throughout large areas of the Sacramento and San Joaquin Valleys--such brines sometimes appear in water pumped from the deep wells in the two valleys, or from areas wherein the fresh ground water levels are markedly lowered through over-draft. In many instances these relatively deep-seated brines are under considerable pressure and readily rise to the surface through defective, abandoned, or improperly constructed wells. A case in point is a natural gas well located near the town of Robbins which yields water under artesian and/or gas pressure at a rate of 200 gallons a minute.

Included in the Resources Board's report was a geochemical study by Davis and Olmsted (1952) to determine the

cause of the high saline water. A complete chemical analysis was run on water samples collected from 38 scattered wells located in Sutter Basin. The water analyses were classified into eight groups according to the range of concentration of total anions. Group 1 was considered unaltered normal ground water and Group 8 was considered briny contaminate. The chemical constituents, in e.p.m. (equivalent parts per million), of Group 1 were subtracted from the chemical constituents of Groups 2 through 7. The resulting chemical constituents, together with Group 8, were tabulated as to percentage. This tabulation indicated that (pg. 37):

> Irrespective of variations in concentration, the character formula of the degradant in each of the ground water Groups 2 through 7 is strikingly similar to that of the brines comprising Group 8. This is especially true of the anions which are not subject to base exchange reactions. This similarity in composition, together with apparent absence of any other like degradant, indicates that the degradation of the native ground water is due to admixture of deep-seated brines of the type exemplified by Group 8.

However, in the U. S. Geological Survey Water-Supply Paper 1497, Olmsted and Davis (1961, page 136) say:

> Its origin is problematical, however; it may be the result of upward migration of deep marine connate waters through defective, abandoned, or improperly constructed deep wells, as suggested by the California State Water Resources Board (1952, page 35); or, on the other hand, it may be merely a large body of evaporation residue in the Sutter Basin.

This conclusion is interesting because some nine years later these two geologists have added evaporation

residue as an alternate theory for the occurrence of saline water in the Sutter Basin.

John Wolfe prepared an office report (Wolfe, 1958) for the California Department of Water Resources and summarized reasons for the theory of rising saline connate water as: (1) subsurface geologic structural highs in marine sediments; (2) artesian and/or gas pressure on connate brines which enable them to rise to the surface through poorly constructed or improperly abandoned water or gas wells; (3) artesian and/or gas pressure on connate brines which permit them to rise through permeable zones in the sediments; and (4) acceleration of rising connates due to lowering of the water table by heavy pumping.

Wolfe still believes (oral communique, 1969) that the geologic conditions favorable to the theory of rising connate water do not exist in the Sutter Basin, and brings forth the following points: (1) there is no known evidence of any structural anomalies in the Sutter Basin; (2) bad water conditions existed in the area before any deep wells were drilled; (3) the area is largely underlain by highly impervious silt and clay; (4) artesian pressure would not be augmented by gas pressure; and (5) an excess of salt and water in the discharge from a basin is no proof of rising saline connate waters.

Wolfe concluded that the saline water in the Sutter Basin is most probably caused by evaporative residues. He

based his conclusion on the observation that salinity and well depth do not seem to correlate, and alkali or salts are known to accumulate in the basin sediments. To support his arguments he quoted Kirk Bryan (1923).

Kirk Bryan, geologist with the U. S. Geological Survey, conducted the first comprehensive ground water investigation of the Sacramento Valley. The field work for his water-supply paper was conducted during 1912 and 1913, a time when the Sacramento Valley was still subject to devastating floods and the basin lands were first being reclaimed and used for rice growing. Bryan (1923, page 85) commented on the accumulation of alkali in the Valley:

> Although there are in the valley large areas that have a shallow water table, which is favorable to evaporation and the accumulation of alkali, only comparatively small areas are unfitted for agriculture from this cause. This condition seems to be due to the following reasons: (1) The ground waters are of good quality. (2) The water table is very flat over the basins, and movements of the ground water are sluggish. Water is supplied more freely at the bases of the slopes, and for this reason the principal concentration of alkali occurs at the edges of the basins. This is particularly the case on the west side, where alkaline patches and areas of salt grass border the basins along their western edges. (3) The heavy winter rains leach out much of the salts concentration at the surface. Similarly flood waters wash out the salts in over-flowed lands, and on the edges of the plains the same waters deposit mud or sediment, which often covers up the alkali.

Bryan mentioned buried alkaline spots along the east side of Colusa Basin and suggested better water could be obtained by casing off the well and going deeper. He

also suggested that the salty spots are usually small in extent. He thought the same conditions might exist along the west side of Sutter Basin.

In the east Sutter Basin area, Bryan spoke of Gilsizer Slough. This slough cuts southwest across the area from Yuba City to the central part of the Sutter Basin (Fig. 4). It is a depression that ranges in width from a hundred yards to a quarter of a mile. Bryan states that the ground water lay close to the surface and evaporation concentrated alkali in the soil. The slough was later drained by a ditch and the land reclaimed and placed under cultivation. However, the water quality of the wells in the Gilsizer Slough area seems to have been little affected by this shallow saline condition (Fig. 6).

History and Methods of the Investigation

During the early 1960s the California Department of Water Resources was conducting a comprehensive study of the ground water in the Sacramento Valley. Among the duties of this investigator was the compilation of a base-of-the-fresh-water map of the Valley. Electric-logs, run in gas wells, were used for the interpretive work. An apparent resistivity of 25 ohm-meters was designated as the dividing point between fresh and brackish ground water. Results of the study confirmed the mound of saline water in the central portion of the Sutter Basin; and further, that the Ione Sand of Eocene age contained fresh water to a depth

of over 2,000 feet around the south central part of the Sutter Buttes. Elsewhere the Ione Sand contains saline connate water.

Correlation section #6, published by the American Association of Petroleum Geologists Committee on Stratigraphic Correlation, shows the stratigraphy of the Sacramento Valley from Red Bluff to Rio Vista. A portion of this section cuts across the Sutter Basin. On this section the Ione Sand crops out in the Sutter Buttes at an elevation of between 250 and 400 feet above the valley floor, is confined by the Nortonville Shale from the Buttes to Humble Oil and Refining Company's "Sutter Basin" #1 well in Section 24, T.13N., R.2E., M.D.B.&M. (well 201 on Fig. 4), and is in contact with the overlying continental sediments in the area of the saline ground water mound in the Sutter Basin. It was therefore believed that here were the conditions necessary for the hydraulic gradient requisite to move the saline water up through the non-marine sediments to the surface in the Sutter Basin.

Permission was obtained from the Department of Geology, University of Arizona, to investigate this phenomenon as a thesis topic.

During the Summer of 1969 the author was employed by the California Department of Water Resources and permitted to use the office facilities during weekends and evenings to collect and analyze data. Some 550 gas well

locations were plotted and electric-logs from more than 400 wells were collected and correlated. Further data were taken from the Department's detailed study of the water quality along both sides of the Feather River, 1964-67, as well as water analyses of wells made during the Department's regular yearly program for succeeding years. Part of this information is displayed graphically on Figure 6 (in pocket), the rest is contained in Appendix A.

Well-numbering System

The customary method of identifying gas and oil wells is to use the name of the operator and the name of the well. To be done legibly would require more space than is available on the base map used in this report. Therefore, each well was assigned a number. In general, the numbering began in Township 10 North, Range 1 West, and moved across to Range 4 East, etc. This places the low numbers in the lower left hand corner of the base map (Fig. 4, in pocket) and the highest numbers in the upper right hand corner. During the process of the investigation the size of the base map was reduced, so as to include only that area most relevant to the study; hence, not all of the wells originally numbered are plotted on the base map.

The water well numbering system used in the study is that of the California Department of Water Resources, and shows the location of wells according to the rectangular system for the subdivision of public land. For

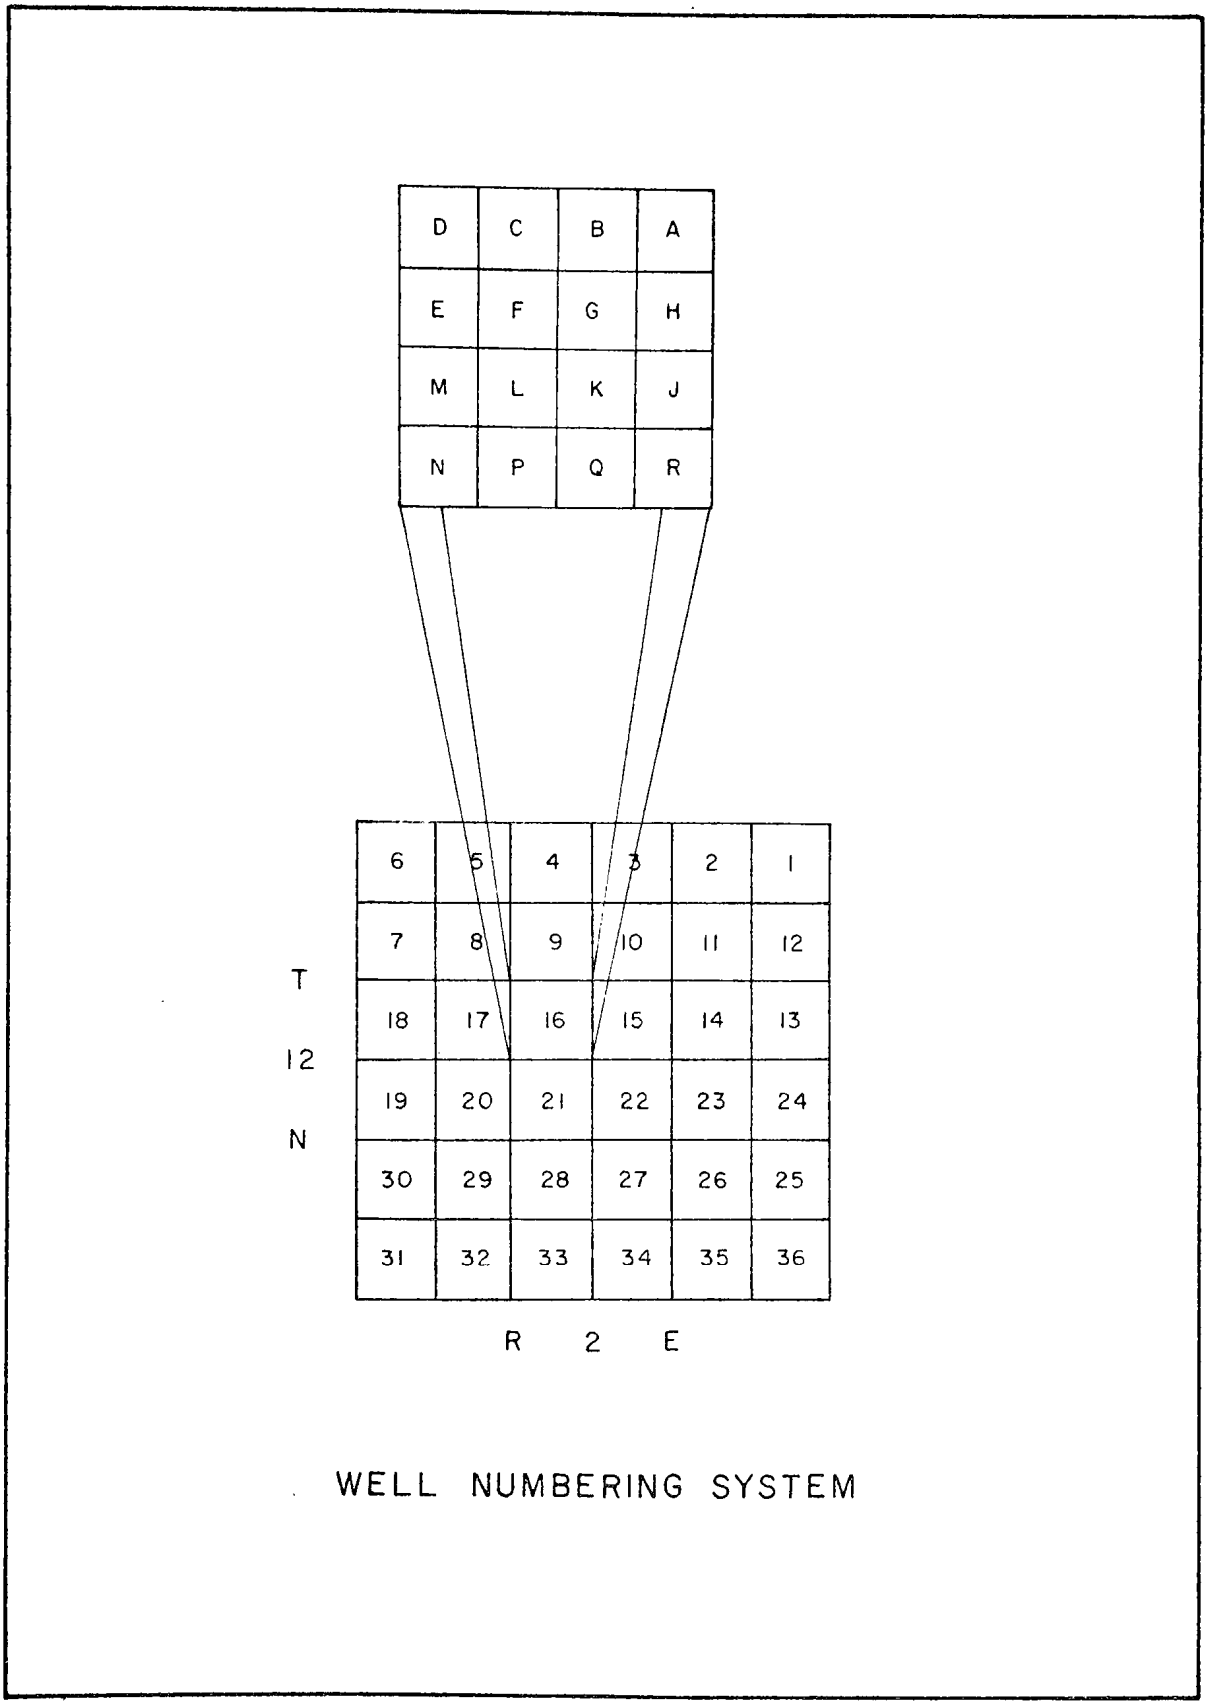

FIGURE 2 DIAGRAM SHOWING WELL NUMBERING SYSTEM

example, in well number 12N/2E-16B2, the segment of the number and letter preceding the bar indicates the Township (T.12N.); the number and letter between the bar and the hyphen, the Range (R.2E.); the digits between the hyphen and the letter, the Section (sec. 16); and the letter following the section number indicates the 40-acre subdivision of the section, as shown in Figure 2. Within each 40-acre tract the wells are numbered serially, as indicated by the final digit. Thus, Well 12N/2E-16B2 is the second well to be listed in NW1/4 NE1/4 Sec. 16, T.12N., R.2E., M.D.B.&M.

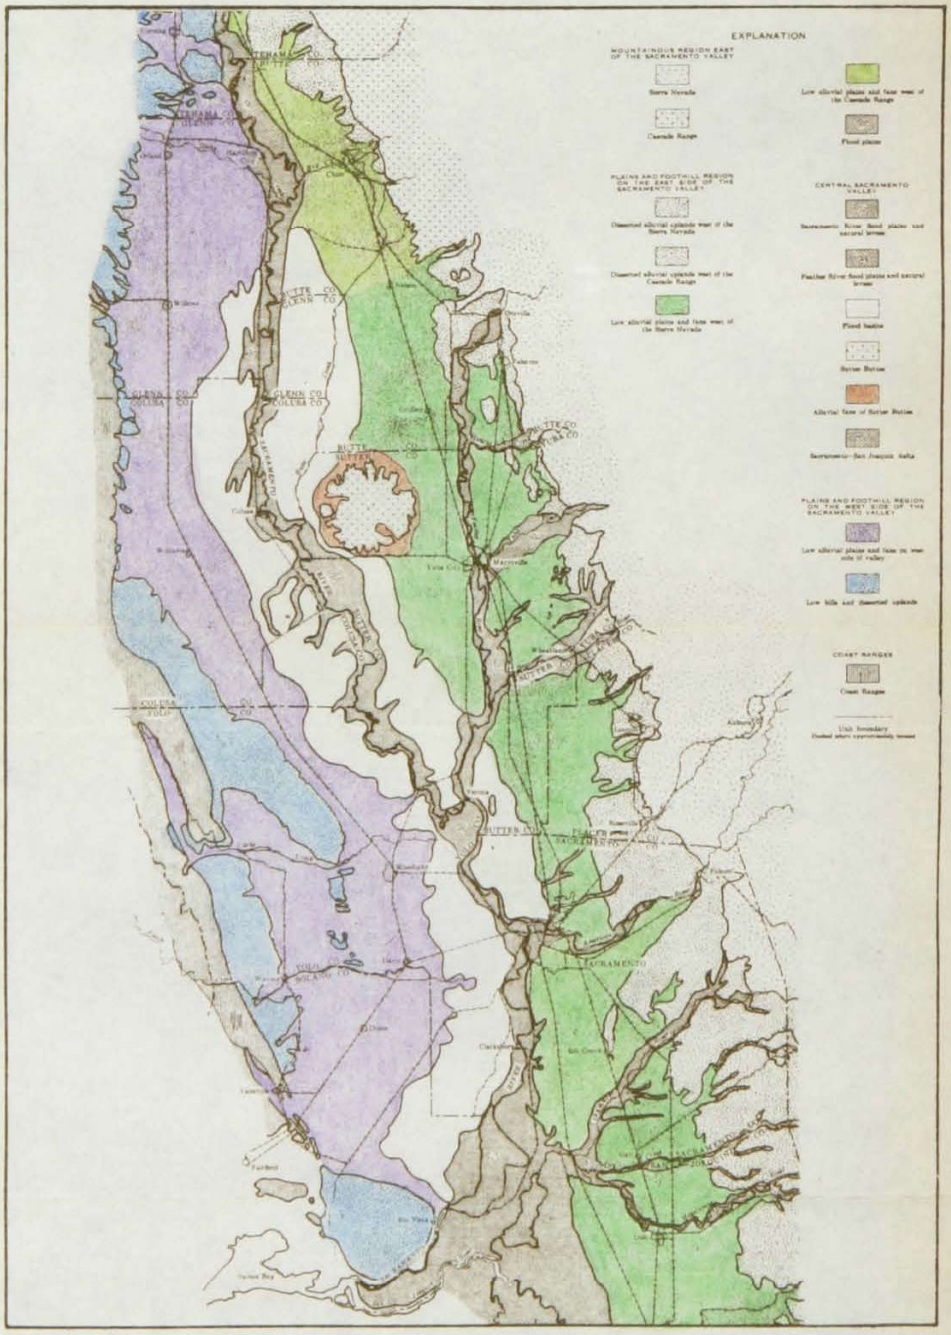
Parts of the study area lie in old Mexican land grants and have never been public land; for these, the rectangular system of subdivision has been projected for reference purposes only.

GEOGRAPHY

Topography

The Sacramento Valley is the northern one-third of the Great Central Valley of California and takes its name from the principal river which flows through it. The Sacramento Valley, as defined by Bryan (1923), extends from Red Bluff to the mouth of the Sacramento River at Suisun Bay, a distance of 150 air miles, or about 240 miles by river. The area of the Valley is approximately 5,000 square miles.

The Valley floor slopes southward from an elevation of nearly 300 feet at the north, near Red Bluff, to sea level at Suisun Bay and varies in width from five miles at the north end to 45 miles in the southern part.



The western boundary of the Valley is the North Coast Ranges, which consist of a series of parallel ridges and inter-montane valleys trending slightly west of north. The ridges rise to elevations of 3,000 feet.

The mountainous regions east and northeast of the Valley include the Sierra Nevada and the Cascade Range. The Sierra Nevada has been described (Lindgren, 1911; Matthes, 1930; Piper et al., 1939) as a single block of the earth's crust which has been uplifted along fractures on its eastern margin and tilted westward. The average slope

of the western surface is $1^{o}40'$ and becomes steeper as it extends beneath the floor of the Sacramento Valley. The crest of the Sierra Nevada, to the east of the valley, varies from 6,000 to 10,000 feet in elevation. The Cascade Range, to the northeast, consists mainly of volcanic rock. It contains Mount Lassen, which is considered the only active volcano in California.

The Sacramento Valley has been divided into 16 geomorphic units by the U. S. Geological Survey (Fig. 3).

The study area for this report (Fig. 4) lies in the central portion of the Sacramento Valley. In this area the major topographic feature is the Sutter Buttes. It is the erosional remnant of a laccolith and volcano formed during late Pliocene time. The outline of the Buttes is an almost perfect circle, 10 miles in diameter, with the highest peak--South Butte--rising to an elevation of 2,117 feet. The only other prominent topographic feature is the Dunnigan Hills on the west flank of the Valley, which consist of Pliocene and Pleistocene sediments which have been folded into a gentle anticline with the axis trending approximately South 40^{o} East. The Hills are severely dissected but the summits are rounded and rise to nearly the same height. The summits decline from an average altitude of 400 feet at the north end to about 200 feet near the south end.

The other topographic features in the study area are of low relief and are related to the fluvial deposition of the Sacramento River and its tributaries. They include the alluvial fans on the west and east sides of the Valley and around the Sutter Buttes, the flood plains and natural levees and the flood basins. These fluviatile features have had a marked influence on the agricultural development of the area.

Drainage

The average annual runoff of the Sacramento River and its tributaries during a 40-year period starting in 1904 was 21,750,000 acre-feet. In the years past most of this flow took place during December to April. Only in the driest years was the Sacramento Valley free from flooding. During the wetter years the flood water would extend from the alluvial fans on the west side of the Valley to the alluvial fans east of the Feather River. Bryan (1923) estimated that before any reclamation had been accomplished, sixty percent of the Valley was subject to overflow--including, in addition to the basins, the river lands and a considerable portion of the low plains. In recent years the construction of levees along the major streams, flood-water bypasses through the Sutter and Yolo Basins, and the building of Shasta Dam on the Sacramento River and Oroville Dam on the Feather River, has greatly limited the large-scale flooding of the basins.

Between Colusa and Verona, the Sacramento River follows a sinuous course, with meanders and oxbow lakes. Over a distance of 63.5 miles the average descent is about 0.4 feet per mile. The channel is narrow--averaging 150 to 600 feet in width--with well-defined broad natural levees. The natural levees are concave upward and relatively flat. In effect, the river is flowing along a broad upraised trench, flanked on either side by poorly drained, low-lying flood basins. The Colusa Basin lies to the West, and the Sutter Basin to the East.

South of Verona at the mouth of the Feather River, the aspect of the Sacramento River changes completely, and the course of the river consists of broad, gentle bends and relatively long straight reaches. The channel averages 600 to 1,200 feet in width, and bars and islands are uncommon. The natural levees are well defined, but are generally narrower than those upstream; the belt of river lands averages about two miles in width.

The Feather River, the principal tributary of the Sacramento River, leaves the Sierra Nevada foothills at Oroville. It follows a southwesterly course for about six miles, then turns sharply south and flows across the Victor Formation of Pleistocene age. Upstream from Marysville, the Feather River flood plain is one to two miles wide and lies 10 to 15 feet below the adjoining low plains. The river pursues a meandering course on its flood plain, and

lakes and abandoned channels are common features, indicating frequent changes in course.

South of Marysville, the Feather River is joined by the Yuba River, and in turn by the Bear River. Here the river occupies a broad channelway, as much as a mile wide, that is choked with sand and gravel contributed by the Yuba and Bear Rivers. This channel aggradation is a direct result of hydraulic mining in the Sierra Nevada.

In the seven-mile reach upstream from its junction with the Sacramento River, the Feather River occupies a channel ridge similar to that of the Sacramento River. The prominent natural levees slope a mile or more toward the Sutter Basin to the west, and the American Basin to the east. Well-formed channel ridges of flood distributaries extend laterally toward the flood basins, and bends and abandoned channels are noticeably absent, suggesting long-continued channel stability.

The average grade of the Feather River from Marysville to the Sacramento River is 1.1 feet per mile.

Climate

The climate of the Sutter area is characterized by dry summers with high daytime temperatures and warm nights, and wet winters with moderate temperatures. More than eighty percent of the precipitation occurs during the five-month period from November to March, inclusive. The eighty-year average precipitation for the City of Marysville is

20.68 inches, with an annual high of 38.91 inches and an annual low of 8.15 inches. The growing season is long, the forty-year recorded average for Marysville being 273 days between killing frosts. Temperatures at Marysville have ranged from 16°F. to 118°F., and the monthly average ranges from 46.9°F. in January to 79.3°F. in July.

Culture

The native vegetation in the study area consisted of grasses and occasional oak trees on the alluvial fans. The swamp and overflow land supported a heavy growth of tules, or rushes, that gave the area its coloquial name of the "Tules." The natural levees supported a heavy growth of trees, predominantly Sycamore and Cottonwood.

It was a natural step for the early settlers to substitute grain such as wheat and barley for the native grasses. The commercial production of wheat in this area was begun by General John Sutter in 1843 on his Hock Farm south of Yuba City. With the influx of settlers during and after the gold rush, a large portion of the higher land was converted to the growing of dry-farmed grain crops and livestock.

The continuing wave of settlers in the area caused an increase in land value and the subdivision of lands into small farms which had to be capable of producing consistently high-value crops in order to support the owners. To the purchasers of such tracts the advantages of

irrigation were apparent. The colonizing of subdivided lands became a business whereby large blocks of land were purchased and surveyed into small tracts with provisions for roads and perhaps for a town site. Irrigation works were provided for some of the subdivided acreages; in others, a demonstration well and pumping plant was built to persuade the settlers of the advantages of installing their own individual wells and pumps. Settlers were attracted by agents and by advertisements in the eastern newspapers of the United States.

The development of the flood basin and overflow land was slowed by recurring floods. However, many public agencies were organized in the area to deal with the problems of land reclamation and drainage. The provisions of California reclamation district laws have been used extensively to effect the unwatering of low lands and their protection from overflow. A canal was excavated to remove the flood and drainage water from Colusa Basin. The function of Sutter Bypass is to receive and convey excess floodwater of the Sacramento River and Butte Basin through Sutter Basin (Fig. 4).

The highest and best use for most of the basin land, because of the heavy soil, is rice production. In 1966, some 66,000 acres of basin land in Sutter County alone, or one quarter of the entire County, were used for the cultivation of rice. The rest of the basin land is

used mainly as irrigated pasture for the raising of livestock.

Other annual crops in the area consist of beans, tomatoes, safflower, corn, hops, sugar beets, and alfalfa seed. Along the Feather River the land is used mainly for deciduous orchards--peaches, apricots, pears, prunes, almonds and walnuts.

Industry in the area is supported largely by agricultural production. About 100 plants are operated during the harvest seasons to can fruits and vegetables and to dehydrate fruits, nuts, rice and seed crops. Packing houses for packing fresh fruits and melons, and cold storage and refrigeration plants, have also been placed in operation.

Following are the population figures for the three counties that comprise most of the study area, and the county seat for each.

	1960	1970
Sutter County	33,380	41,894
Yuba City	11,507	13,740
Yuba County	33,859	43,934
Marysville City	9,553	10,100 (est.)
Colusa County	12,075	11,896
Colusa City	3,518	3,825 (est.)

GEOLOGY

Stratigraphy

The west side of the Sacramento Valley contains one of the thickest and most nearly complete late Mesozoic sections in North America. The Upper Jurassic, Lower Cretaceous, and Upper Cretaceous sequences have a maximum aggregate thickness of sediments in excess of 50,000 feet (not illustrated).

The classification of the Upper Cretaceous by Kirby (1943), the Upper Cretaceous faunal zones of Goudkoff (1945), and the faunal zones of Laiming (1943) for the Paleocene and Eocene sediments have been used in this report (Fig. 5). Where there appear to be differences in opinion as to the stratigraphic relations of the sub-surface geology, Correlation Section No. 6, 1954, "Sacramento Valley from Red Bluff to Rio Vista," of the A.A.P.G. Committee on Stratigraphic Correlations was used as the guide. Where this investigator differs from the A.A.P.G. Committee, these differences are based on electric-log interpretations and discussions with geologic consultants who have worked in the Sacramento Valley.

Upper Cretaceous Units

Forbes Formation.(Figs. 5 and 7, in pocket) The Forbes Formation is the basal member for sub-surface

correlations illustrated, and has the most extensive distribution of any of the units correlated. It crops out along the western margin of the Sierra Nevada and along the eastern margin of the Coast Range. It is believed (Weagant, 1964) to have been deposited in a moderately deep-water environment, too far offshore to be affected by shoreline winnowing processes, and is the result of turbidity currents.

The thickness of the Forbes Formation varies from 2,750 feet to 3,000 feet in the study area. It is dominantly a gray, marine shale with fairly thick, fine-grained sandstone interbeds.

Kione Formation. (Figs. 5 and 7) The Kione Formation represents the shallowing of the Forbes basin, which resulted in the development of a shallow near-shore environment. The Kione sands were probably deposited in a series of deltas that lay at the mouths of the major drainages coming off the Sierran land areas to the east. These deltaic sands were further distributed along the east side of the valley by action of along-shore currents and by normal shoreline processes.

The Kione Formation was named and described by Johnson (1943). It is a medium-grained, well sorted, massive, friable sandstone of granitic origin with shale interbeds. The Kione is in gradational contact with the underlying Forbes Formation. Around the Sutter Buttes the

Kione has a thickness of between 800 and 1,000 feet. To the West, the Kione becomes more broken, tending to turn to shale, and to the south it thins and shales out. In the study area it is everywhere conformably overlain by the "Sacramento Shale", except in the Colusa area where it is reported to occur at a shallow depth and is overlain by the Tehama Formation.

"Sacramento Shale." (Figs. 5 and 7) This marine deposit has not been identified in outcrop, although it is possible that it crops out around the Sutter Buttes. For the purpose of this report it will be identified by the description as shown on A.A.P.G., Pacific Section, 1960, Correlation section from Red Bluff to Rio Vista, Sacramento Valley, "the siltstone which conformably overlies the Kione Sand and is conformably overlain by the 'Winter Sand'." The "Sacramento Shale" is typically 150 to 300 feet thick and light gray in color. It is everywhere present in the study area, and is an excellent electric-log marker.

"Winter Sands and Shales." (Figs. 5 and 7) The main source of the marine "Winters Sands and Shales" appears to have been older Cretaceous deposits, reworked and redeposited. In the Dunnigan Hills the shale is described (Rofe, 1962) as a medium-dull, gray, firm, massive, silty, muscovitic, fossiliferous claystone, grading locally into siltstone. The sand beds are light gray, fine to medium-grained, poorly sorted, massive, silty, micaceous sand with subordinate amounts of claystone that grade upward to well sorted, clean sand.

It is possible that the "Winters" crops out on the south side of the Sutter Buttes but has not been identified. It is not present north of the Buttes, it thins to the north and east, thickens to the south, and its western extent is obscured by uplift and erosion during post-Cretaceous time. The unit unconformably underlies the Starkey Sands in the area south of the Sutter Buttes.

"Starkey Sands." (Figs. 5 and 7) The "Starkey" represents a very shallow sea environment with deposition of a series of regressive-transgressive beach or near-beach sands. The deposits were derived from the east and northeast as the Sierran and northern Sacramento Valley areas were uplifted and eroded. The "Starkey" grades from a medium-grained, clean sand into a shale from east to west. The "Starkey" is everywhere confined by the Martinez Silt of Paleocene age or the Capay Shale of Eocene age, except in the southern Sutter Basin where it is unconformably overlain by the post-Eocene non-marine sediments (Fig. 7). The sand thins or has been removed by erosion to the north and west. To the south it occurs at ever-increasing depths and thickens to approximately 1,900 feet before thinning and shaling out in the Delta area.

Tertiary Units

Meganos-Martinez Formations Undifferentiated.

(Figs. 5 and 7) This group of sediments conformably

overlies the "Starkey Sands" in the southeast portion of the study area.

The type locality of the Martinez Formation is near the town of Martinez on Carquinez Strait, west of Suisun Bay, and was described by Dickerson (1914). Lithologically, it is predominantly a massive, well-sorted, quartzose sandstone with interbedded shale and local conglomerate lenses. Much of the detritus of the Martinez was derived from Cretaceous Formations. A basal shale member is referred to as the Martinez Silt and is an excellent electric-log marker where it overlies the "Starkey Sand." The Martinez contains Laiming's (1943) E fauna zone and is Paleocene in age.

The type locality for the Meganos Formation is in Contra Costa County in the Mount Diablo region and was described by Clark (1918). It consists of friable, fine to medium-grained, micaceous, carbonaceous gray sand and hard, mostly light to dark brown shale with streaks of lignite. For the purpose of this report, it is considered to be those sediments containing Laiming's D fauna zone, and is Lower Eocene in age.

The thickness of the Meganos-Martinez group, in the study area, varies from zero to 240 feet. It occurs only in the south central portion of the study area where it is truncated or pinches out to the north and dips to the south.

Capay Shale. (Figs. 5 and 7) The type section for the Capay Formation is in Capay Valley, to the west of Dunnigan Hills, and was described by Crook and Kirby (1935). Unfortunately, the type section is atypical of most of the Capay in the Sacramento Valley. It consists of as much as 2,000 feet of beds resting unconformably on the Upper Cretaceous rocks, ranging from channel conglomerate to fine-grained estuarine deposits. The source of the detritus was said by Crook and Kirby to have been local. It is now believed that this part of the Capay was deposited in the southern extension of the Princeton Gorge. When the Eocene sea transgressed, the gorge was inundated first and coarse sediments were contributed from immediately adjacent sources. As the sea continued to rise, it topped the gorge and spread out over the floor of the Valley. It was then that the Capay Shale was so extensively deposited.

At Dunnigan Hills the Capay Shale is described by Rofé (1962) as medium gray to dark gray, massive, micaceous, glauconitic, pyritic, fossiliferous claystone with a dark gray, medium-grained, poorly sorted, massive basal gritstone, which is a more typical description of the Capay Shale and is probably the upper part of the Capay Formation. In the study area the Capay Shale is considered Lower Eocene in age.

The Capay Shale acts as a cap rock for many of the gas fields in the Valley. It is present throughout the area except where it has been removed by erosion in the Sutter Basin south of the Sutter Basin Fault, in the "Markley Gorge," and along the western margin of the study area. The Capay Shale varies in thickness from zero to 558 feet and thins to the East. The base of the Capay is one of the major unconformities in the Valley. The Capay progressively overlies older Cretaceous rocks in a northern and eastern direction.

Ione-Domengine Formation. (Figs. 5 and 7) Stewart (1949) divided the Domengine Formation of Clark (1926) into two formations: the Lower Ione Formation, consisting of quartz sand; and the Upper Domengine Formation, consisting of green and brown sand. Both are placed in Middle Eocene and contain Laiming's B-1 faunal assemblage.

In the Dunnigan Hills (Rofé, 1962), the Domengine Formation is 19 to 62 feet thick and consists of dark gray to greenish gray, fine-grained, well sorted, silty sands. It appears that the Lower Ione Formation of Stewart (1949) is not present at this location.

Throughout most of the area, the Middle Eocene is represented by the Ione Formation of Stewart. In the Sutter Buttes, the Ione is described by Johnson (1943) as a white, quartzose, friable sandstone, and probably represents deltaic deposits that have been winnowed by

off-shore currents. Figure 5 indicates that the Ione-Domengine Formation is of rather limited extent in the study area, having been removed by erosion to the west and south. It ranges in thickness from zero to 250 feet.

The Ione-Domengine Formation conformably overlies the Capay Shale of Lower Eocene age and is conformably overlain by the Nortonville Shale of Upper Eocene age.

Nortonville Shale. (Figs. 5 and 7) Stewart (1949) divided the Kreyenhagen Formation of Upper Eocene age into the Nortonville Shale member, the Markley Sandstone member, and the Sidney Shale member, in ascending order. Only the Nortonville Shale has been identified in the study area, and then only in gas wells at Dunnigan Hills and in the Sutter Basin. The extent of the Nortonville sea is obscured by subsequent erosion, but probably did not extend further north than the Sutter Buttes and was not as widespread as the Capay sea.

In the Dunnigan Hills, the Nortonville Shale is described (Rofé, 1962) as blue and brown, firm, mottled, micaceous, sandy claystone, interbedded with grayish green, gritty sands. Its thickness varies from 92 to 235 feet, and contains Laiming's A-1 faunal assemblage.

"Markley Gorge" Fill. (Fig. 5) The "Markley Gorge," a deep canyon that was eroded during Upper Eocene, extends from north of the Bear River, near the foothills of the Sierras, southwest to the northflank of Mount

Diablo. This sub-surface feature is more than 45 miles long and nine miles wide, and reaches a maximum depth of 5,700 feet below sea level. Probably a better name for this feature would be the Sacramento Canyon, but at present it is referred to as the so-called "Markley Gorge."

Davis (1953) first described the Gorge, and believed that it was filled with Upper Eocene deposits. Almgren and Schlax (1957) believed the fill is Oligocene and, in part, possibly Miocene in age. Despite the later conclusions, most geologists with a working knowledge of the "Markley Gorge" Fill believe that it is no older than Late Eocene (Sacramento Petroleum Association, 1962).

The "Markley Gorge" Fill consists of shales, sandstone, and conglomerate which have considerable lateral and vertical lithologic variation. The shales are light olive-gray to grayish, brown, silty, and generally barren of microfauna. Sandstones are of two dominant types: one confined to the lower part of the fill is grayish green to greenish brown, earthy, poorly sorted and consists largely of grains of various volcanic rock types, and subangular to sub-rounded pebbles of gray shale and siltstone occur locally; the other dominant type of sandstone is blue, generally coarse-grained and fairly well sorted.

Post-Eocene Non-Marine Sediments. (Figs. 5 and 7) This classification is a catch-all for the alluvial sediments that have been deposited in the Valley by the

Sacramento River and its tributaries from both an eastern and western source. In the study area it has no commercial accumulation of gas and therefore is of little or no interest to the petroleum industry. Petroleum geologists usually call the entire interval the Tehama Formation, which does make up a large percentage of the sediments.

It appears that the Oligocene epoch was a time of uplift and erosion with little or no sediments being deposited in the study area. The Miocene epoch is represented by sedimentary rocks of volcanic origin. The rocks from the Sierra Nevada are a sequence of fragmental volcanic rocks, the source of which lay near the present crest of the Sierras, about 50 miles east of the Sacramento Valley. These rocks, predominantly andesitic, are extensively exposed on the western slope of the Sierra Nevada and extend westward beneath much of the Valley. They probably extend beyond the Sacramento River in the study area. This unit is believed to be related to the Mehrten Formation of Piper et al. (1939).

The sedimentary rocks of volcanic origin that crop out on the west side of the Valley are a sequence of volcanic shale, sandstone and conglomerate beds. Weaver et al. (1944) assigned most of these rocks to the Neroly Formation (Upper Miocene) of Clark and Woodford (1927), but their age and correlation are in considerable doubt.

Five wells (282, 291, 292, 293, and 296) have been drilled through a basalt flow that is approximately 150 feet thick. This island of basalt in Township 13 North, Range 2 East, is believed to be Upper Miocene in age and lies at the base of the Tehama Formation.

The Pliocene sediments consist of continental deposited Laguna Formation of Piper et al. (1939) and the Tehama Formation of Anderson and Russell (1939).

The Laguna Formation (not illustrated) is a sequence of predominantly fine-grained, poorly bedded, somewhat compacted continental sedimentary deposits derived from the Sierra Nevada. The Laguna appears to form a wedge of alluvial material thinning near the Sierra Nevada and thickening toward the axis of the Valley. The maximum thickness of these deposits may be more than 1,000 feet.

The Tehama Formation (Fig. 4) consists of alluvial material derived from the Coast Ranges. It was inaugurated by the orogeny at the beginning of Late Pliocene time, which raised the present Northern Coast Ranges, and was closed by a Middle Pleistocene orogeny. The Formation has been assigned to the Upper Pliocene and possibly the Lower Pleistocene by Anderson and Russell (1939). They state the Formation consists of poorly sorted fluviatile sediments, comprising massive sandy silt, silty sand, and clayey silt enclosing lenses of crossbedded sand and gravel.

The Tehama forms a thick wedge of sediments that thicken to the east and interfinger with the Laguna Formation beneath the Valley floor. In the study area, the Tehama Formation has a maximum thickness of approximately 2,500 feet.

The Sutter Beds of Williams (1929) which crop out in the Sutter Buttes are correlative to the Tehama Formation according to Johnson (1943). They are comprised of continental fine-grained sediments, tuff, sand, silt, and gravel some 1,800 feet in outcrop. Both Williams (1929) and Johnson (1943) believed that the Sutter Beds had a Sierran source because they are petrologically similar to the Sierran andesites. If this be true, then the Sutter Beds are better correlated to the Laguna Formation of Piper et al. (1939).

Quaternary-Recent Units

During Pleistocene time, some 1.2 million years ago, as indicated by radioactive dating according to Dr. Howel Williams (oral communique, 1969), a series of volcanic episodes--the intrusion of rhyolite porphyry volcanic necks followed by the intrusion of an andesite porphyry plug--resulted in the formation of the Sutter Buttes. The final igneous episode was the explosive phase--the formation of a volcano within the andesite plug--the ejecta of which mantles the slopes with andesitic tuff and breccia.

Along the east side of the study area, the alluvial fans and flood-plain deposits of Pleistocene age have been termed the Victor Formation by Olmsted and Davis (1961), after the type Victor Formation of Piper et al. (1939). The Victor Formation consists of an heterogeneous assemblage of clay, silt, sand and gravel, transported by shifting streams from the Sierra Nevada, and has a maximum thickness of 150 feet. The base of the Victor in most places is in conformable contact with the Laguna Formation. Toward the center of the Valley, it is at many places conformably overlain by basin and river deposits of Recent age. In general, the Victor Formation is not appreciably consolidated, although some of the beds have a high proportion of clay and silt which act as a binder. Hardpan layers, representing buried soil zones, occur at various depths, though most are within six feet of the surface.

The Red Bluff Formation is a poorly sorted gravel which has a distinctly reddish silty or sandy matrix and lies on an erosion surface cut on the Tehama Formation. This Pleistocene deposit is of no importance with regard to this report.

The sediments of Recent age include the river and flood-basin deposits. The river deposits consist predominantly of well-sorted sand, gravel, and silt along the channels, flood plains, and natural levees of the major streams. The basin deposits are largely silt and clay

deposited in the flood basins during floods on the major streams. The sediments of Recent age range in thickness from zero to 100 feet.

Geologic Structure

Regional Features

The Sacramento Valley is a large structural basin filled with sedimentary rocks ranging in age from Early Cretaceous to Recent. The Valley trough is asymmetrical; the deepest part of the basin lies near the western margin of the Valley, west of the present axis and plunges to the south. The plunge of the Valley trough results in the southern part of the Valley--the Rio Vista Basin--containing the thicker and more complete geologic section.

The basement complex, beneath the Valley floor, is a continuation of the Sierra Nevada fault block that has been tilted toward the southwest. Geophysical evidence indicates that the basement lies some 20,000 feet below the surface along the western edge. Deep wells that have cored the basement complex in the Sacramento Valley indicate that the surface of the block slopes more steeply beneath the central part of the Valley than it does to the east.

The western part of the Valley is bounded by strike ridges underlain by Cretaceous and Lower Tertiary marine sedimentary rocks. Compressive forces deformed the

Coast Ranges sediments into tightly folded anticlines, synclines, and local thrust faults. Vaughan (1943) suggested that these same compressive forces caused the tilting of the rigid Sierra Nevada block by forcing its western part down below its position of isostatic equilibrium.

Sutter Buttes

The Sutter Buttes comprise the major structural and topographic feature in the study area, rising some 2,000 feet above the flat Valley floor. The Buttes are the surface expression of an intrusion of rhyolite porphyry, followed by andesite porphyry (Johnson, 1943) that forced its way upward from an unknown, but great depth, through at least a portion of the underlying "Basement Complex" platform, into and through some 7,500 feet of Cretaceous and Tertiary sediments. The rising laccolith greatly disturbed the sediments intruded and not only sharply tilted them away from the locus of intrusion, but produced an intricate series of radial and peripheral faults. Furthermore, radial and lateral anticlines and synclines were developed, some of them of sufficient amplitude to involve all of the exposed sediments.

After a period of quiescence and erosion, a series of violent explosions of steam and mud took place and a mile-wide central crater located just west of the middle of the great andesitic plug. Great angular masses of andesite and rhyolite, some of them measuring 30 feet

or more in diameter, were thrown from this opening and were swept by mudflows down the slopes of the volcano to find a resting place about its periphery.

Erosive processes have brought the Sutter Buttes to their present form. The present-day Buttes are 10 miles in diameter and form an almost perfect circle. The Buttes can be divided into three concentric zones of rock types: the central core, the saddles and low areas surrounding the central core, and an outermost ring of tuff-breccia slopes.

The central core is a roughly circular area three to four miles in diameter, dominated by a cluster of sharp, steep-sided erosional remnants of a laccolith, with South Butte rising to a height of 2,117 feet.

The saddles, low hills, and ridges surrounding the central core are underlain by sedimentary rocks of Tertiary and Late Cretaceous age that were pushed up and fractured when the core was emplaced. This zone is approximately one mile in width and ranges in elevation from 200 to 500 feet above the valley floor.

The tuff-breccia slopes which form the outermost ring are two to three miles wide and have been dissected by erosion. The altitudes range from about 500 to 800 feet at the top of the slopes, and 50 to 100 feet at the foot of the slopes.

Dunnigan Hills Anticline

The Dunnigan Hills structure is an asymetrical anticline, steep on the east flank and gentle on the west flank, and is about 20 miles in length. The anticline plunges to the south, resulting in the subsequent burial of the deformed Tehama and Red Bluff Formations beneath younger valley alluvium along the southern portion. The time of folding is believed to have been during Late Pleistocene.

Faults

The only fault identified in this report is the Sutter Basin Fault (Figs. 5, 6 and 7). The location of this fault is based on electric log correlation and geophysical evidence. It is depicted as a vertical fault, striking N70°W, 11 miles in length, with the south block moving up approximately 500 feet in relation to the north block. The eastern extension of the fault is concealed by the "Markley Gorge," and to the west of the fault appears to die out as it is not discernable in wells further west. The age of the faulting appears to be Upper Eocene.

Around the Sutter Buttes numerous faults occur as the result of the igneous intrusives. The surface expressions of some of these faults have been mapped on Figure 4.

Published investigations of gas fields in the area reveal numerous faults to the south of the Buttes and along

the west side of the Valley. Most of the faulting to the south of the Buttes is confined to the Forbes Formation. The few faults that extend above the Forbes (Weagant, 1964) are strike-slip faults trending to the north or northwest, and terminate at the base of the Capay Shale. Since the strike of the faults is approximately parallel to the direction of the ground water flow and the Capay Shale appears to act as a barrier to the upward migration of saline water, these faults have not been illustrated on Figure 5.

In general, the fault systems can be divided into three groups: (1) those that are confined to the Upper Cretaceous sediments only; (2) those that cut the Eocene and Cretaceous rock units; and (3) those that were formed by the Sutter Buttes intrusives during Upper Pliocene time.

Historical Geology

The first geologic event pertinent to the hydrogeology of the Sutter Basin was the deposition of the Upper Cretaceous sediments. According to Weagant (1964), in F-zone time (Forbes Formation), there was transgression of the sea and sediments were deposited by progressive onlap on the Lower Cretaceous shale. East of the central portion of the study area the Lower Cretaceous sediments are fully overlapped by the F-zone. The Forbes Formation was deposited in a moderately deep water environment too far from the shore to be affected by shore-line winnowing

processes. These sediments consist of interbedded dark gray claystones and siltstones, and gray, fine-grained friable, lenticular sands. The eastern limit of the F-zone transgression is not known but members of the Forbes Formation crop out along the eastern side of the Sacramento Valley.

The rate of sedimentation was slightly greater than the rate of subsidence, so that the basin gradually shallowed and the E-zone Kione sands as well as some of the uppermost F-zone sands are near-shore sands associated with the shallowing.

The Kione sands were probably deposited in a series of deltas that lay at the mouth of the major drainages coming off of the Sierran land areas to the east. These deltaic sands were further distributed along the east side of the valley by action of along-shore currents and by normal shoreline processes.

Basinal shallowing was accompanied by uplift along the western basin margin with the regression of the sea to a position southwest of the Grimes gas field (Fig. 4). The basin then subsided rapidly, and the Sacramento Shale sea transgressed the area. The Sacramento shales were deposited in a moderately deep water basin.

Again the basin became shallow as the Winters Shales and Sands were deposited. The Starkey represents a very shallow sea environment with deposition of a series

of regressive-transgressive beach or near-beach sands.

Following the deposition of the Upper Cretaceous sediments, probably in Late Paleocene time, the basin was uplifted, tilted southerly, and folded into a broad syncline with a north-south trending axis. The eastern margin of the sea was upwarped (Olmsted and Davis, 1961) and a land mass created east of the present position of the Sutter Buttes. The area then underwent extensive peneplanation.

The sea did not completely withdraw from the Sacramento Valley during Paleocene time, as attested by the deposition of the marine sediments of the Martinez Formation, in the southern part of the Valley. The Paleocene sea in which the Martinez Formation was deposited was confined to a restricted portion of the Delta area by barrier beaches (Safonov, 1962). Behind these beaches, lagoonal, swamp, and flood-plain deposits of sand and silt were laid down. The numerous beds of coal and the erratic character of the sediments as shown on electric logs attest to the predominantly nonmarine nature of the Martinez in this area. In late Paleocene time, the sea readvanced, continuing to do so into early Eocene Meganos time.

At the close of Meganos time, gradual subsidence allowed the Eocene sea to continue to spread over the entire Sacramento Valley area. The basin remained

relatively quiet as the Capay Shale was deposited. The Capay Shale marks the last major sea transgression into the Sacramento Valley. Being widespread and conspicuous on electric-logs, it is an excellent marker bed. The Capay Shale reflects the post-Capay movement of the Valley, the southerly tilt, and the trough effect.

During Middle Eocene time the sea shallowed again and the deltaic deposits of the Ione-Domengine Formation of Stewart (1949) were laid down. To the east, the alluvial and lagoonal sediments of the Ione Formation of Allen (1929) were deposited. Lignite seams and severely weathered sediments of the Ione Formation attest to a warm, humid climate.

Following the Capay transgression a minor transgression of the sea in Upper Eocene time is reflected in the deposition of the Nortonville Shale member of the Kreyenhagen Formation. Then the sea began to withdraw from the Sacramento Valley.

Near the end of Eocene time the area was again uplifted, and eroded. The "Markley Gorge" of Davis (1953) was being carved and the entire study area was undergoing erosion. Almgren and Schlax (1957) believe that the "Markley Gorge" Fill was predominantly nonmarine deposits of Oligocene and possibly Miocene time.

Commencing in the Middle or Late Eocene and continuing sporadically into Miocene time, volcanic eruptions

deposited rhyolitic, andesitic, and basaltic pyroclastic and flow rocks near the present crest of the Sierra Nevada (Piper et al., 1939). The streams eroded this material and redeposited it in the valley as water-laid tuff, tuffaceous sand and volcanic gravel. After a period of erosion and relative quiet, predominantly andesitic eruptions began during the Late Miocene in the northern Sierra Nevada and sent a flood of mudflow breccia and ash down the western slopes. Streams continually reworked these deposits and spread them over broad areas to the west.

The volcanic activity waned and died out and the latter part of the Pliocene epoch was marked by erosion in the Sierra Nevada and subaerial deposition (Laguna Formation) in the Sacramento Valley.

In the Middle or Late Pliocene time (Olmsted and Davis, 1961) an uplift of the present northern Coast Ranges inaugurated a period of erosion in the mountains and deposition of coarse detritus to the east. The Sacramento Valley trough began to assume approximately its present outline. Fluviatile deposition continued through the Pliocene and possibly into the early Pleistocene. The streams continually shifted across broad, low flood plains and deposited the Tehama Formation.

During Middle Pleistocene both the Coast Ranges and the Sierra Nevada appear to have been subjected to orogenic processes, and it is possible that this is the

time that the Sutter Buttes were formed. The Coast Ranges were folded, faulted, and elevated and began to assume their present general outline and form. The Pliocene to Pleistocene (?) fluviatile sediments (Tehama Formation) and older rocks were involved in the folding and uplift. Dunnigan Hills anticline was formed at this time. During and after this mountain-building activity, erosion was vigorous, and much of the Tehama Formation was removed and redeposited in the center of the Valley or carried southward by the Sacramento River. Poorly sorted, gravelly material (Red Bluff Formation) eventually was deposited on the eroded surface of the Tehama.

The rejuvenated streams cut laterally and truncated the soft sediments of the Laguna Formation that had been deposited during the Late Pliocene. Most of the detritus was carried westward to be deposited near the axis of the Valley, and in this report is considered part of the Victor Formation.

The present cycle is one of continued erosion of the Coast Ranges, the Sierra Nevada and low hills, and deposition in the Valley.

WATER QUALITY

Connate Water

The term "connate water" has been used several times in this report. Connate water, as originally defined by A. C. Lane (1908) is "water that has remained since burial with the specific rocks in which it occurs, and that its chemical composition has remained unchanged." D. E. White (1965) has summed up the more recent ideas about connate water by saying (pg. 345):

> Much recent evidence indicates that (1) the original interstitial water of sediments normally undergoes diagenetic changes related to bacterial activity and decomposition of organic matter; (2) inorganic reactions between mineral phases and interstitial water occur during early and late diagenesis and also during metamorphism; (3) compaction always occurs, at least to some extent, in response to sediment load, so water must migrate either locally or extensively in directions of decreasing potential; (4) 'salt-sieving' mechanisms, only slightly understood until very recent years, account for changes in salinity of probably all deep waters of sedimentary basins; and (5) other mechanisms, even less well understood, account for changes in chemical composition of saline waters.
>
> Connate water, as here defined, generally is similar in age or somewhat younger, since last direct contact with the atmosphere, than the age of its associated rocks. Most connate waters are probably marine in origin and are associated with normal marine sediments, but some are suspected of being connate to marine and nonmarine evaporites. The dilute meteoric water 'born with' normal nonmarine sediments is probably never preserved in

> its original relationships but is normally displaced after burial by other dilute waters and eventually by any saline water (with higher density) that has access to the sediments.

In this report the water with a high chloride content is believed to have been derived from a marine source when the sediments were deposited in the open sea or in embayments with limited access to the sea. The latter case seems true for the sands of the Upper Cretaceous and Eocene deposits, because their chloride content is about half of that of normal sea water. These waters are termed "connate" under the definition of White (1965).

Basic Data

One hundred thirty-seven water quality analyses were obtained from the files of the California Department of Water Resources for use in this investigation. As many as space would allow are depicted with circle diagrams on Figure 6. Most of the analyses were determined during the 1964-67 period and consist of the standard analyses (i.e., only the major ions were determined). All of the chemical analyses are tabulated in Appendix A.

Approximately 400 electric-logs were used to correlate the formations and zones in the study area. These logs were also used as a guide to the quality of the ground water. The large differences in resistivity for potable and saline water are easily interpreted. Problems

arise when one attempts to relate resistivity to degree of salinity. Besides the many assumptions that must be made, it is necessary to compute the resistivity of the formation from cores or drill cuttings, or have water quality samples from the formation in question. Lacking this, the electric-logs can be used only in a general way for determining water quality.

Variations of Water Quality

Vertical Variation

The entire study area is underlain at varying depths with saline water of marine origin. East of the Feather River, the base of the fresh water is at or near the base of the post-Eocene non-marine sediments. The fresh-water base slopes from near surface, at the areas of outcrop along the eastern margin of the Valley, to depths of 1,100 feet below the town of Verona and approximately 650 feet beneath Yuba City.

Throughout most of the Sutter Basin the base of the fresh water is at a depth of less than 500 feet and in the southern part of the Basin it rises to the surface. Along the western edge of the Sutter Basin the base of the fresh water again deepens and reaches a maximum depth of over 2,300 feet in T.10N., R.1E. A trough of fresh water trends to the northwest beneath Colusa Basin and also shallows to the northwest.

To the west of the trough the base of the fresh water again shallows and is at or near the base of the Tehama Formation along the western boundary of the Valley.

Around the Sutter Buttes the marine sands of the Ione-Domengine and the Kione Formations have been flushed with fresh (meteoric) water to depths of over 2,100 feet. Between the Buttes and the City of Colusa is another mound of saline water which is associated with the near-surface occurrence of Cretaceous beds.

If the base of the fresh water south of the Sutter Buttes were to coincide with the base of the nonmarine sediments, then there would be a gradual deepening of the base of the fresh water across the Sutter and Colusa Basins toward the trough of the Valley. Instead, the base of the fresh water shallows in the Sutter Basin and then deepens in the Colusa Basin.

Horizontal Variation

The river water that flows through the area is very good in quality. It is a calcium bicarbonate type with a total dissolved solid (TDS) content of between 50 and 150 parts per million (ppm). When the river water enters the ground water basin by influent seepage it is in a new environment and changes in quality to reach equilibrium with its new environment. It increases in total dissolved solids and changes to a magnesium bicarbonate type

water. This is due to the large percentage of andesitic and basaltic debris that is present in the alluvial material.

In contrast to the magnesium bicarbonate type fresh water is the poor quality sodium chloride water that occurs in the Sutter Basin between Tisdale Weir and the town of Robbins (Fig. 6). The sodium chloride type water is unlike either the river water or ground water elsewhere in the area. The development of a pumping trough to the northwest along the Feather River has caused the saline water to move into this area and contaminate the ground water. This movement has been continuous over the years and has caused the farmers to abandon their water wells and resort to Feather River water for irrigation.

HYDROCHEMICAL PROCESS

Recharge Waters and Equilibrium

Recharge of the ground water basin is coming from three main sources: infiltration of rain water, river water, and excess irrigation. These three sources consist of water of high quality. One of the conclusions of this paper is that rising connate water is contaminating the ground water basin.

For saline water to move up and displace the fresh water in 2,000 feet of alluvial material requires a driving force or hydraulic head. The saline connate water was originally contained in the marine sediments of Upper Cretaceous and Eocene age. When the igneous intrusives of the Sutter Buttes forced their way up through the overlying sediments they dragged up the marine sediments and exposed them at the surface around the central zone of the Buttes. The marine sediments now stand some 250 to 400 feet above the surrounding flocr of the Valley. In time (some 1,200,000 years) runoff water of meteoric origin infiltrated the Ione-Domengine and Kione sands, both at outcrop and along faults and fractures, and displaced the saline water of marine origin.

Electric-logs run in wells around the southern half of the Buttes indicate that the fresh water has displaced

the connate water to depths of over 2,000 feet. The displaced connate water in the Ione-Domengine Formation has many avenues of escape (Fig. 5) and has contributed saline water to the lower part of the nonmarine sediments in the ground water basin. The hydraulic gradient or head that developed in the Kione Formation, from the Buttes south to the Sutter Basin, has only one avenue of release and that is up the Sutter Basin Fault (Figs. 5, 6 and 7). Therefore it is proposed that the connate water in the Kione Formation moves south from the Sutter Buttes and up the fault, causing a mound of saline water to move to the surface. This movement of high chloride water continues to the present as fresh water infiltrates the Kione sands at the Sutter Buttes. It is possible that the connate water in the Ione-Domengine Formation is also contributing some saline water to the mound, but it appears that the major contributor is the Kione Formation.

There is not enough information available now to determine whether the Sutter Basin Fault zone is pervious and allows the connate water to move through it or that it acts as a barrier and forces the saline water to rise along the north side of the fault.

For a time this investigator thought that the Starkey Sands of Upper Cretaceous age was the main contributor of the saline water. But it now appears that the presence of the Starkey Sands in contact with the

overlying nonmarine alluvium (Fig. 6) beneath the mound of saline water in the Sutter Basin has nothing to do with the saline phenomenon. It was hypothesized that the overburden on the confined portion of the Starkey would develop the required pore pressure to move the connate water up through the valley alluvium to the surface. However, a check of "closed in" pressures conducted in gas wells drilled into the Starkey Sands revealed that the pore pressure was approximately equal to the hydraulic load. This means that no abnormal pore pressure has been developed in the Starkey, and therefore there is no hydraulic head to move the saline water through the alluvium and up to the surface in the Sutter Basin.

Base Exchange

When ground water comes in contact with solid phase materials different from the ones it had been in contact with previously, chemical reactions may occur. This is particularly true when the water comes in contact with finely divided solids such as silt and clay that have an adsorptive capacity. One type of adsorption is termed "ion exchange" and is the replacement of adsorbed ions by ions in solution. The capacity for ion exchange is mostly a result of unsaturation of the chemical bonding in the crystal lattice of the solid having this capacity. In most cases there is an excess of negative bonds in certain areas of the crystal lattice, and positively

charged ions are attracted to these areas. Most of the ion exchange reactions involve cations (calcium, magnesium, potassium, and sodium) and are therefore called base exchange.

After the ground water has been in contact with the solids a sufficient length of time, cations in solution and the adsorbed ions held by the exchange material constitute a system in chemical equilibrium. The degree and readiness for displacement of the equilibrium to the right or left is governed by the law of mass action, which means that if water or mineral holds some base in large excess, the exchange of that base for another proceeds more readily. The replacing power of the different metallic cations differ widely. Calcium possesses high replacing power; magnesium stands next, followed by potassium and then by sodium. Normally, calcium and magnesium ions from solution replace adsorbed sodium on the exchange material and the water is naturally softened. However, under certain conditions explained by the Le Chatelier's principle the system can be reversed and the ground water will undergo a hardening process. According to the principle of Le Chatelier any equilibrium system subjected to a stress tends to change so as to relieve the stress. For a system in chemical equilibrium, changing the concentration of one of the components constitutes a stress (Sienko and Plane, 1966). Thus, if we introduce a large supply of sodium ions into

the ground water body that has reached chemical equilibrium a stress has been applied. Now the adsorbed calcium and magnesium ions will be replaced by the sodium ions in solution and the replacement will continue until the system is again in chemical equilibrium. This is exactly the procedure used in many domestic water softening systems. The water flows in contact with zeolites which act as an ion exchanger. Calcium ions are exchanged for sodium ions being held by the zeolite molecules. Once the exchanger has given up its supply of sodium ions it cannot soften water further. However, it can be regenerated by exposure to a concentrated solution of sodium chloride which reverses the reaction.

Piper et al. (1953) in their study of the contaminated ground water in the Long Beach-Santa Ana area of California found that the introduction of sea water or oil field brines high in sodium chloride resulted in the substitution of calcium (and locally some magnesium) for a large part of the sodium in the contaminating water. In other words, the strongly contaminated waters had been hardened by base exchange reactions, and the degree of hardening was greater than could be explained by the simple admixture of sea water and fresh water. They postulated that the influx of ocean water into the zones of native calcium bicarbonate type water released previously adsorbed calcium and magnesium by base exchange. This

condition is also found in the Sutter Basin, where the rising connate water, high in sodium chloride, comes in contact with the calcium-magnesium bicarbonate type ground water of low total dissolved solids, and is changed to a calcium-magnesium chloride type with a high total dissolved solids. In both instances, we see a case of water being hardened by base exchange.

Source and Movement of Ions

Bicarbonate-Carbonate

There is a very limited occurrence of bicarbonate minerals in the Sutter Basin and the drainage areas of the Sacramento River and its tributaries. Based on the work of Bear (1964), this investigator concludes that the bicarbonate and carbonate anions in the ground water come mostly from the carbon dioxide contained in the soil, and in a small part from the precipitation that has been in contact with carbon dioxide in the atmosphere.

The following chemical equations indicate how these reactions might take place:

$$CO_2(gas) + H_2O = CO_2(aqueous) + H_2O$$
$$CO_2(aqueous) + H_2O = H_2CO_3$$
$$H_2CO_3 = H^+ + HCO_3^-$$
$$HCO_3^- = H^+ + CO_3^{--}$$

Of the 137 water analyses tabulated in Appendix A, 106 samples have the bicarbonate ion as the major anion. This bicarbonate type water is considered the normal condition for the ground water basin and is

found on all sides of the mound of high chloride type water.

Sulfate

Feth, J. H., Robertson, C. E., and Polzer, W. L. (1964) propose that most of the sulfate ions in the runoff water of the Sierra Nevada come from water rising along fault zones. The author is aware of a source of sulfur in the upper Feather River drainage called Sulfur Point. The concentration of the sulfur compounds at Sulfur Point is so high that the stream is uninhabitable for fish within a mile below the Point.

The Bear River carries more sulfate ions than the other rivers flowing through the study area. Surface water samples contain as much as 0.56 equivalent parts per million (epm) with a TDS of 180 ppm. Water in well 13N/4E-21A1 is classified as a magnesium sulfate type and is the only well water that has sulfate as the major anion. Well 13N/4E-17J1, which is also near the Bear River (Fig. 6), has the second highest sulfate content among the ground water analyses used in this report.

Throughout the rest of the area the sulfate ions make up the minor constituent of the anion group. This is particularly true for the ground water with a high chloride content. A case in point is well 12N/2E-2J1 that has a TDS of 3525 ppm and a sulfate content of 2.0 ppm. Several other wells with high chloride water, in the same area,

have no discernible amounts of sulfate in the water analyses.

Hem (1970) has proposed the following reaction for sulfate reduction:

$$SO_4^{--} + CH_4 \text{ (bacteria) } HS^- + H_2O + HCO_3^-$$

This formula suggests that in the reduction of the sulfate the anaerobic bacteria is the most active agent. Methane gas is known to be present in the area. Bear (1964, p. 279) suggests that though the mechanism of sulfate reduction has still not been completely worked out, the activities of sulfate-reducing organisms are chiefly restricted to heavy clays or water logged soils. Such conditions are found in the Sutter Basin. One of the by-products of sulfate-reducing organisms is hydrogen sulfide with its characteristic odor. Bryan (1923) reported that much of the ground water in the eastern part of the Sutter Basin contained small quantities of hydrogen sulfide and that "many local people prefer the 'sulphur' water for drinking."

Chloride

A study of Figure 6 shows that there is a body of high chloride water in the central part of the Sutter Basin. Possible explanations for this are: (1) concentration of the chloride ion by evaporation of the ground water at or near the surface, (2) buried beds of sodium chloride salt, and (3) connate water rising from marine sediments. Byran (1923) noted that the conditions for

residual evaporates existed in the basins of the Sacramento Valley but they were found only in small, isolated bodies. His reasons for the absence of extensive evaporates has already been cited. Drilling has not revealed any buried salt bodies such as exist in the Phoenix area of Arizona. Therefore, it appears most logical that the chloride ions are the result of marine connate water. In the past, the major stumbling block to this theory was that the high chloride occurs in nonmarine alluvial material with a thickness of approximately 2,000 feet.

Chloride ions are resistant to ion exchange, hence maintain their identity as ions after introduction into a ground water body. They are, therefore, ideal for use as tracers in ground water studies. Notice on Figure 6 the area between the Sutter Basin Fault and the Pumping trough to the north, west of the Feather River. The pumping for irrigation water has reversed the natural gradient of ground water and has resulted in the saline water slowly moving north and degrading the ground water. What is of interest to this thesis is that even though the degrading saline water has been diluted and subject to base exchange, the water still maintains a high percentage of chloride ions.

Sodium and Potassium

Feth et al. (1964) state that the igneous rock in the Sierra Nevada contained almost equal portions of sodium and potassium, however, once the ions have been taken into solution by the ground water, the potassium ions are subject to base exchange and rapidly disappear from the ground water, while the sodium ions persist and are carried by the rivers down to the valley ground water basin. This is confirmed in the water analyses in the study area. In both the surface water and the ground water, the sodium ions far outnumber the potassium ions. The two ions have been grouped together in the circle diagrams on Figure 6.

Throughout most of the area, sodium is the minor constituent in the cation group. As the water percolates through interstices of the alluvial material, normally the sodium ions are released to the ground water at the expense of the calcium and magnesium ions in solution. This process of base exchange is known as natural "softening" of the water. There is some evidence that this process is taking place, but in general it is masked by the infiltration of irrigation water diverted from the rivers.

Water analyses of the two deep wells (12N/2E-18 SW1/4 and 12N/2E-24L1, Appendix A) show that the deep waters contain 73.8 and 73.5 percent (of total anion reactance) sodium ions, respectively. South of the Sutter Basin Fault

the deep connate water does not change chemically as it rises to the surface. Yet, as this same water moves Northward it becomes harder by changing from a sodium chloride type to a calcium-magnesium chloride type. As previously stated, this phenomenon was observed by Piper et al. (1953) in the Long Beach-Santa Ana area where fresh ground water was being contaminated with sea water. There, as in the Sutter Basin, the contaminated zone contains water which is higher in calcium and magnesium than can be explained by assuming a simple admixture of the saline water and fresh water involved. The best explanation is that previously adsorbed calcium and magnesium ions are being released by base exchange in the presence of the high sodium ion solution. That is to say, the water moving to the North is undergoing a base exchange, or hardening process. And on the other hand, the water moving Southwesterly from the Sutter Basin Fault is moving through soil that now has a deficiency of exchangeable calcium and magnesium ions and maintains its identity as a sodium chloride type water--the difference being that the saline water has been moving north only since the ground water trough was developed by irrigation pumping, whereas the ground water had been moving in a southerly direction for many thousands of years.

Calcium and Magnesium

The river water flowing through the area and recharging the ground water basin is a calcium-magnesium

bicarbonate type with a TDS of between 50 and 150 ppm. Once it has infiltrated the basin, it changes to a magnesium-calcium type. The probable explanation for this is that the alluvium has a high content of ferromagnesium minerals due to the presence of andesitic volcanic debris. By the law of mass action and through base exchange, the magnesium ions are released to the ground water and the calcium ions are adsorbed by the soil particles.

Boron

The Feather River and its tributaries are free of boron although a trace is reported from time to time along the lower reaches. The ground water being recharged by the Feather River and its tributaries is also free of boron. Along the eastern edge of the Sacramento Valley, some of the water from wells contains boron that is believed to be coming from marine sediments that occur at shallow depths.

The streams and rivers draining the Coast Ranges generally have a high boron content. Cache Creek, in Capay Valley, has a boron content of up to 4 ppm. The ground water recharged by the western streams normally contains one to two parts per million boron.

Within the mound of saline water in the Sutter Basin the boron content ranges from 10.8 ppm at a depth of 1,500 feet to 1.5 ppm at a depth of 285 feet. As the

rising connate water moves laterally away from the mound of saline water, the boron content gradually decreases until it is no longer detected in the analyses. The rapid decrease in boron over a vertical distance of some 1,200 feet is assumed to be largely the result of adsorption.

CONCLUSIONS

On the basis of the findings of this investigation, it is concluded that:

Subsurface Geology

The Kione Formation of Upper Cretaceous age is the chief contributor to the rising connate water in the Sutter Basin.

The Ione-Domengine Formation of Middle Eocene age also contributes saline water to the ground water basin but not in sufficient quantities to raise the base of the fresh water to the surface.

The "Starkey Sands" of Upper Cretaceous age are in direct contact with the overlying alluvial sediments in the southern portion of the Sutter Basin. This happenstance has nothing to do with the mound of saline water in the same area.

Hydraulic Continuity

The Sutter Basin Fault cuts the Upper Cretaceous marine sands and allows the saline water in the Kione Formation to rise along the fault into the post-Eocene alluvium.

Hydraulic Gradient

The head required to move the saline connate water from the underlying marine beds up through 2,000 feet of alluvium is supplied by the position of the Kione Formation which has been dragged up by the Sutter Buttes Intrusives and exposed at elevations between 250 and 400 feet above the Valley floor. The marine sands have been flushed with fresh water to depths of over 2,000 feet below sea level around the south side of the Buttes. The displaced saline water has moved south and up the Sutter Basin Fault and then through the overlying alluvial sediments to the surface.

Water Chemistry

The mound of saline water in the Sutter Basin is coming from connate water related to the marine sediments which underlie the entire area. The connate water is of a sodium chloride type that changes into a calcium-magnesium chloride type due to base exchange as the water moves into an area which previously contained calcium-magnesium bicarbonate type water.

Hi Mary, Paul and Christina,

I wanted to follow up regarding my public comment on the last Butte Basin call. As mentioned in my call, my concern is that the connate seawater under the Sutter Buttes is contaminating groundwater and drinking water quality.

I have previously sent the SWCB Bulletin No. 6 from 1952 and the PHD Paper by George Curtin from 1971. Bulletin No. 6 reported that pumping depressions were drawing salt brines to the surface causing groundwater contamination. Curtin's paper proposes that the connate seawater is moving laterally through faults around the Buttes and researched several hundred gas well logs to express this opinion.

According to the Sutter County GMP on Page 23 "The Sutter Buttes Rampart consists largely of gravel, sand, silt and clay sediments which were deposited circumferentially around the Buttes as a geologic apron. These sediments may extend up to 15 miles north and west beyond the Sacramento River. " On Page 32 the GMP addresses the arsenic contamination issue - "… recent data analysis suggest a possible correlation between elevated arsenic concentrations and the presence of volcaniclastic material of the Sutter Buttes Rampart formation." Since the Colusa and Butter Basins are within the 15 mile circumference of the Sutter Buttes this would impact the analysis for Lower Water Quality and potentially Seawater Intrusion SGMA Sustainability metrics. I am mentioning the Seawater Intrusion metric because of the hydraulic components of pumping depressions and the physics of natural occurring contaminants moving laterally from higher elevations to lower elevations in combination of the force of pulling water to the surface by the operation of groundwater wells.

You will see the elevated EC levels and arsenic levels in the GMP Figures attachments. On Figure 19, there was an observation at T15NR3E of arsenic at 350 ppm and an EC of 1126. To the south at 14NR2E the observation of arsenic at 370 ppm and an EC of 1400. Since this study was focused on Sutter County there were not observations for Colusa County and Butter County. For Colusa County – the attached report regarding Arsenic contamination in public drinking water systems has the Grimes water district at 23.9 ppm which is the worse levels of toxicity of any public system in the Sacramento Valley. To the northwest of the Buttes there is a USGS Gamma well ESAC 21 which seems to be located in the Colusa County portion of the Butte Basic which has an arsenic reading of 80 ppm. Finally ESAC 11 which is due north of the Buttes and appears to be located in Grey Lodge

has an arsenic level of 70.

I can also note that the EPA assessment of the wastewater treatment facility for Yuba City reported that the high levels of arsenic in the wastewater was apparently from the portion of the Yuba infrastructure. Since most of the source of the water for Yuba City is surface water from the Feather River the arsenic contamination is pronounced where ground water is used. Finally as I mentioned in the past you probably are aware that the EPA has entered into an mitigation agreement with Sutter County regarding the arsenic contamination at Robbins. As you know Robins is at lower elevation and due south of the Buttes which would explain the contamination so far away from the Buttes. Robbins arsenic levels are less than the levels observed at Grimes.

I will send the Yuba City EPA report and the USGS Gamma documents next.

My suggestion would be to pick up where the SWRCB left off in 1952 and examine salt water and arsenic levels within a 15 mile circumference around the Buttes and set up a monitoring network to monitor changes in ground water quality going forward. This would not only focus on the southern part of the Buttes but within the whole circumference.

Thank you for your time and consideration.

Best Regards,

Ben

Hi Mary, Paul and Christina

The 2006 USGS Study presents the observations wells on Figure 3 – Page . I have attached a photo of the link to the USGS GAMMA website sorting for Arsenic. I have also include USGS Laux Road which is ESAC 21 and USGS Gray Lodge which is ESAC 11. On the website you can see the actual locations on the satellite imagery.

The 2004 EPA assessment for the Yuba City Sewage infrastructure addresses the arsenic issue on Page 10. It ascribes more than half of the arsenic contamination to groundwater.

Thanks again for your time and consideration

Best Regards,

Ben

ARSENIC IN CALIFORNIA DRINKING WATER

Three Years After EPA Notice of Noncompliance to State, Arsenic Levels Still Unsafe in Drinking Water for 55,000 Californians

ENVIRONMENTAL INTEGRITY PROJECT

SEPTEMBER, 2016

ACKNOWLEDGEMENTS

This report was researched and written by Tom Pelton, Courtney Bernhardt, and Eric Schaeffer of the Environmental Integrity Project. The map was created by Kira Burkhart and the graphics by Alana Natke.

THE ENVIRONMENTAL INTEGRITY PROJECT

The Environmental Integrity Project (http://www.environmentalintegrity.org) is a nonpartisan, nonprofit organization established in March of 2002 by former EPA enforcement attorneys to advocate for effective enforcement of environmental laws. EIP has three goals: 1) to provide objective analyses of how the failure to enforce or implement environmental laws increases pollution and affects public health; 2) to hold federal and state agencies, as well as individual corporations, accountable for failing to enforce or comply with environmental laws; and 3) to help local communities obtain the protection of environmental laws.

For questions about this report, please contact EIP Director of Communications
Tom Pelton at (202) 888-2703 or
tpelton@environmentalintegrity.org.

Arsenic in California Drinking Water

More than three years after the U.S. Environmental Protection Agency found California in noncompliance with the federal Safe Drinking Water Act, 95 community water systems in the state, serving more than 55,000 people, are still providing water with illegal levels of arsenic, according to an examination of state data for the last two years.[1] Arsenic occurs naturally in the soil and groundwater in parts of California and is a known carcinogen that may also damage the developing brains of children and cause other health problems.[2] Many of the people drinking excessive levels of arsenic are poor and/or Latino or African-American, with a cluster in the San Joaquin Valley.[3] Nearly all have been exposed to excessive arsenic levels for at least five years and probably longer.[4]

California requires public water systems to notify their customers when arsenic fails to meet federal health standards. But strangely, the state's language for mailed advisories suggests the water is still safe to drink no matter how high the contimation levels or how long they persist, with the notices telling residents: "You do not need to use an alternative water supply (e.g., bottled water)." [5] That advice conflics with what California tells private well owners (who aren't covered by federal standards) on a state website: "If you suspect that your well may have arsenic, you should not use the water until it is tested, and you take appropriate measures to protect yourself and your family from potential chronic health effects if arsenic is present."[6] Whatever the intention, California's language for people on public water systems is likely to encourage them to drink contaminated water. (For the full text of the California's language, see Appendix A). As the state continues a multi-year effort to solve the contamination problem, it should immediately fix a communications problem so that it clearly warns people not to drink arsenic-tainted tap water.

The highest levels of arsenic in drinking water in California from 2011 through 2015 were in a group home for troubled teenage boys, the Valley Teen Ranch in Madera County. About 50 boys assigned by the courts to the facility have been living in a home with water that has arsenic at concentrations averaging more than 12 times the federal limit (10 parts per billion, or ppb) over these five years, according to state records.[7] "Nobody wants to drink the water because it's brown and nasty,"said Connie R. Clendenan, CEO of the nonprofit organization that runs the group home.[8] "It looks bad."

It is bad. Although California has made substantial progress in addressing

drinking water problems, the state still has 13 school districts, serving a total of 8,822 students, with arsenic in their drinking water that exceeded the federal limit from 2011 to 2015.[9] Twelve mobile home parks in California, serving 889 people, had arsenic in their tap water that averaged up to five times the legal limit. The average annual concentrations of arsenic in the drinking water of 58 residential communities (other than trailer parks) exceeded the legal limit during this time period, as did a military base, three wineries, two food preparation businesses and two campgrounds.

In many of the schools, the group home and military base, administrators say they verbally warn people not to drink tap water. They also provide bottled water as an alternative. But in the residential neighborhoods and trailer parks, it is not clear what warning – if any -- people are receiving. "There is no warning not to drink it. There is no 'non-drink' order out there," said Robert Johnson, President of the Shaver Lake Point 2 Mutual Water Company, which supplies 210 homes in Fresno County with tap water that has seven times the legal limit of arsenic. When asked if these residents should drink bottled water instead of his arsenic-tainted tap water, Johnson said: "It's one of those things, if you want to do it, that's your deal. It's not being recommended. We're not suggesting it. This is per the state of California. We are following their guidance."

The drinking water crisis in Flint, Michigan, was a reminder of how important it is for state governments to issue clear warnings to people with unhealthy tap water. California's mixed message is nearly identical to the one issued by Texas to homeowners with illegal levels of arsenic in their drinking water. Texas also tells consumers with excessive levels of arsenic: "You do not need an alternative water supply."[10] Many other states, however, are more direct in warning people not to drink water with excessive amounts of arsenic, at least for private well owners. Wisconsin, Michigan, Maine, and Washington, for example, simply tell residents not to consume water with more than 10 ppb arsenic (a health standard set by EPA in 2001). Wisconsin advises private well owners: "If your arsenic level is more than 10 ppb, the Wisconsin Department of Health Services recommends that you stop using your water for drinking or food preparation."[11] Florida advises its consumers to avoid water where arsenic contamination persists.[12] The U.S. Department of Health and Human Services makes similar recommendations.[13] If anything, the most recent science suggests that the current 10 ppb arsenic standard is not protective enough and that the IQ of children may be damaged at much lower exposures.[14]

In the wake of a 2013 EPA notice of noncompliance to California over its failure to invest enough money in its drinking water systems, the state has taken several important steps to fix its problems. Over the last three years, the state has more than doubled the amount of funding to build water treatment plants, pipelines, and new wells. The state and counties have filed compliance orders with local utilities to push them to upgrade their systems and are directing small, underfunded water systems to merge with larger utilities. Because of these measures, EPA announced in May 2016 that California was back in compliance with the federal Safe Drinking Water Act.

But in fact, the work is far from done – as witnessed by the 55,985 people in 95 communities across California who still have illegal levels of the carcinogen in their tap water, according to state records.[15] Why the delays? Local officials say that in some cases, bureaucratic

negotiations are holding up projects, which are sometimes stalled because of conflicts between county and state rules. In other cases, local water districts struggle with indecision or a lack of money.

Until these important water system improvements are complete, California and EPA must do a better job of warning consumers to stop drinking water that fails federal health standards. This report recommends:

- California and EPA should revise their regulations and guidance to require that local utilities warn people to stop drinking or cooking with water that fails to meet federal arsenic standards (10 ppb), especially when the contamination persists over several years. The advice should be sensitive to the additional risks posed when children and other sensitive populations drink contaminated water. If there is no reason for consumers to take precautions, there is no reason for Safe Drinking Water Act standards in the first place.

- Public notices mailed to consumers should inform them of options for treating contaminated water at home, e.g., through filtration systems that have proven to be effective. Conversely, the public should be told what doesn't work. For example, boiling water will not reduce arsenic concentrations.

- Federal and state authorities should provide enough money to these 95 California communities to allow them to install water filtration systems or take other steps to eliminate contamination problems. Although the state has already boosted its funding, it still faces a projected $30 billion plus in needed capital improvement projects to help its inadequate systems provide safe drinking water trough 2026.[16]

The big picture is that stepped-up investment in crumbling public infrastructure is sorely needed across the U.S., and it should be regarded as a top priority for both Congress and California lawmakers. But the state also needs to improve its efforts to better inform consumers so people can protect their own health. California does not have to wait for EPA action to strengthen its warnings because the state is already empowered to act independently of EPA.

Public health advisories that are contradictory and confusing – as they are in California -- are as bad as no warnings at all, because they undermine action and weaken public confidence in government.

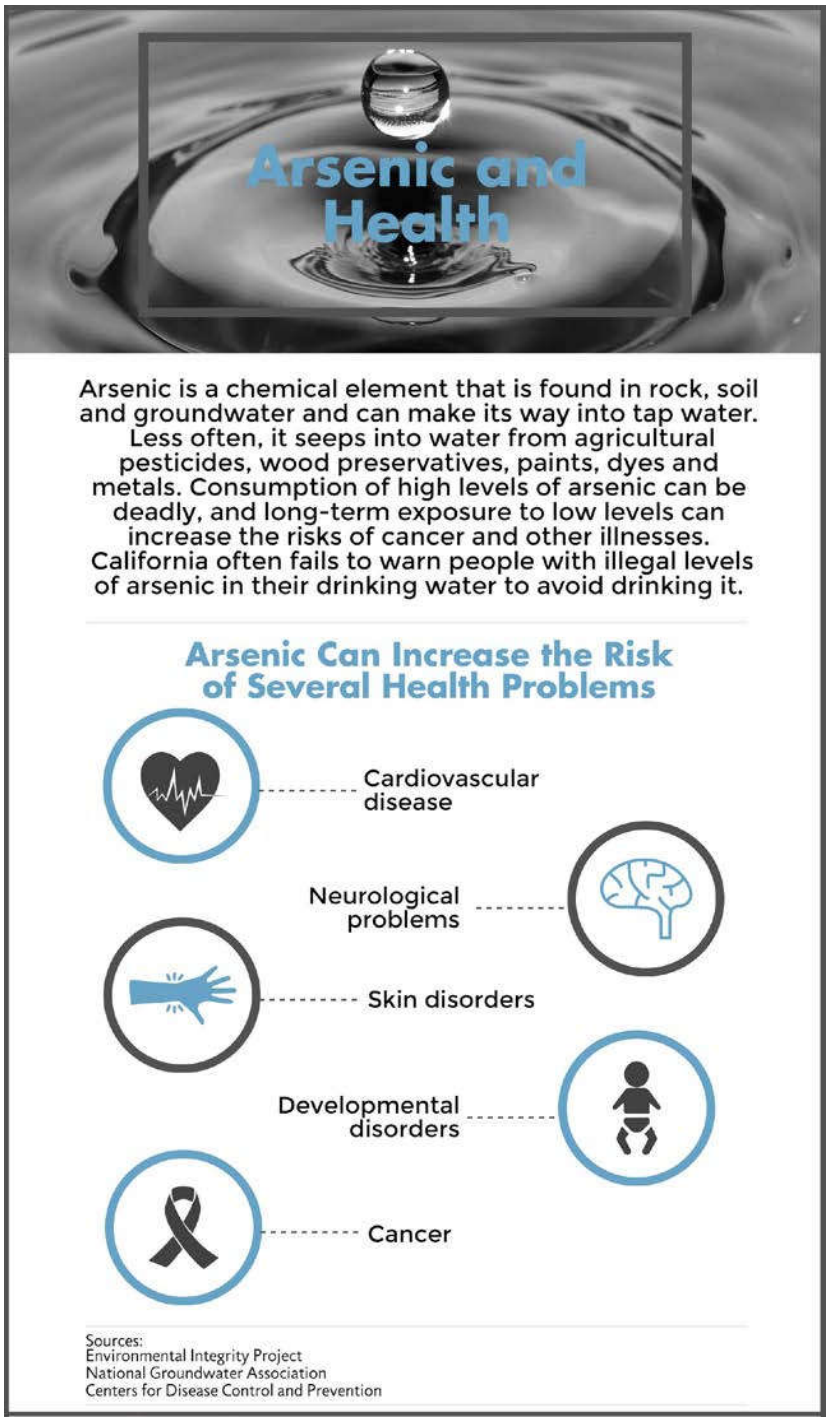

Table 1. Top 20 Arsenic Concentrations in California Public Water Systems

Water System (in Order of Arsenic Levels)	County	Pop. Served	2014-2015 avg (ppb)	2011-2015 avg (ppb)
Lakeview Improvement Association #1	Fresno	160	86.88	86.88*
Fountain Trailer Park Water	Kern	68	85.75	83.90
Hungry Gulch Water System	Kern	33	72.56	70.04
Corral De Tierra Estates WC	Monterey	45	72.50	78.40
Keeler Community Service District	Inyo	50	71.25	75.63
Quail Valley Water District- Eastside System	Kern	60	70.06	69.11
CSA 70 W-4 Pioneertown	San Bernardino	625	64.52	61.55
MD #06 Lake Shore Park	Madera	130	64.25	71.94
Valley Teen Ranch	Madera	50	62.00	120.80
Sierra East Mobile Home Community	Mono	50	54.63	47.03*
Shaver Lake Point #2	Fresno	210	52.31	42.88*
Winterhaven Mobile Estates	Los Angeles	40	52.13	53.35
Olam Spices And Vegetables Inc.	Kings	75	48.38	46.70
The Village Mobile Home Park	Los Angeles	70	45.05	47.04
Callier Water System	San Bernardino	1000	42.13	49.21*
Black Stallion Winery	Napa	25	41.75*	41.75*
Ironwood Camp	San Bernardino	1000	38.38	38.55
Boron CSD	Kern	2500	38.07	37.98
Edgewater Mobile Home Park	Sacramento	40	38.00	37.59
Prunedale MWC	Monterey	252	35.7	32.0

Note: The federal limit for arsenic is 10 ppb. * Average concentrations do not include concentrations from every year. For example, Lakeview Improvement Assn. #1 changed from a non-community water system to a community water system in 2013, and sampling data was only available from 2014 and 2015. Sampling results for Black Stallion Winery were only available for 2015. See Appendix B for annual concentrations in all systems that averaged above 10 ppb.

Health Risks Posed by Arsenic

Arsenic is a chemical element that occurs naturally in geological formations in California and elsewhere, and is also used in a variety of industrial products, including pesticides, paint, and wood preservatives.[17] It is a well-known poison at high doses. At lower doses, researchers have concluded it can cause cancers of the lung, kidney, bladder, skin, and other

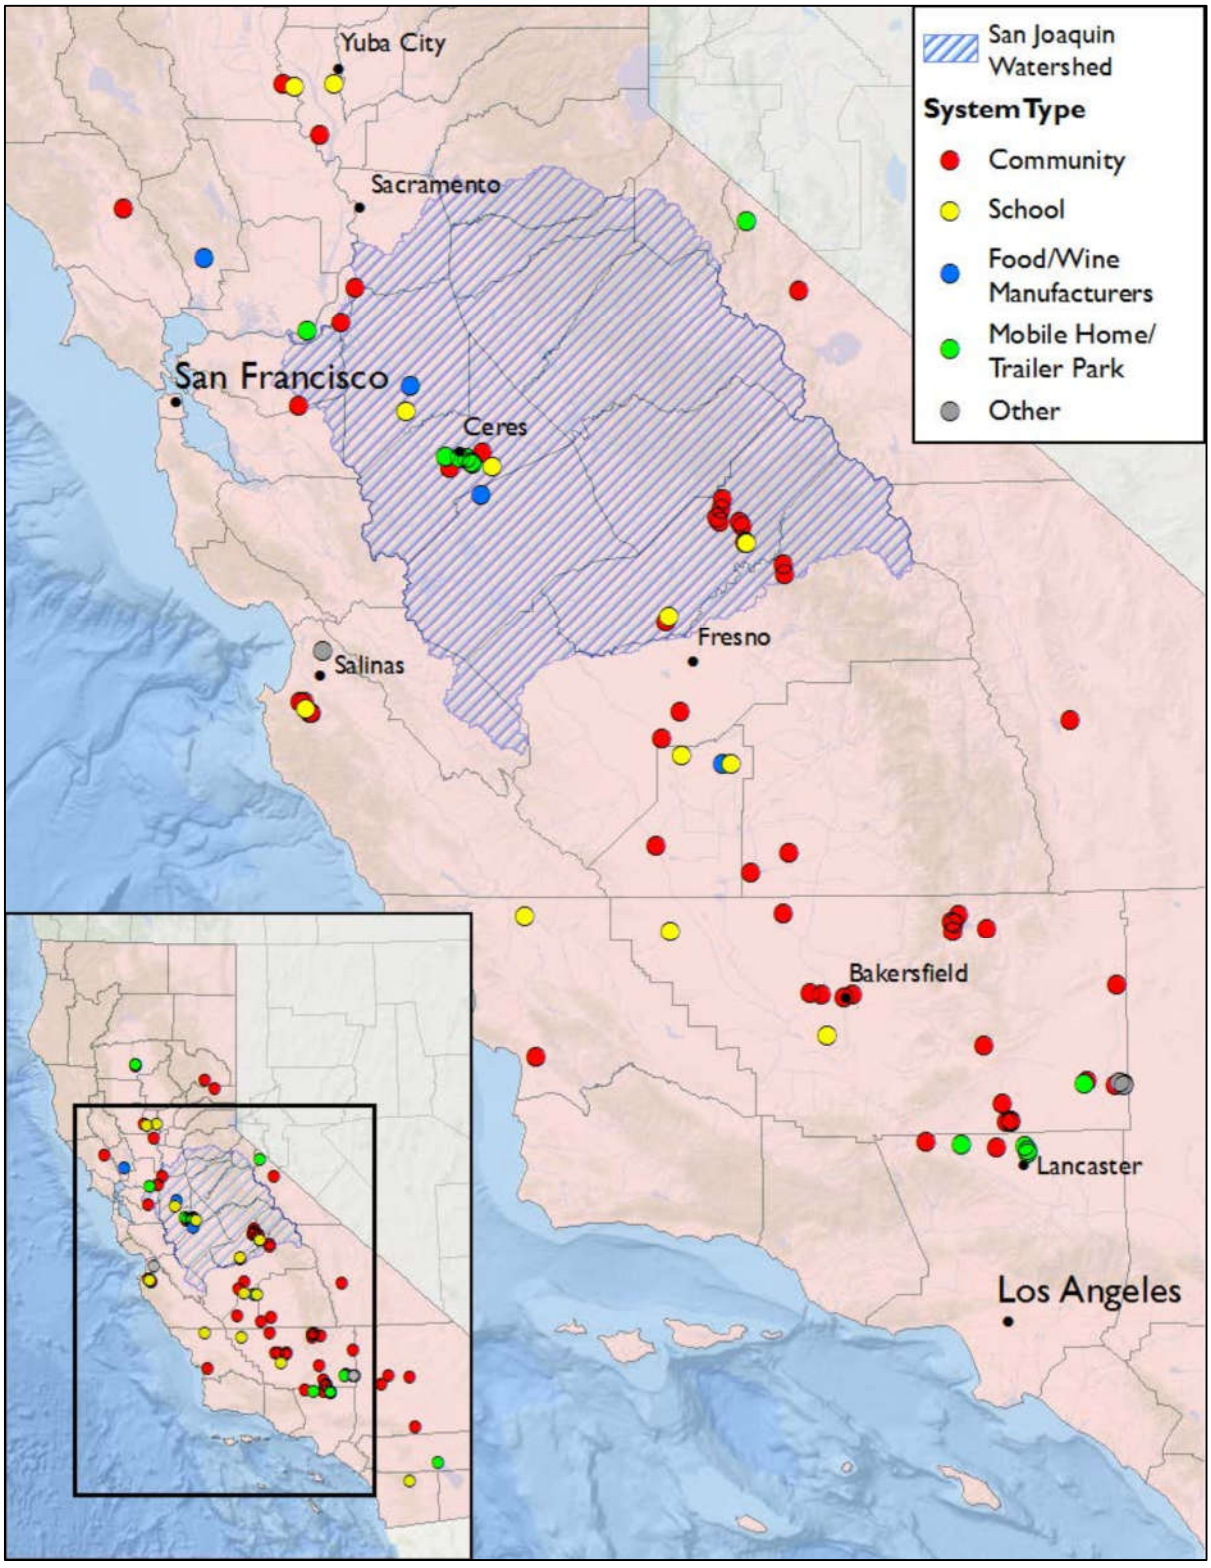
organs with prolonged exposure. Any level of exposure, however, carries some risk.[18] According to EPA, the risk of developing cancer after drinking water containing 10 ppb arsenic over a lifetime is 1 in 2,000.[19] This level of risk is almost never 'acceptable' from a regulatory perspective. The agency usually tries to limit lifetime cancer risk to no more than 1 in 10,000, at most. EPA's risk estimate assumes that the cancer risk is linear, meaning if water contains 20 ppb arsenic, those who drink it over a long period of time have a 1 in 1,000 chance of developing cancer. People exposed over shorter periods of time have lower risks, but exposure during childhood may have a greater impact than exposure during adulthood.[20]

Morever, these risk calculations reflected the old thinking. New evidence suggests that the actual cancer risk may be much higher. EPA is currently revising its assessment of cancer risks from arsenic to incorporate more recent science. A 2010 draft of the assessment indicated that the risk of getting cancer from drinking water containing 10 ppb of arsenic is closer to 1 in 136, more than 17 times higher than current assumptions.[21] In addition to causing cancer, arsenic is also a neurotoxin that can harm developing brains at levels at or below the allowable limit.[22] One recent study in Maine, for example, found significant reductions in IQ and other problems in children exposed to arsenic concentrations of 5 to 10 ppb.[23] Specifically, children in homes with more than 5 ppb arsenic in the tap water tested roughly 6 points lower on a full-scale IQ test.[24] While EPA's

Scientific Advisory Board and the most recent studies suggest that the 'safe' level of arsenic is likely much lower than 10 ppb, any concentration higher than 10 is clearly unsafe.

Background on California's Problem

On April 19, 2013, EPA sent a letter to the California Department of Public Health notifying the state that it was out of compliance with the federal Safe Drinking Water Act.[25] The reason was that California's drinking water system was inadequate – providing contaminated water in many poor, rural communities – and the state was not investing enough money to fix the problem. A state investigation that year revealed that 680 community water systems serving 21 million people relied on groundwater that was compromised by one or more contaminants, with the most common being arsenic.[26]



Not all of these 680 water systems provided tap water that had levels of contaminants in excess of federal health standards. In most wealthier and urban communities, the local water utilities treated the groundwater or diluted it with clean water from other wells so that it met the requirements of the federal Safe Drinking Water Act. But in 265 of these communities – often with small populations in rural, isolated areas – the tap water provided to customers had at least one violation of federal standards from 2002 to 2010 for a variety of contaminants, including nitrates from farm fertilizer, according to a 2013 report by the California Department of Health.[27]

In a separate study, researchers at the University of California, Berkeley, examined 464 community water systems serving 1.1 million people in California's San Joaquin Valley, one of the poorest regions in the state, and found that 15 percent of the systems and 14 percent of the people had tap water with arsenic above the federal limit.[28] Of the people exposed, 61 percent were either Latino or African-American. "Community water systems serving higher percentages of people of color had a 260 percent higher chance of having at least one (arsenic) violation," researcher Dr. Carolina L. Balazs and colleagues wrote.[29]

In response to the chronic drinking water problem, Congress had approved $1.5 billion to California over a decade to upgrade its water systems through a program called the Safe Drinking Water State Revolving Fund.[30] Yet because of bureaucratic obstacles and inefficiencies, the state by 2013 had not spent $455 million of those funds – the largest unspent balance of any state. According to EPA's 2013 letter of noncompliance to the California Department of Health, this violated a federal requirement that the state "make *timely* loan or grants using *all available* drinking water funds."[31]

EPA ordered the state to accelerate its efforts to fix public water systems. California Governor Jerry Brown's administration took action in several steps. These included switching control of the state's drinking water program from the Department of Health (where policy focus was dispersed among numerous problems, including drug abuse and AIDS), to the California State Water Resources Control Board (whose only focus is water) under the California Environmental Protection Agency. Since the EPA issued its

Map 1. Public Water Systems with Illegal Levels of Arsenic, 2014-2015

2013 letter of noncompliance, the state has more than doubled the amount of money it is distributing for water system upgrade projects, to an average of $738 million per year, compared to $366 million per year in the period of 2008 to 2012.[32] The unspent balance in the drinking water fund dropped to about $100 million.[33] As a result, EPA in May 2016 decided that California's system was back in compliance.[34]

Recent Analysis of California Records

The problem, however, is still far from fixed. An examination of California's online records by the Environmental Integrity Project (EIP) in May 2016 revealed that there were still 95 community water systems in the state, serving 55,985 people, providing drinking water with levels of arsenic that exceed the federal standard of 10 ppb in 2014 and 2015, according to two-year averages over those years. [35]

Over a longer period of time, 2011 through 2015, state records show 70 systems serving 46,772 residents, that each year have averaged higher than the limit in the Safe Drinking Water Act. These do not include homes on individual private wells, which are not covered by the federal Safe Drinking Water Act.

For a detailed discussion of the methods used to arrive at these numbers, please see Appendix C.

Examples of Drinking Water Contamination

Some of the worst water in community systems in California can be found in the Lakeview Community Association, which serves 160 residents in Shaver Lake (northeast of Fresno, in Fresno County). This community had an average arsenic concentration of nearly nine times the federal limit – 87 ppb – in 2014 and 2015, according to state data.[36]

Four water systems in the unincorporated community of Boron, in San Bernardino County, provided water to about 5,200 residents that had at least three times the safe limit of arsenic in 2014 and 2015.[37] In the city of Keyes in Stanislaus County, 4,891 people have tap water with arsenic concentrations that averaged above the federal limit each year for the last five years. The Pixley Public Utilities District, serving 3,310 residents, had arsenic levels in its drinking water that averaged 50 percent higher than health standards in 2011-2014.

Twelve school districts, serving a combined total of 5,462 students, had arsenic levels that averaged from 30 percent higher to three times the federal limit over the last five years. (See Table 4. Some of these school districts provided explanations, which will be discussed on pages 15 and 16 of this report).

Across California, there were 12 mobile home parks serving 889 people that had average arsenic levels ranging from 20 percent over legal limits to five times the federal standards from 2011 through 2015.[38]

Table 2: Top 10 Mobile Home Parks for Arsenic Contamination

Water System	County	People Served	2014-2015 Avg. (ppb)	2011-2015 Avg. (ppb)
Fountain Trailer Park Water	Kern	68	85.8	83.9
Sierra East Mobile Home Community	Mono	50	54.6	47.0*
Winterhaven Mobile Estates	Los Angeles	40	52.1	53.4
The Village Mobile Home Park	Los Angeles	70	45.1	47.0
Edgewater Mobile Home Park	Sacramento	40	38.0	37.6
Mitchell's Avenue E Mobile Home Park	Los Angeles	26	21.3	21.0
Millstream Mobile Home Park	Tehama	80	20.5	20.0
Country Western Mobile Home Park	Stanislaus	120	20.4	22.2
Saint Anthony Trailer Park	Riverside	300	19.7	21.5
New Orchard Mobile Home Park LLC	Tehama	125	19.6	19.0

Note: federal limit is 10 ppb arsenic. The 2011-2015 average for Sierra East Mobile Home Community reflects fewer than 5 years.

Response from California Officials

The Environmental Integrity Project asked the California State Water Resources Control Board why so many people are still exposed to contaminated drinking water after the state supposedly returned its system to compliance. Officials at the state agency replied in an interview and emails that they had issued orders to nearly all of the local utilities to fix the arsenic problem, but that some local government still need more time to upgrade their systems. In some cases, local utilities are building water filtration systems to remove arsenic, or digging new wells in an effort to extract cleaner water.

"The State Water Board Division of Drinking Water is working with each of these communities to return them to compliance," said Cindy Forbes, Deputy Director of the Division of Drinking Water at the Water Resources Board.[39] "District Office staff are working with these communities to evaluate alternative solutions, including new treatment options, new wells or modification of existing wells, and in some instances consolidation with larger water systems that can provide drinking water that meets all standards. The State Water Board is also helping communities that are struggling financially to reach compliance by offering financial assistance to solutions through low-interest loans and grants."

Public Notification of Drinking Water Violations

As the work continues to upgrade the drinking water systems, however, many citizens of California have not been given warnings to avoid drinking contaminated water.

The background is this: As part of the federal Safe Drinking Water Act, local water utilities are required to periodically test public drinking water systems that serve at least 25 people. When those results show more than 10 ppb arsenic (a standard imposed by EPA in 2001), the utilities must notify residents of the violation in writing by mail "as soon as practical, but within 30 days."[40] In California, however, the warning notices provide a mixed message, stating: "Our water system recently violated a drinking water standard," but also, "you do not need to use an alternative water supply (e.g., bottled water). This is not an emergency…. However, some people who drink water containing arsenic in excess of the (federal limit) over many years may experience skin damage or circulatory system problems, and may have an increased risk to getting cancer."[41] (For the full text of California's notice template for local utilities to use, see Appendix A)

This advisory says two contradictory things: Warning, you have a problem with your water. But don't worry – keep drinking it. If consumers are being told to ignore the federal health standards and keep drinking the contaminated water, there is no reason for the federal Safe Drinking Water standards for arsenic to exist. As stated previously in this report, California is much more clear about warning private well owners to "protect yourself and your family" from arsenic-tainted tap water. And other states – including Wisconsin, Michigan, Maine, and Washington – bluntly advise people not to drink private well water with more than 10 ppb arsenic.

In addition to receiving advisories about violations when they occur, customers also receive annual reports from their local water utilities called "Consumer Confidence Reports." These reports list the levels of more than a dozen different potential contaminants, including bacteria, lead, copper, nitrates and arsenic. When arsenic levels exceed the limit of 10 ppb, these reports provide the numbers and say: "Some people who drink water containing arsenic in excess of the MCL (maximum contaminant level) over many years may experience skin damage or circulatory system problems, and may have an increased risk of getting cancer."[42] But the reports do not tell consumers to stop drinking water with excessive levels of arsenic, and instead hint that it might not be a problem, saying: "Drinking water, including bottled water, may reasonably be expected to contain at least small amounts of some contaminants."

We asked the California State Water Resources Control Board why the agency doesn't tell people to avoid drinking water with illegal levels of arsenic. In response, Forbes, the deputy director for water, said that the state does provide this kind of blunt and immediate warning for other contaminants that can make consumers sick immediately, such as fecal bacteria. But for arsenic, she said, the threat is more long term. "Arsenic is categorized as a chronic contaminant that poses possible health risks after long-term exposure – 70-plus years of drinking two liters of arsenic-contaminated water a day above the maximum contaminant level," Forbes said. "There are no known acute/immediate health effects that would cause consumers to immediately stop drinking the water."

This answer, however, ignores the fact that many of these California residents have been drinking arsenic-contaminated water for decades. For example, Drs. Carolina Balazs and Isha Ray in 2014 published a study in the American Journal of Public Health in which they interviewed residents with contaminated tap water and found that the current notification requirements are poorly serving people with long-term exposure to pollutants.[43] "A resident from the community of Cutler explained that for years she had received Consumer Confidence Reports indicating that dibromochloropropane levels in the water exceeded the MCL (maximum contaminant level)," Balazs and Ray wrote. "These reports noted that residents should not worry because health impacts were not based on immediate exposure, but rather on lifetime exposure... She had lived in her community for nearly 30 years—so, she asked, should she worry or not? In these situations, water systems simply leave residents to cope with contaminated drinking water as best they can….In these instances, Safe Drinking Water Act regulations ultimately fail the (low-income) household."[44]

California's records identify more than 46,772 people whose tap water has had average levels of arsenic that have exceeded the federal standards for at least five years, from 2011 to 2015. But there is no reason to believe that these people received cleaner water before this. The longer a person drinks water contaminated with excessive levels of arsenic, the higher the increased risk of cancer. In much the same way, smoking a single cigarette is not an immediate health threat, in that it will instantly kill a person. But the longer a person smokes, the worse the health threat. For this reason, California would better protect public health if it told people to stop drinking arsenic-tainted water now, just as health warnings on tobacco required by the U.S. Food and Drug Administration advise, "WARNING: Quitting smoking now greatly reduces serious risks to your health." These advisories do not state, "WARNING: You do not need to change your smoking habits."

Evolution of the Science on Arsenic

One reason for stronger warning language is that scientific research continues to show that arsenic causes health problems – including brain damage in children -- at lower levels than previously thought.

The history of EPA's arsenic rule reflects the continuing evolution of scientific knowledge about the harms that even low levels of the element can cause. Back in 1996, Congress amended the Safe Drinking Water Act and directed EPA to establish new limits for arsenic to replace the old standard of 50 ppb. Based on the best available research, EPA proposed a limit of 5 ppb in 2000. Because arsenic is a carcinogen, some public health experts consider any level above zero to pose some risk. EPA then revised its proposal, based in part on cost considerations, and finalized a new arsenic standard of 10 ppb in 2001.

The EPA Administrator at the time, Christine Todd Whitman, explained that "the 10 ppb protects public health based on the best available science and ensures that the cost of the standard is achievable."[45] The new regulations required that public water systems across the U.S. meet the new standard by January 23, 2006.[46] The law allowed states to grant exemptions until January 23, 2015, for some small community water systems that had trouble complying.[47]

The 2014 Maine study discussed earlier in this report found found significant reductions in IQ in children exposed to arsenic concentrations of 5 to 10 ppb.[48] With this new information, EPA should change its own guidance for notification language so that people – especially parents of young children -- receive a clearer warning not to drink contaminated water. A template for warning language on the federal agency's website for drinking water systems with chemical contaminants such as arsenic advises utilities to tell their customers: "Some people who drink water containing arsenic in excess of the MCL (maxiumum contaminant level) over many years may have an increased risk of getting cancer." But the notices also say: "There is nothing you need to do….If you have specific health concerns, consult your doctor."[49] This is a problem, because many lower-income people do not have doctors with whom they can regularly consult about questions like water quality.

Responses from Local Drinking Water Systems

When asked about their drinking water violations by EIP, some of the utilities in California with illegal levels of arsenic replied that their attempts to fix the problem have been hindered by bureaucratic obstacles at the local level. Others indicated they are taking steps to solve the problem, but simply need more time or money. Not all public systems were contacted by EIP or provided answers.

Table 3. Top 10 Residential Water Systems for Arsenic Contamination (Excluding Mobile Home Parks)

System	County	Population Served	2014-2015 avg (ppb)	2011-2015 avg. (ppb)
Lakeview Improvement Association #1	Fresno	160	86.9	86.9*
Corral De Tierra Estates WC	Monterey	45	72.5	78.4
Keeler Community Service District	Inyo	50	71.3	75.6
Quail Valley Water District-Eastside System	Kern	60	70.1	69.1
MD #06 Lake Shore Park	Madera	130	64.3	71.9
Valley Teen Ranch	Madera	50	62.0	120.8
Shaver Lake Point #2	Fresno	210	52.3	42.9
Boron Community Service District	Kern	2500	38.1	38.0
Monterey Park Tract Comm. Service District	Stanislaus	186	31.9	34.3
North Edwards Water District	Kern	600	31.5	31.6

Note: The federal limit is 10 ppb arsenic. Lakeview had fewer than five years of data available.

At the **Lakeview Improvement Association** in Fresno County, 160 people have been receiving drinking water with more than eight times the legal limit of arsenic on average for

at least the last five years, according to state data. State records show that on May 16, 2016, the California Water Resources Control Board issued a citation to the association's water system, imposing a fine of $1,000 for its failure to follow the directives of two earlier compliance orders, in 2014 and 2015. "The water system continues to violate the arsenic maximum contaminant level (MCL) and does not appear to be making progress toward the compliance deadline," says the most recent letter from the state. "Additionally, the water system has failed to routinely conduct the public notification of the arsenic MCL violation, as required."

Philip Dutton, an engineer for surrounding Fresno County, said that the Lakeview Association's plan, as expressed verbally, is to test some in-home water filtration systems and see how well they perform.[50] "They've got a few of these (filtration systems) installed in homes, but they are sampling from different technologies to try and identify what is going to be the best long-term alternative," Dutton said. The California State Water Resources Control Board's website already lists which types of filtration technologies work well to remove arsenic.[51]

In **Kettleman City**, in Kings County, 1,450 residents have had tap water with excessive levels of arsenic for decades. The average from 2011 to 2015 was 20 percent above the legal limit, according to state data. "I have a daughter, a little one, who's still brushing her teeth with contaminated water, taking a bath in contaminated water," said Maricela Mares-Alatorre, a city resident, during a recent public hearing of the state water board.[52] The Kettleman City Community Services District has promised local residents that it will build a $9 million water treatment plant, but the project has been repeatedly delayed – with a target to open in the fall of 2016 recently pushed back to 2018.[53]

At the **Corral De Tierra Estates** subdivision in Monterey County, 45 people have been exposed to drinking water with arsenic levels almost eight times the legal limit from at least 2011 through 2016, state records indicate. This small water system has received 10 violations notices from the state for excessive levels of arsenic over the last decade, with the most recent in the first quarter of 2016, when it had 77 ppb of the contaminant (compared to the 10 ppb limit).

The manager of Monterey County's drinking water program, Cheryl Sandoval, said Corral De Tierra Estates is among at least five privately-owned water systems that have been issued corrective orders by the county because they are in violation of the arsenic standard. Solving the problem is taking longer than expected, Sandoval said, and some of the local water utilities are still debating the best path forward. "Dealing with the problem is very complicated," Sandoval said.[54] "They haven't made a lot of progress toward compliance, but they are going to have to." One challenge is that a water treatment plant for even a small system can cost hundreds of thousands of dollars and cause new waste disposal problems, because the plants produce concentrated arsenic sludge that must be handled carefully as a hazardous material. Corral De Tierra Estates and other subdivisions want to try in-home water treatment systems as a systemic solution, but county rules don't allow that, Sandoval said. However, debate over this in-home option continues, because new state regulations may open the door for in-home filtration as a systemic solution in the future.

Meanwhile, as the bureaucratic discussions continue, residents are receiving confusing advice about whether they should drink the water pouring from their taps with illegal levels of arsenic. One recent report from Corral de Tierra Estates to local water consumers, displayed on the state website and sent to homeowners in July 2014, advised people that arsenic levels were eight times above the legal limit.[55] But that fact was buried in the middle of a dense report with lots of numbers that also gave the impression that the exceedance was not a problem. The report told homeowners: "The presence of contaminants does not necessarily indicate that the water poses a health risk."[56]

At the **Quail Valley Water District-Eastside System** in Kern County, 60 residents have been receiving drinking water with seven times the legal limit of arsenic over the last five years, state records show. In April 2015, the state issued a compliance order to the local utility and mandated that it fix the problem by April 2018.

Randy Hardenbrook, Director of the Quail Valley Water District, said the problem should be solved within the next two years because a $5.8 million grant from the state is allowing the district to build a new pipeline. The pipe will be about 8.5 miles long and will connect a part of the system with arsenic-tainted water to a well that has good water.[57] In the interim, local residents receive quarterly letters with data on the arsenic exceedances but are not being provided with bottled water. More importantly, they are not being told to refrain from consuming the contaminated water. "We're not telling them not to drink it," Hardenbrook said, "but we are telling them there are long-term health effects."[58]

At the **Shaver Lake Point #2** subdivision in Fresno County, 210 people have been receiving tap water with more than four times legal levels of arsenic for at least the last five years, according to state data. In January 2015, the state wrote to the water system's administrators and ordered them to come into compliance with the federal and state arsenic limits by December 31, 2016.

With only four months left until the deadline, the arsenic levels remain illegally high and Robert Johnson, President of the Shaver Lake Point Mutual Water Company, said he is still thinking about what to do about the problem.[59] "Currently, it's being researched. We have engineers involved. We have water experts involved, and we are trying to figure it out," Johnson said. He added that building a water filtration system could cost as much as $250,000, so the subdivision is considering trying to blend water from its arsenic-tainted wells with cleaner water from different wells.

Meanwhile, nobody in the community is being warned to avoid the contaminated water. "There is no warning not to drink it. There is no 'non-drink' order out there," said Johnson.[60] When asked if his customers should drink bottled water as a precaution instead of the arsenic-tainted tap water, Johnson said: "It's one of those things, if you want to do it, that's your deal. It's not being recommended. We're not suggesting it. This is per the state of California."

Group Home for Troubled Children

The **Valley Teen Ranch**, a Christian residential treatment group home for 32 court-referred abused and neglected boys in Madera County, has arsenic in its tap water that averaged more than 12 times the federal limit from 2011 through 2015, according to state records.[61] "We've been out of compliance, but no children have gotten sick, no adults have gotten sick," said Connie R. Clendenan, CEO of the nonprofit organization that runs the group home. "Nobody wants to drink the water here because it's brown and nasty."[62]

About five years ago, the state approved a $5 million grant to help the group home solve the problem by linking its small water system to a larger one run by the county. But the work has not started yet. Because of ongoing negotiations at the county level, the fix could still be three years or more away, Clendanan said. Meanwhile, children are being given bottled water and are verbally warned not to drink tap water, although there are no warning signs posted above sinks.

"I want to get out of the water business. I'm in the kid business," Clendenan said. Of the continuing delays in fixing the problem with contaminated water, she said: "Nobody's mad. But it's government, and it takes a lot of time. It's just the stupid county."

Table 4. Schools with Excessive Arsenic in Drinking Water

System	County	Population Served	2014-2015 avg. (ppb)	2011-2015 avg. (ppb)
Kit Carson Elem. School	Kings	510	34.7	34.7*
Washington School WS	Monterey	250	26.1	27.7
MUSD-Nile Garden School	San Joaquin	804	20.9	22.8
Liberty High School	Madera	1340	17.9	20.5*
Island Union School	Kings	300	11.9	18.8
Winship Elementary School	Sutter	38	16.4	17.3*
Lakeside School	Kern	800	16.3	16.9
Barry Elementary School	Sutter	650	15.2	15.3
Pleasant Valley Elementary	San Luis Obispo	100	13.8	14.1
Gratton School	Stanislaus	110	13.5	13.5
North Fork Union School	Madera	350	12.9	12.4
Warner Unified School District	San Diego	250	10.9	11.4
Central Union Elementary	Kings	320	10.1	13.5

*Note: federal limit is10 ppb arsenic. *Indicates systems with monitoring gaps (less than five years available data)*

Arsenic in School Drinking Water

At the **Washington School in Salinas,** California, the tap water serving about 250 students has had almost three times the federal limit of arsenic for the last five years, 28 ppb on average over this time period, compared to the limit of 10 ppb.[63] School Principal Whitney Meyer said that the local school district has been discussing the problem for several years but does not yet have a solution. Meanwhile, students are given bottled water, she said.

"We remind them over and over that they cannot drink the water," Meyer said.[64] "Many of the students live out in this area and their homes are similarly impacted (with arsenic), so they also hear the message at home. We have drinking stations with clean water in every classroom, teaching space, and hallway. The fountains have all been shut down."

At the **Barry Elementary School in Yuba City**, California, the arsenic levels have averaged 50 percent above the federal limit for arsenic over the last five years. Because of the violations, the state issued a compliance order to the school in May 2015. Tom Butcher, Director of Maintenance and Facilities for the school system, said that the school has not yet solved the problem, but is giving bottled water to students as officials try to figure out a solution.[65] Adminstrators of the water system are discussing a consolidation with a larger neighboring system that has better water. "The (state) Water Board indicates a best case scenario of a consolidation in approximately 1.5 years," Butcher said. "Until the consolidation is completed (the school district) will continue to provide bottled drinking water."

At the **Kit Carson Elementary School**, in Hanford, Ca., arsenic levels in drinking water averaged more than three times the legal limit in 2011 through 2014, according to state records. In January 2015, the school solved the problem by connecting its pipes to the water system of the surrounding city,[66] whose arsenic levels are below the federal limits.

At the **Lakeside School in Bakersfield,** California, the arsenic levels in the drinking water averaged more than 70 percent above the federal limit for arsenic over the last five years, 17 ppb compared to the limit of 10 ppb. Ty Bryson, District Superintendent, said that the school notified all families by sending home notice letters with the students and by posting warnings in the office. "We provide bottled drinking water for students and staff," Bryson said. "We drilled an alternate well, but that also had unacceptable levels of contaminant. We are now pursuing an alternative source of drinking water by connecting to a local municipal water source via pipeline."

At the **Gratton School in Denair,** California, the drinking water system has had arsenic levels that averaged 40 percent above the federal limit for arsenic over the last five years, state records indicate. The school's superintendent, Shannon Sanford, said that students have been provided bottled water for the last two years. "Students were initially warned (not to drink the water) and signs were used until fountains were disabled," Sanford said. More recently, the school drilled a new well that will be used for the 2016-2017 school year that should solve the problem.

At the **Island Union School in Lemoore,** California, arsenic levels in the drinking water were nearly twice the federal limit from 2011 to 2015, averaging 18.8 ppb compared to

federal limit of 10 ppb, according to state records. Superintendent Charlotte Hines said the school dug a new well in 2015, and provided students and warnings and bottled water in the interim. "We know that bottled water is only a temporary solution," Hines said. "And in an effort to find a permanent solution, the school requested -- and was awarded -- state funding to drill a new well that would meet all primary drinking water standards."[67]

Military Base with Contaminated Water

At the **U.S. Army Base Fort Irwin** in San Bernardino County, 16,000 soldiers live in facilities that have had arsenic in some tap water at levels 50 percent higher than the federal limit from 2011 through 2015, state records indicate. For the last three years, the Army Corps of Engineers has been building a new $100 million water treatment plant at the base to solve the problem. The plant is now undergoing testing and is scheduled to go online in October 2016, base officials indicate.

"The new plant will treat all Fort Irwin water to comply with Safe Drinking Water act Standards for ALL pollutants of concern including …arsenic," said Muhammad A. Bari, Director Public Works at Fort Irwin.[68]

In the interim, soldiers have been provided with bottled water and warned which faucets to avoid, according to base managers.

Vineyards with High Arsenic Levels

In San Joaquin County, the **Delicato Family Vineyards** had arsenic levels in the tap water that averaged 18 ppb from 2011 through 2014, which was 80 percent higher than the federal limits, state records indicate. Kylie Barnett, a spokeswoman for the company, said that the vineyards worked with county officials in 2014 to build a new drinking water system, including by digging two new wells, which brought the arsenic levels down below the federal standard in 2015 and 2016.[69] "The drinking water is not used in production of our wine," Barnett noted. Before the repair, people working at the vineyards and visiting were provided bottled water, she said.

In Napa County, the **Larkmead Vineyards** had drinking water with six times more arsenic than allowed from 2011 through 2013, according to state records. No results were listed for 2014 or 2015, and it is unclear if the drinking water system, which serves 25 people, is used for workers or guests. (Wine making does not generally use tap water.) Emails sent to managers of the vineyard asking about the water were not returned. The researchers of this report also received no response from the **Black Stallion Winery** in Napa County, whose tap water had four times legal limits of arsenic from 2011 through 2015, according to state records.

Conclusion

California is making progress toward solving its drinking water contamination problem. The state has reorganized its drinking water agency, and increased its financial assistance to local utilities to build water treatment systems, dig new wells, and take other steps to resolve the issue. The work, however, is expected to take many more years. In the meantime, tens of thousands of people continue to be exposed to drinking water with illegal levels of arsenic, a carcinogen that could damage the developing brains of children and cause other health problems. And yet, the warnings that some of these residents receive from the government are contradictory and confusing.

Both California and the federal government need to do more to protect consumers, especially the young. This report recommends:

1) California and EPA should both revise the language for written notifications of violations of arsenic standards, so that people are clearly advised to stop drinking contaminated water. If the violations are in schools or group homes, warning signs should also be posted over all sinks and drinking fountains. The state should help provide bottled water as an interim solution.

2) Consumers should be provided more information through the mail about what works and what does not work to remove arsenic from tap water. Residents need to know, for example, that boiling water will not help, but that certain filtration systems can remove the carcinogen. In some cases, residents may need technical help from the state in understanding how to use filtration systems properly.

3) Both Congress and the state government should increase investments in upgrades to California's drinking water systems. This is not only an environmental justice issue, but also a sensible strategy to boost the local economy through the hiring of engineers, construction workers and others to improve local infrastructure.

Counter arguments made by California officials – that the state is already taking action, and that arsenic is not an immediate threat to public health – do not hold water. Although the state has issued enforcement orders to local utilities, some local officials clearly still need more prodding and money to upgrade their water systems. A growing amount of scientific research suggests that arsenic increases the risk of cancer and other diseases and may do so at a lower level than expressed in current federal regulations. Years more of exposure to arsenic-tainted water will only raise the risk of cancer or neurological damage for California residents.

The state and federal governments should advise people to stop drinking contaminated water immediately, just as public health experts urge smokers to change their habits sooner rather than later because it will increase their odds of survival.

With public health warnings, simple and direct is better than bureaucratic and complex, because safe is better than sorry when people's lives and minds are at risk.

APPENDIX A: California's Language for Public Notices about Arsenic Violations

IMPORTANT INFORMATION ABOUT YOUR DRINKING WATER

Este informe contiene información muy importante sobre su agua potable.
Tradúzcalo o hable con alguien que lo entienda bien.

[System] Has Levels of Arsenic Above the Drinking Water Standard

Our water system recently violated a drinking water standard. Although this is not an emergency, as our customers, you have a right to know what you should do, what happened, and what we are doing to correct this situation.

We routinely monitor for the presence of drinking water contaminants. Water sample results received on [date] showed arsenic levels of [level and units]. This is above the standard, or maximum contaminant level (MCL), of 0.010 milligrams per liter.

What should I do?

- **You do not need to use an alternative water supply (e.g., bottled water).**
- This is not an emergency. If it had been, you would have been notified immediately. However, *some people who drink water containing arsenic in excess of the MCL over many years may experience skin damage or circulatory system problems, and may have an increased risk to getting cancer.*
- If you have other health issues concerning the consumption of this water, you may wish to consult your doctor.

What happened? What is being done?

[Describe corrective action]. We anticipate resolving the problem within [estimated time frame].

For more information, please contact [name of contact] at [phone number] or [mailing address].

Please share this information with all the other people who drink this water, especially those who may not have received this notice directly (for example, people in apartments,

nursing homes, schools, and businesses). You can do this by posting this public notice in a public place or distributing copies by hand or mail.

Secondary Notification Requirements

Upon receipt of notification from a person operating a public water system, the following notification must be given within 10 days [Health and Safety Code Section 116450(g)]:

- SCHOOLS: Must notify school employees, students, and parents (if the students are minors).
- RESIDENTIAL RENTAL PROPERTY OWNERS OR MANAGERS (including nursing homes and care facilities): Must notify tenants.
- BUSINESS PROPERTY OWNERS, MANAGERS, OR OPERATORS: Must notify employees of businesses located on the property.

This notice is being sent to you by [system].

** Indicates a system that has had annual concentrations averaging over the federal limit (10 ppb) each year 2011-2015*

^ Indicates that the 2011-2015 average includes years for which data was not available.

APPENDIX C:

Methods

This report is based on public data available from the California Environmental Protection Agency's State Water Resources Control Board (SWRCB) as of May 2016. We downloaded the SWRCB's Water Quality Analyses Database Files for 2011-2016 and identified public water systems that had arsenic concentrations that exceeded the 10 ppb Maximum Contaminant Level, targeting the systems with frequent exceedances between 2011 and 2015. The SWRCB database contained results for each water source used by a drinking water system, such as wells, treated or blended water, and standby wells that are only allowed to be used for a few days during a year. SWRCB warns users of its database that results in the database may not reflect the quality of water that systems actually served their customers.

Calculating average arsenic concentrations

- We calculated the average arsenic concentration from each individual water source at each water system using the sampling results available in SWRCB's database as of May 2016. Some sampling results from the end of 2015 may not have been available in the database at the time we downloaded the data in May.

- We reviewed each water system's source descriptions to determine which sources represented water served to consumers and whether the source should be included in the system-wide average arsenic concentration. For example, if the database showed that a system had two groundwater wells and a 'treated' source, we assumed that consumers would be served the treated source if results for that treated source were available each year. If the database listed a treated source in 2011, for example, but contained no data from that source for the following years, we excluded that source from the average because it was not clear if the system continued treating water for arsenic. If a system listed a source as inactive or as a 'standby' option, we excluded that source from the analysis because we could not determine when or if the water was used. We compared the selected sources with available Consumer Confidence Reports available through California's Drinking Water Watch system and narrative information in public SWRCB enforcement action documents to verify, to the extent possible, that the sources we selected represented water that was provided to consumers. If no information was available for a particular system, we relied on the

assumptions described above (i.e. inactive and standby sources were not used, treated sources were used instead of untreated sources when concentrations were available for each year). We did not include purchased water sources.

- After identifying individual sources, we calculated the system's annual average arsenic concentration using the annual average concentrations from each source. The average concentrations during the two-year period between 2014 and 2015 and the five year period between 2011 and 2015 are time-weighted average concentrations (i.e. we averaged the annual average concentrations from each year). This method is similar to how the California EPA's Office of Environmental Health Hazard Assessment calculated average concentrations at drinking water systems for use in it's 2014 CalEnviroScreen 2.0 tool, except we focused on annual average concentrations from 2011-2015, rather than a single average concentration from 2005-2013.

- We excluded entire systems from the analysis if a) they were inactive, b) the available data and source descriptions did not allow us to confidently assume that customers received the sampled water at their taps, and c) the average concentration over the most recent two years (2014-2015) fell below the MCL.

Mapping Public Water Systems

To map water system locations, we found the centroids of public water system boundaries from the California Environmental Health Tracking Program's Water Systems Geographic Reporting Tool, or Water Boundary Tool (WBT). For systems without boundaries in the WBT, we determined coordinates from the addresses in the SWRCB Water Quality Analysis database files and the California Drinking Water Watch system.

[19] The EPA describes arsenic's cancer-causing potency with a 'slope factor' (because it describes the slope of the dose-response curve). The current EPA slope factor for arsenic is 1.5 per mg/kg-d. This number represents the risk that can be expected from consuming one milligram of arsenic per kilogram of body weight per day. The EPA also translates the slope factor into a 'drinking water unit risk' of 5×10^{-5} per µg/L. For carcinogens, the formal MCL Goal is always zero. Zero is an unattainable goal, so in most cases the EPA will reduce exposure to carcinogens to a level of 'acceptable risk,' something between 10^{-6} (1 in 1,000,000) to 10^{-4} (1 in 10,000).[19] One way of looking at this range is to assume that risks less than 1 in 1,000,000 are always 'acceptable,' while risks greater than 1 in 10,000 never are. The risks of drinking arsenic at the MCL of 10 µg /L are much higher than 1 in 10,000.

[20] See, e.g., National Research Council, Critical Aspects of EPA's IRIS Assessment of Inorganic Arsenic – Interim Report, 82 – 83 (2013). For health endpoints like childhood IQ, the critical window of exposure is obviously much less, encompassing in utero development and childhood.

Yuba City, California 95991

Re: 2004 Pretreatment Evaluation

Dear Mr. Paulucci:

Enclosed is the April 30, 2004 report for our pretreatment evaluation of Yuba City. We ask that the City provide short written responses to each of the findings in Sections 2.0 to 8.0 of this inspection report by **July 30, 2003.** We expect to follow this inspection report with an Administrative Order that establishes a 12-month schedule for upgrading the pretreatment program, starting with the budget cycle on July 1.

The new NPDES permit incorporates a number of permit limits for pollutants that were unregulated in the past. There are now many pollutants of concern for which the City must develop and implement a source control program. One noteworthy finding of this inspection is that for most of the new pollutants of concern, the effluent levels for Yuba City exceed those for sewer districts representative of the industrialized Central Valley. Yuba City=s levels are partly explained by the ground water supply (*arsenic, barium*), water delivery system (*copper*), and the fact that the other districts perform advanced treatment, either nutrient removal or tertiary filtration, and thus have higher removal rates (*chromium, manganese, iron, silver*). Nevertheless, for a number of metals, non-domestic contributions appear to be the primary or at least a significant source in the Yuba City effluent (*aluminum, arsenic, copper, iron, manganese, mercury, molybdenum, selenium, and zinc*).

Otherwise, the most significant findings involve the unrepresentative self-monitoring by the industrial users over their reporting periods, the under-developed industrial user inventory, the incorrectly permitted significant industrial users, the lack of an updated sewer use ordinance as approved in 1995, and outdated local limits. Some of these issues were advanced in the EPA inspection reports and follow-up Administrative Orders to three significant industrial users in Yuba City. It is expected that their efforts to meet the requirements of their Administrative Orders will partly address the issues in this report.

Much of the City=s past efforts to regulate non-domestic contributions to the sewers will not have to be reconsidered or redone. In particular, the work done by the City to identify pollutant sources can be built upon, and the annual reports are informative. But the City will have to provide resources to do a number of required functions to address the deficiencies found in this inspection. Local limits will have to be redetermined. The ordinance will have to be

updated and adopted. Permits will have to be reissued to most significant industrial users. Self-monitoring requirements will have to be re-evaluated. Fact sheets will have to be prepared. All of these requirements are outlined in the enclosed inspection report.

Thank you for your cooperation during and after this inspection. Please do not hesitate to call (415) 972-3504 or e-mail arthur.greg@epa.gov.

Sincerely,

Industrial Users:	Sunsweet Growers, Jerry Ramsey, Engr Mgr, (530) 751-5278 Greenleaf Unit 2, Diane Tullos, Compliance Mgr, (530) 821-2074 Custom Chrome, Gene Hutchinson, Owner, (530) 673-2360

Report Prepared By:	Greg V. Arthur, Environmental Engineer April 30, 2004

Section 1

Introduction and Background

1.0 Scope and Purpose

In April 2004, EPA completed a performance evaluation of the regulatory control of non-domestic wastewaters discharged into the City of Yuba City wastewater treatment plant ("WWTP"). This performance evaluation was one of a series of reviews of small publicly-owned treatment works that accept non-domestic contributions, many of which are not large enough to be mandated to operate EPA-approved pretreatment programs. Yuba City is large enough and has operated an EPA-approved pretreatment program since 1982.

The scope of this performance evaluation comprised:

- Sampling inspection of the Yuba City wastewater treatment plant on August 27, 2003;
- Review of the 2003-2004 Yuba City self-monitoring reports;
- Review of the 2000-2004 influent and effluent sampling records for toxic pollutants;
- Inspections of three significant industrial users including the sampling of two of them;
- Review of the 2000-2003 sampling records for the significant industrial users inspected;
- Interviews with City representatives on August 5, August 20-21, and August 27, 2003;
- Review of the industrial responses to their inspection reports and enforcement actions.

The purpose of this evaluation was to determine if non-domestic discharges into the Yuba City sewer system are properly controlled. The evaluation findings were measured against two fundamental performance objectives. The first is the prevention of sewage treatment works pass-through, interference and sludge contamination as shown by compliance with the Federal sludge limits, the discharge permit limits, and any expected future Clean Water Act requirements. The second is the consistent compliance by the industrial users with their own Clean Water Act requirements, in particular with the Federal best-available-technology standards that apply to certain industrial categories, and any national prohibitions and local limits for pollutants associated with treatment works non-compliance.

This report covers the performance of the pretreatment program as it currently exists in Yuba City. Some pertinent findings from the industrial user inspections are also incorporated. The significant industrial users received individual reports and enforcement actions. Arthur collected samples on August 20, 21, and 27, 2003 for delivery to the EPA Richmond Lab.

1.1 Yuba City Wastewater Treatment Plant

The Yuba City WWTP is a pure-oxygen activated sludge plant that discharges either by diffuser to the Feather River in the winter wet-season or to 120 acres of percolation ponds

Section 1 – Introduction and Background

located alongside the river in the summer dry-season. The wastewater treatment plant provides high-rate treatment of higher-than-typical-strength wastewaters. It has a dry-weather design capacity of 7.0 million gallons per day ("mgd") and a wet-weather design capacity of 11.0 mgd. The average and calculated peak flows were 6.60 and 8.05 mgd in 2003. See Figure 1.

- Primary and Secondary Treatment - The headworks, which provide grinding and aerated grit removal, is followed by primary sedimentation. Ammonia and phosphates are added, usually in the summer, in order to precondition the high-strength and nutrient-poor contributions from Sunsweet Growers. Primary effluent is then aerobically biodegraded in three treatment trains each with four compressed-gas pure-oxygen aeration cells followed by three secondary clarifiers. Activated sludge returns without re-aeration in order to strip carbon dioxide, and does so at rates to support a mean cell residence time of around 3 days. Real-time metering for dissolved oxygen, solids, and redox potential are used to better ensure the treatment plant can respond to the contributions from Sunsweet.

- Advanced Treatment - There is no capability to provide nitrification or denitrification. There is also no tertiary polishing of secondary effluent and, as a result, no capability to reuse treated wastewater off-site.

- Solids Handling - Waste secondary activated sludge and primary sludge are digested in two anaerobic digestors each with detention times of 25 days and operated in series. Digested sludge dosed with anionic polymer is dewatered through belt pressing, with the cake further dewatered in on-site sludge drying beds for off-site disposal as landfill cover. Grit is hauled off-site to a landfill. The waste activated sludge is first thickened in two polymer-aided dissolved air flotation units. Belt press filtrate returns to the lateral leading into the headworks. Dissolved air flotation subnatant returns to the aeration cells.

- WWTP Sampling - The influent sampling point, located upstream of the headworks is designated as IWD-YC1 for the purposes of this report. All return flows except the belt press filtrate rejoin treatment downstream of influent sampling. The effluent compliance sample point, sited immediately after final dechlorination, is designated as IWD-YC2. The accumulation of filter cake for hauling off-site is designated as the sludge sampling point, IWD-YC3. The receiving water sampling point downstream of the Yuba City outfall is designated in the permit as R-1.

- Water Supply - For most of its sewered users, Yuba City provides surface water drawn from the Feather River and treated through its water treatment plant. Some sewered customers located outside of the city limits receive untreated ground water from the former Hillcrest Water Company system. According to the City's Urban Water Management Plan, an estimated 1,000 of the 9,020 water users receive the more mineralized ground water. For the purposes of this report, a ratio of 1:9 ground to surface water was used in estimating the flow-weighted average concentrations for the water supply.

- Receiving Water Hardness - The USGS maintains a station on the Feather River at Nicolaus, approximately 13 miles downstream from the Yuba City outfall. This station and six others in Sacramento River basin were extensively sampled under a full range of conditions for conventional, toxic, and pesticide-related pollutants, as part of the 1995-1998 National Water Quality Assessment Program. The calculated 99th% minimum hardness and the minimum sample result for the Feather River station was 22.6 mg/l and 22 mg/l as CaCO3. The lowest minimum sample result recorded for all seven stations both upstream and downstream of the Feather River station was 16 mg/l. For the purposes of this report, a hardness of 22.6 mg/l is used in the calculations of the permit limits for metals to be in effect in 2007. By then, Yuba City will have a better data set of hardness values for the Feather River near the outfall, as required by the NPDES permit.

1.2 Sewer Service Area

The Yuba City sewer service area comprises the incorporated area of the city that receives city supplied surface water as well as the unincorporated county lands southwest of the city limits that receive ground water. The WWTP also serves as a regional disposal point for septage collected from septic tanks in unsewered areas within both the city limits and in the outlying county land. According to the City's Urban Water Management Plant, the service area has a population in 2004 estimated to be 60,000, and 950 commercial and four industrial users, who together contribute 35-40% of the sewered wastewater. The inventory of industrial users includes at least seven considered to be significant industrial users who together discharged an average of 930,000 gallons per day into the sewers in 2003 (14% of total flows).

1.3 Discharge Requirements

Yuba City is authorized by the June 6, 2003 RWQCB Waste Discharge Requirements, Order R5-2003-0085, ("WDRs"), and a concurrent Cease and Desist Order, Order No. R5-2003-0086, ("CDO"), to discharge treated sewage from the Yuba City WWTP either to the Feather River or to percolation ponds sited along the river or from the percolation ponds to the Feather River. The WDRs also function as National Pollutant Discharge Elimination System ("NPDES") permit CA0079260. The WDRs contain narrative prohibitions, effluent limits that implement the California Toxics Rule, receiving water limitations, monitoring requirements, pretreatment provisions, and sludge disposal requirements. In essence, the WDRs and CDO together require Yuba City to comply with effluent limits for conventional pollutants, disinfection, and pH upon issuance of the permit and for pesticides, metals, surfactants, toxic organics, ammonia, and nitrates by November 2007.

The effluent limitations for a discharge to the Feather River are for conventional pollutants, total coliform, ammonia based on temperature and pH, nitrites and nitrates, surfactants, residual chlorine, pH, acute biotoxicity, and various pesticides, metals, and toxic organics. The effluent limits that take effect on November 1, 2007 are for additional metals based on

the hardness in the river, and for additional toxic organics. The CDO required the completion of the corrective steps necessary to meet the WDRs for organochlorine pesticides, thiobencarb, aluminum, ammonia, arsenic, chloroform, diazinon, cis-1,2-dichloroethene, ethion, iron, manganese, MTBE, surfactants, molybdenum, and nitrates also by November 1, 2007.

The limitations for a discharge to percolation ponds are limited to narrative prohibitions against public contact, objectionable odors, anoxic conditions, the proliferation of mosquitoes, inadequate freeboard, degraded ground waters, and exceeding numerical limitations for pH. The receiving water limitations include narrative provisions against causing a visible film, discoloration, objectionable growths, nuisance conditions, the bioaccumulation of toxics, bad tasting fish, increased temperatures over 5°F, increased turbidity, increased specific conductivity, high or low pH's, and any adverse effect on the beneficial uses of the receiving waters.

1.4 Legal Authorities

Yuba City obtained approval of its pretreatment program in 1982. Yuba City operates under the authority of Public Works Title 6, Wastewater Collection and Treatment Chapter 5 of its municipal code as adopted in 1976. Yuba City began the process of revising its ordinance to be in accord-ance with the requirements of 40 CFR 403 in the late 1980's and submitted a draft ordinance for review in 1990. EPA and the RWQCB provided numerous and extensive reviews of the ordinance culminating in an approval letter from the RWQCB issued on November 29, 1995. Yuba City has not readopted the revised ordinance. As a result, the local limits and the regulatory provisions in effect are those in the 1976 ordinance. The WDRs since 1990 have imposed pretreatment provisions that require implementation of the regulatory controls necessary to enact all of 40 CFR 403. The current WDRs issued in June 2003, require Yuba City to resubmit pretreatment program for approval. Requirements to obtain and implement an approved pretreatment program would include the following:

- The implementation of the general and specific national prohibitions in 40 CFR 403.5 for industrial users against the introduction of incompatible wastewaters;
- The requirement in 40 CFR 403.5 to develop locally-determined limits necessary to protect the treatment works from potential adverse impacts, such as operational interference, worker health and safety risks, the pass-through of pollutants to the receiving waters, and sludge contamination;
- The performance of the program functions set forth in 40 CFR 403.8, such as identifying industrial users, issuing permits, inspecting and sampling industrial users, providing adequate funding, and enforcing against violators;
- The implementation of an industrial users self-monitoring program under 40 CFR 403.12;
- The implementation of Federal categorical standards under 40 CFR 403.6; and
- The enacting of the local legal authorities necessary to operate an approved pretreatment program under 40 CFR 403.8.

Section 1 – Introduction and Background

This evaluation did not involve a review of the 1976 ordinance because the proposed 1990 revised ordinance has not been adopted. As a result, the administrative record since the late 1980's stands as the determination that Yuba City does not have the legal authority to implement all aspects of an approved pretreatment program.

Section 2

Wastewater Treatment Plant Performance

The Yuba City WWTP must meet permit effluent limits for conventional pollutants, nutrients, pesticides, metals, toxic organics, pH, surfactants, and biotoxicity. 40 CFR 403.5(a,b,c) and 403.6.

Non-domestic wastewaters may not result in unpermitted releases, hazardous or explosive conditions with the sewers, or operational interferences in the collection system. 40 CFR 403.5(b).

2.0 Summary

The WWTP has the capacity and capability to handle the domestic wastewaters in the Yuba City service area as well as the high-strength wastes generated by Sunsweet. However, without a change in the influent loadings, removal rates, or disinfection methods, the WWTP is expected to experience the pass-through of a number of metals, chlorination byproducts, toxic organics, and pesticides once their NPDES permit limits take full effect in 2007. Moreover, without nitrification and denitrification, the WWTP is also expected to experience the pass-through of ammonia and the toxicity associated with ammonia. Finally, the nutrient-poor nature of Sunsweet's contributions caused operational interferences related to WWTP responses, however, better metering has lessened those risks.

See Tables 1 - 3 for wastewater and sludge summaries, Table 4 for statistical probabilities of violation, Table 5 for a comparison of Yuba City with representative Central Valley sewer districts, Table 6 for the EPA sampling results, and Table 8 for the definitions of 'pass-through' and 'interference'.

Requirements

- The domestic, non-domestic, and water supply sources of aluminum, arsenic, copper, iron, manganese, molybdenum, and zinc must be identified and quantified.

Recommendations

- The wastewater treatment plant influent should be monitored for aluminum, arsenic, copper, iron, manganese, mercury, molybdenum, selenium, and zinc.
- The receiving waters should be monitored for hardness, pH, and temperature.
- The cause of the instances of low pH in the influent should be determined.

Section 2 – Wastewater Treatment Plant Performance

Recommendations – continued

- Corrosion controls of the water delivery system should be implemented in order to reduce the leaching of copper, thereby reducing the copper discharged from the treatment plant.
- Sunsweet and septage deliveries should be monitored for the farm-related contaminants such as arsenic and selenium.
- Sunsweet and the power plants should be monitored for the corrosion-related contaminants associated with circulating water systems such as iron, molybdenum, and zinc.
- A specific prohibition against abrupt changes in organic loads, such as a restriction in the percentage change in mass loads per day, should be considered for Sunsweet.
- The water service newsletter should be supplemented to also inform rate payers of the wastewater compliance status and the on-going need to fund the capital improvements, pretreatment, and operations to protect and maintain the public wastewater investment.

2.1 Conventional Pollutants

The WWTP produces high-quality secondary-treated wastewaters. As a result, it consistently complies with its permit limits for conventional pollutants. The average and calculated 99th% peaks are less than 11 and 22 mg/l BOD and 9 and 16 mg/l TSS even through Sunsweet's contributions elevate the average influent BOD to 339 mg/l. The WWTP discharged to the percolation basins May 1 through October 31, and to the river otherwise.

There were four instances of the effluent pH below the lower 6.5 limit and one above the upper 8.5 limit. There were also two unrelated instances of low influent pH, (2.62 on 11/14/03 and 4.99 on 11/22/03). The national prohibitions not only prohibit discharges that cause structural damage to the sewerage works but also specifically prohibit discharges below 5.0 s.u. because pHs below that level are known to cause concrete degradation.

2.2 Ammonia Toxicity

The permit sets sliding-scale effluent limits for ammonia which are most stringent when pH and temperature are high. During the winter wet-season when the WWTP discharges to the Feather River, the monthly-average and sample-maximum ammonia limits bottom out at 3.56 and 19.7 mg/l based on and assumed maximums for pH and temperature of 7.2 s.u and 70ºF. Sampling required by the permit would result in actual values for maximum pH and temperature in the Feather River and better establish the ammonia limits. Against these preliminary sliding-scale ammonia limits, the WWTP inconsistently complies when it discharges to the river, with the average and calculated 99th% peak ammonia concentrations

of 12.9 and 36.9 mg/l. As a result, there is a >20% chance of violating the lowest expected maximum limit and 99%+ chance of violating the lowest expected monthly-average limit.

2.3 Nitrates Plus Nitrites

The WWTP complies with the permit limits for nitrite plus nitrate of 10 mg/l primarily because it does not nitrify by design. The WWTP would be expected to comply with the permit limits upon the 2007 compliance deadline only upon completion of upgrades for both full nitrification and denitrification.

2.4 Salts

The permit does not limit salts but requires monitoring for total dissolved solids, hardness, and electrical conductivity. The monitoring results for salts are all well below what could adversely impact reuse, or in the case of sulfate, impart an acute toxicity.

2.5 Toxic Metals

Without decreased loadings, corrosion controls, or increased removals, the WWTP would be expected to exceed the permit limits for aluminum, arsenic, copper, iron, lead, manganese, molybdenum, and zinc. See Table 2 for a summary of toxics in the influent, effluent, and water supply, Table 4 for statistical probabilities of exceeding limits, and Table 5 for comparisons with representative of Central Valley sewer districts with industrial contributions. (The sewer districts selected for comparison were Deer Creek, El Dorado Hills, Grass Valley, Nevada City, Placer County No.1, Red Bluff, and Stockton.)

For most metals, the effluent concentration averages for Yuba City exceed the averages for sewer districts representative of the industrialized Central Valley. Elevated levels for Yuba City are partly explained by the water supply (*arsenic, barium*), water delivery (*copper*), and the fact that the other districts perform advanced treatment of some sort, either nutrient removal or tertiary filtration, and thus have higher removal rates (*chromium, manganese, iron, silver*). Nevertheless, for a number of metals, unidentified non-domestic contributions appear to be the primary or at least a significant cause of the elevated levels in the Yuba City effluent *(aluminum, iron, manganese, mercury, molybdenum, selenium, zinc*).

Aluminum - Influent concentrations are significantly higher than can be explained by the water supply or known non-domestic sources. In fact, the influent levels are so high, up to 6,225 µg/l, that the sources are likely limited to utilities' use of alum for water, wastewater, or sludge conditioning or water conditioning at industries that discharge the generated sludges or backwashes. A sample of 3,600 µg/l from Greenleaf Unit 2 partly bears this out. Since the 85%+ removal rate is typical for secondary wastewater treatment, not only the influent but also effluent concentrations far exceed the averages for representative Central

Section 2 – Wastewater Treatment Plant Performance

Valley sewer districts. The effluent average and calculated 99th% peaks are 256 and 571 µg/l resulting in a >80% chance of a sample violating the 120 µg/l maximum limit.

Arsenic - Influent concentrations are higher than can be explained by known sources. The ground water used in part of the city accounts for nearly half of the elevated influent levels. However, for the remainder, arsenic in fruit pesticides makes it possible that fruit washing at Sunsweet and farm-related run-off or septage are likely sources that account for the increases from 2.5 µg/l in the water supply to 6.1 µg/l in the influent. Both the average influent and effluent concentrations are >400% higher for Yuba City than for representative Central Valley sewer districts. The effluent average and calculated 99% peaks are 7.8 and 33.5 µg/l which result in a >40% chance of samples violating the 10 µg/l monthly limit.

Barium - The permit does not set effluent limits for barium. Average effluent concentrations are >400% higher than representative Central Valley sewer districts, and ground water may account for nearly half of the elevated levels. Potential non-domestic sources might include the removal of barium sulfate deposits from circulating cooling water circuits.

Cadmium - The industrial discharge from Custom Chrome is the likely source of the small concentrations of cadmium found in the influent and effluent. No cadmium was detected in the water supply and the WWTP levels are consistent with those for representative Central Valley sewer districts. The effluent average and calculated 99% peaks are 0.17 and 0.31 µg/l which result in far less than a 1% chance of a sample exceeding the calculated 0.85 µg/l maximum limit.

Chromium - The industrial discharge from Custom Chrome is the likely source of the small concentrations of chromium found in the influent and effluent. No chromium was detected in the water supply and the WWTP levels are consistent with those for representative Central Valley sewer districts. The effluent average and calculated 99% peaks are 0.94 and 1.14 µg/l which result in far less than a 1% chance of a sample exceeding the calculated 106 µg/l maximum limit.

Copper – Corrosion of household plumbing appears to be the principal source. Surveys conducted by Yuba City found 10% of the households with copper concentrations at their taps over 199 µg/l if served by surface water and 459 µg/l if served by ground water. These concentrations are high enough to account for the significant increases from 1.3 µg/l in the surface water supply to 50.1 µg/l in the WWTP influent. The removal rate of 80%+ is in the typical range for secondary wastewater treatment. As a result, the effluent average and calculated 99th% peaks are 8.5 and 18.7 µg/l which result in a >90% chance of a sample violating the 2.65 µg/l maximum limit. This means Yuba City is likely to nearly always exceed permit limits without preconditioning the water supply to inhibit corrosion.

Section 2 – Wastewater Treatment Plant Performance

The principal corrosion control methods in use by other water suppliers include the following:

- carbonate passivation of copper pipes through the increase of both pH and alkalinity,
- silicate passivation of copper pipes through the application of sodium silicates and sodium carbonate, and
- precipitation of scale within the pipes through the supersaturation of calcium.

(EPA publication EPA-811-B-92-002, September 1992, "Lead and Copper Rule Guidance Manual, Vol. II: Corrosion Control Treatment).

Iron - Lone samples of 15,000 and 9,800 µg/l from Sunsweet and Greenleaf Unit 2, respectively, could easily account for the significant increase between the flow-weighted average of 25.3 µg/l for the water supply and the average WWTP influent of 960 µg/l. The removal rate of 80%+ is typical for secondary wastewater treatment. The effluent concentrations exceed the averages for repre-sentative Central Valley sewer districts. The effluent average and calculated 99th% peaks are 164 and 309 µg/l which result in a slight >1% chance of a sample violating the 300 µg/l maximum limit.

Lead - There is not enough data to make conclusions regarding future compliance with the 0.83 µg/l maximum or 0.38 µg/l monthly-average limits. All water supply samples were below detection, but the 1 µg/l detection limit is over the limits.

Manganese - Effluent concentrations are far higher than typical for representative Central Valley sewer districts because treatment plant removals are essentially 0% in Yuba City but between 60% and 97% at the representative Central Valley sewer districts. The effluent average and calculated 99th% peaks are 53 and 156 µg/l which result in a >50% chance of a sample violating the 50 µg/l maximum limit. Influent concentrations are typical for representative sewer districts, although there are no sources identified at this time that could account for the increase between the flow-weighted average for the water supply of 11.5 µg/l and the WWTP influent of 49.8 µg/l.

Mercury – There is a negligible chance of even a single sample violating the 0.05 µg/l monthly-average limit, even though both influent and effluent concentrations exceed the averages for representative Central Valley sewer districts. The removal rate of 95%+ is typical for secondary wastewater treatment. Effluent average and calculated 99th% peaks are 0.017 and 0.048 µg/l.

Molybdenum - Molybdate is a corrosion inhibitor in widespread use in circulating cooling water circuits, which account for a significant fraction of the non-domestic contributions into the Yuba City sewers. As a result, circulated cooling at Sunsweet and the power plants are likely sources of the significant increase in the average concentration from less than 1.0 µg/l in the water supply to 10.3 µg/l in the influent. Both influent and effluent concentrations exceed the averages for the representative Central Valley sewer district with molybdenum

samples. The effluent average and calculated 99th% peaks for Yuba City are 11.0 and 31.6 µg/l which result in a >50% chance of a sample violating the 10 µg/l maximum limit.

Nickel - The industrial discharge from Custom Chrome is the likely source of the small concentrations of nickel found in the influent and effluent. No nickel was detected in the water supply and the WWTP levels are consistent with representative Central Valley sewer districts. The effluent average and calculated 99th% peak concentrations are 1.78 and 3.96 µg/l, which result in less than a 1% chance of a sample violating the 23.6 µg/l maximum limits.

Selenium - The permit does not set effluent limits. Selenium has farm-related uses in veterinary medicine, fungicides, and insecticides. As a result, fruit washing at Sunsweet and farm related run-off or septage are likely sources of the increase in the average concentration from less than 1.0 µg/l in the water supply to 7.1 µg/l in the influent. Both influent and effluent concentrations far exceed the averages for the representative Central Valley sewer district. The effluent average and calculated 99th% peaks for Yuba City are 7.1 and 44.7 µg/l.

Silver - There is not enough data to make conclusions regarding future compliance with the 0.31 µg/l maximum limits, even though the single effluent sample exceeded the limit. All water supply samples were below detection, but the 1 µg/l detection limit is over the limit.

Zinc - Zinc phosphates are corrosion inhibitors in widespread use in circulating cooling water circuits, which account for a significant fraction of the non-domestic contributions into the Yuba City sewers. As a result, the circulated cooling at Sunsweet and the power plants are likely sources of the huge increase in the average concentration from less than 1.0 µg/l in the water supply to 157 µg/l in the influent. The influent and effluent concentrations are within the ranges at the representative Central Valley sewer districts. The effluent average and calculated 99th% peaks for Yuba City are 51.8 and 86.7 µg/l which result in a >80% chance of a sample violating the 34.0 µg/l maximum limit.

2.6 Toxic Organics and Pesticides

A number of other toxic pollutants were detected but most of them did not or will not exceed the permit limits. Those detected but not exceeding permit limits include MTBE (*methyl-tert-butyl ether*). The principle exceptions were the permit limits for two chlorination byproducts (*dichloro-bromomethane, dibromochromomethane*), a pesticide (*diazinon*), and two chlorinated solvents (*chloroform, tetrachloroethylene*). However, no definitive conclusions regarding any of these pollutants can be made at this time because there are only three samples for each and the permit limits are not much higher than the detection limits.

Section 2 – Wastewater Treatment Plant Performance

2.7 Federal Sludge Limits

The WWTP sludges consistently comply with the Federal sludge limits for disposal as landfill cover. The WWTP sludges also would likely consistently comply with the Federal clean sludge limits suitable for any reuse in Table 3 of 40 CFR 503.13 although the more stringent limits do not apply as long as the Yuba City disposes of sludge as landfill cover.

2.8 WWTP Interference

Sunsweet poses two operational risks to the Yuba City treatment works. First, sharp drops in loadings have in the past resulted in operational interferences at the WWTP related to the treatability of the nutrient-deficient discharges from Sunsweet and the responsive dosing of nutrients by Yuba City. Second, the high-strength organic discharges could cause sulfide degradation of concrete sewers if they become anoxic.

Yuba City has instituted permit requirements to Sunsweet to keep the pH above 8.5 and to provide 48-hour prior notification for impending shutdowns of more than 24 hours. Yuba City also has real-time probes with automatic alarms for dissolved oxygen, solids, and redox potential at various locations in the WWTP. Nevertheless, within the permit requirements, the variabilities in the organics, suspended solids, and hydraulic loadings from Sunsweet still have the potential to be large enough to adversely effect the operation of the WWTP because the mitigating actions rely solely on operators and procedures. It would be better for the City if Sunsweet installed some form of built-in load equalization that does not rely on operating procedures. See the February 20, 2004 EPA report of the inspection of Sunsweet and Sunsweet's May 26, 2004 response for a larger discussion.

Section 3

Local Limits

Pretreatment programs are required to develop local limits to prevent pass-through, interference, sludge contamination or other adverse effects upon the treatment works. 40 CFR 403.5(c).

3.0 Summary

Yuba City has an ordinance to prohibit discharges that exceed local limits or could harm the treatment works. However, the technical basis of the local limits is questionable since they are not based on the current conditions or permit. Furthermore, Yuba City did not adopt an updated sewer ordinance reviewed by EPA and approved by the RWQCB to reflect changes in the Federal pretreatment rule promulgated after 1982. Sampling has indicated that without a change in the influent loadings, or removal rates, the WWTP would be expected to experience the pass-through of a number of metals, toxic organics, and pesticides once the permit limits take full effect in 2007. See Table 7 for a definition of 'local limits'. Also see Item 1.4 of this report for more detail regarding Yuba City's legal authority.

Requirements

- Yuba City must determine the maximum allowable headworks loadings for aluminum, arsenic, copper, iron, manganese, molybdenum, and zinc, and enact new local limits, prohibitions or control strategies.
- The sewer use ordinance must be updated to reflect the changes in the Federal rules.

Recommendations

- The WWTP influent and effluent should be sampled to determine whether diazinon, chloroform, tetrachloroethylene are pollutants of concern present at levels above their detection limits.

3.1 Sewer Use Ordinance

This pretreatment program evaluation did not include a new review of the sewer use ordinance. However, the ordinance has not be updated to reflect the changes in the Federal pretreatment rules in the ways outlined in the reviews by EPA of the ordinance and culminating in the approval letter issued by the RWQCB on November 29, 1985.

Section 3 – Local Limits

3.2 National Prohibitions

The national prohibitions apply to every non-domestic discharge into the sewers nationwide to prevent harm to the treatment works. They consist of the general prohibitions in 40 CFR 403.5(a) against harm and the specific prohibitions in 40 CFR 403.5(b). In practice, local limits, covering a range of pollutants, and developed in accordance with 40 CFR 403.5(c), replace most of the effective span of the national prohibitions.

3.3 Pollutants of Concern

The pollutants of concern are those related to non-domestic sources with a statistical chance of over 1% to cause a violation of the WDRs or the Federal sludge limits. The pollutants with a statistical chance over 1% are aluminum, ammonia, arsenic, chloroform, copper, diazinon, dibromochloro-methane, dichlorobromomethane, iron, lead, manganese, molybdenum, tetrachloroethylene, and zinc. Of these, dibromochloromethane and dichromobromomethane would not be pollutants of concern because they are chlorination by-product unrelated to influent quality. Ammonia and nitrates also would not be pollutants of concern because their effluent concentrations are a function of the treatment plant operations. It cannot be determined without further monitoring of both the influent and effluent whether diazinon, chloroform, and tetrachloroethylene are pollutants of concern.

A number of other pollutants with a statistical chance below 1% to cause a violation, nevertheless, should be pollutants of concern because of discernible sources. Cadmium, chromium, and nickel are entrained in solution and rinse tanks at metal finishers (*Custom Chrome*). Selenium is associated with farm-related uses (*Sunsweet, septage*). Lead and barium are scoured from boilers (*Sunsweet, power plant*). Mercury has non-domestic commercial sources (*dentists*). MTBE at aquifer clean-up sites are pollutants of site-specific concern. And oil & grease is a concern in every sewer district.

3.4 Maximum Allowable Headworks Loadings

Every sewer district must determine the maximum loading of pollutants it can accept and still comply with the permit requirements and Federal sludge limits. The maximum allowable headworks loadings ("MAHLs") form the technical basis for determining local limits. All this requires influent, effluent, and sludge monitoring under the range of conditions expected during the year, in order to determine the WWTP removal efficiencies. EPA has a free spread sheet program called Prelim to assist in the calculations. WEF also has a fate and transport model available for purchase on its web-site.

Section 3 – Local Limits

3.5 Allocation Method

The MAHLs for each of the pollutants of concern must be allocated between uncontrollable and controllable sources. The uncontrollable sources comprise domestic sewage, and infiltration and inflow. The controllable sources are those that could be regulated under permits or best-management practices. This will require background monitoring of domestic sewage, and infiltration and inflow, in order to determine the pollutant loadings that cannot be allocated to the controllable sources. The remaining loadings can then be allocated in any fashion to the individual industrial and commercial sources. For example, Yuba City could set different local limits by individual industrial discharge, or by flow-weighted average, or uniformily across the entire service area for some pollutants but differentially set for others. The allocation method does not matter as long as the total allocation out to the domestic and non-domestic users does not exceed the calculated MAHLs.

It is possible that the main sources of certain pollutants are domestic in nature and largely uncontrollable by ordinance through permitting or best-management practices. For example, significant loadings of copper likely come from the delivery pipes and pesticides may come primarily from infiltration and inflow off of nearby fields, or household use. In these cases, Yuba City would have to redetermine the MAHLs after the sources are mitigated through some other means.

3.6 Industrial User Compliance with Local Limits

The Federal regulations do not define how to determine regulatory success. Moreover, any conclusion regarding industrial user compliance with the local limits would be premature since they are not technically-based to protect the Yuba City treatment works from adverse impacts, and the sources of the pollutants of concern are not yet identified. Once the local limits are sound and implemented through industrial user permits, however, the following performance measures determine regulatory success in achieving industrial user compliance.

- Treatment Plant Performance - EPA Region 9 bases its primary determinations on the purpose of local limits and the national prohibitions to prevent pass-through, interference, sludge con-tamination, or potential worker safety risks. As a result, the best measure of a program's effectiveness is consistent compliance with the NPDES permit and sludge limits. By this measure, Yuba City would not be successful if the pass-through of aluminum, arsenic, chloro-form, copper, diazinon, iron, lead, manganese, molybdenum, tetrechloroethylene, and zinc continues to persist.

- Cost Effective On-Site Treatment - Conventional pollutants can be treated at the sources and the sewage treatment plant. In general, primary treatment for solids and organics, pH adjustment, and gravity oil-water separation, are cost effective at the sources, while secondary treatment for dissolved organics, nitrification and denitrification are much more cost effective at the sewage treatment plant. On the other hand, toxics must be entirely controlled by the sources since sewage treatment plants are not designed to for

Section 3 – Local Limits

toxics. By this measure, Yuba City would not be successful in ensuring all non-domestic dischargers of acidic and alkaline wastewaters provide final pH adjustment.

- Significant Non-Compliance - Significant non-compliance will be based on industrial user compliance rates once the local limits are re-developed and implemented into the permits.

Section 4

Industrial User Compliance with Federal Standards

Pretreatment programs are required to be administered to ensure industrial user compliance with Federal categorical pretreatment standards. 40 CFR 403.8(b).

4.0 Summary

Best-available-technology ("BAT") treatment or its equivalent was not applied and in place at the identified Federally-regulated industrial process within the Yuba City service area.

Requirements

- Compliance sampling points, monitoring requirements, and on-demand rinsing practices must be established and implemented in order to determine whether treatment is necessary at Custom Chrome.

Recommendations

- The operational and disposal procedures to ensure compliance with Federal categorical pretreatment standards through the achievement of zero-discharge should be determined.

4.1 Treatment In-Place

EPA Region 9 uses two performance measures that together reflect the purpose of the various Federal categorical pretreatment standards to bring about the nationwide use of model BAT treat-ment. The first measure is BAT treatment across the industrial inventory. The Federal standards for each Federally-regulated industrial category were based on the statistical performance of model BAT treatment as it is separately defined for each category. For job-shop electroplating, BAT treatment is metals precipitation, settling and solids removal, and if necessary, cyanide destruction and chromium reduction.

The lone industrial user identified during this evaluation by EPA as a Federally-regulated user, was not found to comply with its Federal standards either through BAT treatment or through facility configurations and practices to keep from discharging to the sewers.

Custom Chrome - This metal finishing job-shop is required to comply with either the expanded list of pollutants in the Federal job-shop electroplating for dischargers over 10,000 gpd, or the abbreviated list of standards for dischargers under 10,000 gpd. Compliance cannot be determined at this time with either set of standards because the rinses discharge continuously irrespective metal finishing work and the spent solutions

are not specifically monitored. This constitutes "dilution as a substitute for treatment" since the Federally-regulated wastewaters discharge without treatment for metals or cyanide. None of the previous samples are usable for the determination of compliance.

- Power Plants - No Federal categorical standards apply (*Calpine Greenleaf Unit 2, Calpine Feather River Energy Center, Calpine Yuba City Energy Center, and Yuba City Cogeneration*).

4.2 Comparison with Model IU Performance

The second measure, derived from statistical comparisons with the performance of model categorical industrial users, only applies to larger industrial user inventories.

Section 5

Industrial User Inventory

Pretreatment programs are required to develop a complete inventory of industrial users, as part of ensuring industrial user compliance. 40 CFR 403.8(b,f1iii,f2i).

5.0 Summary

Yuba City has identified for regulation its significant industrial users ("SIUs"). However it has misclassified the SIUs qualifying as either categorical industrial users. Yuba City does not have a current inventory of non-significant industrial users nor of any zero-discharge categorical industrial users who would be subject to Federal standards if they discharged. Yuba City does have an unverified business list. See Table 7 for a list of identified SIUs and Table 8 for a definition of SIU.

Requirements

- Yuba City must field verify its industrial user inventory and institute formal documented procedures to continually identify additions, deletions and changes.
- Yuba City must re-identify the SIUs in its inventory as categorical, non-categorical, and zero-discharging categorical.

Recommendations

- Yuba City should maintain its industrial user inventory by non-domestic wastewater discharge point, with each discharge point characterized by Federal point source category, annual average flow rate, type of wastewater, and owner or operator.

5.1 Inventory Completeness

Yuba City has identified SIUs but has not identified, visited, or permitted all of its commercial and industrial users in its sewer service area. As a result, EPA could not produce a completed inventory during this performance evaluation and cannot verify that all SIUs are identified. The following four characteristics would be considered by EPA as good indications of a complete inventory. First, the inventory should include commercial sources, such as dentist, supermarkets, restaurants, and automobile repair shops, none of which would be expected to pose a significant risk to the treatment works. Second, the inventory should include commercial and industrial dischargers of less than 25,000 gpd designated by SIC code. Third, the inventory should include "zero-dischargers" that would be categorical if they discharged. Fourth, the industrial users with multiple non-domestic discharges to the

sewers should be identified and permitted by separate discharge points. All of these modifications to the basic definition in 40 CFR 403.3(t) of an SIU are good indications of the successful identification of the potential threats to its treatment works. EPA found none of these modifications to the basic definitions in effect in Yuba City, however, the inventory would include two non-categorical power plants with discharges averaging less than 25,000 gpd once they are reclassified.

5.2 Inventory Classifications

The Yuba City must re-determine which industries qualify as SIUs and re-classify the five of SIUs identified by Yuba City that were found to be misclassified.

- Custom Chrome - Job-shop electroplaters subject to the Federal standards in 40 CFR 413 qualify for regulation under either a full set of regulated pollutants or an abbreviated set depending on the discharge flow rate. If every day of discharge to the sewers is under 10,000 gpd, then the abbreviated set of standards apply for cadmium, lead, cyanide, and toxic organics. If any one day exceeds 10,000 gpd, then the full set of standards apply for cadmium, lead, cyanide, and toxic organics, as well as chromium copper, nickel, silver, and zinc. Yuba City classified Custom Chrome as a job-shop electroplater discharging more than 10,000 gpd. Custom Chrome has show that its average discharges are less than 10,000 gpd. It is not clear that there is not any one day exceeding 10,000 gpd. EPA expects Custom Chrome to qualify as a job-shop electroplater that always discharges less than 10,000 gpd once it documents its daily discharges and reduces flow by instituting on-demand rinsing in response to an EPA Order.

- Calpine Greenleaf Unit 2 - This industry qualifies as an SIU because the highly mineralized nature of its wastewater discharges poses the risks of sewer line disintegration and the pass-through of toxics. Furthermore, its discharges average more than 25,000 gpd. It was misclassified as a steam electric power generating station subject to the Federal standards in 40 CFR 423. It does not qualify because it does not generate any power through steam-driven turbines. The steam electric rule would cover combined-cycle cogeneration plants that use steam-driven turbines to generate power from exhaust heat.

- Calpine Feather River Energy Center - This industry qualifies as an SIU and was misclassified as a steam electric power generating station for the same reasons stated above for Calpine Greenleaf Unit 2.

- Calpine Yuba City Energy Center - This industry qualifies as an SIU and was misclassified as a steam electric power generating station for the same reasons stated above for Calpine Greenleaf Unit 2, except its discharges do not average more than 25,000 gpd.

Section 5 – Industrial User Inventory

- Yuba City Cogeneration - This industry qualifies as an SIU and was misclassified as a steam electric power generating station for the same reasons stated above for Calpine Greenleaf Unit 2, except its discharges do not average more than 25,000 gpd.

- Sunsweet and Franklin Circle K - These are properly classified as non-categorical SIUs.

- Metal-Bearing Discharges - These might include glass polishers, metal finishers, metals formers, radiator shops, water purification facilities, and agricultural-chemical sources. See the discussion in item 2.5 of this report for sources of aluminum, arsenic, copper, iron, manganese, molybdenum, and zinc. Possibles: Chipco Mfg., Transitional Systems Mfg., Cal Classic Custom Trim.

- Other Possibles - These would include any other large dischargers, categoricals, or toxic loaders. Possibles: Paperboard Packaging Corp.

5.3 Zero-Discharging Categorical Industrial Users

Yuba City should institute the good practice of identifying and permitting industrial users that would qualify as categoricals if they discharged their Federally-regulated process-related wastewaters to the sewers. In essence these are the industrial users that comply with their Federal standards by maintaining the steps necessary to prevent the discharge of process-related wastewaters to the sewers. Including zero-discharging CIUs in the inventory ensures the local regulatory control over industrial users who would violate their Clean Water Act requirements and could endanger the operations of the treatment works if they discharged to the sewers.

Section 6

Industrial User Permits

Pretreatment programs are required to issue permits with standards and limits, sampling locations, self-monitoring requirements, and a 5-year or less expiration, as part of ensuring industrial user compliance. 40 CFR 403.8(b,f1iii,f2i).

6.0 Summary

Yuba City has a good permit program and has successfully issued valid permits to all of its identified SIUs. The permits all have standards and limits, self-monitoring requirements, and a 2-year expira-tion, but they do not specify sampling locations nor define what constitutes representative sampling. Permits will have to be re-issued once the local limits are re-determined, the SIU inventory is re-determined, and the Federal standards are re-applied. See item 7.0 for this report for a discussion on representative sampling.

Requirements

- Each permit issued to an SIU must explicitly state all applicable Federal standards, national prohibitions, and local limits, as well as the self-monitoring and reporting requirements, and sampling locations.

Recommendations

- Permits should be issued with the applicable Federal standards and national prohibitions, and then reissued to include the local limits once they are re-determined.
- Each permit issued to an SIU should list all standards, limits, self-monitoring and analytical requirements on one page, and the sampling location(s) on a site map.
- The information in the permit applications as well as any other information gathered to issue the permits, such as statistical analyses of sample representativeness, should be field verified and documented in fact sheets prepared for each SIU.

6.1 Permit Accuracy and Fact Sheets

Yuba City will have to reissue permits with the applicable Federal standards and national prohibit-tions to all of its SIUs, and then reissue them again with local limits once they are re-determined. Fact sheets should be prepared to document the information and decisions behind the permit provisions, such as Federal category, sample point, pollutants of concern, representative sampling, and self-certifications in lieu of self-monitoring.

Section 6 – Industrial User Permits

- Sunsweet - A permit must be reissued to apply the national prohibitions and the local limits, once they are re-determined. The permit should require self-monitoring for all of the local limits as well as any other toxics that identified by Sunsweet under the EPA Order, with a provision to re-open the self-monitoring requirements depending on the results. The national prohibitions should be restated to explicitly prohibit the identified discharges and conditions from Sunsweet that have or could have adversely effected the sewers or the WWTP. See items 2.0 and 2.8 of this report. Sampling protocols set in the permit should reflect the variabilities from plant operations and treatment associated with the defined sample point not only over the sampling day but also over the reporting period.

- Power Plants - The permits for the power plants must be reissued to apply the national prohibitions, to remove the Federal standards for steam electric power stations, and add the local limits, once they are re-determined. The permits should require self-monitoring for all of the local limits, with a provision to re-open the self-monitoring requirements depending on the results. The national prohibitions should be restated to explicitly prohibit the discharges and conditions that could adversely affect the sewers or the WWTP. Sampling protocols set in the permit should reflect the variabilities from plant operations and treatment associated with the defined sample points not only over the sampling day but also over the reporting period. In particular, the permit should address the entire schedule of batch, slug, blowdown, or continuous discharges through the sample point.

- Zero-Discharging CIUs - Zero-discharge permits should be issued to any industries found to comply with Federal categorical pretreatment standards by not discharging Federally-regulated process-related wastewaters. A zero-discharge permit should explicitly prohibit the discharge of the Federally-regulated wastewaters and require the industry to certify every six months to not discharging in lieu of self-monitoring. A zero-discharge permit would strengthen enforcement efforts against the illegal dumping to the sewer because the establishment of violation depends only on whether a discharge occurred and not on surveillance sampling and the difficult arguments surround the representativeness of sampling.

6.2 Permit Clarity

All of the permits issued to the SIUs should clearly communicate the applicable Federal standards, national prohibitions, local limits, sample type, sampling frequency, self-certifications in lieu of self-monitoring, analytical test methods and the associated detection limits, and, if necessary, the flow and production rates behind the Federal standards. All of this information can be presented in table form on a single page of the permit with one line per pollutant. The compliance sampling locations also could be clearly delineated on a site map annotated with a description of the location. Each permit should clearly state the effective duration and the procedures for re-applying.

Section 7

Monitoring, Self-Monitoring and Inspections

Pretreatment programs, as part of ensuring industrial user compliance [40 CFR 403.8(b)], are required to:

- Cause industrial users to self-monitoring at least twice per year unless the program samples for them [40 CFR 403.8(f1iii), 403.12(e1,g10)];
- Inspect industrial users at least once per year;
- Sample industrial users at least once per year if they self-monitor or twice per year if they are not required to self-monitor [40 CFR 403.8(f2v), 403.12(i2,e1,g10)];
- Ensure that all sampling and self-monitoring is representative of the reporting period [40 CFR 403.12(g3)].

7.0 Summary

For the most part, Yuba City successfully obtains self-monitoring as well as performs the inspections and city sampling necessary to determine compliance independent of the information submitted by the SIUs. However, the self-monitoring is not representative over the reporting periods and the sample records do not cover all of the pollutants of concern.

Requirements

- The self-monitoring records for each SIU must be complete in the number and type of

- Yuba City must sample each SIU, including Franklin Circle K, at least once per year.

Recommendations

- Inspection reports should include an analysis that the sampling is representative of both the sampling day and reporting period.

- Inspection reports should document the findings that establish the sewer discharge permit conditions and prompt any necessary revisions or enforcement actions.

- All self-certifications in lieu of self-monitoring should be explicitly stated in the permit.

Section 7 – Monitoring, Self-Monitoring and Inspections

7.1 City Inspections and Sampling

Yuba City performs routine inspections of each SIU once per year and samples them at least once per year since its permits require self-monitoring. Sunsweet is sampled each weekday and the power plants are sampled once per week. The one exception is the contaminated groundwater clean-up site, Franklin Circle K, which is not sampled by the City.

7.2 Self-Monitoring

Frequency and Coverage - The permits require daily self-monitoring for Sunsweet and quarterly self-monitoring for the others. However, the self-monitoring and city monitoring do not cover all of the pollutants of concern (aluminum, arsenic, chloroform, copper, diazinon, iron, lead, manganese, molybdenum, tetrachloroethylene, and zinc), nor the potential pollutants of concern (barium, cadmium, chromium, mercury, nickel, oil & grease, selenium, and MTBE).

Sampling Representativeness - Representative sampling points have been established and known even though they are not specified in the permits. However, the self-monitoring frequencies do not ensure representative sampling over the reporting period because the significant slug, batch and variable discharges, such as spent solutions, blowdowns and regenerants, are not specifically required by the permits to be self-monitored. Both of these findings regarding the representative-ness of sampling were illustrated at each of the SIUs inspected during this inspection.

7.3 Self-Certifications

Self-certifications in lieu of any required self-monitoring for Federal standards or local limits should be explicitly stated in the permits. In particular, the Custom Chrome permit should explicitly state which toxic organic pollutants do not have to be self-monitored if Custom Chrome self-certifies to following a previously submitted and approved toxic organics management plan, as allowed under the Federal job-shop electroplating standards in 40 CFR 413.

Section 8

Enforcement and Compliance Assistance

Pretreatment programs, as part of ensuring industrial user compliance are required to enforce their permits following an enforcement response plan, and to publish annual significant non-compliance lists [40 CFR 403.8(b,f1ii,f2vii,f5)].

8.0 Summary

The Federal regulations do not define how to determine a program's success in enforcing permit limits. However, an evaluation of enforcement and the City's enforcement response plan is premature since the SIU permits need to be revised to include updated local limits, result in representative sampling records, and apply the proper Federal standards.

Requirements

- Approved pretreatment programs are required to develop and follow an enforcement response plan that specifies the actions, and their time frames, that the City will take in response to each type of industrial user permit.

Recommendations

- None.

non-cat	Non-Categorical SIU
BAT	Best-Available-Technology treatment (equivalent to the model treatment used in setting the Federal standards)
BAT+	Exceeds BAT treatment
BAT-	Falls short of BAT treatment
n/a	No applicable Fed standards that are that are based on model treatment

Treatment-In-Place

CARBON	Activated Carbon
PH	pH Adjustment
SCRN	Screening

Table 8

Pretreatment Program Definitions

Pass-Through: A non-domestic discharge which exits the treatment works in quantities or concentrations which, alone or in conjunction with other non-domestic discharges, *is a cause of violation* of any requirement of the NPDES permit, 40 CFR 403.3(n).

Interference: A non-domestic discharge, including excessive or slug loads of conventional pollutants, which inhibits or disrupts the treatment with other non-domestic discharges, inhibits or disrupts the treatment works, its treatment processes or operations, or its sludge processes, use or disposal, *thereby causing a violation* of any requirement of the NPDES permit or any Federal, state or local sludge regulation, 40 CFR 403.3(i).

Local Limits: Specific limits developed and enacted by the local authority, designed to prevent pass-through, interference, sludge contamination, and potential threats to worker health and safety, and to ensure renewed and continued compliance with the NPDES permit or sludge use or disposal practices, 40 CFR 403.5(c).

Significant Industrial User: A non-domestic source that either (1) is subject to Federal categorical pretreatment standards, or (2) discharges an average of more than 25,000 gpd of process wastewater, or (3) makes up more than 5% of the flow or organic capacity of the treatment plant, or (4) is determined by the local authority or State to have a reasonable potential to adversely effect the treatment works, 40 CFR 403.3(t).

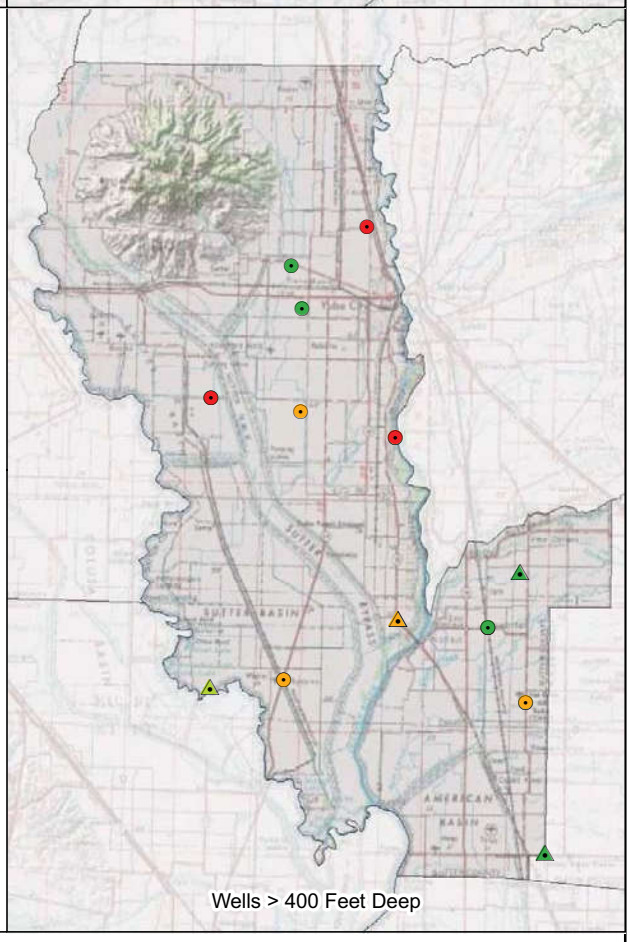
EC in DWR Wells (µmhos/cm)

- < 600
- 600 - 900
- 900 - 1600
- > 1600

EC in USGS Wells (µmhos/cm)



- < 600
- 600 - 900
- 900 - 1600
- > 1600

Note:
"EC" is an abbreviation for specific conductance, which is related to the salt content of a water sample.

For public drinking water systems, the secondary (aesthetic) maximum contaminant levels for EC are 900 micromhos/centimeter (µmhos/cm) (recommended), 1600 µmhos/cm (upper), and 2200 µmhos/cm (short-term).

For irrigation, crop yields decrease above a threshold EC value, which is crop-dependent. Crop yield potential decreases above these threshold levels:

Almonds - 1000 µmhos/cm
Beans - 700 µmhos/cm
Rice - 2000 µmhos/cm
Squash - 2100-3100 µmhos/cm
Tomatoes - 1700 µmhos/cm
Wheat - 4000 µmhos/cm

Wells < 150 Feet Deep

Wells 150 - 400 Feet Deep

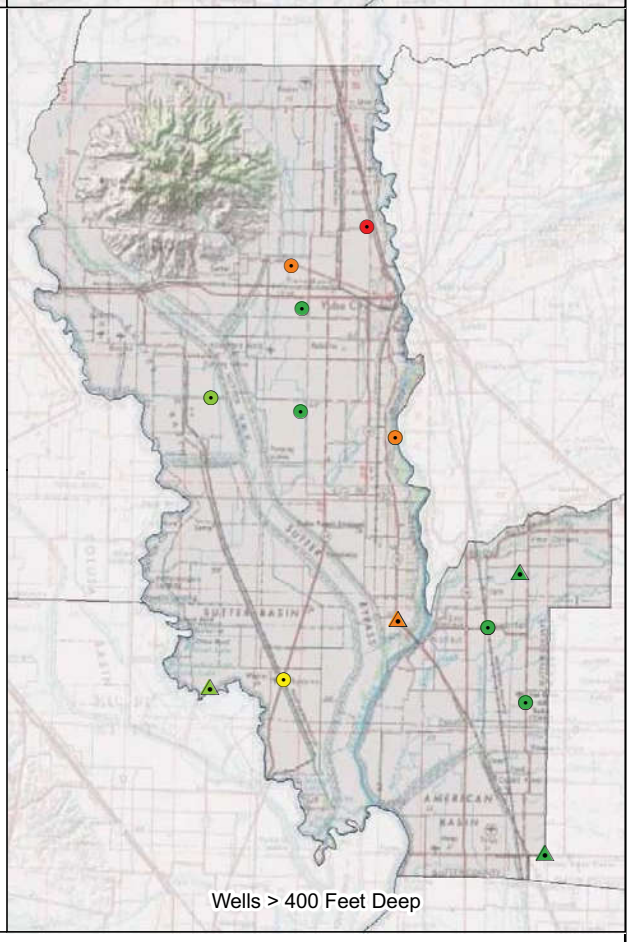
Boron in DWR Wells (µg/L)

- < 500
- 500 - 750
- 750 - 1000
- 1000 - 2000
- > 2000

Boron in USGS Wells (µg/L)

- < 500
- 500 - 750
- 750 - 1000
- 1000 - 2000
- > 2000

Note:
Boron is naturally occurring and leaches from aquifer materials into groundwater.



For public drinking water systems, there is a notification level for boron of 1000 micrograms/liter (µg/L).

For irrigation, boron is necessary for crop growth but becomes toxic to the point that yields may decrease above these threshold levels:

Beans - 750 - 1000 µg/L
Grapes - 500 - 750 µg/L
Squash - 2000 - 4000 µg/L
Tomatoes - 4000 - 6000 µg/L
Walnuts - 500 - 750 µg/L
Wheat - 750 - 1000 µg/L

Many other trees are vulnerable to boron toxicity above 500 - 750 µg/L.

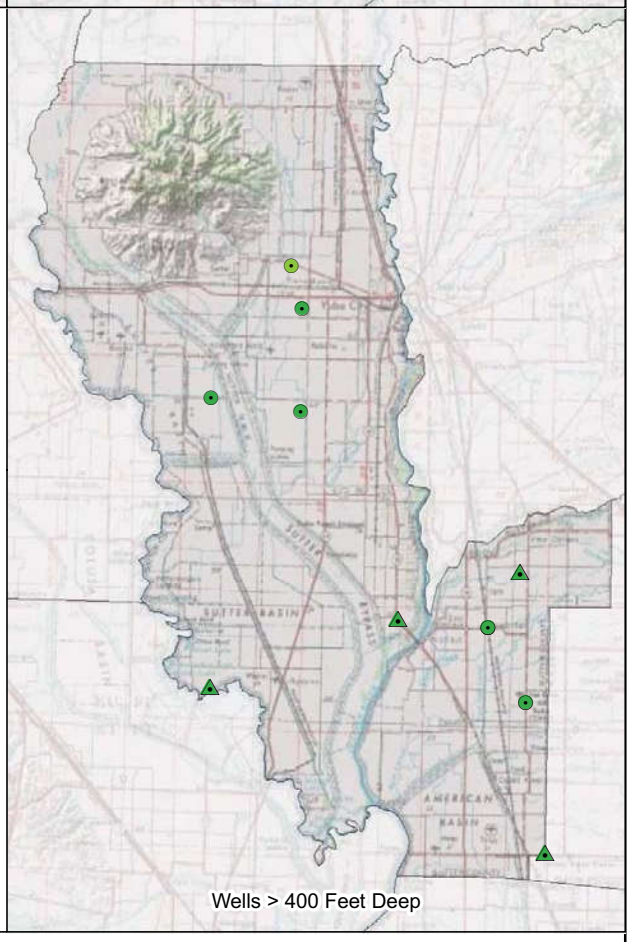
- > 45



Nitrate in USGS Wells (mg/L)

- < 15
- 5 - 15
- 15 - 30
- 30 - 45
- > 45

Note:
Nitrate is generally introduced into groundwater by septic systems, fertilizers, or confined animal operations.

For public drinking water systems, the primary (health-based) maximum contaminant level for nitrate as NO3 is 45 milligrams/liter (mg/L).

At concentrations exceeding the maximum contaminant level, nitrate can interfere with the blood's ability to carry oxygen. This effect can be especially pronounced in infants, where it is known as "blue baby syndrome".

Manganese in DWR Wells (µg/L)

- < 25
- 25 - 50
- 50 - 150
- 150 - 500
- > 500

Manganese in USGS Wells (µg/L)

- < 25
- 25 - 50
- 50 - 150
- 150 - 500
- > 500

Note:
Manganese is naturally occurring and leaches from aquifer materials into groundwater.

For public drinking water systems, the secondary (aesthetic) maximum contaminant level for manganese is 50 micrograms/liter (µg/L). There is also a notification level for manganese of 500 µg/L. Notification levels are health-based advisory levels for chemicals that do not have primary maximum contaminant levels.

Manganese can cause staining of plumbing and fixtures, and can contribute a metallic odor to water. At very high concentrations (above the notification level) manganese may cause neurologic problems.

Analysis for manganese is very sensitive to turbidity of samples - turbid samples will often have artificially high results for manganese.

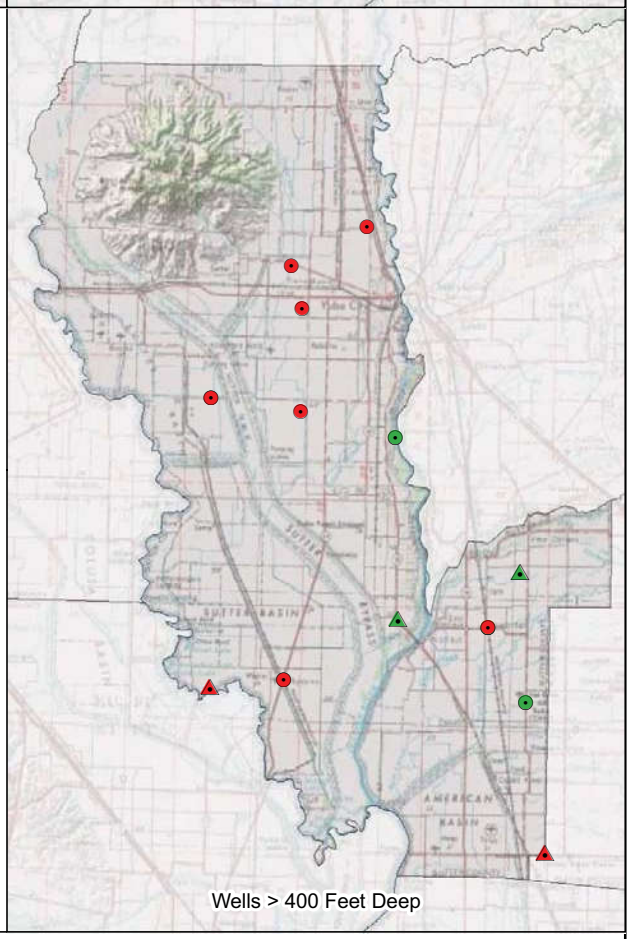
Arsenic in DWR Wells (µg/L)

- < 5
- 5 - 10
- > 10

Arsenic in USGS Wells (µg/L)



- < 5
- 5 - 10
- > 10

Note:
Arsenic is naturally occurring and leaches from aquifer materials into groundwater.

For public drinking water systems, the primary maximum contaminant level for arsenic is 10 micrograms/liter (µg/L).

Exposure to arsenic can cause both short and long term health effects. Long term exposure to arsenic has been linked to cancer of the bladder, lungs, skin, kidneys, nasal passages, liver and prostate. Short term exposure to high doses of arsenic can cause other adverse health effects.

Analysis for arsenic is very sensitive to turbidity of samples - turbid samples will often have artificially high results for arsenic.

1. INTRODUCTION

1.1. Purpose of Groundwater Management Plan

Sutter County (County) has prepared this Groundwater Management Plan (GMP) with input and direction from County stakeholders, and with financial and technical assistance from the California Department of Water Resources (DWR). Preparing this GMP is one step Sutter County is taking to promote and encourage groundwater users in the County to be responsible stewards of the water resources.

Sutter County's purposes for preparing this GMP are to:

- Summarize the current understanding of the groundwater underlying Sutter County and its role in the County's overall water supply, and make that information publicly available.
- Formulate goals and objectives that can be used as guidelines to help manage groundwater resources to meet current and future demands in Sutter County.
- Establish a plan for the County's involvement in ongoing monitoring and management of groundwater to promote those goals and objectives.
- Maintain eligibility for grant funding administered by the California Department of Water Resources to increase the understanding of the groundwater basins underlying Sutter County.

1.2. Sutter County's Role in Groundwater Management

Sutter County has the authority to adopt and implement this GMP under California Water Code §10750 et seq., which states that a local agency that overlies part of a groundwater basin can "by ordinance, or by resolution…adopt and implement a groundwater management plan…within all or part of its service area," so long as the area is:

- Not served by another local agency, a water corporation regulated by the Public Utilities Commission, or a mutual water company.
- Served by a local agency, when the majority of the agency's governing body declines to exercise its authority to manage groundwater and enters into an agreement with the local agency developing the GMP.

Sutter County's intended role in groundwater management, as discussed in this GMP, is to help coordinate the various groundwater users in the County, and encourage them to be

responsible stewards of the water resources. The County does not have the budget or staff to act as an "enforcer" with regards to groundwater use, and does not intend to do so.

1.3. Plan Area

Sutter County intends this GMP to be relevant for the entire County. Sutter County overlies the south central part of the Sacramento Valley Groundwater Basin, and specifically the Sutter Subbasin and portions of the East Butte and North American Subbasins, as shown in Figure 1. The majority of the County is serviced by water and irrigation districts, reclamation districts, cities, and public utility districts (Figure 2), which have the authority to manage groundwater in their service areas. Unless those entities decline to manage groundwater on their own, and instead enter into agreements with the County, this GMP does not formally apply to those areas. If those entities choose not to adopt their own GMPs, they have the option of taking formal action to adopt the Sutter County GMP for their areas. By doing so, they will fulfill the requirements of the groundwater management provisions of the California Water Code.

Some of the water purveyors in the County have prepared groundwater management plans established under provisions of Sections 10750-10756 of the California Water Code (Assembly Bill 3030). Four of these plans have been submitted to DWR for final adoption.

1.4. Public Involvement in Plan Development

Throughout the development of this GMP, Sutter County solicited public input to help guide the direction and content. Aside from the required public notices and hearings related to the GMP development, Sutter County undertook an extensive public outreach program to encourage public involvement in the GMP development and to solicit public input for the GMP. To help guide the development of the GMP, a Plan Advisory Group (PAG) was formed that included representatives of water purveyors, cities, and the general public (attendance sheets provided in Appendix A)

The Sutter County Water Resource Department and the Board of Supervisors approved a Public Outreach Plan (Appendix B) for the GMP process. The Public Outreach Plan established the following objectives:

- Establish an open process to facilitate stakeholder input.
- Provide information to facilitate stakeholder education on material forming the basis of the GMP.

- Provide a framework by which stakeholders are kept informed of the process, issues, and potential solutions.
- Incorporate public comments throughout the decision-making process.

Various entities – including the Board of Supervisors, Plan Advisory Group, and the general public – were involved in the development, approval, and adoption of the GMP.

While developing the GMP, eleven public meetings were held. The location and time for each of the PAG meetings were advertised in local media. Attendance at each PAG meeting was recorded and a mailing list was created to disseminate meeting times and important information regarding the GMP progress. Participation in the PAG was voluntary and the public was invited to attend and comment at public workshops held in Yuba City. At each of the public workshops, Wood Rodgers, Inc. presented a PowerPoint® presentation of the purpose, scope, and schedule for preparing the GMP, along with educational information related to groundwater, geology, wells, and information about the hydrogeology within the County. The PAG meetings were held in 2008 on June 10, August 14, October 17, and December 9; in 2009 on February 10; in 2010 on June 17, August 19, October 28, and December 15; and in 2011 on April 14[1] and October 20. The Sutter County Water Resources Department hosted a website for the GMP at:

http://www.co.sutter.ca.us/doc/government/depts/pw/wr/gmp/gmphome

All of the presentations and applicable meeting information were posted on the GMP website. Presentations, attendance sheets, and a summary of public comments from the workshops are included in Appendix B.

1.4.1. GMP Survey

The County circulated a voluntary Public Opinion Survey to obtain participation and feedback from stakeholders. The surveys were distributed to interested individuals at the PAG meetings and were also made available for download on the County's website. In order to differentiate between individual well owner concerns and water district concerns, two surveys were distributed. Unfortunately, due to the limited returns, the surveys were not beneficial in identifying countywide concerns related to groundwater.

[1] The reason the meetings extended over four years is that DWR issued a stop work order in 2009 due to uncertainties with the State of California budget. Consequently, the GMP process was temporarily delayed from February 2009 to May 2010. Resumption of the GMP process required approval of a new Notice of Intent and a contract amendment with DWR.

1.5. Issues of Concern

A variety of issues and/or concerns with regard to groundwater and groundwater management have been raised by residents of the County during the development of this GMP. These issues and concerns include the following.

1.5.1. Protect private groundwater rights.

The development of the GMP has raised concerns about how individual groundwater rights will be affected. California State Water Law gives property owners the right to make reasonable and beneficial use of the groundwater resource underlying their property. The GMP does not encroach upon or place any restrictions on groundwater rights. Furthermore, the County does not have the budget or staff to act as an "enforcer" with regards to groundwater use, and does not intend to do so.

1.5.2. Is there enough groundwater to sustain a drought?

Water districts within the County have been able to provide groundwater when surface water supplies were reduced during past droughts. Conversely, the use of groundwater when surface water is in short supply allows the aquifer(s) to recharge when surface water is available and is known as conjunctive use.

Increased use of groundwater in some areas is perceived to be taxing the available supply, and there is concern that wells will go dry during a drought. A related concern is that existing wells may be damaged by increased pumping. This concern is particularly widespread in the southeastern portion of the County, where groundwater is used extensively for irrigation. Additionally, changes in cropping trends to more permanent crops have raised concerns about the ability to reduce groundwater use during drought periods without sustaining substantial economic losses in areas that do not use groundwater conjunctively with surface water.

This concern is understandable given the history of significant groundwater level fluctuations in the southeastern portion of the County during past drought periods. Data also indicate that during wetter periods, or when pumping is reduced, groundwater levels have started to recover. The need for water supply reliability to support water users in the County can be addressed through the conjunctive use/management of available surface water, groundwater, and recycled water supplies. Together, these water sources comprise the irrigation water supply for the County, and can be used in fluctuating proportions to meet demands during different hydrologic (including climatic) and economic conditions. Successful management will also require better coordination among water users, and water users will need to work together to develop strategies for curtailing water use

during drought periods. If intra-county water transfers (transfers from one party to another within Sutter County) are possible, they can become an important water management tool and consideration during these periods.

1.5.3. Are there plans to "export" water out of Sutter County?

There is general concern that projects related to groundwater studies and groundwater management (including this GMP) are somehow related to the desire to "export" water from the County. Those who express this concern feel that the State (and other parties within and outside of the County) cannot be trusted to protect the interests of the community within the County. Currently, under state law, groundwater substitution water transfers are allowed. A groundwater substitution water transfers occurs when an entity with surface water rights makes an agreement to transfer some or all of its surface water to downstream users (by not diverting it), and then pumps groundwater to make up for the "lost source supply" that results from the transfer.

This concern can be somewhat allayed by maintaining local water district control of water management decisions. Also, establishing an open process for discussing groundwater conditions and making management decisions will help the stakeholders within the County have a better understanding of the resources and issues and to voice their concerns and have them addressed.

1.5.3.1. Sutter County Conjunctive Water Use Success (Case Study)

The Department of Water Resources provided the following case study for inclusion in this GMP to demonstrate the effectiveness of conjunctive water use.

"An example of a successful conjunctive use program was implemented by the South Sutter Water District (SSWD or District). The SSWD is located in southern Sutter and western Placer counties, with the Bear River as the northern boundary and stretching southwest between Highway 65 and Highway 70 to Pleasant Grove and Curry Creeks. The District was formed in 1954 to develop, store and distribute surface water supplies and to augment and replenish over-drafted groundwater supplies. Figures 3 and 4 are groundwater level hydrographs illustrating the recovery of groundwater levels after the implementation of the

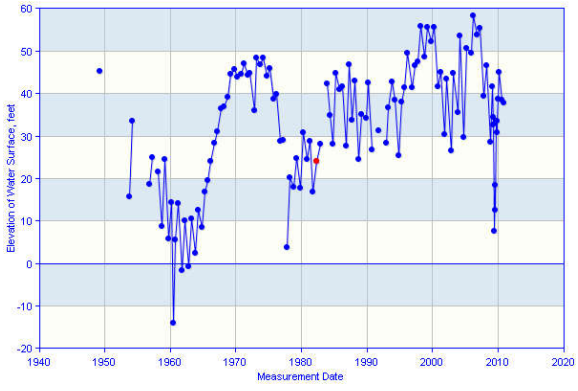

Figure 3 - Hydrograph for Well 13N/5E-30A1M

conjunctive use program. Today SSWD encompasses a total gross area of nearly 64,000 acres, including 57,012 acres that are authorized to receive surface water. According to the District,41,946 acres have actually been irrigated in recent years using a combination of surface and groundwater supplies. By far the majority of those acres grow rice (roughly 34,834 acres, or 83%), while the balance is apportioned between orchards (2,881 acres, or 5%), irrigated pasture (2,088 acres, or 5%), row and field crops (1,742 acres, or 4%) and the remaining 3%, which is fallowed in certain years.

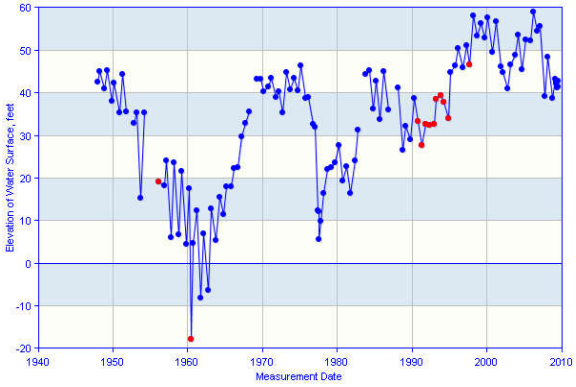

Figure 4 - Hydrograph for Well 13N/4E-13R1M

The enlarged New Camp Far West (NCFW) Reservoir was completed in 1964 with a storage capacity of 104,400 acre-feet (AF). SSWD and Camp Far West Irrigation District (CFWID), formed in 1924, holds the water rights for operating the reservoir. Surface supplies are managed conjunctively with groundwater supplies. The seven (7) megawatts of power generated by the NCFW powerhouse is wholesaled to Sacramento Municipal Utility District. The Federal Energy Commission (FERC) license for NCFW was issued on July 2, 1981.

One and a quarter miles downstream of NCFW Dam (and about 15 miles above the confluence with the Feather River), water is diverted by a diversion dam designed to move 30 cubic feet per second (cfs) north into the CFWID and 380 cfs south into the SSWD. In 1994, SSWD, CFWID, and the Department of Water Resources entered into a settlement agreement to meet the District's obligations under the State Water Resources Control Board's (SWRCB) Water Quality Control Plan for the Bay-Delta. Under the agreement, SSWD agreed to release up to 4,400 AF of water from NCFW, when requested by DWR, in all dry and critical year types. The present water rights require minimum in stream flows below the diversion works of 25 cfs from April 1 through June 30 and 10 cfs from July 1 through March 30. Under the new agreement, SSWD would increase the flow releases to the lower Bear up to 37 cfs in dry and critical years for up to sixty days in July through September.

SSWD receives anywhere from 5,000-20,000 AF of surplus water from Nevada Irrigation District (NID) annually. That water is currently conveyed to SSWD from Rollins Reservoir via the Bear River/Wise Canal system. When completed, SSWD's Canal Expansion project, including related conveyance system improvements, could

well provide previously-unforeseen opportunities for delivering a portion of surplus NID supplies to SSWD directly via the Bear River and NCFW Reservoir."

1.5.4. Will there be taxes or fees for groundwater use?

Concerns have been expressed about the sources of funding for the GMP and other groundwater programs in the County. Funding would be necessary should staff be required to perform new monitoring and evaluation activities or to undertake groundwater investigations. Funding for the latter may be available from DWR and other grant programs, under which this GMP maintains eligibility for the County. Currently, the County assesses fees only for exploratory drilling, well construction, and well destructions, as shown in the following table (Table 1).

Table 1
***Current* Sutter County Fee Assessments (as of January 1, 2012)**

Well Permit	***Fee***
Well Construction	$470.00
Well Destruction	$376.00
Water Exploration and Test Holes	$376.00
Permit Extension (1 year)	$47.00

There is concern about the potential for taxes and fees on groundwater use, and metering of pumps. This GMP does not contain any recommendation to meter groundwater pumping or to enact use-based fees or taxes, although they are considerations and are used in other areas. State law affords property owners the right to make beneficial use of groundwater on their land.

1.5.5. How can we obtain good quality water?

Water quality problems are significant within the County and concerns have been expressed about water quality with regard to salinity, arsenic, and manganese. The hydrogeology of the County as it relates to water quality is not well-understood, and further study will be necessary to develop guidelines for how to obtain good-quality water in different areas of the County, and to determine how to manage groundwater without causing water quality deterioration in areas with otherwise good quality water. As discussed in Section 4.4, this GMP illustrates water quality in different areas of the

County, and shows the geographic areas (and depths) where poorer quality groundwater can be anticipated. As more data becomes available, the County will be able to incorporate it into the existing understanding of the groundwater subbasins.

1.5.6. Is this going to generate new regulations on groundwater?

Concern has been expressed about the potential for additional layers of bureaucracy and regulations on groundwater use. In general, stakeholders recognize a need to better understand and manage groundwater in the County, but have expressed a desire for a "balance" between achieving this objective and minimizing bureaucracy and regulations.

To implement the GMP, an institutional framework (not yet determined) will be needed; however, the intent of this GMP is to minimize the bureaucracy and regulations needed to achieve the goals and objectives of the GMP. The GMP provides a framework and a forum for studying, discussing, and managing groundwater within the County. Ideally, management will be accomplished cooperatively amongst the groundwater users in the County.

2. THE COUNTY

2.1. Physical Setting

Sutter County encompasses approximately 607 square miles (389,443 acres) in the central portion of the Sacramento Valley. As shown in Figure 5, Sutter County is bound by Butte County to the north, Colusa and Yolo Counties to the west, Yuba and Placer Counties to the east, and Sacramento County to the south. The County seat, Yuba City, is located approximately 50 miles north of Sacramento. The 2010 U.S. Census reported that the population of the County in 2010 was 94,737, with the majority of the population residing in Yuba City and Live Oak, and about 25 percent of the population in the rural communities. Land use within the County is principally agricultural, with approximately 318,701 acres in production (Sutter 2010a).

The two main population centers in the County are Yuba City, with 67 percent of the population, and the City of Live Oak, approximately 10 percent of the population (U.S. Census 2010). The remaining County residents live within the small communities of Tierra Buena, Meridian, Rio Oso, Trowbridge, Sutter, Pleasant Grove, Nicolaus, East Nicolaus, Riego, Robbins, or in the vast rural agricultural areas which make up Sutter County. Future major growth areas planned for Sutter County include Sutter Pointe (Measure M). The Sutter Pointe Specific Plan details a large-scale development project that is currently on file with and being processed by Sutter County. This plan area is located in the southern most portion of the County adjacent to the Sacramento County border and a portion of the Placer County border. The plan area includes the development of approximately 7,500 acres into mixed use and residential properties and has been structured to facilitate future incorporation as an independent city (Sutter 2010).

The main transportation routes connecting the County with the region are Highway 99, which runs north-south through the County, California State Route 20, which runs east-west through the County and Highway 113, which runs from the south-west portion of the County and terminates at Highway 99 (connecting Woodland with the County).

Land elevations range between 80 and 20 feet above sea level throughout the County with the exception of the Sutter Buttes, where elevations are more than 2,100 feet above sea level. The lowest land elevations are located towards the southern portion of the County.

Sutter County has abundant surface water, including the Sacramento, Feather, and Bear Rivers, as shown in Figure 5. A number of the water districts in the County (Figure 2) divert and transfer surface water.

2.2. Water Purveyors and Users

Water resources in the County are managed by water purveyors and individual water users who have "hands on" control of both surface water and groundwater for agricultural, urban, environmental, and domestic uses. These water managers represent a complex mix of organized water purveyors, non-organized areas, and areas within National Wildlife Refuges. A brief discussion of each category is presented below.

2.2.1. Water Purveyors

There are 48 water purveyors in Sutter County which provide water service to their customers (Figure 2). These water purveyors include water districts, irrigation districts, reclamation districts, mutual water companies, public utilities districts, and incorporated cities. Additionally, there are many private water users including community service districts (CSD's) and farming interests.

Six water purveyors provide water service not only in Sutter County, but in the counties that share borders with Sutter. They are:

- Reclamation District No. 1004 (Colusa County)
- Biggs-West Gridley Water District (Butte County)
- Butte Water District (Butte County)
- Dry Creek Mutual Water Company (Yuba County)
- South Sutter Water District (Placer County)
- Natomas Central Mutual Water Company (Sacramento County)

2.2.2. Non-Organized Areas

The non-organized areas within the County are not within the boundaries or service area of established water purveyors.

2.2.3. National Wildlife Refuges

The Sacramento National Wildlife Refuge Complex consists of five national wildlife refuges and three wildlife management areas. Portions of Sutter County have been dedicated, both through public and private efforts, as wildlife refuges. Exclusively in Sutter County, the Sutter National Wildlife Refuge has 2,591 total acres, with the majority (83%) located inside the Sutter Bypass. According to U.S. Fish and Wildlife

Service, the refuge "consists of approximately 1,881 acres of seasonal and summer wetlands and approximately 674 acres of unmanaged wetlands, grasslands, and riparian habitats" (USFW 2009).

The Natomas Basin Conservancy also owns nearly 1,000 acres of wildlife habitat/mitigation lands within the southern portion of the County.

2.3. Land Use

The predominant land use within the County is agriculture. The 2008 Sutter County General Plan Technical Background Report estimates that 322,240 acres (83%) of Sutter County is agricultural land. An estimated 44,581 acres (11%) is designated as open space. The remaining 6% of the County is designated as residential, public and vacant, commercial, industrial, and transportation and utilities. As stated above, agriculture dominates land uses within Sutter County. Figure 6 shows the distribution of land uses, with regard to crop type and water source, for the entire County. It is apparent that permanent crops dominate the eastern portion of the County, along the Feather River, while rice and other non-permanent crops dominate the central and western portion of the County.

2.4. Water Use

The amount of water applied for agricultural production and urban or community use has been estimated using information from DWR with respect to unit crop, consumptive use, and applied water, with corresponding losses included and accounted for. Water use within cities and communities was estimated using limited production data from some water purveyors from 2008 to 2010.

2.4.1. Agricultural Water Use

Water use during the 2009 growing season was calculated based on the Sutter County 2009 Crop Report. Estimates of applied water for irrigated agriculture are 1,122,018 AF.

Sutter County's agricultural water usage is approximately 60 percent surface water, 20 percent groundwater, and 20 percent that is irrigated by both surface water and groundwater. Figure 6 illustrates the source of water for crops grown in the County. The predominant source of water for permanent crops is groundwater.

2.4.2. Urban/Community Water Use

Water for urban and community use is from groundwater and surface water. From available DWR records, the minimum urban water use was 1,770 AF in 2010 (records for

all urban water suppliers was not available). Yuba City provides mostly surface water (15,682 AF in 2008) while smaller communities rely exclusively on groundwater.

3. HYDROLOGY AND SURFACE WATER

3.1. Seasonal and Long-Term Hydrology

Annual fluctuations in northern California precipitation directly influence the volume of water flowing in the Sacramento River. Precipitation and climate data from the Western Regional Climate Center (WRCC) suggest the average annual precipitation for the west side of the County (Colusa Station) is 16.40 inches per year and on the east side of the County (Marysville Station), it is 20.96 inches per year. In Nicolaus, the average annual precipitation is 18.27 inches per year. Collectively, average annual precipitation is 18.54 inches per year. Snow-fall within Sutter County is rare, measuring on average 0.01 inches per year. Precipitation is highly variable throughout the State, from year to year. Precipitation usually takes place from October to May and on average no precipitation occurs from June to September. The water year, defined as starting on October 1 and ending September 30, is classified as one of five water year types: critical, dry, below normal, above normal, or wet[2]. Within the past ten years, only two water years were classified as wet and one year was classified above normal. The remaining years were either dry, critical, or below normal. The average annual temperature is approximately 62° F, with an average high of 95.7° F in July and an average low of 37.4° F in January.

Precipitation in the Sierra Nevada, Coast Range, Klamath, and Cascade Mountains contribute to surface water flow and groundwater recharge in the Sacramento River Basin. The general direction of surface water flow is toward the center of the valley, flowing south. Water diversions, evaporation, and groundwater recharge reduce flows as the Sacramento River approaches the Delta.

3.2. Surface Water

Sutter County is located in the Sacramento River Basin, with the Sacramento River on the west and the Feather River on the east. The Sacramento River is the largest river in northern California and drains the northern central part of California. The watershed for the Sacramento River includes tributaries originating in the Sierra Nevada, the Coast Range, and the Cascade Mountains. The main tributaries in Sutter County include the Feather River, Bear River, Dry Creek, Pleasant Grove Creek, Auburn Ravine, and Coon Creek.

During periods of heavy precipitation and runoff, a portion of the flow within the Sacramento River is diverted through the Sutter Bypass. The Sutter Bypass is a man-made feature in Sutter County and was designed to alleviate the flood control system along the Sacramento

[2] http://cdec.water.ca.gov/cgi-progs/iodir/wsihist

River. Aside from the major rivers and tributaries within Sutter County, there are no significant surface water storage reservoirs within Sutter County.

It is important to note that flows in all the major rivers in northern California are managed by dams, e.g. the Feather River by Lake Oroville and the Sacramento River by Lake Shasta. The reservoirs are managed to provide flood protection while collecting runoff from the watershed. Releases from the reservoirs occur from spring through summer to provide irrigation water for agriculture as well as to provide drinking water downstream.

The following discussion provides information on the location, ownership, infrastructure, and an overview of the operational practices of the major water bodies that relate to or are within Sutter County.

3.2.1. The Sacramento River

The Sacramento River is the major surface water feature in Sutter County. Running north-south along the western part of the County, the Sacramento River is the main drainage for the Sacramento Valley Basin on its way to the Delta and the San Francisco Bay. The Sacramento River supports many beneficial uses including recreational, agricultural, and wildlife. The river is currently not used for municipal or domestic water supplies in the County. There are, however, future plans to utilize the Sacramento River, in conjunction with groundwater, to provide municipal water supply to the Measure M Sutter Pointe development (Sutter 2011).

Many tributary streams flow from the mountains on both sides of the valley into the Sacramento River. According to a 2005 report by the Glenn County Department of Agriculture (GCDA), flows in the Sacramento River near Grimes in Southern Colusa County range from 6,500 cfs to 16,900 cfs for the period of record of 1946-2003 (GCDA 2005).

3.2.2. The Feather River

The Feather River is a major tributary of the Sacramento River and outlines a major portion of Sutter County's eastern boundary. The river trends north-south along the northern and central portions of the County to the convergence with the Bear River, where it changes course and flows southwest through the south-central portion of the County until it intersects the Sutter Bypass and the Sacramento River. Like the Sacramento River, the Feather River provides beneficial uses including recreation, agricultural, and wildlife. Yuba City obtains a large portion of its annual water supplies for municipal and domestic use from the Feather River.

3.2.3. The Bear River

The Bear River is a tributary of the Feather River and enters Sutter County from Placer County near the City of Wheatland in Yuba County. It forms the boundary between Sutter and Yuba Counties up to the convergence with the Feather River. The Bear River generally flows west until it converges with the Feather River, approximately one mile upstream from the rural community of Nicolaus. Although smaller than the Sacramento and Feather Rivers, the Bear River also provides beneficial uses that include recreation, agricultural, and wildlife. Discharges within the river are partially controlled by several upstream reservoirs. The Camp Far West Reservoir (located in the counties of Yuba, Placer and Nevada) is the last downstream reservoir on the river and subsequently regulates surface water discharges to downstream users, which has been the source of surface water for a very successful conjunctive water use program for the South Sutter Water District.

3.2.4. The Sutter Bypass

The Sutter Bypass (Bypass) is an artificial flood corridor constructed in the 1930's. As described by the Army Corp of Engineers, "the Sutter Bypass, which began operation in the 1930's, is a leveed portion of the natural floodway in the Sutter Basin. The bypass is south of the Sutter Buttes from Colusa to Verona between the Sacramento and Feather rivers. Flows enter the Sutter Bypass from the Butte Basin at its upper end near Colusa at the Butte Slough. Other flows enter from Wadsworth Canal, interior drainage from pumping plants, and the Sacramento River by way of the Tisdale Weir and Bypass. Flows exit the Sutter Bypass and combine with the Sacramento River, Feather River, Natomas Cross Canal, and Yolo Bypass upstream from the Fremont Weir near the town of Verona"(USACE).

3.3. Seasonal and Long-Term Water Quality

Under the USGS National Water Quality Assessment (NAWQA) Program, the USGS conducted an intensive study of the Sacramento River Basin and collected data between 1995 and 1998. Through the sampling process, the USGS selected indicator streams that were based upon the characterization that "they drain small to intermediate sized watersheds with relatively homogeneous land use and geology" (USGS 1998). The Colusa Basin Drain is located entirely in the Sacramento Valley and was chosen as an indicator stream to determine the impacts of agriculture on stream-water quality (USGS 1998). At the indicator water quality station, Colusa Basin Drain at Road 99E near Knights Landing, it was determined that pH levels were generally on the higher end, with declining suspended sediment concentrations over the two-year sampling period. The higher concentrations of mercury

correlate with suspended sediment because much of the load of total mercury is transported with the suspended material.

The findings of the USGS study also indicated that the water of the Sacramento River and its major tributaries is generally of good quality. As stated in the U.S. Geological Survey Circular 1215:

> "the amount of dissolved solids in the Sacramento River and its major tributaries (Yuba, Feather, and American rivers) was low at all of the sampled locations. Higher median concentrations of dissolved solids occurred at agricultural sites such as the Sacramento Slough and Colusa Basin Drain, but those are diluted upon mixing with Sacramento River water. Nutrient concentrations such as nitrate also were low throughout the Sacramento River Basin, and drinking-water standards for nitrate were not exceeded during the course of this study. The concentrations of Molinate and other pesticides (used in rice farming) measured during this study in the Colusa Basin Drain or in the Sacramento River, represent a significant improvement over concentrations measured in previous years".

3.4. Surface Water Supply Contracts

3.4.1. Settlement Contracts

USBR currently contracts with approximately 145 water districts, water purveyors, or private users for water rights to the Sacramento River. The total amount of water under the settlement contracts is approximately 2.2 million acre-feet and cover a total of almost 440,000 acres of land bordering the Sacramento River and its tributaries between Redding and Sacramento. The Settlement Contracts were originally executed in 1964 with a term not to exceed 40 years. New contracts have been executed with approximately 145 existing Sacramento River Settlement Contracts.

The Settlement Contracts include a Base Supply and Project Water. The Base Supply is the amount that reflects the agreed-upon water right of the respective entity. This is generally regarded as pre-1914 water rights and also water rights perfected after 1914 and reflect water that would be available to the respective entities under "natural" conditions. Project Water represents the amount of water the Bureau of Reclamation agrees to provide from its Central Valley Project (CVP) yield. Under the provisions of the Settlement Contracts both the Base Supply and Project Supply could be reduced by 25 percent of the total contract amount, but only in certain water year types.

3.4.2. Long-Term Renewal Contracts

In accordance with the CVP Improvement Act (CVPIA), the USBR negotiated long-term water service contracts in 2007. According to Section 3404c of the CVPIA, Renewal of Existing Long-Term Contracts requires the USBR to renew any existing long-term repayment or water service contract for the delivery of water from the CVP for a period of 25 years and may renew such contracts for successive periods of up to 25 years each. The USBR anticipates that, "as many as 113 CVP water service contracts, located within the Central Valley of California, may be renewed during this negotiation process" (USBR 2007a).

The long-term renewal contracts, unlike the Settlement Contracts, have no specified reduction in delivery; during critically dry or water-short years, the water supply available from the Project will be allocated among the contractors.

Also, the long-term renewal contracts contain a tiered pricing provision. The Base Supply is 80 percent of the total contract amount, and Tier 1 and Tier 2 supplies represent 10 percent each of the remaining contract amount. Each tier has an incrementally higher water cost. The Tier 1 and Tier 2 water, which is available in most years, is not used due to the incremental higher cost of water.

4. GROUNDWATER

4.1. Groundwater Basins and Subbasins

Sutter County is underlain by the Sacramento Valley Groundwater Basin. The Sacramento Valley Groundwater Basin covers a vast area and encompasses the alluvial deposits under the valley floor from the Sierra Nevada Mountains to the east, the Coast Range mountains to the west, the Sacramento-San Joaquin Delta to the south, and the Klamath and Cascade Ranges to the north. The Sacramento Valley Groundwater Basin covers over 5,900 square miles and 10 counties, and has been divided into 18 subbasins. The GMP area is underlain by three groundwater subbasins (Figure 1) as defined by the California Department of Water Resources (DWR) in "California's Groundwater, Bulletin 118 – Update 2003". These subbasins are: the East Butte Subbasin, the Sutter Subbasin, and the North American Subbasin. According to DWR,

"A groundwater basin is defined as an alluvial aquifer or a stacked series of alluvial aquifers with reasonably well-defined […] features that significantly impede groundwater flow such as rock or sediments with very low permeability or a geologic structure such as a fault. […]

"A subbasin is created by dividing a groundwater basin into smaller units using geologic and hydrologic barriers or, more commonly, institutional boundaries […]. These subbasins are created for the purpose of collecting and analyzing data, managing water resources, and managing adjudicated basins."

4.2. Hydrogeology

4.2.1. Overview of Groundwater and Geology

Groundwater is water that is underground and below the water table (saturated zone), as opposed to surface water, which flows across the ground surface. There are three main types of subsurface geology where groundwater can exist:

- Hard Rock – Groundwater can be present in cracks or fractures in the rocks.
- Underground Caverns – Groundwater can fill these underground voids.
- Porous Sediments – Groundwater can fill the pore spaces between grains of sand and gravel.

In Sutter County, groundwater exists in porous sediments, alluvial aquifers, or fractured volcanic rock such as in the vicinity of the Sutter Buttes. Figure 7 shows a simplified surface geologic map with the major faults in the County. Sutter County is situated along

the axial portion of the Sacramento Valley Groundwater Basin. The subsurface aquifers consist generally of layers of gravel, sand, clay, and in some cases volcanic ash. The characteristics of different aquifers, and zones within each aquifer, are related to the aquifer materials (sands, gravels, clays, etc.). Within a single aquifer zone, nearby wells with similar construction can have very similar well yields and water quality. It should be noted that many of the geologic formations that make up the alluvial aquifers are continuous units that are also present in other counties as discussed.

In the northern portion of Sutter County, the geologic setting changes rapidly from the stratigraphic succession observed in the rest of the County. A thick sequence of volcaniclastic sediments derived from the Sutter Buttes volcanic epoch form a volcanic fan apron of alluvial deposits around its perimeter. These deposits have been characterized recently by DWR as consisting largely of gravel, sand, silt, and clay. These deposits are observed at ground surface around the Buttes, and may extend up to a 15 mile radius in the subsurface (Springhorn 2008). Sediments deposited under marine sedimentary processes are also observed at ground surface and at shallow depths in the subsurface around the Buttes. These deposits were elevated from depth to their current position during the emplacement of the volcanic intrusion which formed the Sutter Buttes. Water quality in these sediments is generally poor and deteriorates with depth.

There is a large amount of hydrogeologic data available in the Sacramento Valley which has been widely studied, and groundwater is continuous within specific aquifer zones (although discontinuous between different aquifer zones) over large areas within the Sacramento Valley.

4.2.2. Status of Understanding of Regional and Local Geology

The geology of the Sacramento Valley has been studied for at least 95 years, and much has been learned over this time. However, there are still many areas of active study and debate. In Sutter County, areas that are not well-understood and/or are actively being studied include:

- The connection between the Coast Range-sourced Tehama Formation and the analogous Sierra Nevada-sourced deposits, and where this interaction occurs.
- The possible existence of subsurface barriers to groundwater flow within the County.
- The source of poor water quality in parts of the County.

4.2.3. Regional Geology and Structure

The Sacramento Valley Groundwater Basin is a north-south trending structural trough which is filled with layers of sediments. The stratigraphic succession of the basin deposits, from oldest to youngest (deep to shallow), depict a regional change in depositional environment from one dominated by marine sedimentary processes to that of continental (alluvial) processes. The deepest portions of the basin generally consist of marine sedimentary rocks, ranging in age from Late Jurassic to early Miocene (160 million years ago to 24 million years ago). These marine deposits are overlain by younger alluvial and locally prominent volcanic rocks of early Miocene to Holocene age (Harwood and Helley 1987). Within the Basin, these deposits are disrupted by deformational stresses derived from east-west compressional forces associated with regional uplift along the western margin of the valley and extensional forces to the east, within the Basin and Range Provenance (Harwood and Helley 1987). Over time, these forces have applied great stresses and strain on valley deposits, creating complex and diversely-oriented fold and fault structures.

The prominent fault system that occurs in Sutter County is the Willows Fault. The Willows Fault is an active northwest-trending fault that dips steeply to the east and shows reverse displacement, meaning the ground east of the fault has moved up relative to the west side. The Willows Fault enters into the County from Colusa County southwest of the Sutter Buttes and extends to the southeast portion of the County towards Sacramento.

The most prominent and recognizable geologic feature in Sutter County are the Sutter Buttes. The Sutter Buttes are composed of late Cenozoic volcanic rocks that rise over 2,000 feet above the Sacramento Valley floor. The Sutter Buttes formed between 2.4 and 1.4 million years ago as magma at depth was injected into the overlying Cretaceous and Tertiary rocks, causing deformation in the form of faulting, folding, and uparching (Harwood and Helley 1987).

4.2.4. Regional Stratigraphy

The prominent non-marine, fresh water-bearing stratigraphic units found within the East Butte, Sutter, and North American Subbasins include (from youngest to oldest):

- Recent Alluvial Deposits (stream channel, basin, and flood plain);
- the Modesto Formation;
- the Riverbank Formation;

- the Sutter Buttes Rampart;
- the Victor Formation;
- the contiguous Laguna, Tuscan, and the Tehama Formations;
- the Mehrten Formation; and
- the informally named Sutter Formation (Springhorn 2008).

Except for the Sutter Formation, the stratigraphic descriptions presented herein are based upon the California Department of Water Resources "Bulletin 118 – California's Groundwater" and are shown in the geologic cross-sections (Figure 8). The location of the cross-section is shown in Figure 7.

Locally, the stratigraphic succession observed in each subbasin differs slightly; therefore, each subbasin and its associated geologic setting are described separately with regard to their relative positions and occurrences in the specific subbasin.

4.2.4.1. East Butte Subbasin (Basin Number 5-21.59)

The northern section of Sutter County is underlain by the East Butte Subbasin. The East Butte Subbasin is bounded by the Sutter Buttes to the south, Butte Creek to the west and northwest, the Cascade Mountain range to the northeast, and the Feather River to the southeast. The East Butte Subbasin aquifer system consists of late Tertiary to Quaternary aged deposits comprised of Sierra and Cascade sourced material, and in the southern portion of the subbasin around the Sutter Buttes, by volcanic and volcaniclastic rocks. The geologic formations that comprise the East Butte Subbasin are (from youngest to oldest):

- Recent Alluvial Deposits;
- the Pleistocene aged Modesto and Riverbank Formations;
- the Sutter Buttes Rampart; and
- the Tertiary aged Laguna and Tuscan Formations.

Recent Alluvial Deposits

Stream channel deposits are Holocene in age and were deposited between 11,000 years ago and present day. The stream channel deposits occur along the current and ancestral paths of streams and rivers in Sutter County. Where present, the stream channel deposits extend from ground surface up to a depth of 80 feet below ground surface (Helley and Harwood 1985). The stream channel deposits consist of unconsolidated gravels, sand, silt, and clay, derived from the erosion and reworking of the Modesto and Riverbank Formations (described below). This unit is moderately to highly permeable, but because of its shallow depth and limited thickness, it possesses limited water-bearing capacity.

Basin deposits are Holocene in age and, like the stream channel deposits, were deposited between 11,000 years ago and present day. Basin deposits occur where sediment-laden floodwaters breached natural stream and river levees and spread across lower-lying topography. Where present, the basin deposits extend from ground surface up to a depth of 150 feet. The basin deposits consist mainly of silt and clay. These units have low permeability and generally yield small quantities of water to wells.

The Modesto Formation

The Modesto Formation is Pleistocene in age and is a stream terrace deposit that was deposited between 12,000 to 50,000 years ago (Helley and Harwood, 1985). Within this subbasin, the Modesto Formation consists of poorly indurated gravel and cobbles, sand, and clay and is derived from the reworking and deposition of the Riverbank Formation, Laguna Formation, and Tuscan Formation (DWR 2004). The Modesto Formation was likely deposited by the same stream and river systems that flow today, because it generally borders existing channels (Blake et. al. 1999). This formation may extend across the entire subbasin and where present, may range in thicknesses from 50 to 150 feet (DWR 2000). The sediments of the Modesto Formation are moderately to highly permeable and can yield moderate quantities of water to wells.

The Riverbank Formation

The Riverbank Formation is Pleistocene in age and was deposited between 120,000 and 500,000 years ago (Helley and Harwood, 1985). The Riverbank Formation consists of gravel and small cobbles, and is interbedded with reddish-clay, sand and silt. Like the Modesto Formation, the Riverbank Formation is a stream terrace deposit. However, the Riverbank Formation is older than the Modesto Formation. The

Riverbank Formation may extend across the entire subbasin, underlying the Modesto Formation, with thicknesses ranging from 50 to 200 feet. The Riverbank Formation is poorly to highly permeable and can yield moderate quantities of water to wells.

Sutter Buttes Rampart

The Sutter Buttes Rampart was deposited during the Middle to Lower Pleistocene period and is encountered in the southern portion of the subbasin. This unit is up to 600 feet thick in the subsurface (DWR 2000). In several studies (William and Curtis 1977, Springhorn 2008) the Sutter Buttes Rampart has been separated into two distinct units: the Rhyolitic Rampart and the Andesitic Rampart. The Andesitic Rampart phase of volcanism was much larger than the Rhyolitic phase. All the large peaks of the Sutter Buttes are andesitic domes and comprise the majority of the Rampart on the surface and the subsurface. The Sutter Buttes Rampart consists largely of gravel, sand, silt, and clay sediments which were deposited circumferentially around the Buttes as a geologic apron. These sediments may extend up to 15 miles north of the Sutter Buttes and west beyond the Sacramento River. Certain zones within these units yield large quantities of water (DWR 2004).

Laguna Formation

The Laguna Formation is Plio-Pleistocene in age and was deposited between 4 million and 2 million years ago. The Laguna Formation is comprised of Sierra Nevada sourced sediments, consisting of consolidated alluvial gravel, sand, and silt, comprised of granitic, metamorphic, and volcanic material. Estimates of the thickness of the Laguna Formation range from 180 feet (Helley and Harwood 1985) to 1,000 feet (Olmstead and Davis 1961). The Laguna Formation is characterized as being moderately consolidated and poorly to moderately cemented. Because of this, the permeability of formation is generally low to moderate. Wells completed in this formation have been observed to yield only moderate quantities of water (DWR 2003).

Tuscan Formation

The Tuscan Formation has been the subject of much interest in recent years. The Tuscan Formation is a regional aquifer system wholly or in parts of Tehama, Butte, Glenn, Colusa, and Sutter County. Within Sutter County, there has been limited analysis done on the subsurface extent of the Tuscan Formation. It is likely that the Tuscan Formation is only present in the northern portion of the County and consequently is not a major water resource for the County.

The Tuscan Formation is Plio-Pleistocene in age and was deposited between 4 million and 2 million years ago. The Tuscan Formation was derived by alluvial deposition associated with the erosion of volcanic material derived from Cascade volcanism. The formation outcrops from Red Bluff, in the northern part of the Sacramento Valley, to Oroville, southeast of Chico, and has been recognized in the subsurface at a distance of about 15 miles west of the Sacramento River (DWR 2003a). The deposits of the Tuscan Formation thin from east to west, from about 1,600 feet thick in the foothills of the Sierra Nevada to about 300 feet thick in the subsurface of the Sacramento Valley (Lydon 1969). In surface outcrops, the exposures of the Tuscan Formation are described as four separate, but lithologically similar units: Units A through D (Helley and Harwood 1985). Units A, B, and C are found within the subsurface in the northern part of the subbasin and units A and B are found in the southern part of the subbasin (DWR 2004). All of the units of the Tuscan Formation contain stratigraphic sequences of volcanic mudflows, volcanic conglomerates, volcanic sandstones, siltstones, and tuff deposits. In the subsurface, the Tuscan Formation consists largely of black volcanic sand and gravel, with interbedded layers of tuff breccias and tuffaceous clays (Ferriz, H. 2001). Unit A is the oldest (deepest) water-bearing unit and is distinguished from Units B and C by the presence of metamorphic clasts. Unit B contains equal distributions of volcanic mudflows, conglomerates, and tuffaceous sandstones. Units A and B are referred to as the "Lower Tuscan Formation". Unit C is capped by massive volcanic mudflows with some interbedded conglomerates and sandstones. In the subsurface, the volcanic mudflows of Unit C act as a confining layer to groundwater flow, separating the more permeable deposits of the Lower Tuscan Formation (Helley and Harwood 1985).

4.2.4.2. Sutter Subbasin (Basin Number 5-21.62)

The Sutter Subbasin underlies the central portion of Sutter County and is wholly within the boundaries of the County. The subbasin is bound by the confluence of Butte Creek with the Sacramento River and the Sutter Buttes to the north, by the Feather River to the east, by the confluence of the Sutter Bypass and Sacramento River to the south, and by the Sacramento River to the west. The Sutter Subbasin aquifer system consists of late Tertiary to Quaternary aged deposits comprised of Sierra-sourced (Sierra Nevada) detritus and volcanic and clastic rocks in the northern portion of the subbasin around the Sutter Buttes. The identified geologic formations that comprise the Sutter Subbasin are (from youngest to oldest):

- Recent Alluvial Deposits;
- the Pleistocene aged Sutter Buttes Rampart and Victor Formation;
- the Pliocene Laguna Formation; and
- the informally named Sutter Formation.

Recent Alluvial Deposits

The Holocene aged stream channel and flood plain deposits occur along the current and ancestral paths of streams and rivers in Sutter County. The stream channel and flood plain deposits consist of unconsolidated gravel, sand, silt, and clay. Both thickness and grain size decrease as the distance increases from their source. Where present, the stream channel and flood plain deposits extend from ground surface to an estimated depth of 100 feet (Helley and Harwood 1985). These units are highly permeable and provide for large amounts of groundwater recharge within the subbasin. This unit is highly permeable, and yields significant quantities of water to wells (DWR 2000).

Sutter Buttes Rampart

The Sutter Buttes Rampart is Middle to Lower Pleistocene aged alluvial deposit that is encountered in the northern portion of the subbasin. This unit can be up to 600 feet thick in the subsurface (DWR 2000). In several studies (William and Curtis 1977, Springhorn 2008), the Sutter Buttes Rampart has been separated into two distinct units: The Sutter Buttes Rhyolitic Rampart and the Sutter Buttes Andesitic Rampart. The deposition and composition of Rhyolitic Rampart reflects the initial stages of volcanism and deposition around the Sutter Buttes, while the Andesitic Rampart reflects the later stages. These fan deposits form an apron around the Buttes and consist largely of gravel, sand, silt, and clay, and may extend up to 15 miles north of the Sutter Buttes and west beyond the Sacramento River. Certain zones within these units yield large quantities of water (DWR 2004).

Victor Formation

The Pleistocene aged Victor Formation is comprised of alluvial fan deposits composed of Sierra-sourced loosely consolidated gravel, sand, and silt. The Victor Formation has an estimated thickness of 100 feet (DWR 2004). This unit is observed to have an impermeable surface due to the presence of hardpan and clay pan soils (DWR 2003). At its base, the Victor Formation has been observed to have moderate

permeability and provides most of the groundwater for domestic and shallow irrigation wells in Sutter County (DWR 2003). Wells completed in this unit have been reported to have yields as high as 1,000 gpm.

Laguna Formation

The Laguna Formation is comprised of Sierra sourced, consolidated alluvial gravel, sand, and silt, which consist of granitic, metamorphic, and volcanic material. Estimates of the formations thickness range from 180 feet (Helley and Harwood 1985) to 1,000 feet (Olmstead and Davis 1961). The Laguna Formation is characterized as being moderately consolidated and being poorly-to-moderately cemented, because of this, the formation generally has a low to moderate permeability. Wells completed in this formation have been observed to yield only moderate quantities of water (DWR 2003).

Sutter Formation

The Mio-Pliocene aged Sutter Formation is an informally named stratigraphic unit that underlies the area around the Sutter Buttes and the central portion of Sutter County. The extent of the deposits have been characterized on a local to sub-regional scale and have been generally classified as volcanic and epiclastic[3] sediments derived from volcanic sources located to the east in the Sierra Nevada, western Nevada, and the southern Cascade Volcanic Province (Springhorn 2008). Due to the complexity of identifying distinguishable characteristics within these deposits, informal and formal stratigraphic units within this region have been grouped together. Some of the major regional stratigraphic units that have been included in the Sutter Formation (from youngest to oldest) are the Tuscan, Mehrten, and Princeton Valley fill deposits.

4.2.4.3. North American Subbasin (Basin Number 5-21.65)

A portion of the North American Subbasin underlies the southeastern section of Sutter County. The North American subbasin is bound by the Bear River to the north, the Feather River to the west, the Sacramento River to the south, and in the east by a north-south trending line that represents the approximate edge of the alluvial basin (DWR 2004). The North American Subbasin is dominated by late Tertiary to Quaternary aged deposits consisting of Sierra-sourced volcanic sediments and alluvial derived sediments. The identified geologic formations that comprise the North American Subbasin are (from youngest to oldest):

[3] Consisting of fragments of preexisting rocks

- Recent Alluvial Deposits;
- Older alluvial deposits (the Pleistocene aged Modesto, Riverbank, Victor, and Laguna Formations); and
- the Mio-Pliocene aged Mehrten Formation.

Recent Alluvial Deposits

Stream channel deposits are Holocene in age and were deposited between 11,000 years ago and present day. The stream channel deposits occur along the current and ancestral paths of streams and rivers in Sutter County. The stream channel deposits consist of unconsolidated gravels, sand, silt, and clay, derived from active stream deposition, overbank sedimentation, and the erosion and deposition of existing Quaternary stream terrace deposits such as the Modesto and Riverbank Formations. Where present, the stream channel deposits extend from ground surface to a depth of 100 feet (Helley and Harwood 1985). This unit is highly permeable, and yields significant quantities of water to wells (DWR 2000).

The flood plain deposits consist primarily of silt and clay size sediments, with intermittent lenses of stream channel deposits. These deposits are generally observed along the flanks of existing and ancestral stream and river systems. These deposits have an estimated thickness up to 100 feet. Being that this unit is primarily comprised of finer-grained material, permeability is generally poor and generally yields low quantities of water. Brackish water is commonly encountered within this unit (DWR 2000).

Older Alluvial Deposits

Within this subbasin, a number of geologic formations have been assigned to the category "older alluvium" including: the Modesto, Riverbank, Victor, and Laguna Formations (DWR 2004). These deposits generally underlie the Recent Alluvial Deposits and consist of loosely to moderately compacted gravel, sand, silt, and clay size sediments that were derived and deposited under alluvial conditions. The thickness of these units ranges from approximately 100 to 650 feet (DWR 2004).

Mehrten Formation

The Mehrten Formation is Mio-Pliocene in age and consists of a sequence of volcaniclastic and volcanic rocks. In the subsurface, the Mehrten Formation ranges in thickness from 200 feet to 1,000 feet along the axis of the Sacramento Valley (DWR

2003). The Mehrten Formation is comprised of two distinct geologic units. The first unit consists of sediments deposited under alluvial and fluvial conditions and are comprised of gravel, sand, silt, and clay size sediments. This unit is highly permeable and wells constructed within this unit have been observed to produce yields exceeding 1,000 gpm (DWR 2003). The second unit consists of dense volcanic flows of tuff breccias with some interbedded conglomerates and sandstones. This unit acts as a confining layer between sand intervals and has a thickness that ranges from 200 to 1,200 feet in the subsurface (DWR 2003).

4.2.5. Areas Outside a Designated Groundwater Basin

The only part of the County that is not within a designated groundwater basin is the area consisting of the Sutter Buttes. Groundwater is likely found in the subsurface in fractures of the volcanic rock; however, historic groundwater levels and water quality were not reviewed in the preparation of this GMP. There are no local entities, aside from private domestic water users, that utilize groundwater resources in this area.

4.3. Groundwater Levels

DWR does not currently consider any of the groundwater subbasins underlying the County to be in overdraft. Overdraft is characterized by a declining trend in groundwater levels over multiple years without recovery during recharge events. Historic groundwater level data were reviewed for each of the subbasins within the County. DWR maintains a publicly available on-line database, which includes groundwater level data for the County. The DWR Water Data Library (WDL) website can be found at http://www.wdl.water.ca.gov. Wells monitored by DWR and cooperating agencies are identified by the State Well Number (SWN). Data can be obtained for specific wells by means of a map interface, by groundwater basin, or by the assigned SWN.

A 79-year period of record for water level measurements in Sutter County depicts a groundwater system that has experienced changing conditions over time. A number of DWR monitored wells were selected throughout the County to represent these changes. The locations of these wells, along with their associated hydrographs illustrating the historic groundwater levels, are shown in Figure 9. Groundwater level data from well 10N/4E-12A1, a 290-foot-deep well located in the southeast portion of Sutter County, and well 13N/3E-32N1, a shallow (less than 100 feet deep) well located in the southern portion of the County show the groundwater levels typical of different areas of the County. Groundwater levels in well 10N/4E-12A1 are characteristic of areas of high groundwater use and differing water conditions. Water levels fluctuate, sometimes dramatically, in response to changes in groundwater use and hydrologic conditions. This well is located in an area where agricultural

demands are supplied entirely with groundwater. The Sacramento County Department of Water Resources website includes published groundwater elevation maps and indicates that this well is in close proximity to a large pumping depression in northern Sacramento County. Groundwater levels in well 13N/3E-32N1 are characteristic of areas with lower groundwater use and more stable water conditions, and as such, water levels have not exhibited significant fluctuations over times. This well is located in an area where agricultural demands have been met almost entirely with surface water and groundwater demands have consequently been small.

Groundwater levels in well 10N/4E-12A1 have varied from 20 to 80 feet below ground surface over time. The combination of high groundwater use, the close proximity to a pumping depression, and changing climatic conditions has led to significant declines in groundwater levels from the early 1950' through the late 1970's. In the middle to late 1970's, drought conditions increased the rate of decline of groundwater levels on an even larger scale. In the mid 1980's and early 1990's, private and municipal water agencies in a collaborative effort started to implement conjunctive water use programs. With the availability of surface water, and the decrease in groundwater pumpage, groundwater levels have been steadily recovering from the early 1980's through present. Groundwater levels in this well are currently about 35 to 40 feet higher than they were in the late 1970's.

Groundwater measurements in well 13N/3E-32N1 shows very stable groundwater levels since measurements began in 1942. Groundwater levels have remained virtually unchanged, with water levels within 5 to 6 feet of ground surface and seasonal fluctuations of less than 10 feet.

The direction of groundwater flow during the fall season within the County has not changed significantly from 1912-1913 (Bryan 1923) to 2007; with the exception of the southeastern portion of the County. Contours of equal groundwater levels from fall 1912-1913 and fall 2007 were compared to identify changes over the 95 year period. Figure 10 depicts changes in groundwater levels over the aforementioned period. In most areas within the County, groundwater levels were not dramatically different in 2007 than they were in 1912-1913. In the central portion of the County, an increase in groundwater levels is observed in the data, which may be likely due to applied surface water for irrigation. In the southeastern portion of the County, a significant decline in groundwater levels is observed, which can be related to the high usage of ground water for irrigation of crops, and the influence of the large pumping depression in the northern portion of Sacramento County.

Fall and spring contour maps of equal groundwater elevation for 2007, 2008, 2009, and spring 2010 were reviewed (Figures 11 through 17) to determine groundwater gradient and

flow direction. The fall 2009 and spring 2009 groundwater contours generally follow the topography of the County and indicate that groundwater flows from the Sierra Nevada toward the Sacramento Valley (east to west), and north to south within the Valley. The fall 2007 contour map of equal groundwater elevations indicates a few locations where small pumping depressions are present, but in general, suggests the same direction of groundwater flow as seen in the spring 2007 groundwater contour map. Differences in groundwater levels between fall and spring appear to be a result of normal fluctuations in groundwater conditions from seasonal pumping and from wet and dry climatic cycles.

Data from the nested monitoring well at the extensometer site in the southern portion of the County indicates that, for the 14 years of available data, the spring groundwater levels in the monitored aquifer zones have been very similar, within a few feet of one another; except for the deepest completion where groundwater levels are approximately 10 feet lower than the shallower completions.

4.4. Groundwater Quality

The quality of groundwater is a product of the material through which it flows, or that flows into it. Local variations in the quality of the County's groundwater can limit its use for either potable water supply and/or agricultural applications. Groundwater contamination is a result of naturally occurring, point source contamination, and/or regional contamination. Naturally occurring contaminants of concern include dissolved salts [as measured by the specific conductance or electrical conductance (EC)], boron, nitrate, manganese, arsenic, and mercury. Point source contamination typically involves solvent releases originating mostly from gas stations and dry cleaners. Regional sources of contamination include applied fertilizers, salts, and leaky septic systems (nitrate and salt loading).

Historic and current water quality data (collected by the DWR, USGS, and local water purveyors) for wells located within the County were analyzed to characterize spatial and depth dependent water quality trends within the County's groundwater subbasins. The data was separated by well depth into the following three categories: less than 150 feet deep, 150 to 400 feet deep and more than 400 feet deep, as shown in Figures 18 through 23. The categories were chosen based on the occurrence at which certain stratigraphic units are observed in the subsurface in Sutter County.

4.4.1. Specific Conductance

Specific conductance was selected as an indicator of overall water quality. Specific conductance is a property of groundwater that is relatively simple to collect in the field at the well head and can help identify and characterize the condition of the non-marine fresh water

bearing aquifer system. Specific conductance is a measure of how effectively water will conduct electricity and is reported in micro Siemens (µS/cm) per centimeter and provides for the indirect measurement of the amount of dissolved solids (salts) in the groundwater. Lower specific conductance generally indicates better water quality (fresh water) while higher specific conductance generally indicates poorer water quality (brackish to saline water).

Applied irrigation and fertilizers can add salts to the water that percolate into the hydrogeologic system, increasing the specific conductance of the groundwater. Increased specific conductance values of the groundwater can also be attributed to naturally occurring brackish or saline water, such as geologic formations (aquifers) which are, or have been in the past, directly connected to a salt water body or where geologic formations were deposited under marine (salt water) conditions and which have inherently high dissolved salt concentrations. As shown in Figures 18 and 19, specific conductance values within the County are generally acceptable for agricultural and domestic use east of Highway 99 and in the northern half of the County. Elevated values for specific conductance are near to and/or exceed the recommended maximum contaminant level (MCL)[4] for domestic use in the shallow aquifers near the Sacramento River and in the aquifers below 900 feet. The elevated specific conductance could potentially be problematic for agricultural use. It is unclear why there is elevated specific conductance in this area.

4.4.2. Boron

Boron is a naturally occurring element. As shown in Figure 20, boron concentrations in the County are generally acceptable. Some deeper wells, which likely encounter more marine sediments, do contain elevated boron concentrations. Boron is a necessary element for agriculture, but may become toxic to crops above 500 micrograms per liter (µg/L). For public drinking water systems, the California Department of Public Health (CDPH) has established a notification level of 1,000 µg/L for boron. Increased concentrations of boron are observed in wells greater than 400 feet as well as in the southwestern portion of the County.

4.4.3. Nitrate

Nitrate is a contaminant which does not naturally occur in the subsurface. Elevated concentrations of nitrate are widespread in the Sacramento Valley. As shown in Figure 21, concentrations of nitrate in the populated areas of Sutter County are near or above the MCL for nitrate (as NO_3). The CDPH has established a primary MCL of 45 milligrams per liter (mg/L) for nitrate (as NO_3). Near the Sutter Buttes and Yuba City, nitrate concentrations in several wells (less than 150 feet) exceed the MCL. Where present, elevated concentrations of

[4] Recommended CDPH MCL for Specific Conductance is 900 µS/cm; upper limit is 1,600 µS/cm; short term is 2,200 µS/cm

nitrate are likely a result of overlying land uses, such as septic systems, animal enclosures, or applied fertilizers.

4.4.4. Manganese

Manganese is a naturally occurring element found in rocks and minerals. Its presence in groundwater is a result of the dissolution of the naturally occurring element in sediments containing minerals composed of manganese. As illustrated in Figure 22, manganese concentrations are elevated in all portions of the County, at levels that may cause aesthetic problems (odor or staining) for domestic and municipal uses, but generally below levels that could represent a health risk. There are, however, a few locations where manganese concentrations are near or exceed the CDPH established Notification Level of 50 µg/L, and may pose a health risk.

4.4.5. Arsenic

Arsenic is a naturally occurring element commonly found in alluvial sediments. Its presence in groundwater is a result of the dissolution of the element in sediments containing minerals containing arsenic. The CDPH has established a primary MCL of 10 µg/L for arsenic. As illustrated in Figures 19 and 23, arsenic concentrations are near to or above the CDPH MCL throughout the County in each of the aquifer zones assessed; conversely, concentrations of arsenic below the CDPH MCL are also present throughout the County in each of the aquifer zones assessed. Countywide, arsenic concentrations do not appear to be isolated to any one specific aquifer zone in the subsurface. However, recent data analysis suggests a possible correlation between elevated arsenic concentrations and the presence of volcaniclastic material of the Sutter Buttes Rampart formation. Concentrations of arsenic in the stratigraphic units that occur above and below the Rampart are generally less than 10 µg/L, whereas concentrations of arsenic within the Rampart material are between 10 to 370 µg/L (Springhorn, 2008). Concentrations of arsenic tend to be under the CDPH MCL southeast of Highway 99 and in the shallow aquifers.

4.4.6. Mercury

Historic gold mining processes and operations introduced toxic mercury into the surface water system throughout Northern California in the late 1800's. Due to the proximity of these operations to Sutter County, the PAG requested an assessment of the concentrations of mercury in the groundwater. A limited number of wells have been sampled within Sutter County for mercury, and as such, concentrations of mercury in the groundwater within Sutter County can not be well characterized. The few wells that have been sampled for mercury

indicate that mercury concentrations were low. In most cases, the concentrations were below the analytical detection limit (not detectable by the laboratory method used at the time).

4.5. Land Subsidence

Land subsidence is the gradual or sudden lowering of the land surface due to compaction of the underlying sediments. Two types of land subsidence are observed within alluvial sediments: inelastic and elastic. Inelastic land subsidence is a result of the compression of geologic formations and is irreversible. Inelastic land subsidence can be caused by excessive extractions of groundwater, oil, or natural gas. In discussing land subsidence, it is important to note that elastic (reversible) land subsidence is a normal occurrence, whereas inelastic land subsidence has associated negative impacts.

Although there are several causes of inelastic land subsidence, the compression of clay as a result of groundwater extraction is considered the most likely cause of subsidence north of the Sacramento-San Joaquin Delta (Page 1998). Once water is removed (mined) from compressible clay, the clay compresses and cannot accept water again, thus resulting in the permanent lowering of the overlying land surface (inelastic land subsidence). Clay compression has occurred in several locations in California, including the San Joaquin Valley. Compressible clay, such as the Corcoran Clay member of the Tulare Lake Formation, has been mapped over much of the western side of the San Joaquin Valley and can be over 130 feet thick. The subsidence documented in the San Joaquin Valley extends over a very large area, with over 30 feet of subsidence recorded in some areas.

North of the Sacramento-San Joaquin Delta in the Sacramento Valley, inelastic land subsidence, which has been directly related to clay compression as a result of groundwater extraction, has occurred in portions of Solano, Yolo, and Colusa Counties (Page 1998). Recorded land subsidence of more than two feet, and possibly as much as five feet, has occurred in this area. Subsidence in the Sacramento Valley appears to extend from Davis to Arbuckle. The area of subsidence appears to follow a local geologic feature known as the Zamora Syncline. A syncline is a structural fold that is formed by compressional forces which cause the sedimentary layers to have a concave, or a bowl-like geometry. Lakebeds are often associated with structural lows such as synclines. Lakebed deposits typically consist of fine-grained, clayey sediments, which settle out to the bottom of standing bodies of water and of which can include large volumes of freshwater diatoms[5]. Along with sediments, the microscopic diatoms settle and collect on the bottom of a lakebed. In Yolo County, diatomaceous (diatom rich) clay sediments have been identified within the geologic formations of Zamora Syncline. These diatomaceous clay sediments were identified to be

[5] Diatoms are unicellular aquatic algae, typically 20 to 200 microns (Prothero, 1998)

highly compressible (Page 1998). Although diatomaceous clay has been identified in numerous boreholes drilled in Sutter County, there have not been any recorded land subsidence issues.

Elastic land subsidence is observed to be cyclical and does not result in permanent compaction of subsurface materials. One example of elastic land subsidence is seasonal fluctuations in ground surface elevations that coincide with fluctuations in groundwater levels (and associated aquifer pressure). In elastic land subsidence, the subsurface pressures acting on the aquifer do not decrease enough so that subsurface materials permanently compact.

The DWR, in cooperation with federal, state and local agencies, installed and surveyed Global Positioning System (GPS) monuments to be able to measure and monitor ground surface elevations over time in the Sacramento Valley. The project, titled "The Sacramento Height-Modernization Project", consists of 339 monuments, spaced approximately 7 kilometers apart, in 10 counties. There are 32 monuments located in Sutter County. The GPS monuments will augment the existing network of extensometers which DWR currently monitors for land subsidence. In total, there are 13 extensometers located in Glenn, Colusa, Butte, Yolo, and Sutter Counties. The land subsidence monitoring network is shown in Figure 24. Only one of these extensometers, State Well Number 11N/4E-04, is located within Sutter County. It is located in the south-central part of the County along Highway 99, and extends to a depth of 1,003 feet, extending over a large portion of the fresh-water formations. The extensometer is installed in a dedicated monitoring well and is designed to measure any change in distance between the bottom of the well and the ground surface. DWR reports the accuracy of the extensometer to be ±0.001 feet. The extensometer provides for ongoing, real-time data collection, of land surface elevation changes. The Sutter County extensometer has been recording data since early 1994. In the 14 years since it began recording, the extensometer in Sutter County has recorded seasonal (cyclic) elastic land subsidence of approximately 0.03 feet (approximately one-third inch). There has been no indication over the period of record that any inelastic subsidence has occurred.

4.6. Groundwater-Surface Water Interaction

Several clustered monitoring wells located throughout the county adjacent are used to monitor changes in surface flow or quality that directly affect the groundwater system (levels or quality), and/or to monitor changes in surface flow or quality that are caused by groundwater pumping. These monitoring wells are adjacent to surface water bodies, and have a river stage gage located in the immediate vicinity.

Several of the network wells are located along the banks of the Sacramento, Feather, and Bear Rivers, as shown in Figure 25. The relationship between the volume of water flowing in the major rivers/streams and the influence the surface water imparts on groundwater elevation are being monitored with a combination of nested monitoring wells and river stage gages. Four stations exist in the County for observing this interaction: on the Sacramento River below Wilkins Slough (WLK), on the Bear River at Pleasant Grove Road (BPG), on the Sutter Bypass at RD 1500 pump (SBP), and along the Feather River above Star Bend (FSB). Sutter County also monitors a river stage gage at Boyd's Landing (FBL). At stations BPG and FBL, observations of water surface/groundwater elevations trend closely during high flow/stage events in the rivers, suggesting a significant hydrologic connection between the groundwater in the shallow aquifers and the surface water.

4.7. Groundwater Recharge

Groundwater recharge is the process in which groundwater is replenished. The geologic formations that comprise the aquifer system underlying the County extend well beyond the County's jurisdictional boundaries. Several processes are responsible for recharge of the groundwater basin. On a regional scale, surface water flowing over the surface expression of the geologic formations (surface outcrops) allows for direct infiltration into the hydrogeologic system. Figure 26 depicts contours of equal groundwater elevations, superimposed over the surface geology, for the Sacramento Valley Groundwater Basin. Groundwater flow is perpendicular and down gradient to the contour interval. On the east side of the Sacramento Valley Groundwater Basin, the groundwater contours become parallel to and follow the margin of the valley, indicating groundwater is moving through the subsurface from the east to the west. Locally, groundwater recharge occurs where surface water flows over permeable sediments (gravel and sand) in the river channels, allowing for the direct infiltration of surface water. Deep percolation of applied irrigation water also recharges the groundwater basin. Additionally, surface water deliveries have increased the quantity of water flowing down the river, adding available water to recharge the underlying aquifers helping to improve groundwater elevations.

The amount of groundwater recharge is dependent on the available storage space within the aquifer(s). Depending on the degree of separation between the elevation of the bottom of the river or stream and that of the groundwater, streams can either "lose" water into the underlying aquifer(s) or "gain" water. Where groundwater levels are at or above the elevation of surface water, groundwater will discharge into the stream (gaining stream). Where there is a separation between the groundwater and surface water, water flowing downstream will recharge into (losing stream) the groundwater basin (although the contribution has not been

studied). Conversely, if groundwater levels are at land surface, there will be refusal of any "new" water into the subsurface.

The State Water Resources Control Board has identified hydrogeological vulnerable areas, meaning vulnerable to groundwater contamination, where geologic conditions allow recharge to the underlying aquifers. Generally, these areas include the coarse deposits associated with the Feather River.

4.8. Groundwater Infrastructure

According to DWR records, 6,742 well completion reports have been filed for wells constructed in Sutter County. Well completion reports are not always filed with DWR, even though they are required by law, so the number of reports likely under-represent the actual total for the County. Of the wells for which well completion reports have been filed:

- 3,344 are domestic wells
- 1,167 are irrigation wells
- 854 have unknown or other uses
- 308 are monitoring wells
- 75 are municipal wells
- 34 are industrial wells
- 13 are test wells
- Seven (7) are stock-watering wells
- 12 are fire or frost protection wells
- Two (2) are cathodic protection wells

Figure 27 shows the number of DWR well completion reports filed for Sutter County from 1928 through 2007. The figure only illustrates wells that were classified as either: domestic, irrigation, or public supply. Domestic wells were constructed at a rate of approximately five per year from 1941 through 1950, but have been constructed at a rate of approximately 59 per year since then. Irrigation wells tend to be constructed more frequently during drought periods, in the mid-1970's and early 1990's. On average, 16 irrigation wells are constructed per year; however, significantly more wells are constructed during droughts. Municipal well construction has averaged two-and-a-half per year. Of the wells for which records exist, approximately 700 wells are classified as either abandoned or destroyed.

Figure 28 shows the average depth of wells constructed from 1950 through 2005. The average depth of domestic wells has fluctuated since the 1930's, but has generally been about 100 feet deep. The average depth of irrigation wells has fluctuated significantly, but has been about 160 feet deeper than the average depth of domestic wells in any give year, or an average of about 260 feet deep. Municipal well depths are inconsistent and vary widely in

depth, from about 50 to 700 feet deep. Combined with the small number constructed annually, calculation of an average depth of new municipal wells would not be meaningful.

5. GROUNDWATER MANAGEMENT PLAN REQUIRED, VOLUNTARY, AND RECOMMENDED COMPONENTS

California Water Code §10750 et seq., as amended by Senate Bill (SB) 1938, defines the required and voluntary components of a GMP and establishes procedures by which they must be developed. DWR recommends additional elements to include in a GMP in Bulletin 118 Update 2003, Appendix C. The Sutter County GMP includes the components required in the Water Code and has been developed in accordance with the required procedures. This GMP also includes many of the voluntary and recommended GMP components. This GMP also includes components designed to address the requirements of California Water Code §10920 et seq., which establish requirements for groundwater monitoring that affect eligibility for grant funding.

5.1. California Water Code Requirements

Section 10750 et seq. of the California Water Code, as amended by SB 1938, requires GMPs to include six mandatory components to be eligible for the award of funds administered by DWR for the construction of groundwater projects or groundwater quality projects. These components are listed below.

Description	*GMP Section*
Make available to the public a written statement describing the manner in which interested parties would be allowed to participate in the development of the GMP.	1.4
Include Basin Management Objectives (BMOs), including components relating to the monitoring and management of groundwater levels, groundwater quality degradation, inelastic land subsidence, and changes in surface flow and surface water quality that directly affect groundwater levels or quality or are caused by groundwater pumping.	6.2
Prepare a plan that involves other agencies that enables Sutter County to work cooperatively with other public entities whose service area or boundary overlies the groundwater basin.	7.1.5
Prepare a map that details the area of the groundwater basins, Sutter County's boundaries, and other local agencies within the groundwater basins.	Figure 1

Description	*GMP Section*
Adopt monitoring protocols to detect changes in groundwater levels, groundwater quality, inelastic surface subsidence, and flow and quality of surface water that directly affects groundwater levels or quality or are caused by groundwater pumping.	7.1
For areas outside the groundwater basins, use geologic and hydrologic principles appropriate to those areas.	4.2.5;7.1.4

5.2. DWR Bulletin 118 Recommended Components

DWR's Bulletin 118 recommends other components that may voluntarily be included in a GMP. These are listed below.

Description	*GMP Section*
Establish an advisory committee of stakeholders to help guide the development and implementation of the plan and provide a forum for resolution of controversial issues.	1.4
Describe the area to be managed under the GMP.	1.3
Describe how meeting each BMO will contribute to a more reliable long-term groundwater supply, and describe management actions to achieve each BMO.	6.2
Describe GMP monitoring program.	7.1
Describe integrated water management planning efforts.	7.1.5
Periodically report groundwater basin conditions and management activities.	7.1.6
Evaluate GMP periodically.	7.1.6

5.3. California Water Code Voluntary Requirements

California Water Code §10753.8 lists twelve issues of groundwater management which may voluntarily be included in a groundwater management plan.

Description	*GMP Section*
Control of saline water intrusion.	6.1.3
Identification and management of wellhead protection areas and recharge areas.	4.7; 6.1.3
Regulation of the migration of contaminated groundwater.	N/A
Administration of well abandonment and well destruction program.	6.1.3
Mitigation of conditions of overdraft.	4.3
Replenishment of groundwater extracted by water producers.	N/A
Monitoring of groundwater levels and storage.	4.3; 5.4
Facilitating conjunctive use operations.	6.1.3
Identification of well construction policies.	6.1.3
The construction and operation of groundwater contamination cleanup, recharge, storage, conservation, water recycling, and extraction projects.	N/A
The development of relationships with state and federal regulatory agencies.	7.1.5
Review of land use plans and coordination with land use planning agencies to assess activities which create a reasonable risk of groundwater contamination.	7.1.6

5.4. California Water Code Groundwater Monitoring Components

On November 4, 2009 the State Legislature amended the Water Code with Senate Bill SBx7-6, which mandates a statewide groundwater elevation monitoring program to track seasonal and long-term trends in groundwater elevations in California's groundwater basins. To achieve that goal, the amendment requires collaboration between local monitoring entities

and DWR to collect groundwater elevation data. Collection and evaluation of such data on a statewide scale is an important fundamental step toward improving management of California's groundwater resources.

In accordance with this amendment to the Water Code, DWR developed the California Statewide Groundwater Elevation Monitoring (CASGEM) program. The intent of the CASGEM program is to establish a permanent, locally-managed program of regular and systematic monitoring in all of California's alluvial groundwater basins. The CASGEM program will rely and build on the many, established local long-term groundwater monitoring and management programs. DWR's role is to coordinate the CASGEM program, to work cooperatively with local entities, and to maintain the collected elevation data in a readily and widely available public database. DWR will also continue its current network of groundwater monitoring as funding allows.

The law anticipates that the monitoring of groundwater elevations required by the enacted legislation will be done by local entities. The law requires local entities to notify DWR in writing by January 1, 2011 if the local agency or party seeks to assume groundwater monitoring functions in accordance with the law (Water Code §10928).

Additionally, on or before January 1, 2012, the law requires that Monitoring Entities shall begin reporting seasonal groundwater elevation measurements to DWR (Water Code §10932).

Local entities in Sutter County that have submitted official notifications to DWR to be considered for CASGEM Monitoring Entities include:

- Sutter Extension Water District
- Feather Water District
- Reclamation District 1500 (including RD 1500, Pelger Mutual Water Company and Sutter Mutual Water Company)
- Natomas Central Mutual Water Company
- South Sutter Water District

Garden Highway Mutual Water Company has shown interest in participating in CASGEM but has not yet completed the official notification submittal process include.

Local entities that submit complete Monitoring Entity notifications and adequate groundwater monitoring plans and well networks will be officially designated by DWR to be

the Monitoring Entities for their respective subbasin or portion of a subbasin for the purposes of the CASGEM Program. However, if no local monitoring entity volunteers or is identified for a particular area or groundwater basin, DWR may assume the monitoring and reporting duties and certain entities in the basin may not be eligible for water grants or loans administered by the state.

Sutter County is severely limited in its ability to take a lead in groundwater monitoring because of budget and staff shortages. Furthermore, the County does not own any groundwater monitoring wells and does not conduct any groundwater monitoring on its own. For this reason, Sutter County does not seek to assume groundwater monitoring functions under California Water Code §10920 et seq. However, the County does promote the coordinated collection of groundwater elevation data through its Groundwater Monitoring Program, discussed in Section 7.1 of this GMP.

6. GROUNDWATER MANAGEMENT GOALS AND BASIN MANAGEMENT OBJECTIVES

6.1. Groundwater Management Goals

Sutter County's groundwater management goals represent the overarching intent of the County with regard to groundwater management. Basin Management Objectives (BMOs) and Management Actions must be consistent with these Groundwater Management Goals, and must contribute to achieving the goals. Sutter County's goals for groundwater management (as developed with input from the public through PAG meetings and workshops) are:

- To promote responsible groundwater use in Sutter County so groundwater is available to meet present and future demands.
- To provide groundwater users with information and guidance to help them be responsible stewards of the groundwater resources in Sutter County.
- To discourage activities that could reduce the long-term availability of high-quality groundwater in Sutter County.

Each of the Groundwater Management Goals is discussed below.

6.1.1. To Promote Responsible Groundwater Use in Sutter County So Groundwater is Available to Meet Present and Future Demands.

One of Sutter County's main goals for groundwater management is to ensure that a reliable water supply is available so that water users in the County can be confident that water will be available to meet domestic, irrigation, and other demands on an ongoing basis.

The goal to promote responsible groundwater use in Sutter County is intended to provide the County with useable groundwater resources now and in the future. This is important because the socio-economic well being of the County could be adversely affected if the groundwater supply becomes less useable from a supply or quality standpoint. Ensuring responsible groundwater use will help protect groundwater rights and maintain local control because adjudication of the groundwater basin will not be warranted if long-term groundwater sustainability can be achieved.

6.1.2. To Provide Groundwater Users with Information and Guidance to Help Them Be Responsible Stewards of the Groundwater Resources in Sutter County.

It is important to understand that in order to responsibly manage groundwater to ensure long-term groundwater sustainability, it is necessary to thoroughly understand the groundwater system underlying the County, along with its capabilities and limitations. Sutter County's water resources should be viewed as a dynamic system with the amount of available surface water and groundwater varying over time with fluctuations in hydrologic and climatic conditions. The implementation of a surface/groundwater monitoring program to observe and document the County's resources is essential to provide the community with the necessary information to accomplish this management objective.

6.1.3. To Discourage Activities that Could Reduce Long-Term Availability of High-Quality Groundwater in Sutter County.

It is important to recognize that this management objective is not intended to restrict the users within the community from exercising their legal rights to groundwater. Groundwater is a resource that should remain available for the people of the County to use beneficially on their property. The intent of this objective is for groundwater management to be accomplished in a way that minimizes activities that could potentially reduce the long-term availability of high-quality groundwater in Sutter County. There are a number of management practices that can be utilized to accomplish this goal. Two of the main practices that should be considered are conjunctive use programs and improving County well standards.

The goal of optimizing the conjunctive use of surface water and groundwater will enhance the County's water supply reliability and maximize the available water supply. The term "conjunctive use" basically means using surface water and groundwater together to meet water demands, using different proportions of each depending upon availability. For example, in years of reduced surface water availability, more groundwater would be used and groundwater levels might decline. Conversely, in years of full surface water availability, less groundwater would be used and groundwater levels would be allowed to recover. Optimizing conjunctive use generally means that, whenever possible, surface water is used to the fullest extent with groundwater serving as a "back-up" supply. This maximizes the available water supply because unused surface water generally flows downstream and is lost, but unused groundwater remains in the ground and would be available for later use.

On the other hand, the potential may exist in some areas of the County where groundwater levels are (and have historically been) high, to utilize more groundwater and thus induce more recharge (by creating additional storage space within the aquifer) thereby increasing the total water supply available in the County.

A related goal is to "even out" water availability in the County. There are cases when surplus water is available in some areas of the County, but other areas have inadequate supplies. For example, an area with high groundwater levels may have adequate or excess surface water, while another area may have low groundwater levels and inadequate surface water. In this case, groundwater could be pumped in the area with high groundwater levels, and their surface water could be transferred to the area with low groundwater levels so that area does not have to rely as much on groundwater. If possible, undertaking such projects will help improve the overall water supply reliability in the County.

The goal for updating the County's well standards is to add additional levels of protection to ensure that the design of new well structures prohibit the downward migration of surface/shallow contaminants or cross contamination of aquifers. The County has adopted standards as set forth in Chapter II of the State Department of Water Resources Bulletin 74-81, and as supplemented by Bulletin 74-90, entitled "Water Well Standards: State of California", except as otherwise provided in Section 700, Chapter 765 "Water Wells" of the Sutter County Municipal Code[6]. Some amendments that could be made to the existing well standards are: (1) require the use of geophysical surveys for all new well projects, (2) increase the required minimum sanitary seal depths, (3) institute water quality sampling during cable tool well drilling, (4) institute well restriction zones where poor water quality is known, and (5) improve/implement well destruction programs.

Requiring the use of geophysical surveys (spontaneous potential, 16- and 64-inch resistivity) in all new boreholes can help to enhance groundwater protection by identifying the zone(s) of poor water quality, as well as the depths of confining layers, which can be used to design adequate sanitary/annular seals. With this data, future wells can be designed to effectively seal against poor water quality while providing adequate measures for aquifer protection.

Increasing the minimum sanitary seal depth required for new wells is a proactive measure that can effectively increase aquifer protection. Increasing the required sanitary seal to a minimum depth of 50 feet for all new wells can seal off shallower aquifers with poorer water quality from the deeper aquifers with better water quality, as well as impede the

[6] http://www.co.sutter.ca.us/doc/government/bos/ordinance

downward migration of surface contaminants. Currently, the standards in force require a minimum 50-foot sanitary seal for municipal supply wells and 20-foot sanitary seal for all other wells (Bulletin 74-90).

Many wells in Sutter County have been drilled and constructed utilizing the cable tool drilling method. One of the main troubles with cable tool wells is that they usually are constructed across, and connect, multiple aquifer zones. Some of these well structures likely have become conduits for the downward migration and cross contamination of aquifer zones. Water quality sampling during the drilling of these wells (field tests for TDS or specific conductance) would delineate between problematic and non-problematic aquifer zones. If an existing well is deemed problematic (i.e. poor water quality), corrective measures through well modification or even well destruction could help mitigate the movement of poorer water quality between aquifer zones.

Implementing well restriction zones where water quality contamination is known to exist in specific aquifers can aide in protecting aquifers with acceptable water quality. Restricting the construction of wells or requiring specific seal intervals can provide an additional level of aquifer protection. Certain areas within Sutter County have localities of poorer water quality. It may be beneficial to assess the risk of drilling and constructing new wells within these areas. If adequate aquifer protection can not be achieved during construction activities, it may be warranted to designate well exclusion zones.

Unused, unsecured, abandoned, or improperly destroyed wells can act as a direct conduit for surface water infiltration or degradation of one or more aquifers, if they are connected by the well structure. Well destruction requirements adopted by the County currently require abandoned wells to be destroyed. Currently, these requirements require the uppermost 20 feet of the well/borehole be filled with impervious material. Special situations, in the case where vertical movement of poor water quality could contaminate an aquifer with good water quality, require impervious sealing material to be placed adjacent to confining layers. Increasing oversight of the permitting process during the planning and design of well destruction programs can ensure added protection against the vertical migration of poor water quality.

6.2. Basin Management Objectives

Basin Management Objectives (BMOs) are guidelines established to ensure that the County's basin management goals are being fulfilled. BMOs create a systematic method for collecting and monitoring data for specific components of the groundwater system and to provide for the dissemination of such information to the public. The objective of the BMOs is not to assign a fixed value, or level, to each parameter, but to allow for the early identification of

potential problems with sufficient time for the County and its groundwater users to formulate an action plan to mitigate adverse effects to its groundwater resource.

Sutter County's BMOs address the following parameters:

- Groundwater levels
- Groundwater quality
- Inelastic land subsidence
- Surface water
- Coordination

6.2.1. Groundwater Levels BMO

There are three BMOs for groundwater levels:

- *Avoid ongoing declines in groundwater levels during water year types identified by DWR to be "above normal" or "wet" for the Sacramento Valley.*
- *Avoid problematically high groundwater levels.*
- *Provide assistance with assessing problems and resolve disputes related to groundwater levels.*

Groundwater levels are to be managed to ensure adequate water supplies while avoiding adverse impacts and mitigating them if and when they do occur. Adverse impacts related to groundwater levels can occur from excessively high or low groundwater levels. What constitutes an excessively high or low groundwater level may change over time, and will also vary by land use and hydrologic and climatic conditions.

Excessively high groundwater levels are problematic in some areas of the County. High groundwater levels in Sutter County are often naturally occurring. However, groundwater levels can be raised by application of water to the ground surface through irrigation, surface storage, or recharge projects. When groundwater levels are high, there is no storage capacity available in the underlying aquifer for groundwater recharge from precipitation, stream flow, or excess applied irrigation water. This represents a lost opportunity to capture recharge and increase the overall water supply for the County. Adverse impacts related to high groundwater levels include:

- Damage to foundations, roads, and other infrastructure.

- Water-logging the root zone of certain crops.

Groundwater levels decline when pumping exceeds recharge and rise when recharge exceeds pumping. It is important to note that periodic short-term declines in groundwater levels (during drought periods and/or increased pumping), which are then followed by recovery to at or near historic highs (during wet periods and/or decreased pumping), are normal and do not represent overdraft. Excessively low groundwater levels that are caused by long-term declines without recovery, thus overdraft, can be avoided by reducing pumpage. This can be accomplished by expanding the conjunctive use with surface water. Adverse impacts related to low groundwater levels include:

- Infrastructure problems when lowered groundwater levels dewater pumps or wells, so groundwater cannot be extracted using existing infrastructure even though it is available at greater depths.
- Depleted available groundwater supply.
- Inelastic land subsidence.
- Riparian and/or native vegetation destroyed.
- Reduced surface water flow due to increases in streambed infiltration, or increases in the capture of groundwater that otherwise would have contributed to increasing the base flow of a surface water system.

6.2.2. Groundwater Quality BMO

The BMO for groundwater quality is to:

- *Improve the understanding of groundwater quality in Sutter County.*
- *Maintain or improve groundwater quality.*

Adverse impacts to groundwater quality most commonly occur when degradation of groundwater renders groundwater unsuitable for intended uses. Accordingly, what constitutes a significant adverse impact to groundwater quality is related to the purposes for which groundwater is used, and may change over time as land uses and water quality regulations change. Groundwater quality degradation can occur when groundwater pumping causes poor quality water (surface water or groundwater) to migrate into areas with good quality groundwater. It can also occur when surface contaminants migrate into groundwater. As a consequence, it is important to coordinate land use planning and

resource management activities in order not to create opportunities for water quality deterioration. Adverse impacts related to groundwater quality include:

- Degradation of groundwater quality so that yields are reduced for crops irrigated with groundwater.
- Degradation of groundwater quality so that it does not comply with drinking water quality standards.
- Degradation of groundwater quality so that it is no longer suitable for beneficial uses.

There are some areas in Sutter County that currently have problems with groundwater quality (particularly arsenic and salinity) that appear to be naturally-occurring. The BMO of maintaining or improving groundwater quality reflects the County's desire to improve the quality of naturally-occurring groundwater where possible, so that it is more useful as a water supply.

6.2.3. Inelastic Land Subsidence BMO

The BMO for inelastic land subsidence is to:

- *Avoid inelastic land subsidence that is linked to declines in groundwater levels.*

Inelastic land subsidence is the permanent compaction of the subsurface. In Sutter County, the activities that have the most potential to cause inelastic land subsidence are withdrawals of groundwater or natural gas from the subsurface. Adverse impacts related to inelastic land subsidence include:

- Reduction in the volume of the subsurface that results in a permanent loss in aquifer storage.
- Damage to foundations, roads, bridges, and/or other infrastructure.
- Change in surface topography that reverses the gradients in canals and ditches, and/or changes floodplains.

6.2.4. Surface Water

There are three BMOs for surface water:

- *To improve the understanding of the relationship between surface water and groundwater.*

- *To avoid changes in surface water flow and surface water quality that adversely affect groundwater levels or are caused by groundwater pumping.*
- *Avoid changes in surface water flow and water quality that adversely affect groundwater quality.*

Pumping from very shallow aquifer zones or poorly sealed wells has the potential to affect surface water or wetlands. Adverse impacts related to surface water or wetlands include:

- Depletion of surface flows and/or degradation of water quality.
- Destroying riparian and/or native vegetation and habitat.

6.2.5. Coordination

This BMO for coordination is to:

- *Coordinate County groundwater management efforts with other groundwater management efforts within and surrounding Sutter County.*

This BMO establishes the importance of local coordination of groundwater management and sharing of hydrogeologic data. To make effective and relevant decisions, the County must rely on current data regarding the quality and quantity of the underlying groundwater.

7. PLAN IMPLEMENTATION

Sutter County intends to implement this GMP through a Groundwater Monitoring Program and an Action Plan. In order to recognize and mitigate adverse impacts to the underlying groundwater system, a system is required to collect and disseminate information to the appropriate groundwater users and agencies.

7.1. Groundwater Monitoring Program

The role of monitoring is essential to implementing the BMOs. Monitoring is the process of collecting data that is used to better understand the groundwater basin underlying the County, evaluate groundwater conditions, facilitate groundwater management, and other related activities. In order for the County to promote sustainable groundwater management, as well as for groundwater users to make effective and relevant decisions, the data needs to be made publicly available.

7.1.1. Groundwater Level Monitoring

There is an extensive network of DWR monitored wells, both dedicated monitoring wells and wells with other uses, within Sutter County. Additionally, several water purveyors within the County monitor groundwater levels within their service areas by means of dedicated monitoring wells and production wells. There is an extensive inventory of wells with groundwater measurements within Sutter County. Historically, DWR and its partners have monitored 172 wells in Sutter County, including 15 dedicated monitoring wells. The earliest recorded DWR water level measurement in Sutter County took place in 1929. Wells accessible to DWR are typically agricultural or domestic wells in which the land owners have previous agreements with DWR to allow access for measurements. Overall, the County has adequate spatial distribution of its current network to obtain groundwater level measurements. For this GMP, DWR utilized 122 of the 172 wells to produce groundwater contour maps of equal elevation.

Water level measurements are generally made two times each year, in spring and fall. Measurements have been made at some monitoring wells on an almost-monthly basis. Twice-annual (spring/fall) water level measurements are generally sufficient for the purpose of determining changes in overall groundwater conditions over time. However, these measurements should reflect the annual high (spring) and low (fall) water levels. More frequent (i.e. at most monthly) measurements are necessary to confirm that the months chosen for spring and fall measurements reflect the months with the highest and lowest groundwater elevations, on average. Water level data is currently available from DWR's Water Data Library, at: http://well.water.ca.gov.

7.1.1.1. Vertical Groundwater Gradients – Nested and/or Clustered Monitoring Wells

The vertical gradients between aquifer zones are important because they give an indication of the direction (up or down) that groundwater will migrate if a pathway, such as a well that connects multiple aquifer zones, is present. To evaluate the vertical gradient between aquifer zones, data for the different aquifer zones at a single location is needed. The preferred way to obtain this data is with nested and/or clustered monitoring wells. Nested monitoring wells have multiple wells within a single borehole, with each well isolated from the others by annular seals. Clustered monitoring wells have a single well in each borehole, with the boreholes in close proximity to one another. Figure 19 shows the locations of the 15 nested and/or clustered monitoring wells in Sutter County. Eleven of these wells are in the DWR monitoring network with measurements taken twice a year, in spring and fall. The remaining four nested monitoring wells are pending inclusion into the network because they were constructed by private parties. All of these wells are dedicated monitoring wells.

7.1.1.2. Groundwater Flow Direction – Contour Maps

The direction of groundwater flow is evaluated with groundwater level contour maps. Groundwater contours are created which connect surfaces of equal elevation (or levels). Figure 17 illustrates the contours of equal groundwater elevation for measurements taken in the spring of 2010.

The current water level monitoring network spacing is suitable for contouring groundwater elevations. Additionally, it would be beneficial to include data from nearby monitored wells in Butte, Yolo, Sacramento, and Yuba Counties to better characterize the groundwater flow direction at the County lines.

7.1.2. Water Quality

Water quality samples from wells within the County have, in the past, been obtained either by local water purveyors, the DWR, or the USGS. Currently, the County only samples groundwater in Robbins, its only public water supply system. Groundwater samples have been collected for analysis in a total of 133 wells. The DWR has sampled 34 of these wells in Sutter County, fifteen of which are nested multiple-completion monitoring wells, as shown in Figure 19. The USGS has sampled 94 of these wells, and the remaining wells were sampled by water purveyors which have shared their data. The DWR expects to conduct water quality sampling of these wells every three years, or as funds are available. The water quality data is disseminated on the DWR WDL.

The results for the USGS water quality sampling are available on the National Water Information System (NWIS) website[7]. The USGS sampled these wells as part of a larger investigation to document the condition of the groundwater throughout the valley. It is not expected that the USGS will routinely sample these wells.

The current water quality monitoring network consists of DWR owned multiple-completion monitoring wells with a sparse distribution covering the entire County. Routine sampling of these wells will allow for water quality trends to be identified. As stated within this GMP, the County does not own any dedicated monitoring wells. In conjunction with DWRs efforts to collect and distribute water quality information of the groundwater resource, the County encourages private water purveyors to disseminate their water quality data to aid in documenting depth specific and County-wide water quality trends.

7.1.3. Land Subsidence

Land subsidence has not been historically reported or documented within Sutter County. Nevertheless, DWR installed an extensometer and began monitoring for ground surface displacement in 1994. Measurements are recorded on a daily basis, offering real-time and site specific measurements. On a more regional scale, DWR and its cooperating agencies, have implemented the Sacramento Valley GPS Height Modernization Project which will provide significant enhancements to a Sacramento Valley subsidence monitoring program. It is reported by DWR that the GPS monuments will be re-surveyed approximately every three years. The monitoring of land surface elevations will allow for periodic measurements of permanent land subsidence induced by groundwater pumping and/or natural processes. The surveys will be conducted in accordance with the National Geodetic Survey Standards for two centimeter accuracy.

When used in conjunction with surface subsidence survey data (GPS), the extensometer data could aide in identifying whether subsidence is occurring over the total depth of the monitoring well.

7.1.4. Future Groundwater Monitoring

The County's existing monitoring network is described above. Groundwater monitoring within the County is currently conducted by DWR and local water purveyors. The County will continue to cooperate with DWR and encourage the local water purveyors to continue to monitor groundwater levels. Under the voluntary guidelines of SBx7-6, selected local water purveyors will continue to monitor groundwater elevations for their

[7] http://waterdata.usgs.gov/nwis

respective service area(s), along with the DWR, under protocols established by DWR. The possibility exists that in the future, DWR may cease their monitoring if they lose funding for groundwater level measurements, and the responsibility of groundwater level monitoring will be entirely upon the local water purveyors.

All new wells should be sampled for basic water chemistry (i.e. specific conductance, arsenic, manganese, and nitrate). Although not required, the County may, in the future, consider requesting copies of laboratory reports to be submitted through the permit process. Water quality results from wells sampled by DWR are routinely placed on the WDL, and are often sampled every three years, or as funding allows.

The overall subsidence monitoring program should continue to be monitored by the extensometer and GPS monuments throughout the County. The Sacramento Valley GPS Network incorporates existing GPS networks and monuments to create a regional network that covers part or all of Colusa, Sutter, Glenn, Butte, Yolo, Yuba, Tehama, and Placer Counties.

For the area encompassing the Sutter Buttes, which is outside of a DWR delineated groundwater basin, groundwater is likely contained in the fractures of the volcanic rock as well as in the marine sands that compromise the Sutter Buttes. The area encompassing the Sutter Buttes is primarily privately owned and groundwater use is unknown but is likely limited to domestic wells or stock watering wells. It is suggested that private well owners monitor groundwater levels at least twice a year (fall and spring) in order to realize changing conditions. It is also good practice to test the quality of the groundwater for health based constituents.

7.1.5. Local and Regional Groundwater Management Coordination

Coordinating local and regional groundwater management is important to meeting Sutter County's Groundwater Management Goals because groundwater, like other resources, does not respect administrative/jurisdictional boundaries, and actions outside the County can affect groundwater in the County. Further, in order to achieve the Groundwater Management Goals, the County needs to be an "effective participant" in local and regional management efforts and work cooperatively with water managers to conduct effective groundwater management. To be an "effective participant", the County needs to be informed of its groundwater conditions and activities underway or planned, which may affect the resources positively or negatively. With time and appropriate documentation of water management activities and monitoring, an understanding of the resources can be obtained so that groundwater conditions can be the result of deliberate water management choices.

Coordinating groundwater management across local and regional jurisdictions will contribute to ensuring a reliable water supply by working towards management of entire groundwater basins, not just the portions underlying the County. Involvement in regional activities will help ensure that activities outside of Sutter County that affect the reliability of the groundwater supply in the County can be addressed through regional management actions. This involvement will also help protect water rights because the County's involvement with regional groundwater management will allow it to be part of a larger group that can exert more influence in preserving water rights north of the Delta. Finally, regional coordination will help the County maintain local control by ensuring that the County's interests are represented in regional groundwater management activities.

Sutter County recognizes the importance of regional coordination, collaboration, and communication and is signatory to the "Four-County Group," which has evolved into the "Northern Sacramento Valley – Integrated Regional Water Management Group", consisting of Butte, Glenn, Colusa, Tehama, Shasta, and Sutter Counties.

In addition to the water management coordination addressed above, which is more at a technical and operational level, it is important that coordination occur at the policy level as well. This is especially important for effective and consistent operations within water purveyors whose geographic jurisdiction extends beyond Sutter County. The processes to addressing water transfers, in particular, are different in each of the three counties. It would be important, as the GMP is implemented and the institutional structure and management processes become solidified, that a dialogue be established with the neighboring counties to address the need for developing consistency in processes that affect the management and operation of the respective water purveyors.

7.1.6. State of the Basin Report - Groundwater Condition and Groundwater Management Plan Evaluation

In the future, Sutter County and local water purveyors may benefit from preparing an annual report of the conditions of its groundwater basin. However, the present County staffing and funding levels are unable to accommodate this work effort. Groundwater elevation data for the County will be available through the CASGEM program and continued DWR monitoring. Additionally, new and/or current water quality data is periodically submitted and is available through the DWR Water Data Library. The County encourages cooperation among all groundwater users to share data (groundwater level and/or quality) which is not reported or what is readily available through the Water Data Library. Water quality data is also accessible through the Department of Public Health for permitted public water systems. Through this report, the County will encourage its groundwater users to be responsible stewards of the County's resources.

This GMP prepared by the County is not intended to be a static document. As conditions change, such as population, land uses, or climate, it may be warranted to revisit the County's goals and BMOs to ensure that the overall goals of sustaining its groundwater resources to meet current and future demands for the County are being satisfied. The County encourages cooperation among its groundwater users to keep these goals in mind. It is not Sutter County's intent of this GMP to be an enforcer with regards to groundwater use; however, as climatic and groundwater usage change in the future, it may be necessary to "check in" and adjust or expand this GMP.

7.2. Action Plan

7.2.1. Actions for Groundwater Levels BMO

To avoid ongoing declines in groundwater, to avoid abnormally high groundwater levels, the County has taken and will take the following actions:

Action	*Frequency*	*Status*
Participation in the "Northern Sacramento Valley – Integrated Regional Water Management Group"	As needed	2008 - Present
Maintain relationships with state and federal agencies	Annual	1850 - Present
Promote conjunctive use through public outreach	Annual	2008 - Present
Coordination with local and regional jurisdictions on groundwater.	Annual	2008 - Present
Ensure compliance with adopted policies in 2008 General Plan (Goal ER 6)	Annual	2008 - Present
Review groundwater contour maps prepared by DWR	Annual	2008 - Present
Disseminate groundwater level data on County's website	As needed	2010 - Present

7.2.2. Actions for Groundwater Quality BMO

To improve the understanding of groundwater quality, the County has taken and will take the following actions:

Action	*Frequency*	*Status*
Cooperate with DWR in its monitoring efforts	Annual	2010 - Present
Maintain relationships with neighboring counties	Annual	1850 - Present
Ensure compliance with adopted policies in 2008 General Plan (Goal ER 6)	Annual	2008 - Present
Ongoing coordination with local and regional jurisdictions on groundwater	Annual	unknown - Present

7.2.3. Actions for Inelastic Land Subsidence BMO

To avoid inelastic land subsidence that is linked to declines in groundwater levels, the County has taken and will take the following actions:

Action	*Frequency*	*Status*
Cooperate with DWRs monitoring efforts	Annual	2010 - Present
Participate in the "Northern Sacramento Valley – Integrated Regional Water Management Group"	Annual	2008 - Present
Establish and update a groundwater management plan website	Annual	2008 - Present
Review data from the extensometer installed in Sutter County	6 months	2010 - Present
Maintain relationships with state and federal agencies	Annual	1850 - Present

7.2.4. Actions for Surface Water BMO

To improve the understanding of the relationship between surface water and groundwater; to avoid changes in surface water flow and surface water quality that directly affect groundwater levels or are caused by groundwater pumping; and to avoid changes in surface flow and surface water quality that directly affect groundwater quality, the County has taken and will take the following actions:

Action	*Frequency*	*Status*
Engage in the "Northern Sacramento Valley – Integrated Regional Water Management Group"	Annual	2008 - Present
Establish a groundwater management plan website	Annual	2008 - Present
Maintain relationships with state and federal agencies	Annual	1850 - Present
Ensure compliance with adopted policies in 2008 General Plan (Goal ER 5)	Annual	2008 - Present

7.2.5. Actions for Coordination BMO

To coordinate County groundwater management efforts with other groundwater management efforts within and surrounding Sutter County, the County has taken and will take the following actions:

Action	*Frequency*	*Status*
Engage in the "Northern Sacramento Valley – Integrated Regional Water Management Group"	Annual	2008 - Present
Maintain relationships with state and federal agencies	Annual	1850 - Present
Establish and update a groundwater management plan website	As needed	2008 - Present

$CaCO_3$	calcium carbonate
CO_3^{-2}	carbonate
DOC	dissolved organic carbon
HCl	hydrochloric acid
HCO_3^-	bicarbonate
MTBE	methyl *tert*-butyl ether
NDMA	*N*-Nitrosodimethylamine
1,2,3-TCP	1,2,3-trichloropropane
TDS	total dissolved solids
THM	trihalomethane
VOC	volatile organic compound

Abbreviations and Acronyms—Continued

Units of Measurement

ft	foot (feet)
in.	inch
L	liter
mg	milligram
mg/L	milligrams per liter (parts per million)
mi	mile
mL	milliliter
mm of Hg	millimeters of mercury
µg/L	micrograms per liter (parts per billion)
µL	microliter
µm	micrometer
NTU	nephelometric turbidity units
pCi/L	picocuries per liter
per mil	parts per thousand
$\delta^{i}E$	standard delta notation, the ratio of a heavier isotope of an element (^{i}E) to the more common lighter isotope of that element, relative to a standard reference material, expressed in per mil

Notes

Temperature in degrees Celsius (°C) may be converted to degrees Fahrenheit (°F) as follows:

$$°F = (1.8 \times °C) + 32$$

Vertical coordinate information is referenced to the North American Vertical Datum of 1988 (NAVD 88).

Specific conductance is given in microsiemens per centimeter at 25 degrees Celsius (µS/cm at 25°C).

Concentrations of chemical constituents in water are given either in milligrams per liter (mg/L) or micrograms per liter (µg/L). Milligrams per liter is equivalent to parts per million (ppm) and micrograms per liter is equivalent to parts per billion (ppb).

Ground-Water Quality Data in the Middle Sacramento Valley Study Unit, 2006—Results from the California GAMA Program

By Stephen J. Schmitt, Miranda S. Fram, Barbara J. Milby Dawson, and Kenneth Belitz

Abstract

Ground-water quality in the approximately 3,340 mi^2 Middle Sacramento Valley study unit (MSACV) was investigated from June through September, 2006, as part of the California Groundwater Ambient Monitoring and Assessment (GAMA) program. The GAMA Priority Basin Assessment project was developed in response to the Groundwater Quality Monitoring Act of 2001 and is being conducted by the U.S. Geological Survey (USGS) in cooperation with the California State Water Resources Control Board (SWRCB).

The Middle Sacramento Valley study was designed to provide a spatially unbiased assessment of raw ground-water quality within MSACV, as well as a statistically consistent basis for comparing water quality throughout California. Samples were collected from 108 wells in Butte, Colusa, Glenn, Sutter, Tehama, Yolo, and Yuba Counties. Seventy-one wells were selected using a randomized grid-based method to provide statistical representation of the study unit (grid wells), 15 wells were selected to evaluate changes in water chemistry along ground-water flow paths (flow-path wells), and 22 were shallow monitoring wells selected to assess the effects of rice agriculture, a major land use in the study unit, on ground-water chemistry (RICE wells).

The ground-water samples were analyzed for a large number of synthetic organic constituents (volatile organic compounds [VOCs], gasoline oxygenates and degradates, pesticides and pesticide degradates, and pharmaceutical compounds), constituents of special interest (perchlorate, *N*-nitrosodimethylamine [NDMA], and 1,2,3-trichloropropane [1,2,3-TCP]), inorganic constituents (nutrients, major and minor ions, and trace elements), radioactive constituents, and microbial indicators. Naturally occurring isotopes (tritium, and carbon-14, and stable isotopes of hydrogen, oxygen, nitrogen, and carbon), and dissolved noble gases also were measured to help identify the sources and ages of the sampled ground water.

Quality-control samples (blanks, replicates, laboratory matrix spikes) were collected at approximately 10 percent of the wells, and the results for these samples were used to evaluate the quality of the data for the ground-water samples. Field blanks rarely contained detectable concentrations of any constituent, suggesting that contamination was not a noticeable source of bias in the data for the ground-water samples. Differences between replicate samples were within acceptable ranges, indicating acceptably low variability. Matrix spike recoveries were within acceptable ranges for most constituents.

This study did not attempt to evaluate the quality of water delivered to consumers; after withdrawal from the ground, water typically is treated, disinfected, or blended with other waters to maintain acceptable water quality. Regulatory thresholds apply to treated water that is served to the consumer, not to raw ground water. However, to provide some context for the results, concentrations of constituents measured in the raw ground water were compared with health-based thresholds established by the U.S. Environmental Protection Agency (USEPA) and California Department of Public Health (CDPH) and thresholds established for aesthetic concerns (secondary maximum contaminant levels, SMCL-CA) by CDPH. Comparisons between data collected for this study and drinking-water thresholds are for illustrative purposes only and are not indicative of compliance or noncompliance with regulatory thresholds.

Most constituents that were detected in ground-water samples were found at concentrations below drinking-water thresholds. VOCs were detected in less than one-third and pesticides and pesticide degradates in just over one-half of the grid wells, and all detections of these constituents in samples from all wells of the MSACV study unit were below health-based thresholds. All detections of trace elements in samples from MSACV grid wells were below health-based thresholds, with the exceptions of arsenic and boron.

Arsenic concentrations were above the USEPA maximum contaminant level (MCL-US) threshold in eight grid wells, and boron concentrations were above the CDPH notification level (NL-CA) in two grid wells. Arsenic was detected above the MCL-US in two flow-path wells. Arsenic, barium, boron, molybdenum, strontium, and vanadium were detected above health-based thresholds in a few of the RICE wells; these wells are not used to supply drinking water. All detections of radioactive constituents were below health-based thresholds, although six samples had activities of radon-222 above the lower proposed MCL-US threshold. Most of the samples from the MSACV wells had concentrations of major elements, total dissolved solids, and trace elements below the non-enforceable thresholds set for aesthetic concerns. Chloride and sulfate concentrations exceeded SMCL-CA thresholds in two and one grid well, respectively. Iron, manganese, and total dissolved solids concentrations were above the SMCL-CA thresholds in 1, 12, and 6 grid wells, respectively. Nitrate (nitrite plus nitrate, as dissolved nitrogen) concentrations from two grid wells were above the MCL-US threshold. There were no detections of microbial indicators in MSACV.

Introduction

Ground water comprises nearly half of the public water supply used in California (Hutson and others, 2004). To assess the quality of ground water from public-supply wells and establish a program for monitoring trends in ground-water quality, the California State Water Resource Control Board (SWRCB), in collaboration with the U.S. Geological Survey (USGS) and Lawrence Livermore National Laboratory (LLNL), implemented a statewide Groundwater Ambient and Monitoring and Assessment (GAMA) program (http://www.waterboards.ca.gov/gama). The GAMA program consists of three projects: Priority Basin Assessment, conducted by the USGS (http://ca.water.usgs.gov/gama/); Voluntary Domestic Well Assessment, conducted by the SWRCB; and Special Studies, conducted by LLNL.

The SWRCB initiated the GAMA Priority Basin Assessment project in response to the Ground-Water Quality Monitoring Act of 2001 (Sections 10780–10782.3 of the California Water Code, Assembly Bill 599). AB 599 is a public mandate to assess and monitor the quality of ground water used as public supply for municipalities in California. The project is a comprehensive assessment of statewide ground-water quality designed to help better understand and identify risks to ground-water resources and to increase the availability of information about ground-water quality to the public. As part of the AB 599 process, the USGS, in collaboration with the SWRCB, developed the monitoring plan for the project (Belitz and others, 2003; State Water Resources Control Board, 2003). Key aspects of the project are interagency collaboration and cooperation with local water agencies and well owners. Local participation in the project is entirely voluntary.

The GAMA Priority Basin Assessment project is unique in California because the data collected during the study include analyses for an extensive number of chemical constituents at very low concentrations—analyses that are not normally available. A broader understanding of ground-water composition will be especially useful for providing an early indication of changes in water quality and for identifying the natural and human factors affecting water quality. Additionally, the GAMA Priority Basin Assessment project will analyze a broader suite of constituents than required by the California Department of Public Health (CDPH, formerly the California Department of Health Services). An understanding of the occurrence and distribution of these constituents is important for the long-term management and protection of ground-water resources.

The range of hydrologic, geologic, and climatic conditions that exist in California must be considered in an assessment of ground-water quality. Belitz, and others (2003) partitioned the state into 10 hydrogeologic provinces, each with distinctive hydrologic, geologic, and climatic characteristics (fig. 1), and representative regions in all 10 provinces were included in the project design. Eighty percent of California's approximately 16,000 public-supply wells are located in ground-water basins within these hydrologic provinces. These ground-water basins, defined by the California Department of Water Resources, generally consist of relatively permeable, unconsolidated deposits of alluvial or volcanic origin (California Department of Water Resources, 2003). Ground-water basins were prioritized for sampling on the basis of the number of public-supply wells in the basin, with secondary consideration given to municipal ground-water use, agricultural pumping, the number of leaking underground fuel tanks, and pesticide applications within the basins (Belitz, and others, 2003). In addition, some ground-water basins or groups of adjacent similar basins with relatively few public-supply wells were assigned high priority so that all hydrogeologic provinces would be represented in the subset of basins sampled. The 116 priority basins were grouped into 35 study units. Some areas not in the defined ground-water basins were included in several of the study units to achieve representation of the 20 percent of public-supply wells not located in the ground-water basins.

Figure 1. The hydrogeologic provinces of California and the location of the Middle Sacramento Valley Groundwater Ambient Monitoring and Assessment (GAMA) study unit (black area).

Three types of water-quality assessments are being conducted with the data collected in each study unit: (1) Status: assessment of the current quality of the ground-water resource, (2) Trends: detection of changes in ground-water quality, and (3) Understanding: identification of the natural and human factors affecting ground-water quality (Kulongoski and Belitz, 2004). This report is one of a series of status reports presenting water-quality data collected in each study unit; previous reports in this series include Wright and others (2005), Kulongoski and others (2006), Bennett and others (2006), Fram and Belitz (2007), Dawson and others (2008), and Kulongoski and Belitz (2007). Subsequent GAMA reports will address the trends and understanding aspects of the water-quality assessments.

The Middle Sacramento Valley GAMA study unit, hereinafter referred to as "MSACV," lies in the Central Valley hydrogeologic province (Belitz and others, 2003). MSACV contains eight subbasins of the Sacramento Valley ground-water basin (California Department of Water Resources, 2003) (fig. 2). MSACV was considered high priority for sampling because of the number of public-supply wells, basin area, number of sections with pesticide applications, and the amount of agricultural pumping (Belitz and others, 2003).

Purpose and Scope

The purposes of this report are: (1) to describe the study design and study methods; (2) to present the sampling, analytical, and quality assurance methods used during the study; (3) to present the results of quality-control (QC) tests; and (4) to present the analytical results for ground-water samples collected in MSACV.

Ground-water samples were analyzed for organic, inorganic, and microbial constituents, field parameters, and chemical tracers. The chemical and microbial data presented in this report were evaluated by comparison with state and federal drinking-water regulatory thresholds and other health-based standards that are applied to treated drinking water. Regulatory thresholds considered for this report are those established by the U.S. Environmental Protection Agency (USEPA) and the California Department of Public Health (CDPH) (U.S. Environmental Protection Agency, 2008a, 2008b, 2008c; California Department of Public Health, 2008a, 2008b).

The data presented in this report are intended to characterize the quality of untreated ground-water resources within the study unit, not the treated drinking water delivered to consumers by water purveyors. Discussions of the factors that influence the distribution and occurrence of the constituents detected in ground-water samples will be the subject of subsequent publications.

Acknowledgments

The authors thank the following cooperating agencies for their support: the State Water Resources Control Board (SWRCB), California Department of Public Health, California Department of Water Resources, and Lawrence Livermore National Laboratory. We especially thank the well owners and water purveyors for their generosity in allowing the U.S. Geological Survey (USGS) to collect samples from their wells. Three reviewers, Jan Stepek (SWRCB), George Bennett (USGS), and Jacob Fleck (USGS) provided comments to improve this report. Funding for this work was provided by state bonds authorized by Proposition 50 and administered by the SWRCB.

Hydrogeologic Setting

Knowledge of the hydrogeologic setting is important in the design of a ground-water-quality investigation. MSACV lies within the Central Valley hydrogeologic province of California and covers approximately 3,340 mi^2 in Butte, Colusa, Glenn, Sutter, Tehama, Yolo, and Yuba Counties (fig. 2). The long axis of the study unit trends north-south for a distance of approximately 90 mi along the Sacramento River, and the short axis is approximately 40 mi long and corresponds to the width of the Central Valley between the Coast Ranges to the west and the Sierra Nevada to the east (fig. 2). MSACV contains eight subbasins of the Sacramento Valley ground-water basin (California Department of Water Resources, 2003) (fig. 2). For the purposes of this study, these eight subbasins were grouped into the East and West study areas, separated by the Sacramento River (fig. 3). The East study area includes the subbasins of Vina, West Butte, East Butte, North Yuba, South Yuba, and Sutter, whereas the West study area includes the Colusa and Corning subbasins.

The main water-bearing deposits of MSACV are primarily composed of continental and marine sediments overlying the consolidated Sierra Nevada block (California Department of Water Resources, 2003). These recent Quaternary (Holocene) to Late Tertiary (Miocene) deposits have a cumulative thickness of several hundred feet near the foothills of the Coast Ranges and Sierra Nevada and deepen to approximately 2,000 ft near the valley center. Sources of ground-water recharge include deep infiltration of precipitation, river and stream flow, and agricultural irrigation return flow.

The primary surface-water features of MSACV include the Sacramento River and smaller rivers and their principal tributaries. The rivers and tributaries include Stony Creek and Cache Creek in the West study area, and Butte Creek, the Feather, Yuba, and Bear Rivers in the East study area (fig. 2).

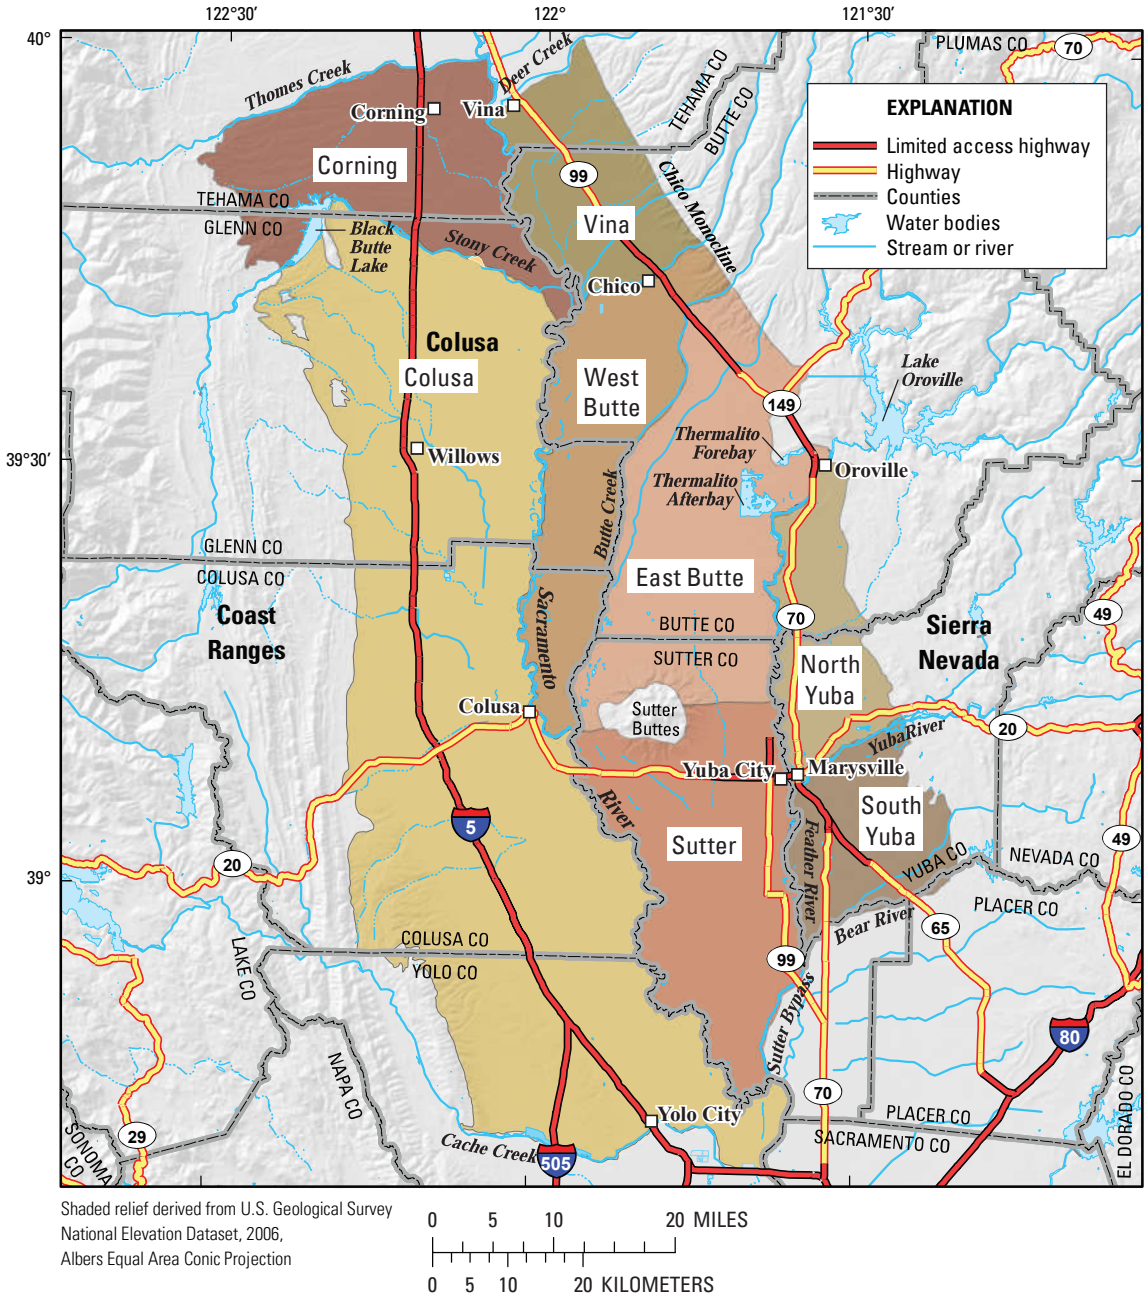

Figure 2. The Middle Sacramento Groundwater Ambient Monitoring and Assessment (GAMA) study unit showing the California Department of Water Resources defined ground-water basins and major hydrologic features within the study unit.

West Study Area—Corning and Colusa Subbasins

The West study area is bounded to the north by Thomes Creek, to the south by Cache Creek, to the west by the Coastal Ranges, and to the east by the Sacramento River (fig. 3). It covers an area of approximately 1,756 mi^2 and includes parts of Colusa, Glenn, Tehama, and Yolo Counties (California Department of Water Resources, 2003). The average annual precipitation ranges from 17 to 27 in., increasing to the north and west. The main water-bearing aquifer within this study area is the Tehama formation (Pliocene). The formation consists of unconsolidated to moderately consolidated coarse- and fine-grained sediments, indicative of floodplain deposits. The Tehama formation is up to 2,000 ft thick and varies in depth from a few feet to several hundred feet below the land surface with depth generally increasing to the east. The Tehama formation is confined by the Tertiary-age Tuscan formation, which contains low permeability lahar layers (California Department of Water Resources, 2003).

East Study Area—Vina, W. Butte, E. Butte, N. Yuba, S. Yuba, and Sutter Subbasins

The East study area is bounded to the north by Deer Creek, to the south by Sutter Bypass and Bear River, to the west by the Sacramento River, and to the east by the Chico Monocline and the Sierra Nevada (fig. 3). It covers an area of approximately 1,584 mi^2 and includes parts of Butte, Colusa, Glenn, Sutter, Tehama and Yuba Counties (California Department of Water Resources, 2003). The average annual precipitation is 17 to 32 in., with increasing rainfall to the north and east. Aquifers within this study area are composed of Tertiary to late Quaternary age deposits, with the younger Quaternary deposits typically representing the unconfined portion of the aquifer system. The Quaternary portion of the aquifer system is largely composed of unconsolidated gravel, sand, silt, and clay stream channel and alluvial fan deposits. South and east of the Sutter Buttes, the deposits contain Pleistocene alluvium, which is composed of loosely compacted silts, sands, and gravels that are moderately permeable; however, nearly impermeable hardpans and claypans do exist in this deposit, which restrict the vertical movement of ground water. The confined portion of the aquifer system includes the Tertiary-age Tuscan and Laguna formations. The Tuscan formation consists of volcanic mudflows, tuff breccia, tuffaceous sandstone, and volcanic ash deposits up to 1,250 ft thick. The Laguna formation consists of moderately consolidated and poorly to well cemented interbedded alluvial sand, gravel, and silt with a low permeability, overall (California Department of Water Resources, 2003).

Methods

The methods used for the GAMA program were selected to achieve the following objectives: (1) design a sampling plan suitable for statistical analysis, (2) collect samples in a consistent manner, (3) analyze samples using proven and reliable laboratory methods, (4) assure the quality of the ground-water data, and (5) maintain data securely and with relevant documentation.

Study Design

The wells selected for sampling in this study reflect the combination of two well selection strategies. Seventy-one wells were selected to provide a statistically unbiased, spatially distributed assessment of the quality of ground-water resources used for public drinking-water supply (fig. 3), and 37 additional wells were selected to provide greater sampling density in several areas to address specific ground-water quality issues in the study unit (fig. 4).

The spatially distributed wells were selected using a randomized grid-based method (Scott, 1990). Each of the study areas was subdivided into grid cells that were 38.6 mi^2 (100 km^2) in area. This grid-cell size met GAMA objectives for the Central Valley hydrogeologic province of a sampling density of at least one well per 38.6 mi^2 and having at least 10 grid cells per study area. For this assessment, the East study area was divided into 41 grid cells and the West study area into 46 grid cells.

Seventy-one of the 87 grid cells in MSACV contained wells that could be sampled; the other 16 grid cells did not contain accessible wells. If a grid cell contained more than one public-supply well, each well was randomly assigned a rank. The highest ranking well that met basic sampling criteria (for example, sampling point prior to treatment, capability to pump for several hours, and available well-construction information), and for which permission to sample could be obtained was then sampled. If a grid cell contained no accessible public-supply wells, domestic and irrigation wells were considered for sampling. An attempt was made to select domestic and irrigation wells with depths and screened intervals similar to those in public-supply wells in the area. Wells sampled as part of the randomized grid-cell network are hereinafter referred to as “grid wells.” Grid wells sampled in MSACV were numbered in the order of sample collection, with the following prefixes that are based on study area: “ESAC” for the East study area of the Middle Sacramento Valley study unit, and “WSAC” for the West study area of the Middle Sacramento Valley study unit.

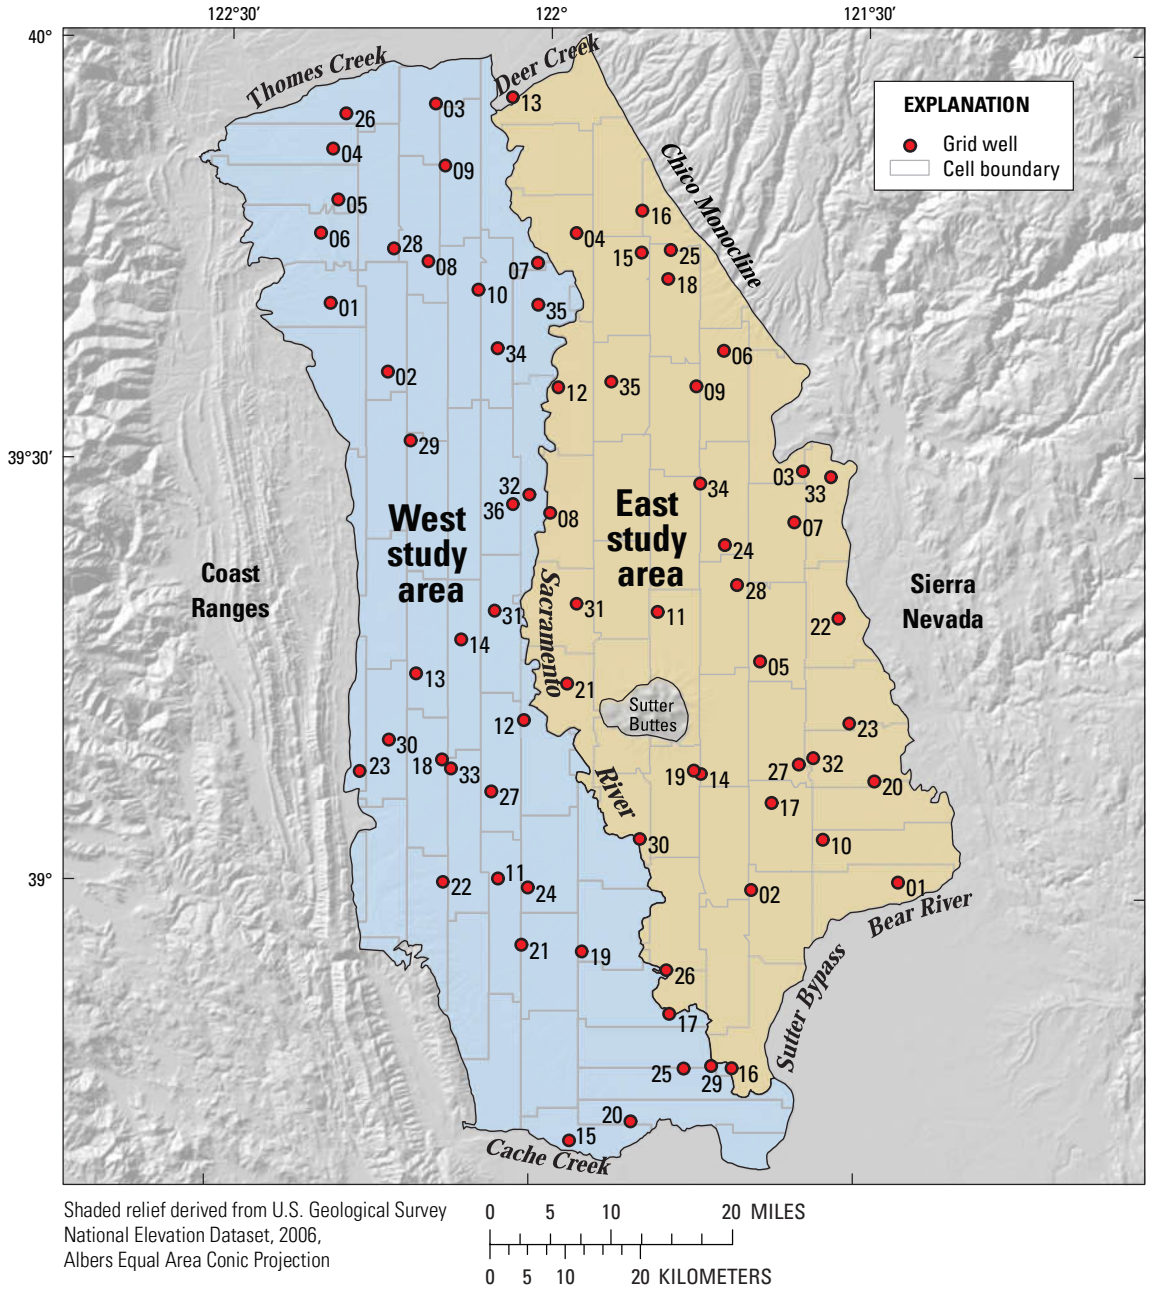

Figure 3. The East and West study areas of the Middle Sacramento Groundwater Ambient Monitoring and Assessment (GAMA) study unit showing the distribution of study area grids cells, the locations of sampled grid cell wells, and the study area boundaries.

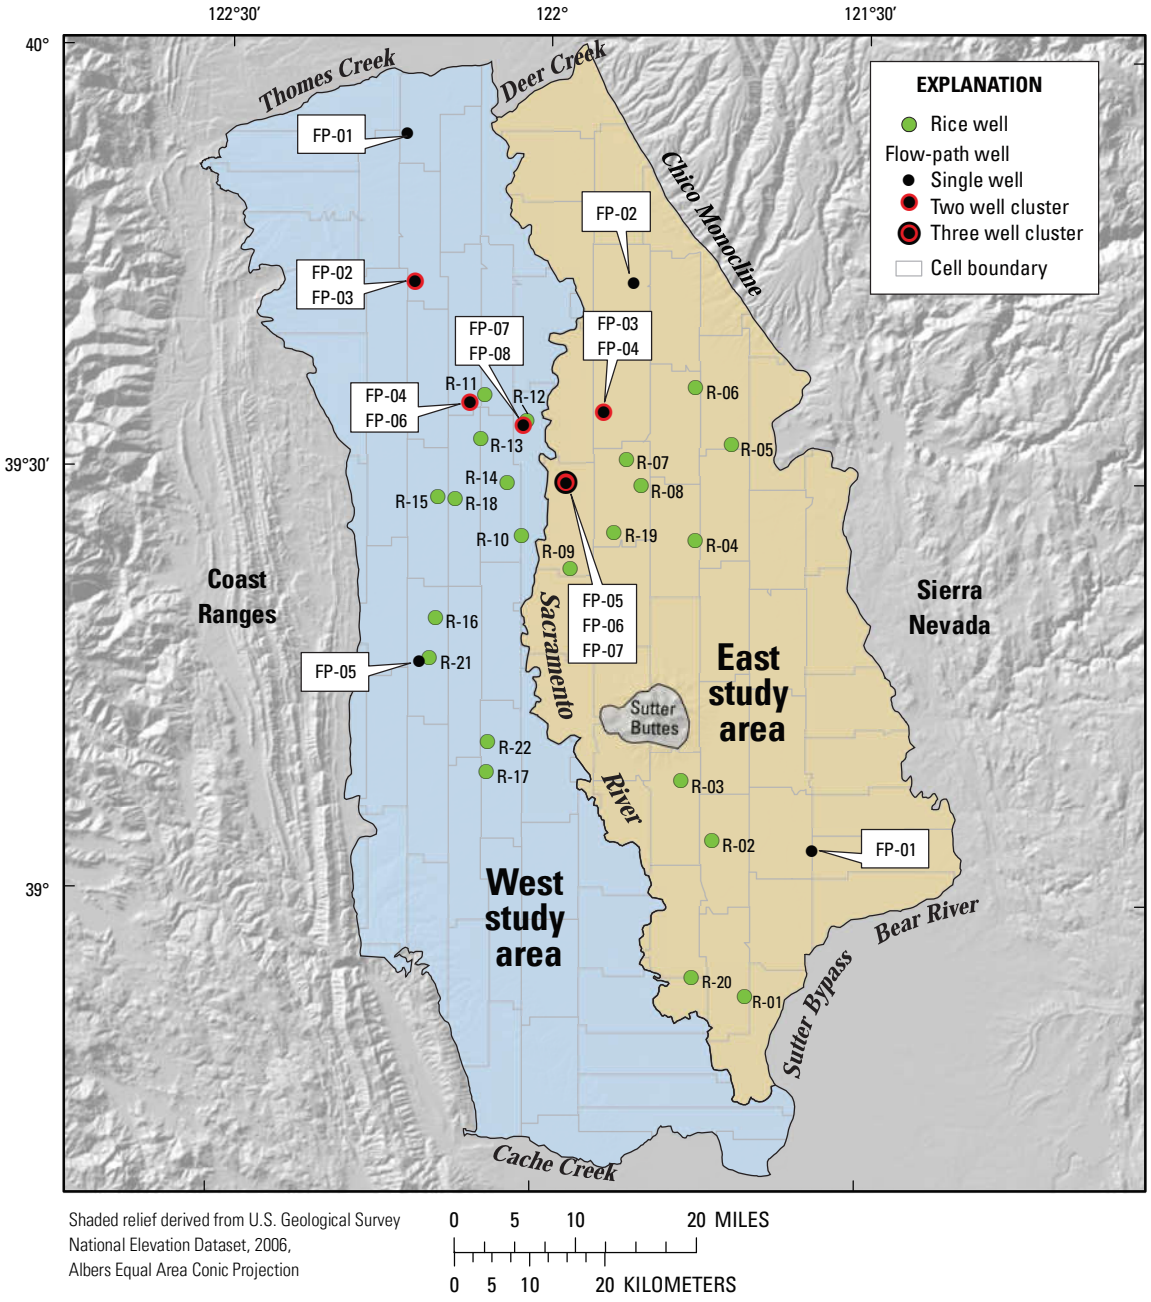

Figure 4. The East and West study areas of the Middle Sacramento Groundwater Ambient Monitoring and Assessment (GAMA) study unit showing the distribution of study area grid cells, the locations of sampled flow-path (FP) and RICE (R) wells (RICE wells are part of a well network monitoring the shallow ground-water quality associated with rice agriculture), and the study area boundaries.

In addition to the 71 grid wells, two types of nonrandomized wells were sampled in the East and West study areas. The first type of nonrandomized wells included 15 wells to evaluate changes in water chemistry along ground-water flow paths; these wells are referred to as "flow-path wells." Flow-path wells were numbered in the order of sample collection, with the prefixes ESAC-FP for wells in the East Sacramento Valley study area and WSAC-FP for wells in the West Sacramento Valley study area. The second type of nonrandomized wells consisted of 22 shallow monitoring wells selected to assess the effects of rice agriculture, a major land-use in the study unit, on shallow ground-water chemistry. In 1997, the USGS installed and sampled a set of monitoring wells in rice-growing areas of the Sacramento Valley as part of the National Water-Quality Assessment Program (Milby Dawson, 2001). Many of those monitoring wells are in the MSACV area and were resampled as part of this study. The monitoring wells are numbered in the order of sample collection with the prefix "RICE." Flow-path wells and RICE wells sampled as part of this study for better understanding were not included in the statistical characterization of water quality in MSACV, as the inclusion of these wells would have caused overrepresentation of certain grid wells and of shallow ground water.

Table 1 provides the GAMA alphanumeric identification number for each well, along with the date sampled, sampling schedule, well elevation, and well-construction information.

Well locations and identifications were verified using a global positioning system (GPS) receiver, 1:24,000 scale USGS topographic maps, comparison with existing well information in USGS and CDPH databases, and information provided by well owners. Drillers' logs for wells were obtained when available. Well information was recorded by hand on field sheets and electronically using specialized software on field laptop computers. All information was verified and then uploaded into the USGS's National Water Information System (NWIS). Well owner information is confidential. Well location information and all chemical data are currently inaccessible from NWIS's public website.

The wells in MSACV were sampled using a tiered analytical approach. All wells were sampled for a standard set of constituents, including field water-quality indicators, volatile organic compounds (VOCs), pesticides and pesticide degradates, perchlorate, stable isotopes of water, and dissolved noble gases and tritium and helium age dates. The standard set of constituents was termed the fast schedule (table 2). Wells on the intermediate schedule were sampled for all the constituents on the fast schedule, plus pharmaceuticals, *N*-nitrosodimethylamine (NDMA), 1,2,3-trichloropropane (1,2,3-TCP), nutrients, stable isotopes of oxygen and nitrogen in nitrate, major and minor ions, trace elements, species of arsenic, iron, and chromium, and carbon isotopes. Wells on the slow schedule were sampled for all the constituents on the intermediate schedule, plus dissolved organic carbon, radium 226/228, radon-222, gross alpha and beta radiation, coliform, coliphage, alkalinity, and turbidity (table 2). Fast, intermediate, and slow refer to the time required to sample the well for all the analytes on the schedule. Generally, one slow, two intermediate, or three fast wells could be sampled in one day. RICE wells were sampled on a modified intermediate schedule. In MSACV, 26 wells were sampled on the fast schedule, 52 were sampled on the intermediate schedule, 8 on the slow schedule, and 22 on the RICE monitoring-well schedule (table 2).

Sample Collection and Analysis

Samples were collected in accordance with the protocols established by the USGS's National Water Quality Assessment (NAWQA) program (Koterba and others, 1995) and the National Field Manual (U.S. Geological Survey, variously dated). These sampling protocols ensure that a representative sample of ground water is collected at each site, and that the samples are collected and handled in a way that minimizes the potential for contamination. The methods used for sample collection are described in the Appendix section "Sample Collection and Analysis."

Tables 3A–L list the compounds analyzed in each constituent class. Raw (untreated) ground-water samples were analyzed for 85 VOCs (table 3A) and 8 gasoline additives (table 3B), 135 pesticide and pesticide degradates (tables 3C, 3D), 14 pharmaceutical compounds (table 3E), 3 constituents of special interest (table 3F), 5 nutrients and dissolved organic carbon (table 3G), 10 major and minor ions and total dissolved solids (table 3H), 25 trace elements (table 3H), 6 species of arsenic, iron, and chromium (table 3I), 5 stable isotope ratios and 7 radioactive constituents, tritium, and carbon-14 (table 3J), 5 dissolved noble gases, helium stable isotope ratios, and tritium (table 3K), and 4 microbial constituents (table 3L). The methods used for sample analysis are described in the Appendix section "Sample Collection and Analysis."

Data Reporting

The methods and conventions used for reporting the data are described in the Appendix. Thirteen constituents analyzed in this study were measured by more than one method at the USGS's National Water Quality Laboratory (NWQL), but only the results from the preferred method for each of the constituents are reported. Arsenic, iron, and chromium concentrations, and tritium activities were analyzed by more than one laboratory, and both sets of results are reported.

Quality Assurance

The protocols used for this study are those used by the NAWQA program (U.S. Geological Survey, variously dated; Koterba and others, 1995), and the quality assurance protocols are described in the NWQL quality assurance plan (Maloney, 2005; Pirkey and Glodt, 1998). QC samples collected in the MSACV study include source-solution blanks, field blanks, replicates, and matrix and surrogate spikes. QC samples were collected to evaluate contamination, bias, and variability of the water-quality data that may have resulted from sample collection, processing, storage, transportation, and laboratory analysis. Quality-assurance methods and results are described in the Appendix section "Quality Assurance."

Water-Quality Results

Quality-Control Sample Results

Results of QC analyses (blanks, replicates, matrix spikes, and surrogates) were used to evaluate the quality of the data for the ground-water samples (see Appendix). Assessment of the QC data from blanks resulted in some ground-water samples being censored, as indicated with "V" codes in tables 5–14. Of the 300 constituents analyzed, 35 were detected in at least one field blank. For 15 of these constituents, concentrations detected in the field blanks were below the lowest concentration detected in ground-water samples, or the constituent was not detected in ground-water samples; thus, no data were affected. Some reported detections for five organic constituents in ground-water samples were flagged as potentially contaminated, and, therefore, were not considered as detections for ground-water quality assessment. Some low concentration detections of 12 inorganic constituents were flagged because contamination may have raised the concentrations sufficiently to have changed a nondetection into a low-level detection relative to the stated reporting limit.

Data from replicates indicate that variability between measurements generally was low, with relative standard deviations (RSD) below 5 percent for most replicate pairs for most constituents. Of the 30 pairs with RSDs above the acceptable limit of 20 percent, 29 had data that were estimated concentrations at or below the laboratory reporting level (LRL) for the constituent analyzed. At these low concentrations, small differences in the measured values in the replicate pairs account for the large RSDs. These results from the replicates confirm that the procedures used to collect and analyze the samples were consistent.

Median matrix-spike recoveries for 35 of the 232 constituents analyzed were lower than the acceptable limits, which may indicate that these constituents might not have been detected in some samples if they were present at very low concentrations.

More than 90 percent of the samples analyzed with surrogates had surrogate recoveries within acceptable limits. The QC results are described in the Appendix section "Quality-Control Sample Results."

Comparison Thresholds

Concentrations in ground-water samples were compared with CDPH and USEPA drinking-water health-based thresholds. Concentrations were also compared with thresholds established for aesthetics—secondary maximum contaminant levels (SMCLs) (California Department of Health Services, 2007a; California Department of Public Health, 2008a, 2008b; U.S. Environmental Protection Agency, 2006, 2008a, 2008b, 2008c). CDPH became the California Department of Health Services (CDHS) on July 1, 2007. The chemical and microbial data presented in this report are meant to characterize the quality of the untreated ground-water resources within MSACV, and are not intended to represent the treated drinking water delivered to consumers by water purveyors. The chemical and microbial composition of treated drinking water may differ from untreated ground water because treated drinking water may be subjected to disinfection, filtration, mixing with other waters, and exposure to the atmosphere prior to its delivery to consumers.

The following thresholds were used for comparisons:

MCL—Maximum Contaminant Level. Legally enforceable standards that apply to public-water systems and are designed to protect public health by limiting the levels of contaminants in drinking water. National MCLs established by the USEPA are the minimum standards with which states are required to comply, and individual states may choose to set more stringent standards. CDPH has established MCLs for additional constituents not regulated by the USEPA, as well as lowered the threshold concentration for a number of constituents with MCLs established by the USEPA. In this report, a threshold set by the USEPA is labeled "MCL-US," and one set by CDPH that is different from the MCL-US is labeled "MCL-CA." CDPH is notified when constituents are detected at concentrations exceeding MCL-US or MCL-CA thresholds in samples collected for the GAMA Priority Basin Assessment, but these detections do not constitute violations of CDPH regulations

AL—Action Level. Legally enforceable standards that apply to public-water systems and are designed to protect public health by limiting the levels of copper and lead in drinking water. Detections of copper or lead above the action-level thresholds trigger requirements for mandatory water treatment to reduce the corrosiveness of water to water pipes. The action levels established by the USEPA and CDPH are the same, thus these thresholds are labeled "AL-US" in this report.

TT—Treatment Technique. Legally enforceable standards that apply to public-water systems and are designed to protect public health by limiting the levels of microbial constituents in drinking water. Detections of microbial

constituents above the treatment-technique thresholds trigger requirements for mandatory additional disinfection during water treatment. The action levels established by the USEPA and CDPH are the same, thus these thresholds are labeled "TT-US" in this report.

SMCL—Secondary Maximum Contaminant Level. Non-enforceable standards applied to constituents that affect the aesthetic qualities of drinking water, such as taste, odor, and color, or technical qualities of drinking water, such as scaling and staining. Both the USEPA and CDPH define SMCLs, but unlike MCLs, SMCLs established by CDPH are not required to be at least as stringent as those established by USEPA. SMCLs established by CDPH are used in this report (SMCL-CA) for all constituents that have SMCL-CA values. The SMCL-US is used for pH because no SMCL-CA has been defined.

NL—Notification Level. Health-based notification levels established by CDPH for some of the constituents in drinking water that lack MCLs (NL-CA). If a constituent is detected above its NL-CA, California state law requires timely notification of local governing bodies and recommends consumer notification.

HAL—Lifetime Health Advisory Level. The maximum concentration of a constituent at which its presence in drinking water is not expected to cause any adverse carcinogenic effects for a lifetime of exposure. HALs are established by the USEPA (HAL-US) and are calculated assuming consumption of two liters of water per day over a 70-year lifetime by a 70-kilogram adult and that 20 percent of a person's exposure comes from drinking water.

RSD5—Risk-Specific Dose. The concentration of a constituent in drinking water corresponding to an excess estimated lifetime cancer risk of 1 in 100,000. RSD5 is an acronym for risk-specific dose at 10^{-5}. RSD5s are calculated by dividing the 10^{-4} cancer risk concentrations established by the USEPA by ten (RSD5-US).

For constituents with MCLs, detections in ground-water samples were compared with the MCL-US or MCL-CA. Constituents with SMCLs were compared with the SMCL-CA. For chloride, sulfate, specific conductance, and total dissolved solids, CDPH defines a "recommended" and an "upper" SMCL-CA; detections of these constituents in ground-water samples were compared with both levels. The SMCL-US for these constituents corresponds to the recommended SMCL-CA. Detected concentrations of constituents that lack MCLs and SMCLs were compared with NL-CAs. For constituents that lack an MCL, SMCL, or NL-CA, detected concentrations were compared with the HAL-US. For constituents that lack an MCL, SMCL, NL-CA, or HAL-CA, detected concentrations were compared with the RSD5-US. Note this hierarchy of selection of comparison thresholds means that for constituents with multiple types of established thresholds, the threshold used for comparison purposes may not be the one with the lowest concentration. The comparison thresholds used in this report are listed in tables 3A–L for all constituents and in tables 4–14 for constituents detected in ground-water samples from the MSACV. Not all constituents analyzed for this study have established thresholds. Concentrations greater than the selected comparison threshold are marked with asterisks in tables 4–14.

Ground-Water-Quality Data

Results from analyses of raw (untreated) ground-water samples from MSACV are presented in tables 4–14. Ground-water samples collected in MSACV were analyzed for up to 280 constituents, and 195 of those constituents were not detected in any of the samples (tables 3A–L). The results tables present only the constituents that were detected and list only samples that had at least one constituent detected. For constituent classes that were analyzed at all of the grid wells, the tables include the number of wells at which each analyte was detected, the frequency at which it was detected (in relation to the number of grid wells), and the total number of constituents detected at each well. Results from the flow-path and RICE wells are presented in the tables, but these results were excluded from the detection frequency calculations to avoid statistically over-representing the areas in the vicinity of these wells.

Table 4 includes water-quality indicators measured in the field and at NWQL. Tables 5–14 present the results of ground-water laboratory analyses organized by compound classes:

- Organic constituents
  - VOCs and gasoline oxygenates and degradates (table 5)
  - Pesticides and pesticide degradates (table 6)
- Constituents of special interest (table 7)
- Inorganic constituents
  - Nutrients and dissolved organic carbon (table 8)
  - Major and minor ions (table 9)
  - Trace elements (table 10)
  - Species of inorganic arsenic, iron, and chromium (table 11)
- Inorganic tracer constituents
  - Hydrogen and oxygen isotopes and tritium (table 12)
  - Stable isotopes of nitrogen and carbon and carbon-14 (table 13)
- Radioactive constituents (table 14)

Results for pharmaceutical compounds, dissolved noble gases, and tritium/helium age dates are not presented in this report; they will be included in subsequent GAMA

publications. No summary table is presented for microbial constituents because none were detected in any of the samples analyzed.

Water-Quality Indicators

Field and laboratory measurements of water-quality indicators, including dissolved oxygen, pH, specific conductance, alkalinity, and associated parameters (turbidity and water temperature) are presented in table 4. Dissolved oxygen and alkalinity are used as indicators of natural processes that control water chemistry. Specific conductance is the unit electrical conductivity of the water and is proportional to the amount of total dissolved solids (TDS) in the water. The pH value indicates the acidity or basicity of the water. Six wells (3 grid wells, 2 flow-path wells, and 1 RICE well) had pH values outside of the SMCL-CA range for pH. Laboratory pH values may be higher than field pH values because the pH of ground water often increases upon exposure to the atmosphere (see Appendix). Twenty-two wells (11 grid, 1 flow-path well, and 10 RICE wells) had specific conductance values above the recommended SMCL-CA, with 9 of those wells (4 grid wells and 5 RICE wells) above the upper threshold.

Organic Constituents

VOCs are widely used and can be found in paints, solvents, fuels, fuel additives, refrigerants, fumigants, and disinfected water and are characterized by their tendency to evaporate. VOCs generally persist longer in ground water than in surface water because ground water is isolated from the atmosphere.

Of the 85 VOCs analyzed, 24 were detected in ground-water samples; all detections were below health-based thresholds and most were less than one-hundredth of the threshold values (table 5). The only VOC detected in more than 10 percent of the grid wells was chloroform, a byproduct of drinking-water disinfection. Chloroform was the most frequently detected VOC in ground water nationally (Zogorski and others, 2006).

Pesticides include herbicides, insecticides, and fungicides, and are used to control weeds, insects, fungi, and other pests in agricultural, urban, and suburban settings. Of the 135 pesticides and pesticide degradates analyzed, 30 were detected in ground-water samples; all detections were below health-based thresholds and all were less than one-hundredth of the threshold values (table 6). The only pesticides detected in more than 10 percent of the grid wells were the herbicides bentazon, simazine, atrazine, and deethylatrazine, a degradate of atrazine. Simazine, atrazine, and deethlyatrazine are among the most commonly detected pesticide compounds in ground water nationally (Gilliom and others, 2006). Bentazon is primarily used in rice agriculture.

Constituents of Special Interest

Perchlorate, 1,2,3-TCP, and NDMA are constituents of special interest in California because they may adversely affect water quality and recently have been found in water supplies (California Department of Health Services, 2007b). Perchlorate is used as an oxidizer in rocket fuel and explosives, 1,2,3-TCP is used as a chemical synthesis product, and NDMA is an industrial by-product. Perchlorate was detected in approximately 6 percent of the grid wells, and all concentrations measured in the MSACV wells were less than one-third of the NL-CA (table 7). 1,2,3-TCP and NDMA were not detected in any samples.

Inorganic Constituents

Unlike the organic constituents and the constituents of special interest, most of the inorganic constituents are naturally present in ground water, although their concentrations may be influenced by human activities.

The nutrients, nitrogen and phosphorus, and dissolved organic carbon present in ground water can affect biological activity in aquifers and in surface water bodies that receive ground-water discharge. Nitrogen may be present in the form of ammonia, nitrite, or nitrate depending on the oxidation–reduction state of the ground water. High concentrations of nitrate can adversely affect human health, particularly the health of infants. Ground-water samples from two grid wells in MSACV had concentrations of nitrate (nitrite plus nitrate, dissolved as nitrogen) above the health-based threshold (table 8). All concentrations of nitrite and ammonia measured in ground-water samples were below health-based thresholds. Concentrations of orthophosphate (as phosphorus) and dissolved organic carbon were also low.

The major-ion composition, total dissolved solids (TDS) content, and levels of certain trace elements in ground water may produce undesirable effects on the aesthetic and technical properties of the water. Undesirable aesthetic properties include poor taste, color, or odor, and staining. Undesirable technical properties include scaling, and reduced effectiveness of treatment for other contaminants. CDPH has established non-enforceable thresholds (SMCL-CAs) that are based on aesthetic or technical properties rather than on health-based concerns for the major ions chloride and sulfate, TDS, and several trace elements. Chloride was detected in two grid wells above the recommended SMCL-CA, with one of those detections above the upper SMCL-CA. Sulfate was detected in one grid well above the lower SMCL-CA. Samples from six grid wells contained TDS above the recommended SMCL-CA, although only two of these samples were also above the upper SMCL-CA for TDS (table 9).

Iron and manganese are trace elements whose concentrations are affected by the oxidation–reduction state of the ground water. Precipitation of minerals containing iron or manganese may cause orange or black staining of surfaces. Samples from 12 grid wells had manganese concentrations above the SMCL-CA, and one of these samples also had an iron concentration above the MCL-CA (table 10).

Eighteen of the 25 trace elements analyzed in this study have health-based thresholds. Of the 18 trace elements with health-based thresholds, 2 were not detected in any samples, and all detections of 16 trace elements were below health-based thresholds (table 10). Samples from eight grid wells had arsenic concentrations above the MCL-US and samples from two grid wells had concentrations of boron above the NL-CA.

Arsenic, iron, and chromium occur in different species depending on the oxidation–reduction state of the ground water. The oxidized and reduced species have different solubilities in ground water and may have different effects on human health. The relative proportions of the oxidized and reduced species of each element can be used to aid in interpretation of the oxidation–reduction state of the aquifer. Table 11 reports measured concentrations of total arsenic, iron, and chromium, and the concentrations of the oxidized or the reduced species of each element. The concentration of the other species can be calculated by difference. For example, chromium(III) is equal to chromium(total) minus chromium(VI). The concentrations of arsenic, iron, and chromium reported in table 11 may be different than those reported in table 10 because different analytical methods were used (see Appendix). The concentrations reported in table 10 are considered more accurate.

Inorganic Tracer Constituents

Stable isotope ratios, tritium and carbon-14 activities, and noble gas concentrations are used as tracers of natural processes affecting ground-water composition. The stable isotope ratios of oxygen and hydrogen in water (table 12) may aid in interpretation of ground-water recharge sources. These stable isotope ratios reflect the altitude, latitude, and temperature of precipitation and the extent of evaporation of surface water or soil water. The nitrogen and oxygen stable isotope ratios in nitrate (table 13) may aid in interpretation of sources and processes affecting nitrate concentrations in ground water. Concentrations of dissolved noble gases are used to estimate the conditions of ground-water recharge, particularly the temperature of the recharge water. Noble gases from air dissolve in water that is in contact with the atmosphere, and the solubilities of the different noble gases vary with temperature. Results of noble gas analyses were not available in time for inclusion in this report; they will be presented in a subsequent GAMA report.

Tritium activities (table 12), carbon-14 activities (table 13), and helium isotope ratios provide information about the age of the ground water. Tritium is a short-lived radioactive isotope of hydrogen that is incorporated into the water molecule. Low levels of tritium are continuously produced by interaction of cosmic radiation with the earth's atmosphere, and a large amount of tritium was produced by atmospheric testing of nuclear weapons between 1952 and 1963. Thus, concentrations of tritium above background levels generally indicate the presence of water recharged since the early 1950s (Thatcher and others, 1977). Helium isotope ratios are used in conjunction with tritium concentrations to estimate ages for young ground water. Helium isotope analyses were not completed in time for inclusion in this report; they will be presented in a subsequent GAMA report.

Carbon-14 (table 13) is a radioactive isotope of carbon. Low levels of carbon-14 are continuously produced by interaction of cosmic radiation with the earth's atmosphere and incorporated into atmospheric carbon dioxide. The carbon dioxide dissolves in precipitation and water that is in contact with the atmosphere. Because carbon-14 decays with a half-life of approximately 5,700 years, low activities of carbon-14 relative to modern values generally indicate presence of ground water that is several thousand years old.

Of the inorganic tracer constituents analyzed for this study, the only one with a health-based threshold is tritium. All measured tritium activities in samples from MSACV wells were less than one-thousandth of the MCL-CA (table 12).

Radioactive Constituents

Radioactivity is the release of energy or energetic particles during changes in the structure of the nucleus of an atom. Most of the radioactivity in ground water comes from decay of naturally occurring isotopes of uranium and thorium that are present in minerals in the sediments or fractured rocks of an aquifer. Both uranium and thorium decay in a series of steps, eventually forming stable isotopes of lead. Radium-226, radium-228, and radon-222 are radioactive isotopes formed during the uranium and thorium decay series. In each step of the decay series, one radioactive element turns into a different radioactive element by emitting an alpha or a beta particle from its nucleus. For example, radium-226 emits an alpha particle and, therefore, turns into radon-222. Radium-228 decays to form actinium-228 by emission of a beta particle. The alpha and beta particles emitted during radioactive decay are hazardous to human health because these energetic particles may damage cells. Radiation damage to cell DNA may increase the cancer risk in humans.

Activity is often used instead of concentration for reporting the presence of radioactive constituents. Activity of radioactive constituents in ground water is measured in units of picocuries per liter (pCi/L), and one picocurie is approximately equal to two atoms decaying per minute. The number of atoms decaying is equal to the number of alpha or beta particles emitted.

The eight MSACV samples analyzed for radioactive constituents had activities of radium and of gross alpha and beta emitters less than established health-based thresholds (table 14). Activities of radon-222 in samples from six grid wells were above the proposed MCL-US of 300 pCi/L, but all were below the proposed alternative MCL-US of 4,000 pCi/L. The alternative MCL-US will apply if the state or local water agency has an approved multimedia mitigation program to address radon levels in indoor air (U.S. Environmental Protection Agency, 1999a).

Microbial Indicators

Water is disinfected during drinking-water treatment to prevent diseases that may be spread by water-borne microbial constituents derived from human or animal wastes. The specific viruses and bacteria responsible for diseases generally are not measured because routine analytical methods are not available. Measurements are made of more easily analyzed microbial constituents that serve as indicators of the presence of human or animal waste in water. Drinking-water purveyors respond to detections of microbial indicators by applying additional disinfection techniques to the water.

Samples from eight MSACV wells were analyzed for microbial indicators. None of the samples contained viral indicators F-specific and somatic coliphage, and none contained the bacterial indicator *Escherichia* coliform (*E. coli*) or total coliforms.

Future Work

Subsequent reports will focus on assessment of the data presented in this report using a variety of statistical, qualitative, and quantitative approaches to evaluate the natural and human factors affecting ground-water quality. Water-quality data contained in the CDPH and NWIS databases, and water-quality data available from other state and local water agencies, will be compiled, evaluated, and used in combination with the data presented in this report.

Summary

Ground-water quality in the approximately 3,340 mi^2 Middle Sacramento Valley study unit (MSACV) was investigated from June to September, 2006, as part of the Priority Basin Assessment project of Ground-Water Ambient Monitoring and Assessment (GAMA) program. The California State Water Resources Control Board (SWRCB), in collaboration with the U.S. Geological Survey and the Lawrence Livermore National Laboratory, is implementing the GAMA program (http://www.waterboards.ca.gov/gama/). The Priority Basin Assessment project was designed by the SWRCB and the USGS in response to the Ground-Water Quality Monitoring Act of 2001 (Belitz and others, 2003; State Water Resources Control Board, 2003). The project is a comprehensive assessment of statewide ground-water quality designed to identify and characterize risks to ground-water resources and to increase the availability of information about ground-water quality to the public. MSACV was the twelfth study unit sampled as part of the project.

MSACV is in the Central Valley hydrogeologic province, and includes within it eight ground-water basins, as defined by the California Department of Water Resources (California Department of Water Resources, 2003). The MSACV study included assessment of ground-water quality from 108 wells in Butte, Colusa, Glenn, Sutter, Tehama, Yolo, and Yuba Counties. Seventy-one of the wells (grid wells) were selected using a spatially distributed, randomized grid-based method to achieve statistically unbiased representation of the portion of the ground-water resource used for public drinking-water supplies. Fifteen of the wells (flow-path wells) were selected to provide additional sampling density to aid in understanding processes affecting ground-water quality. Twenty-two of the wells (RICE wells) were sampled for better understanding of the contribution of rice agriculture land use to ground-water conditions.

Ground-water samples were analyzed for volatile organic compounds (VOCs), pesticides and pesticide degradates, constituents of special interest, pharmaceutical compounds, nutrients, major and minor ions, trace elements, radioactivity, and microbial indicators. Naturally occurring isotopes (stable isotopes of hydrogen, oxygen, nitrogen, and carbon, and activities of tritium and carbon-14) and dissolved noble gases also were measured to provide a dataset that will be used to help interpret the source and age of the sampled ground water. This report describes the hydrogeologic setting of the MSACV region, details the sampling, analytical, and quality-assurance methods used in the study, and presents the results of the chemical and microbial analyses made of the ground-water samples collected during June to September, 2006.

QC samples (blanks, replicates, samples for matrix spikes) were collected at approximately 10 percent of the wells, and the results for these samples were used to evaluate the quality of the data for the ground-water samples. Field blanks rarely contained detectable concentrations of any constituent, suggesting that contamination was not a noticeable source of bias in the data for the ground-water samples. Most of the differences between replicate samples were within acceptable ranges, indicating acceptably low variability. Matrix spike recoveries were within acceptable ranges for most compounds.

This study did not attempt to evaluate the quality of water delivered to consumers; after withdrawal from the ground, water typically is treated, disinfected, and blended with other waters to maintain acceptable water quality. Regulatory

thresholds apply to treated water that is served to the consumer, not to raw ground water. However, to provide some context for the results, concentrations of constituents measured in the raw ground water were compared with health-based thresholds established by the U.S. Environmental Protection Agency (USEPA) and the California Department of Public Health (CDPH).

All detections of VOCs, pesticides, and pesticide degradates were below health-based thresholds, and most were less than one-hundredth of the threshold values. All detections of perchlorate, and radioactive constituents were below established thresholds. Arsenic, nitrate, and boron were the only constituents detected at concentrations above health-based thresholds in samples from the grid wells. Total dissolved solids, specific conductance, pH, iron, chloride, sulfate, and manganese were detected at concentrations above the SMCL-CA, a non-enforceable threshold set for aesthetic concerns, in samples from several of the grid wells.

[1] Sampling schedules are described in table 2.

[2] Land-surface datum (LSD) is a datum plane that is approximately at land surface at each well. The elevation of the LSD is described in feet above the North American Vertical Datum 1988.

[3] Well sampled twice (well was partially resampled to replace some sample containers lost in shipping prior to analysis).

Table 2. Classes of water-quality indicators, chemical constituents, and microbial constituents collected for the slow, intermediate, fast, and RICE well sampling schedules in the Middle Sacramento Valley Groundwater Ambient Monitoring and Assessment (GAMA) study, California, June to September, 2006.

[DO, dissolved oxygen; NDMA, *N*-nitrosodimethylamine; SC, specific conductance]

Analyte classes	Analyte list table	Slow schedule	Intermediate schedule	Fast schedule	RICE schedule
Water-quality indicators					
DO, SC, pH, temperature		X	X	X	X
Alkalinity, turbidity		X			X
Organic constituents					
Volatile organic compounds	3A	X	X	X	X
Gasoline additives and oxygenates	3B	X			
Pesticides and pesticide degradates	3C, 3D	X	X	X	X
Pharmaceutical compounds	3E	X	X		X
Constituents of special interest					
Perchlorate	3F	X	X	X	X
N-Nitrosodimethylamine (NDMA)	3F	X	X		
1,2,3-Trichloropropane (1,2,3-TCP)	3F	X	X		
Inorganic constituents					
Nutrients	3G	X	X		X
Dissolved organic carbon (DOC)	3G	X			X
Major and minor ions and trace elements	3H	X	X		X
Arsenic, iron, and chromium speciation	3I	X	X		X
Stable isotopes					
Stable isotopes of hydrogen and oxygen in water	3J	X	X	X	X
Stable isotopes of nitrogen and oxygen in nitrate	3J	X	X		
Stable isotopes of carbon and carbon-14 abundance	3J	X	X		
Radioactivity and gases					
Tritium	3J	X	X	X	
Tritium and noble gases	3K	X	X	X	X
Radium isotopes	3J	X			
Radon-222	3J	X			
Gross alpha and beta radiation	3J	X			
Microbial constituents					
Escherichia coliform and total coliform	3L	X			
F-specific and somatic coliphage	3L	X			

Table 3A. Volatile organic compounds, primary uses or sources, comparative thresholds, and reporting information for the U.S. Geological Survey's (USGS) National Water Quality Laboratory Schedule 2020.

[The five-digit USGS parameter code is used to uniquely identify a specific constituent or property. CAS, Chemical Abstracts Service; CDPH, California Department of Public Health; D, detected; HAL-US, Lifetime Health Advisory Level (USEPA); LRL, laboratory reporting level; MCL-CA, maximum contaminant level (CDPH); MCL-US, maximum contaminant level (USEPA); na, not available; NL-CA, notification level (CDPH); RSD5-US, U.S. Environmental Protection Agency risk specific dose at a risk factor of 10^{-5} µg/L (RSD5s are calculated by dividing the 10^{-4} cancer risk concentration established by the USEPA by 10); THM, trihalomethane; USEPA, U.S. Environmental Protection Agency; µg/L, micrograms per liter; —, analyzed but not detected]

Constituent	Primary use or source	USGS parameter code	CAS number	LRL (µg/L)	Threshold type	Threshold value (µg/L)	Detection

[1] These constituents were reported using method reporting levels (MRLs) during the period of this study.

Table 3E. Pharmaceutical compounds, primary uses or sources, comparative thresholds, and reporting information for the U.S. Geological Survey's (USGS) National Water Quality Laboratory Schedule 2080.

[The five-digit USGS parameter code is used to uniquely identify a specific constituent or property. Thresholds and threshold values as of February 10, 2007. CAS, Chemical Abstracts Service; MDL, method detection limit; na, not available; µg/L, micrograms per liter]

Constituent	Primary use or source	USGS parameter code	CAS number	MDL[1] (µg/L)	Threshold type	Threshold value (µg/L)
Acetaminophen	Analgesic	62000	103-90-2	0.60	na	na
Albuterol	Anti-inflammatory; bronchodilator	62020	18559-94-9	0.03	na	na
Caffeine	Stimulant	50305	58-08-2	0.40	na	na
Carbamazapine	Anticonvulsant; mood stabilizer	62793	298-46-4	0.02	na	na
Codeine	Opiod narcotic	62003	76-57-3	0.02	na	na
Cotinine	Nicotine metabolite	62005	486-56-6	0.03	na	na
Dehydronifedipine	Antianginal metabolite	62004	67035-22-7	0.03	na	na
Diltiazem	Antianginal; antihypertensive	62008	42399-41-7	0.02	na	na
Diphenhydramine	Antihistamine	62796	58-73-1	0.03	na	na
Paraxanthine	Caffeine metabolite	62030	611-59-6	0.10	na	na
Sulfamethoxazole	Antibacterial, antiprotozoal	62021	723-46-6	0.05	na	na
Thiabendazole	Anthelmintic	62801	148-79-8	0.02	na	na
Trimethoprim	Antibacterial	62023	738-70-5	0.01	na	na
Warfarin	Anticoagulant	62024	81-81-2	0.03	na	na

[1]The California Groundwater Ambient Monitoring and Assessment (GAMA) program uses more conservative reporting limits for the pharmaceutical compounds than recommended by the USGS's National Water Quality Laboratory. For albuterol, carbamazepine, codeine, dehydronifedipine, diltiazem, sulfamethoxazole, thiabendazole, trimethoprim, and warfarin, the MDL corresponds to the long-term method detection limit determined by the USGS's Branch of Quality Systems in October 2007 (BQS LT-MDL). For acetaminophen, caffeine, cotinine, diphenhydramine, and paraxanthine, the MDL corresponds to the effective method detection limit determined from assessment of quality-control data associated with GAMA samples collected from May 2004 to September 2007 (GAMA E-MDL). The GAMA E-MDL is higher than the BQS LT-MDL for those compounds. Detections reported by the USGS's National Water Quality Laboratory with concentrations lower than the BQS LT-MDL or GAMA E-MDL are reported as nondetections by the GAMA program.

Table 3F. Constituents of special interest, primary uses or sources, comparative thresholds, and reporting information for the Montgomery Watson Harza laboratory.

[The five-digit U.S. Geological Survey (USGS) parameter code is used to uniquely identify a specific constituent or property. Thresholds and threshold values as of October 18, 2007. The laboratory entity code for the Montgomery Watson Harza laboratory in the USGS's National Water Information System (NWIS) is CA-MWHL. CAS, Chemical Abstracts Service; CDPH, California Department of Public Health; D, detected; HAL-CA, Lifetime Health Advisory Level (CDPH); MCL-CA, maximum contaminant level (CDPH); MRL, minimum reporting level; NL-CA, notification level (CDPH); µg/L, micrograms per liter; —, not detected]

Constituent	Primary use or source	USGS parameter code	CAS number	MRL (µg/L)	Threshold type	Threshold value (µg/L)	Detection

[1]A TT-US threshold of 5 NTU does exist, but it applies to surface water and, therefore, is not included with this table.

[2] Specific conductance has a recommended and an upper threshold value. The upper value is shown in parentheses.

Table 5. Volatile organic compounds (VOCs), and gasoline oxygenates and degradates detected in samples collected for the Middle Sacramento Valley Groundwater Ambient Monitoring and Assessment (GAMA) study, California, June to September, 2006.

[Samples from all 108 wells were analyzed, but only wells with detections are listed. Constituents are grouped by primary use or source, and within each group are listed in order of decreasing detection frequency in the 71 grid wells. The five-digit number in parentheses below the constituent name in the headings is used by the U.S. Geological Survey to uniquely identify a specific constituent or property. [1]Maximum contaminant level thresholds are listed as MCL-US when MCL-US and MCL-CA are identical, and as MCL-CA when the MCL-CA is lower than the MCL-US or no MCL-US exists.

[2] The MCL-US threshold for trihalomethanes is the sum of chloroform, bromodichloromethane, dibromochloromethane, and bromoform.

[3] Frequency of detection of at least one VOC in the grid wells. Detections with V remark codes are not included.

Table 6. Pesticides and pesticide degradates detected in samples collected for the Middle Sacramento Valley Groundwater Ambient Monitoring and Assessment (GAMA) study, California, June to September, 2006. —Continued

[Results are from the U.S. Geological Survey's (USGS) National Water Quality Laboratory Schedules 2032, 2033, and 2060. Samples from all 108 wells were analyzed, but only wells with detections are listed. Constituents are grouped by primary use of source and within each group are listed in order of decreasing detection frequency in the 71 grid wells. The five-digit number in parentheses below the constituent name is used by the USGS to uniquely identify a specific constituent or property. CDPH, California Department of Public Health; E, estimated value; ESAC, East study area of the middle Sacramento Valley study unit; ESAC-FP, East study area of the middle Sacramento Valley study unit–flow path; HAL-US, Lifetime Health Advisory Level (USEPA); LRL, laboratory reporting level; MCL-CA; maximum contaminant level (CDPH); MCL-US, maximum contaminant level (USEPA); na, not available; no., number; RICE, RICE well; RSD5-US, U.S. Environmental Protection Agency risk specific dose at a risk factor of 10^{-5} µg/L (RSD5s are calculated by dividing the 10^{-4} cancer risk concentration established by the USEPA by 10); USEPA, U.S. Environmental Protection Agency; V, analyte detected in sample and an associated blank—thus data are not included in ground-water quality analysis results; WSAC, West study area of the middle Sacramento Valley study unit; WSAC-FP, West study area of the middle Sacramento Valley study unit–flow path; µg/L, micrograms per liter; —, analyzed but not detected]

[1] Maximum contaminant level thresholds are listed as MCL-US when MCL-US and MCL-CA are identical, and as MCL-CA when the MCL-CA is lower than the MCL-US or no MCL-US exists.

[2] Frequency of detection of at least one pesticide in the grid wells. Detections with V remark codes are not included.

Table 7. Constituents of special interest (perchlorate, *N*-nitrosodimethylamine [NDMA], and 1,2,3-trichloropropane [1,2,3-TCP]) detected in samples collected in the Middle Sacramento Valley Groundwater Ambient Monitoring and Assessment (GAMA) study, California, June to September, 2006.

[Samples from all 108 wells were analyzed for perchlorate; samples from 45 grid wells and 15 flow-path wells were sampled for NDMA and 1,2,3-TCP; only wells with at least one detection are listed. Analyses done by the Mongomery Watson Harza laboratory. The laboratory entity code for the Montgomery Watson Harza laboratory in the U. S. Geological Survey's National Water Information System (NWIS) is CA-MWHL. CDPH, California Department of Public Health; ESAC, East study area of the middle Sacramento Valley study unit; MCL-CA, maximum contaminant level (CDPH); MRL, minimum reporting level; no., number; RICE, RICE well; WSAC, West study area of the middle Sacramento Valley study unit; µg/L, micrograms per liter]

[1]Maximum contaminant level thresholds are listed as MCL-US when the MCL-US and MCL-CA are identical, and as MCL-CA when the MCL-CA is lower than the MCL-US or no MCL-US exists.

[2] The HAL-US is 30 mg/L "as ammonia." To facilitate comparison to the analytical results, we have converted and reported this HAL-US as 24.7 mg/L "as nitrogen."

[3]Total nitrogen in these samples is less than the sum of the filtered nitrogen analytes, but falls within the USGS's National Water Quality Laboratory acceptance criteria of a 10 percent relative percent difference.

[4]Total nitrogen in these samples is less than the sum of the filtered nitrogen analytes and exceeds the USGS's National Water Quality Laboratory acceptance criteria of 10 percent relative difference, but the sum of the filtered nitrogen analytes is less than the LRL for total nitrogen.

[5]Total nitrogen in these samples is less than the sum of the filtered nitrogen analytes and exceeds the USGS's National Water Quality Laboratory acceptance criteria of 10 percent relative difference. Values were verified by the laboratory.

Table 9. Major and minor ions and total dissolved solids detected in samples collected for the Middle Sacramento Valley Groundwater Ambient Monitoring and Assessment (GAMA) study, California, June to September, 2006.

[Samples from the 45 slow and intermediate grid wells, 15 flow-path wells, and 22 RICE wells were analyzed. The five-digit number in parentheses below the constituent name in the headings is used by the U.S. Geological Survey to uniquely identify a specific constituent or property. CDPH, California Department of Public Health; E, estimated value; ESAC, East study area of the middle Sacramento Valley study unit; ESAC-FP, East study area of the middle Sacramento Valley study unit–flow path; LRL, laboratory reporting level; MCL-CA, maximum contaminant level (CDPH); mg/L, milligrams per liter; na, not available; no., number; RICE, RICE well; SMCL-CA, secondary maximum contaminant level (CDPH); WSAC, West study area of the middle Sacramento Valley study unit; WSAC-FP, West study area of the middle Sacramento Valley study unit–flow path; —, analyzed but not detected; *, value above threshold level; **, value above upper threshold level]

[1]Bicarbonate and carbonate concentrations were calculated from the laboratory alkalinity and pH values (table 4) using the advance speciation method (http://or.water.usgs.gov/alk/methods.html).

[2]Maximum contaminant level thresholds are listed as MCL-US when the MCL-US and MCL-CA are identical, and as MCL-CA when the MCL-CA is lower than the MCL-US or no MCL-US exists.

[3]The SMCL-CA for chloride, sulfate, and total dissolved solids have recommended and upper threshold values. The upper value is shown in parentheses.

[4]Laboratory reporting level is 4.5 mg/L.

Table 10. Trace elements detected in samples collected for the Middle Sacramento Valley Groundwater Ambient Monitoring and Assessment (GAMA) study, California, June to September, 2006.

[Samples from the 45 slow and intermediate grid wells, 15 flow-path wells, and 22 RICE wells were analyzed. The five-digit number in parentheses below the constituent name in the headings is used by the U.S. Geological Survey to uniquely identify a specific constituent or property. AL-US, action level (USEPA); CDPH, California Department of Public Health; E, estimated value; ESAC, East study area of the middle Sacramento Valley study unit; ESAC-FP, East study area of the middle Sacramento Valley study unit–flow path; HAL-US, Lifetime Health Advisory Level (USEPA); LRL, laboratory reporting level; MCL-CA, maximum contaminant level (CDPH); MCL-US, maximum contaminant level (USEPA); na, not available; nc, not collected; NL-CA, notification level (CDPH); no., number; RICE, RICE well; SMCL-CA, secondary maximum contaminant level (CDPH); USEPA, U.S. Environmental Protection Agency; V, analyte detected in sample and an associated blank—thus data are not included in groundwater quality analysis results; WSAC, West study area of the middle Sacramento Valley study unit; WSAC-FP, West study area of the middle Sacramento Valley study unit–flow path; µg/L, micrograms per liter; —, analyzed but not detected; *, value above threshold level]

Table 11. Species of inorganic arsenic, iron, and chromium detected in samples collected for the Middle Sacramento Valley Groundwater Ambient Monitoring and Assessment (GAMA) study, California, June to September, 2006.—Continued

[Samples from the 45 slow and intermediate grid wells, 15 flow-path wells, and 22 RICE wells were analyzed for iron, arsenic, and chromium; only wells with at least one detection are listed. The five-digit number in parentheses below the constituent name in the headings is used by the U.S. Geological Survey (USGS) to uniquely identify a specific constituent or property. Analyses made by the USGS's Trace Metals Laboratory. The laboratory entity code for the USGS's Trace Metals Laboratory in the USGS's National Water Information System (NWIS) is USGSTMCO. CDPH, California Department of Public Health; ESAC, East study area of the middle Sacramento Valley study unit; ESAC-FP, East study area of the middle Sacramento Valley study unit–flow path; MCL-CA, maximum contaminant level (CDPH); MCL-US, maximum contaminant level (USEPA); MDL, method detection limit; na, not available; no., number; NRP, National Research Program (USGS); NWQL, National Water Quality Laboratory (USGS); RICE, RICE well; RSD, relative standard deviation; SMCL-CA, secondary maximum contaminant level (CDPH); USEPA, U.S. Environmental Protection Agency; V, analyte detected in sample and an associated blank—thus data are not included in ground-water quality analysis results; WSAC, West study area of the middle Sacramento Valley study unit; WSAC-FP, West study area of the middle Sacramento Valley study unit–flow path; µg/L, micrograms per liter; —, analyzed but not detected; *, value above threshold level]

[1] Maximum contaminant level thresholds are listed as MCL-US when the MCL-US and MCL-CA are identical, and as MCL-CA when the MCL-CA is lower than the MCL-US or no MCL-US exists.

[2] V codes were applied to ground-water samples for which the concentration measured by the NRP laboratory was greater than the concentration measured by the NWQL preferred method (table 10), and the difference between the results was greater than 20 percent RSD.

[3] Concentration measured by the NRP laboratory was less than the concentration measured by the NWQL preferred method (table 10), and the difference between the results was greater than 20 percent RSD.

Table 12. Stable isotope ratios of water and tritium detected in samples collected for the Middle Sacramento Valley Groundwater Ambient Monitoring and Assessment (GAMA) study, California, June to September, 2006.

[Samples from 70 of the grid wells (WSAC-14 not analyzed), the 15 flow-path wells, and 2 of the RICE wells were analyzed for stable isotopes of water; samples from 70 of the grid wells (WSAC-13 not analyzed), and the 15 flow-path wells were analyzed for tritium. The five-digit number in parentheses below the constituent name in the headings is used by the U.S. Geological Survey (USGS) to uniquely identify a specific constituent or property. Stable isotope ratios are reported in the standard delta notation (δ), the ratio of a heavier isotope to more common lighter isotope of that element, relative to a standard reference material. The laboratory entity codes for the laboratories in the USGS's National Water Information System (NWIS) listed in the footnotes are shown in parentheses following the laboratory name. CDPH, California Department of Public Health; ESAC, East study area of the middle Sacramento Valley study unit; ESAC-FP, East study area of the middle Sacramento Valley study unit–flow path; MCL-CA, maximum contaminant level (CDPH); nc, sample not collected; no., number; pCi/L, picocuries per liter; RICE, RICE well; WSAC, West study area of the middle Sacramento Valley study unit; WSAC-FP, West study area of the middle Sacramento Valley study unit–flow path; <, less than]

[1] Maximum contaminant level thresholds are listed as MCL-US when the MCL-US and MCL-CA are identical, and as MCL-CA when the MCL-CA is lower than the MCL-US or no MCL-US exists.

[2] The MCL-US threshold for radium is the sum of radium-226 and radium-228.

[3] Two MCL-US thresholds have been proposed: 300 pCi/L and 4,000 pCi/L.

[4] Potential to be biased low for gross alpha 72-hour and gross alpha 30-day radioactivity counts because of relatively high concentration of calcium.

Appendix

The appendix discusses methods used to collect and analyze ground-water samples and to report the data for the MSACV study unit. These methods were selected to obtain representative samples of the ground water used for drinking-water supplies in the study and to minimize potential bias of the data. Procedures to analyze and interpret QC data collected as part of the ground-water sampling are also discussed.

Sample Collection and Analysis

Ground-water samples were collected using standard and modified USGS protocols (Koterba and others, 1995), the National Field Manual for the collection of water quality data (U.S. Geological Survey, variously dated) and protocols described by Weiss (1968), Shelton and others (2001), Ball and McClesky (2003a,b), and Wright and others (2005).

Prior to sampling, each well was pumped continuously to purge at least three casing-volumes of water from the well (Wilde and others, 1999). Wells were sampled using Teflon tubing with brass and stainless-steel fittings attached to a sampling point on the well discharge pipe as close to the well as possible. The sampling point was always located upstream of any well-head treatment system or water storage tank. If a chlorinating system was attached to the well, the chlorinator was shut off at least 24 hours prior to purging and sampling the well to clear all chlorine out of the system.

For the *fast* and *intermediate* schedules, samples were collected at the well head using a foot-long length of Teflon tubing. For the *slow* schedule, the samples were collected inside an enclosed chamber located inside a mobile laboratory and connected to the well head by a 10- to 50-ft length of Teflon tubing (Lane and others, 2003).

For intermediate monitoring schedules (flow-path and RICE wells), samples were collected using a portable, 2-in. diameter submersible pump (Grundfos RediFlo2 pump) attached to reels of approximately 300 ft of Teflon tubing. The 10- to 50-ft Teflon tubing used to sample slow schedules was attached to the outflow section of the reels and samples were collected inside an enclosed chamber in a mobile laboratory. Two separate submersible pumps and reels were used to collect samples from monitoring wells in MSACV. All fittings and lengths of tubing were cleaned between samples (Wilde, 2004).

For the field measurements, ground water was pumped through a flow-through chamber fitted with a multiprobe meter that simultaneously measures the water-quality indicators dissolved oxygen, temperature, pH, turbidity, and specific conductance. Field measurements were made in accordance with protocols in the USGS's National Field Manuals (Lewis, 2006; Radtke and others, 2005; Wilde, 2006; Wilde and others, 2006; Wilde and Radtke, 2005). All sensors on the multiprobe meter were calibrated daily. Measurements of temperature, dissolved oxygen, pH, and specific conductance values were recorded at 5-minute intervals for at least 30 minutes, and when these values remained stable for 20 minutes, samples for laboratory analyses were then collected. Field measurements and instrument calibrations were recorded by hand on field record sheets and electronically in PCFF ("Personal Computer Field Forms")-GAMA, a software package designed by the USGS with support from the GAMA program. Analytical service requests were also managed by PCFF-GAMA. Chain of custody documentation forms were completed by hand or electronically. Information from PCFF-GAMA was uploaded directly into NWIS at the end of every week of sample collection.

For analyses requiring filtered water, ground water was diverted through a 0.45-µm pore size vented capsule filter, a disk filter, or a baked glass-fiber filter depending on the protocol for the analysis (Wilde, 2004; Wilde and others, 1999). Prior to sample collection, polyethylene sample bottles were prerinsed twice using dionized water and once with sample water before collection. Samples requiring acidification were acidified to a pH of 2 or less with the appropriate acids using ampoules of certified, traceable concentrated acids obtained from NWQL.

Temperature-sensitive samples were stored on ice prior to, and during, daily shipping to the various laboratories. The nontemperature-sensitive samples, tritium, noble gases, chromium speciation, and stable isotopes were shipped monthly, whereas VOCs, pesticides and pesticide degradates, constituents of special interest, dissolved organic carbon, radium isotopes, gross alpha and beta radioactivity, and radon-222 samples were shipped daily.

Detailed sampling protocols for individual analyses and groups of analytes are described in Koterba and others (1995) and the USGS's National Field Manuals (Wilde, 2004; Wilde and others, 1999) and in the references for analytical methods listed in table A1; only brief descriptions are given here. VOCs and gasoline oxygenates and degradates, and 1,2,3-TCP samples were collected in 40-mL baked amber glass sample vials that were purged with three vial volumes of sample water before bottom-filling to eliminate atmospheric contamination. Six normal (6 N) hydrochloric acid (HCl) was added as a preservative to the VOC samples, but not to the gasoline oxygenate and degradate samples, or the 1,2,3-TCP samples. Perchlorate samples were collected in 125-mL polyethylene bottles. Tritium samples were collected by bottom-filling two 1-L polyethylene bottles with unfiltered ground water, after first overfilling the bottle with three volumes of water. Stable isotopes of water were collected in 60-mL clear glass bottles filled with unfiltered water, sealed with a conical cap, and secured with electrical tape to prevent leakage and evaporation.

Pesticides and pesticide degradation products, pharmaceutical compounds, and NDMA samples were collected in 1-L baked amber glass bottles. Pesticide and pharmaceutical samples were filtered with a glass-fiber filter during collection, whereas the NDMA samples were filtered at the Montgomery Watson Harza laboratory prior to analysis.

Ground-water samples for major and minor ions, trace elements, alkalinity, and total dissolved solids analyses required filling one 250-mL polyethylene bottle with raw ground water, and one 500-mL and one 250-mL polyethylene bottles with filtered ground water (Wilde, 2004). A Whatman capsule filter was used for filtration. Each 250-mL filtered sample was then preserved with an ampoule of 7.5 N nitric acid. Mercury samples were collected by filtering ground water into a 250-mL glass bottle and preserving with an ampoule of 6 N HCl. Arsenic and iron speciation samples were filtered into 250-mL polyethylene bottles that were covered with tape to prevent light exposure and preserved with 6 N HCl. Nutrient samples were filtered into 125-mL brown polyethylene bottles. Nitrate isotope samples were filtered into 125-mL polyethylene bottles. Radium isotopes and gross alpha and beta radiation samples were filtered into 1-L polyethylene bottles and acidified with nitric acid. Carbon isotope samples were filtered and bottom-filled into two 500-mL glass bottles that were first overfilled with three bottle volumes of ground water. These samples had no headspace and were sealed with a conical cap to avoid atmospheric contamination. Samples for alkalinity titrations were collected by filtering ground water into 500-mL polyethylene bottles.

Dissolved organic carbon (DOC), chromium, radon-222, dissolved gases, and microbial constituents were collected from the hose bib at or near the well head, regardless of the sampling schedule (fast, intermediate, or slow). DOC was collected after rinsing the sampling equipment with universal blank water (Wilde, 2004). Using a 50-mL syringe and 0.45-µm disk filter, ground-water samples were filtered into 125-mL baked amber glass bottles and preserved with 4.5 N sulfuric acid. Chromium speciation samples were collected using a 10-mL syringe with an attached 0.45-µm disk filter. After the syringe was thoroughly rinsed and filled with ground water, 4 mL was forced through the disk filter; the next 2 mL of the ground water was then slowly filtered into a small centrifuge vial for analysis of total chromium. Hexavalent chromium, Cr(VI), was then collected by attaching a small cation-exchange column to the syringe filter, and after conditioning the column with 2 mL of sample water, 2 mL was collected in a second centrifuge vial. Both vials were preserved with 10 µL of 7.5 N nitric acid (Ball and McClesky, 2003a,b).

For the collection of radon-222, a stainless steel and Teflon valve assembly was attached to the sampling port at the well head (Wilde, 2004). The valve was partially closed to create back pressure, and a 10-mL sample was taken through a Teflon septum on the value assembly using a glass syringe affixed with a stainless-steel needle. The sample was then injected into a 25-mL vial partially filled with scintillation mixture (mineral oil) and shaken. The vial was then placed in a cardboard tube to shield it from light during shipping.

Noble gases were collected in 3/8-in. copper tubes using reinforced nylon tubing connected to the hose bib at the wellhead. Ground water was flushed through the tubing to dislodge bubbles before flow was restricted with a back pressure valve. Clamps on either side of the copper tube were then tightened, trapping a sample of ground water for analyses of noble gases (Weiss, 1968).

Samples for analysis of microbial constituents also were collected at the well head (Bushon, 2003; Myers, 2004). Prior to the collection of samples, the sampling port was sterilized using isopropyl alcohol, and ground water was run through the sampling port for at least three minutes to remove any traces of the sterilizing agent. One sterilized 3-L carboy was filled for coliphage analyses (F-specific and somatic coliphage determinations), and two sterilized 250-mL bottles were filled with ground water for coliform (total coliforms and *Escherichia* coliform) analyses. Total coliforms and *Escherichia* coliform (*E. coli*) plates were prepared using sterilized equipment and reagents (Myers, 2004). Plates were counted under an ultraviolet light, following a 22- to 24-hour incubation time.

Turbidity and alkalinity were measured in the mobile laboratory at the well site. Turbidity was measured in the field with a calibrated turbidity meter. Alkalinity concentrations were measured on filtered samples by Gran's titration method (Rounds, 2006). Titration data were entered directly into PCFF-GAMA, and the concentrations of bicarbonate (HCO_3^-) and carbonate (CO_3^{2-}) were automatically calculated from the titration data using the advanced speciation method. Concentrations of HCO_3^- and CO_3^{2-} were also calculated from the laboratory alkalinity and pH measurements. Calculations were made in a spreadsheet using the advanced speciation method (http://or.water.usgs.gov/alk/methods.html) with pK_1 = 6.35, pK_2 = 10.33, and pK_W = 14.

Ten laboratories performed chemical and microbial analyses for this study (see table A1), with most of the analyses being performed at NWQL or by laboratories contracted by NWQL. NWQL maintains a rigorous quality-assurance program (Maloney, 2005; Pirkey and Glodt, 1998). Laboratory QC samples, including method blanks, continuing calibration verification standards, standard reference samples, reagent spikes, external certified reference materials, and external blind proficiency samples, are analyzed regularly. Method detection limits are continuously tested and laboratory reporting levels updated accordingly. NWQL maintains National Environmental Laboratory Accreditation Program

(NELAP) and other certifications (http://nwql.usgs.gov/Public/lab_cert.shtml). In addition, the Branch of Quality Systems within the USGS's Office of Water Quality maintains independent oversight of quality assurance at NWQL and laboratories contracted by NWQL. The Branch of Quality Systems also runs a National Field Quality Assurance program that includes annual testing of all USGS field personal for proficiency in making field water-quality measurements (http://bqs.usgs.gov/nfqa/). Results for analyses made at NWQL or by laboratories contracted by NWQL are uploaded directly into NWIS by NWQL.

Data Reporting

Laboratory Reporting Conventions

NWQL uses the LRL as a threshold for reporting analytical results. The LRL is set to minimize the reporting of false negatives (not detecting a compound when it is actually present in a sample) to less than 1 percent (Childress and others, 1999). The LRL is set at two-times the long-term method detection level (LT-MDL). The LT-MDL is derived from the standard deviation of at least 24 MDL determinations made over an extended period of time. LT-MDLs are continually monitored and updated. The method detection limit (MDL) is the minimum concentration of a substance that can be measured and reported with 99 percent confidence that the concentration is greater than zero (at the MDL, there is less than 1 percent chance of a false positive) (Childress and others, 1999; U.S. Environmental Protection Agency, 2002a). NWQL updates LRL values regularly, and the values listed in this report were in effect during the period analyses were made for ground-water samples from the MSACV study (June to September, 2006).

Detections between the LRL and the LT-MDL are reported as estimated concentrations (designated with an "E" before the value in the tables and text). For information-rich methods, detections below the LT-MDL have high certainty of detection, but the precise concentration is uncertain. Information-rich methods are those that utilize gas chromatography or high-performance liquid chromatography (HPLC) with mass spectrometry detection (VOCs, gasoline oxygenates and degradates, and pesticides and pesticide degradates). For these methods, compounds are identified by presence of characteristic fragmentation patterns in their mass spectra in addition to being quantified by measurement of peak areas at their associated chromatographic retention times. E-coded values also may result from detections outside the range of calibration standards for detections that did not meet all laboratory QC criteria and for samples that were diluted prior to analysis (Childress and others, 1999).

Some compound concentrations in this study are reported using minimum reporting levels (MRLs) or method uncertainties. The MRL is the smallest measurable concentration of a constituent that may be reliably reported using a given analytical method (Timme, 1995). The method uncertainty generally indicates the precision of a particular analytical measurement; it gives a range of values wherein the true value will be found.

The reporting levels for radiochemical constituents (gross-alpha radioactivity, gross-beta radioactivity, radium-226, and radium-228) are based on a sample-specific minimum detectable concentration (SSMDC), a sample-specific critical value, and the combined standard uncertainty (CSU) (Bennett and others, 2006; U.S. Environmental Protection Agency, 2004). A result above the critical value represents a greater-than-95-percent certainty that the result is greater than zero (significantly different from the instrument's background response to a blank sample), and a result above the SSMDC represents a greater-than-95-percent certainty that the result is greater than the critical value. Using these reporting level elements, three unique cases were possible when screening the raw analytical data, as described in Bennett and others (2006). If the analytical result was less than the critical value (case 1), the analyte was considered not detected, and the concentration was reported as less than the SSMDC. If the analytical result was greater than the critical value, the ratio of the CSU to the analytical result was calculated as a percent (percent relative CSU). For those samples with percent relative CSU greater than 20 percent (case 2), concentrations were reported as estimated values (designated by an "E" preceding the value). For those samples with percent relative CSU less than 20 percent, concentrations were reported unqualified (case 3). For table clarity, only the screened results were reported in table 14; the raw analytical results with their corresponding SSMDCs, critical values, and CSUs, are on file at the USGS California Water Science Center.

Stable isotopic compositions of oxygen, hydrogen, carbon, and nitrogen are reported as relative isotope ratios in units of per mil using the standard delta notation $\delta^{i}E$ (Coplen and others, 2002):

$$\delta^{i}E = \left[\frac{R_{sample}}{R_{reference}} - 1\right] \bullet 1{,}000 \text{ per mil}, \quad (1)$$

where

^{i}E is the heavier isotope (^{18}C, ^{13}C, or ^{2}H),

R_{sample} is the ratio of the abundance of the heavier isotope to the lighter isotope (^{16}O, ^{12}C, or ^{1}H) in the sample, and

$R_{reference}$ is the ratio of the abundance of the heavier isotope to the lighter isotope (^{16}O, ^{12}C, or ^{1}H) in the reference material.

The reference material for oxygen and hydrogen is Vienna Standard Mean Ocean Water (VSMOW), which is assigned $\delta^{18}O$ and $\delta^{2}H$ values of 0 per mil (note than $\delta^{2}H$ is also written as δD because the common name of the heavier isotope of hydrogen, hydrogen-2, is deuterium). The reference material for carbon is Vienna Peedee Belemnite (VPDB), which is assigned a $\delta^{13}C$ value of 0 per mil. Positive values indicate enrichment of the heavier isotope and negative values indicate depletion of the heavier isotope, compared with the ratios observed in the standard reference material.

Constituents on Multiple Analytical Schedules

Eighteen constituents targeted in this study are measured by more than one analytical schedule or more than one laboratory (table A2). The preferred methods for these constituents were selected on the basis of the procedure recommended by NWQL (http://wwwnwql.cr.usgs.gov/USGS/Preferred_method_selection_procedure.html). Methods with full approval are preferred over those with provisional approval and approved methods are favored over research methods. The method with greater accuracy and precision and lower LRLs for the overlapping constituents is generally preferred. However, the method with higher LRLs may be selected as the preferred method to provide consistency with historical data analyzed by the same method.

Five constituents appear on NWQL Schedules 2020 and 4024, and the preferred method is Schedule 2020 to provide consistency. All samples collected for the GAMA Priority Basin Assessment project are analyzed using Schedule 2020, whereas, only a subset are analyzed using Schedule 4024. Six constituents appear on NWQL Schedules 2032/2033 and 2060, and the preferred method is Schedule 2032/2033 because it has greater precision and accuracy for the six overlapping constituents. For constituents that appear on two NWQL schedules, only the values determined by the preferred method are reported.

The water-quality indicators pH, specific conductance, and alkalinity were measured in the field and at NWQL. The field measurements are the preferred method for all three constituents; however, both are reported because the laboratory alkalinity measurements were made on a greater number of samples.

The field and laboratory data were compared using the Wilcoxon signed-rank test, a nonparametric statistical test that is analogous to the parametric statistical test the paired t-test (Helsel and Hirsch, 2002). A nonparametric test was used because the data are not normally distributed. The Wilcoxon signed-rank test evaluates the null hypothesis that the median of the paired differences between the two datasets is zero. Results are reported as the probability, P, of obtaining the observed distribution of data, or one even less likely, when the null hypothesis is true. Therefore, a P value of 0.01 indicates 99 percent confidence that the two datasets are different.

Specific conductance was measured in both the field and the laboratory for 82 samples, and there was no statistical significance between the two datasets (P = 0.1035). Both laboratory and field pH measurements were made for 80 samples, and the two datasets were systematically different (P = <0.0001). Field pH values were lower by a median of 0.3 pH units. The increase in pH between field and laboratory measurement may be explained by equilibration of the sample with the atmosphere after collection. The partial pressure of CO_2 in ground water is often greater than the atmospheric partial pressure (Appelo and Postma, 2005); thus, CO_2 degasses from the ground water when it is brought in contact with the atmosphere. CO_2 loss results in increased pH. Field and laboratory alkalinities were measured for seven samples, and the two datasets were significantly different (P = 0.0156). Field alkalinity values were lower by a median of 11 mg/L as $CaCO_3$. The differences between the field and laboratory values were greater than 5 percent for all but two samples.

For arsenic, chromium, and iron concentrations, the standard methods used by NWQL are preferred over the research methods used by the USGS National Research Program (NRP) Trace Metal Laboratory (TML) in Boulder, Colorado. The concentrations measured by TML are used only to

calculated ratios of redox species for each element, $\frac{As(V)}{As(III)}$ for arsenic, $\frac{Cr(VI)}{Cr(III)}$ for chromium, and $\frac{Fe(III)}{Fe(II)}$ for iron. For example:

$$\frac{Fe(III)}{Fe(II)} = \frac{Fe(T) - Fe(II)}{Fe(II)}, \quad (2)$$

where

Fe(T) is the total iron concentration (measured),

Fe(II) is the concentration of ferrous iron (measured), and

Fe(III) is the concentration of ferric iron (calculated).

Quality Assurance

The purpose of quality-assurance is to identify which data best represent environmental conditions and which may have been affected by contamination or bias during sample collection, processing, storage, transportation, or laboratory analysis. Four types of QC tests were used in this study: blank samples were collected to assess contamination; replicate samples were collected to assess reproducibility; matrix spike tests were done to assess accuracy of laboratory analytical methods; and surrogate compounds were added to samples analyzed for organic constituents to assess bias of laboratory analytical methods. In the tables of this report, detections of organic constituents in ground-water samples that may have resulted from contamination were flagged with a “V” remark code, and were not considered detections for calculations

of detection frequencies in water-quality assessments. Detections of inorganic constituents in ground-water samples that may have resulted from contamination were flagged with a "V" remark code to indicate that the amount of potential contamination may have been sufficient to change a nondetection into a detection relative to the stated reporting level.

The quality-assurance used for this study followed the protocols used by the USGS's NAWQA program (Koterba and others, 1995) and described in the National Field Manual (U.S. Geological Survey, variously dated). The quality assurance plan followed by NWQL, the primary laboratory used to analyze samples for this study, is described in Maloney (2005) and Pirkey and Glodt (1998).

Blanks

Blank samples (blanks) were collected using two types of water certified by NWQL to contain less than the LRL or MRL of the analytes investigated in the study. First, inorganic blank water (IBW) was used to collect sample blanks of perchlorate, major ions and trace elements, nutrients, arsenic and iron speciation, and chromium speciation. All other blanks were collected using VOC-free (nitrogen-purged) blank water (VBW). Two types of blanks were collected: source-solution and field blanks. Source-solution blanks were collected to verify that the blank water used for the field blanks was free of analytes. Field and source solution blanks were collected at approximately 10 percent of the wells sampled to determine if equipment or procedures used in the field or laboratory introduced contamination. Field blanks were analyzed for VOCs, gasoline oxygenates and their degradates, pesticides and pesticide degradates, pharmaceuticals, perchlorate, NDMA, 1,2,3-TCP, nutrients, DOC, major and minor ions, trace elements, iron, arsenic, and chromium speciation, and radioactive constituents (table A3). NWQL-certified blank water is not available for tritium or noble gases; thus, source solution and field blanks were not collected for these constituents.

Field blanks were collected by pumping or pouring blank water through the sampling equipment (fittings and tubing) used to collect ground water, then processing and transporting the blank samples using the same protocols for the ground-water samples. The equipment used to collect samples from monitoring wells was significantly different than that used to collect samples from production wells; thus, the field blanks were separated into monitoring well and production well groups for comparison with ground-water data. Source-solution blanks were collected at the sampling site by pouring blank water directly into sample containers that were preserved, stored, shipped, and analyzed in the same manner as the ground-water samples. Source-solution blanks were not divided into two classes because they were not collected using the field sampling equipment.

If a constituent was detected in field or source-solution blanks, the data for that constituent in ground-water samples were examined for potential contamination. Detections in ground-water samples with concentrations less than the highest concentration measured in a blank plus the LT-MDL were marked with a "V" in the data tables (LRL equals twice the LT-MDL). The highest concentration measured in a blank was assumed to represent the highest potential amount of contamination. Thus, the V remark code flags results that could have changed from a nondetection to a detection relative to the LT-MDL because of contamination. For example, if the LT-MDL for a constituent is 0.10 µg/L, the measured concentration in a ground-water sample with a true concentration of 0.05 µg/L would be reported as a nondetection. But, if the ground-water sample was contaminated with 0.20 µg/L of the constituent, the measured concentration would be reported as 0.25 µg/L, a detection. If the maximum potential amount of contamination is 0.20 µg/L, then ground-water samples with measured concentrations less than 0.30 µg/L may actually have true concentrations less than the LT-MDL.

For organic constituents, results with V codes are not considered to be detections of the constituent when calculating detection frequencies for ground-water quality assessments. For inorganic constituents, results with V codes are considered to have concentrations less than the reported value (including the possibility of the concentration being less than the LT-MDL).

Replicates

Sequential replicate samples were collected to assess variability that may result from the processing and analyses of inorganic and organic constituents. RSD of the measured values was used to express the variability between replicate pairs for each compound (table A4). The RSD is defined as the standard deviation divided by the mean concentration for each replicate pair of samples, multiplied by 100 percent. If one value in a sample pair was reported as a nondetection and the other value was reported as an estimated value below the LRL or MRL, the RSD was set to zero because the values are analytically identical. If one value in a sample pair was reported as a nondetection and the other value was greater than the LRL or MRL, then the nondetection value was set equal to one-quarter of the LRL, and the RSD was calculated (Hamlin and others, 2002). Values of RSD less than 20 percent are considered acceptable in this study. An RSD value of 20 percent corresponds to a relative percent difference (RPD) value of 29 percent. High RSD values for a compound may indicate analytical uncertainty at low concentrations, particularly for concentrations within an order of magnitude of LT-MDL or MDL. Sequential replicate samples were collected at approximately 10 percent of the wells sampled.

Matrix Spikes

Addition of a known concentration of a constituent ("spike") to a replicate environmental sample enables the laboratory to determine the effect of the matrix, in this case ground water, on the analytical technique used to measure the constituent. The compounds added as matrix spikes are the same as those being analyzed in the method. This enables an analysis of matrix interferences on a compound by compound basis. Matrix spikes were added at the laboratory performing the analysis. Compounds with low recoveries are of particular concern if environmental concentrations are close to the MCLs; a concentration below an MCL could be above this threshold. Conversely, compounds with high recoveries are of potential concern if the environmental concentrations exceed MCLs; a high recovery could falsely indicate a concentration above the MCL.

Acceptable ranges for matrix-spike recoveries are based on the acceptable ranges established for laboratory "set" spike recoveries. Laboratory set spikes are aliquots of laboratory blank water to which the same spike solution used for the matrix spikes has been added. One set spike is analyzed with each set of samples. Acceptable ranges for set spike recoveries are 70 to 130 percent for NWQL Schedules 2020 and 4024 (VOCs and gasoline additives; Connor and others, 1998; Rose and Sandstrom, 2003; Zaugg and others, 2002), 60 to 120 percent for NWQL Schedules 2032, 2033, and 2060 (pesticides; Sandstrom and others, 2001), and 60 to 130 percent for Schedule 2080 (pharmaceuticals; Kolpin and others, 2002). On the basis of these ranges, we defined 70 to 130 percent as the acceptable range for matrix-spike recoveries for organic compounds in this study.

Laboratory matrix spikes were performed for VOCs, gasoline oxygenate and their degradates, pesticide compounds, pharmaceutical compounds, NDMA, and 1,2,3-TCP because the analytical methods for these constituents are chromatographic methods that may be susceptible to matrix interferences. Replicate samples for matrix-spike additions were collected at approximately 10 percent of the wells sampled, although not all analyte classes were tested for every well (tables A5A–D).

Surrogates

Surrogate compounds are added to environmental samples in the laboratory prior to analysis to evaluate the recovery of similar constituents. Surrogate compounds were added to all ground-water and QC samples that were analyzed for VOCs, gasoline oxygenates and their degradates, pesticide compounds, NDMA, and 1,2,3-TCP (table A6). Most of the surrogate compounds are deuterated analogs of compounds being analyzed. For example, the surrogate toluene-*d*8 used in the VOC analytical method has the same chemical structure as toluene, except that the eight hydrogen-1 atoms on the molecule have been replaced by deuterium (hydrogen-2). Toluene-*d*8 and toluene behave very similarly in the analytical procedure, but the small mass difference between the two results in slightly different chromatographic retention times; thus, the use of a toluene-*d*8 surrogate does not interfere with the analysis of toluene. Only 0.015 percent of hydrogen atoms are deuterium (Firestone and others, 1996); thus, deuterated compounds like toluene-*d*8 do not occur naturally and are not found in environmental samples. Surrogates are used to identify general problems that may arise during sample analysis that could affect the analysis results for all compounds in that sample. Potential problems include matrix interferences (such as high levels of dissolved organic carbon) that produce a positive bias, or incomplete laboratory recovery (possibly attributed to improper maintenance and calibration of analytical equipment) that produces a negative bias. A 70 to 130 percent recovery of surrogates is generally considered acceptable. Values outside this range indicate possible problems with the processing and analysis of samples (Connor and others, 1998; Sandstrom and others, 2001).

Quality-Control Sample Results

Detections in Field and Source-Solution Blanks

Field blanks were collected at approximately 10 percent of the sites sampled in MSACV. Table A3 presents a summary of compound detections in field blanks. Field blank results were grouped according to sampling methods (see "Sample Collection and Analysis" section) and analyzed to determine how field blank detections affected environmental data.

Seven source-solution blanks, seven field blanks at production wells, and five field blanks at monitoring wells were collected for analysis of VOCs. Eleven VOC constituents were detected in field blanks collected at production wells or in source-solution blanks (table A3). Only 2 of these 11 VOCs—chloroform and 1,2,4-trimethylbenzene—were detected in ground-water samples collected at production wells. Chloroform was detected in one field blank at a concentration of E0.04 µg/L. Three detections in ground-water samples with concentrations less than 0.05 µg/L (E0.04 µg/L plus one-half of the LRL of 0.02 µg/L) were flagged with a V code (table 5). 1,2,4-trimethlybenzene was detected in one source-solution blank at a concentration of E0.04 µg/L. Four detections in production well samples with concentrations less than 0.07 µg/L (E0.04 µg/L plus one-half the LRL of 0.056 µg/L) were flagged with a V code (table 5). The V-coded results were counted as nondetections for calculation of the detection frequency of chloroform and 1,2,4-trimethylbenzene in the grid wells.

Three VOC constituents were detected in field blanks collected at monitoring wells or in source-solution blanks (table A3), and all three were detected in ground-water samples collected at monitoring wells. 1,2,4-trimethlybenzene was detected in one source-solution blank and one field blank with a maximum concentration of E0.04 µg/L. A single detection in a ground-water sample with a concentration less than 0.07 µg/L (E0.04 µg/L plus one-half the LRL of 0.056 µg/L) was flagged with a V code (table 5). *m-* and *p-Xylene* was detected was detected in two fields with a maximum concentration of E0.07 µg/L. *m-* and *p-Xylene* was detected in one ground-water sample collected from a monitoring well. The concentration of *m- and p-Xylene* detected in the sample was less than 0.10 µg/L (0.07 µg/L plus one-half the LRL of 0.06 µg/L) and was, therefore, flagged with a V code. Toluene was detected in three source solution blanks and three field blanks with a maximum concentration of E0.07 µg/L. Low levels of toluene were detected in source-solution and field blanks in many of the earlier GAMA study units (Bennett and others, 2006; Dawson and others, 2008; Fram and Belitz, 2007; Kulongoski and Belitz, 2007; Kulongoski and others, 2006; Wright and others, 2005). Toluene was detected in one ground-water sample collected from a monitoring well. The concentration of toluene detected in the sample was less than 0.08 µg/L (0.07 µg/L plus one-half the LRL of 0.02 µg/L), and was, therefore, flagged with a V code. Seven field blanks were collected at production wells and four field blanks were collected at monitoring wells for analysis of pesticides and pesticide degradates. Three pesticide compounds were detected in one field blank collected at a production well (table A3), and one of these compounds, bromacil, was detected in ground-water samples collected from production wells. The concentration of bromacil detected in the field blank was E0.11 µg/L. All three detections of bromacil in ground-water samples were less than 0.012 µg/L (0.11 µg/L plus one-half the LRL of 0.018 µg/L), and were, therefore, flagged with a V code (table 6). The V-coded results were counted as nondetections for calculation of the detection frequency of bromacil in the grid wells.

Constituents of special interest (perchlorate, 1,2,3-TCP, and NDMA) and radioactive constituents (radium isotopes and gross alpha and beta radiation) were not detected in any source-solution or field blanks. One field blank was collected at a production well for analysis of radium isotopes and gross alpha and beta radiation. Eleven source-solution blanks, seven field blanks at production wells, and four field blanks at monitoring wells were collected for analysis of perchlorate. Six source solution-blanks, five field blanks at production wells, and one field blank at a monitoring well were collected for analysis of 1,2,3-TCP and NDMA.

DOC was analyzed in one field blank collected at a production well and three field blanks collected at monitoring wells. DOC was detected in all three field blanks collected at monitoring wells, with a maximum concentration of 0.7 mg/L. Six ground-water samples collected at monitoring wells had detections of DOC at concentrations less than 0.9 mg/L (0.7 mg/L plus one-half the LRL of 0.33 mg/L). These six samples were flagged with V codes (table 8), indicating that the concentration of DOC in the samples may be as high as the reported value, but may also be as low as a nondetection relative to the stated detection limit (one-half the LRL).

Nutrients were analyzed in five field blanks collected at production wells and four field blanks collected at monitoring wells. Nitrate and nitrite were not detected in any of the field blanks. Orthophosphate was detected at a concentration of E0.003 mg/L in one field blank collected at a production well, and in two field blanks collected at monitoring wells. One production well sample had an orthophosphate concentration less than 0.006 mg/L (0.003 plus one-half the LRL of 0.006 µg/L); this result was flagged with a V code. Ammonia was detected in two field blanks collected at monitoring wells, with a maximum concentration of E0.007 mg/L. Seventeen ground-water samples collected from monitoring wells had ammonia concentrations less than 0.012 mg/L (E0.007 mg/L plus one-half the LRL of 0.01 mg/L). These results were flagged with V codes, indicating that the ammonia concentration in the samples could be as high as the reported value if no contamination had occurred, but also be as low as a nondetection relative to the LT-MDL of 0.005 mg/L if the maximum potential amount of contamination (0.003 mg/L) had occurred. Total nitrogen was detected in three field blanks collected at production wells, with a maximum concentration of 0.26 mg/L, and in two field blanks collected at monitoring wells with a maximum concentration of 0.45 mg/L. The LRL for total nitrogen is 0.06 mg/L; thus, the threshold concentration for flagging results with V codes was 0.29 mg/L for ground-water samples collected at production wells and 0.48 mg/L for ground-water sampled collected at monitoring wells. Total nitrogen results for the 10 ground-water samples collected from production wells and the 14 collected from monitoring wells with concentrations less than these threshold concentrations were flagged with V codes.

Major ions were analyzed in five field blanks collected at production wells and four collected at monitoring wells. Calcium, chloride, magnesium, and silica were each detected in at least one field blank (table A3). However, for all four ions, the maximum concentration detected in the field blanks plus one-half the LRL was less than the minimum concentrations detected in ground-water samples. Therefore, no data were flagged with V codes.

Trace elements were analyzed in five field blanks collected at production wells and in five field blanks collected at monitoring wells. Maximum concentrations for the three trace elements detected in field blanks collected at production wells were: chromium, 0.04 µg/L; nickel, 0.05 µg/L; and zinc, 1.0 µg/L (table A3). The threshold concentration for flagging results with V codes in table 10 was the maximum concentration of the constituent detected in a field blank plus one-half the LRL for that constituent. Nine detections of chromium with concentrations less than 0.06 µg/L, 10 detections of nickel with concentrations less than 0.08 µg/L, and 16 detections of zinc with concentrations less than 1.3 µg/L in ground-water samples collected from production wells were flagged with V codes, indicating that the concentration in the ground-water sample may be as high as the reported concentration, but also may be as low as a nondetection. In all cases, the results flagged with V codes had concentrations far below health-based or other drinking-water quality thresholds (the MCL-CA for chromium is 50 µg/L; the MCL-CA for nickel is 100 µg/L; and the SMCL-CA for zinc is 5,000 µg/L).

Maximum concentrations for the 11 trace elements detected in at least one field blank collected at a monitoring well were: aluminum, E1 µg/L; barium, E0.9 µg/L; chromium, 0.10 µg/L; copper, 1.80 µg/L; iron, 8 µg/L; manganese, 0.7 µg/L; nickel, 0.20 µg/L; strontium, 0.55 µg/L; tungsten, E0.04 µg/L; vanadium, E0.08 µg/L; and zinc, 2.4 µg/L (table A3). The threshold concentration for flagging results with V codes in table 10 was the maximum concentration of the constituent detected in a field blank plus one-half the LRL for that constituent. Sixteen detections of aluminum, 6 detections of chromium, 18 detections of copper, 7 detections of iron, 5 detections of manganese, 2 detections of nickel, 2 detections of tungsten, and 23 detections of zinc in ground-water samples collected from monitoring wells were flagged with V codes, indicating that the concentration in the ground-water sample may be as high as the reported concentration, but also may be as low as a nondetection. In all cases, the results flagged with V codes had concentrations far below health-based or other drinking-water quality thresholds (table 10). No detections of barium, strontium, or vanadium were flagged with V codes because the maximum concentration detected in the field blanks plus one-half the LRL was less than the minimum concentration detected in ground-water samples.

Arsenic and iron were detected in field blank samples analyzed by the NRP (table A3). Arsenic was detected in two of five field blanks collected at production wells and in two of five field blanks collected at monitoring wells. The maximum concentration of arsenic detected in a field blank analyzed by the NRP laboratory was 4.5 µg/L. Arsenic was not detected in any field blank samples analyzed by NWQL; therefore, the arsenic detected in field blanks analyzed at the NRP laboratory were considered to have originated in the laboratory. Because the arsenic contamination was not related to sampling equipment, there was no basis for assessing NRP arsenic data differently for the two different types of sampling equipment. Because the arsenic concentration data from NWQL Schedule 1948 are preferred over the concentration data from the NRP laboratory, comparisons between the two sets of data were used in conjunction with the detections in the field blanks analyzed at the NRP laboratory to assess the NRP arsenic data. Arsenic concentrations from the NRP were greater than those from NWQL for 27 of the 82 ground-water samples analyzed, and for 19 of the 27, the difference was greater than 20 percent RSD, the criteria for acceptable replicate pairs. The NRP arsenic concentrations were up to 3.5 µg/L greater than the NWQL arsenic concentration in these 19 ground-water samples, a difference that is comparable to the maximum concentration of arsenic detected in the field blanks. Arsenic results from the NRP laboratory for these 19 ground-water samples were flagged with V codes (table 11) to indicate that disagreement between the NWQL and NRP arsenic concentrations may be due to contamination of ground-water samples analyzed at the NRP laboratory. The ratio of arsenic species, $\frac{\text{As(V)}}{\text{As(III)}}$, for these 19 samples may not be representative of the redox conditions in the ground water.

Iron was detected in 2 of 10 field blanks analyzed by the NRP laboratory, with a maximum concentration of 15 µg/L. For eight ground-water samples with iron concentrations greater than 6 µg/L (the NWQL LRL for iron), iron concentrations measured by the NRP laboratory were higher than those measured by NWQL. However, all eight pairs differed by less than 10 percent RSD; thus, none of the NRP iron results were flagged with V codes.

Variability in Replicate Samples

Most of the replicate sample pairs collected during the MSACV study had relative standard deviations (RSDs) of less than 20 percent (table A4). Replicate sample pairs for analytes not detected in any ground-water samples are not reported in table A4. Thirty replicate sample pairs, representing 20 chemical constituents, had RSDs greater than 20 percent; see table A4 for details. However, the replicate sample pairs with high RSDs had very low concentrations. At low concentrations, small deviations in measured values account for large RSDs. Because the variability in measurements occurred at low concentrations, well below regulatory thresholds, this variability was not of QC concern, and no detections were censored as a result of variability in replicate samples.

Matrix Spike Recoveries

Tables A5A–D present a summary of matrix-spike recoveries for the MSACV study. The addition of a spike or known concentration of a constituent to an environmental sample enables the laboratory to determine the effect of the matrix, in this case ground water, on the analytical technique used to measure the constituent. Thirteen environmental samples were spiked with VOCs to calculate matrix-spike recoveries (table A5A). Seventy-one of the 85 VOCs had matrix-spike recoveries in the acceptable range between 70 and 130 percent. Eleven VOCs had at least one-matrix spike recovery greater than 130 percent; however, of these compounds, 6 were not detected in ground-water samples. Seven VOCs had a recoveries below 70 percent; however, of these compounds, 4 were not detected in ground-water samples. The three VOCs that had recoveries less than 70 percent and were detected in ground water included carbon disulfide, 1,2,3,4-tetramethylbenzene, and 1,2,3,5-tetramethylbenzene, with recoveries of 67, 69, and 62 percent, respectively. The four VOCs that had recoveries less than 70 percent, but were not detected in ground water included dichloromethane, 2,2-dichloropropane, styrene, and 1,2,3-trichlorobenzene, with recoveries of 28, 62, 69, and 56 percent, respectively (NOTE: low recoveries may indicate that these compounds may not have been detected if they were present at very low levels).

Twelve environmental samples were spiked with pesticide and pesticide degradate compounds to calculate matrix-spike recoveries, although the number of spiked samples varied depending on laboratory procedures (table A5B). Forty-one of the 136 spike compounds had recoveries in the acceptable range between 70 and 130 percent. Eighteen of the compounds detected in ground-water samples had spike recoveries that exceeded the acceptable range. Twenty-three spike compounds had at least one recovery greater than 130 percent. Ninety-one spike compounds had at least one recovery below 70 percent, with recovery of phosmet being particularly poor. (NOTE: low recoveries may indicate that the compound might not have been detected in some samples if it was present at a very low concentration).

One, 7, and 5 ground-water samples were spiked with perchlorate, 1,2,3-TCP, and NDMA, respectively (table A5C). All spike recoveries were within the acceptable range of 70 to 130 percent.

Two ground-water samples were spiked with radium-226 and radium-228 (table A5D). All spike recoveries were within the acceptable range of 70 to 130 percent with the exception of gross alpha 72-hour and gross alpha 30-day counts for one of the samples. The spiked sample (WSAC-08) that had poor recovery of alpha radioactivity had relatively high concentration of calcium (table 9). Because calcium is known to interfere with alpha counts (Sinojmeri, 1999), this sample and WSAC-18, which had similar major-ion chemistry, were coded as having the potential to be biased low for gross alpha 72-hour and gross alpha 30-day counts.

Surrogate Compound Recoveries

Surrogate compounds were added to environmental samples in the laboratory and analyzed to evaluate the recovery of similar constituents. Table A6 lists each surrogate, the analytical schedule on which it was applied, the number of analyses for blank and nonblank samples, the number of surrogate recoveries below 70 percent, and the number of surrogate recoveries above 130 percent for the blanks and environmental samples. Blanks and environmental samples were considered separately to assess whether the matrices present in ground water affect surrogate recoveries. No systematic differences between surrogate recoveries in blanks and environmental samples were observed. Ninety-one percent of the surrogate recoveries in analyses of VOC and gasoline oxygenate and degradates were in the acceptable range of 70 to 130 percent recovery, as were 96 percent of the surrogate recoveries for pesticides and pesticide degradates, and 89 percent for NDMA and 1,2,3-TCP analyses.

Table A4. Quality-control summary of replicate samples for constituents collected for the Middle Sacramento Valley Groundwater Ambient Monitoring and Assessment (GAMA) study, California, June to September, 2006.

[The laboratory entity codes for the laboratories in the U.S. Geological Survey's (USGS) National Water Infomation System (NWIS) listed in the footnotes are shown in parentheses following the laboratory name. E, estimated value; mg/L, milligrams per liter; pCi/L, picocuries per liter; RSD, relative standard deviation; TU, tritium unit; µg/L, micrograms per liter; <, less than; —, no value]

Constitutent	Number of RSDs greater than 20 percent/number of replicates	Maximum RSD (percent)	Median RSD (percent)	Concentrations for replicates with RSDs greater than zero (environmental, replicate)
Volatile organic compounds, gasoline oxygenates and additives from Schedules 2020 and 4024				
1,2,4-Trimethylbenzene (µg/L)	2/15	40.4	23.6	(E0.07, E0.05), (0.10, 0.18)
Toluene (µg/L)	1/15	47.1	47.1	(E0.02, E0.01)
Chloroform (Trichloromethane) (µg/L)	2/15	28.3	16.5	(E0.08, E0.06), (E0.02, E0.03)
All other VOCs from Schedules 2020 and 4024	0/15	< 20	—	—
Pesticides and pesticide degradates from Schedules 2032, 2033, and 2060				
All pesticides and pesticide degradates from Schedule 2032	0/12	< 20	—	—
All pesticides and pesticide degradates from Schedule 2033	0/2	< 20	—	—
All pesticides and pesticide degradates from Schedule 2060	0/13	< 20	—	—
Pharmaceuticals				
All pharmaceuticals from Schedule 2080	0/9	< 20	—	—
Constituents of special interest[1]				
Perchlorate	0/15	< 20	—	—
1,2,3-Trichloropropane (1,2,3-TCP)	0/7	< 20	—	—
N-Nitrosodimethylamine (NDMA)	0/5	< 20	—	—
Major ions, minor ions, trace elements, and nutrients				
Ammonia (mg/L)	1/11	23.6	23.6	(E0.005, E0.007)
Dissolved organic carbon (DOC) (mg/L)	1/5	26.2	5.2	(1.6, 1.1)
Bromide (mg/L)	2/10	122.6	1.3	(0.03, E0.02), (0.07, 0.005)
Aluminum (µg/L)	1/6	47.1	47.1	(2, E1)
Cadmium (µg/L)	1/8	47.1	47.1	(0.04, E0.02)
Cobalt (µg/L)	4/8	101	18.0	(0.01, 0.06), (0.07, E0.03), (0.06, E0.02), (E0.03, 0.04)
Copper (µg/L)	1/8	32.9	3.4	(E0.28, 0.45)
Iron (µg/L)	2/10	47.1	3.3	(E3, 6), (6, E3)
Lead (µg/L)	1/8	97.9	2.9	(0.10, 0.08)
Nickel (µg/L)	1/8	60.6	1.8	(1.10, 0.44)
Selenium (µg/L)	1/8	20.2	20.2	(0.08, E0.06)
Tungsten (µg/L)	1/8	28.3	28.3	(0.09, 0.06)
Zinc (µg/L)	1/8	41.9	2.2	(E0.51, 0.94)
All other nutrients from Schedule 2755	0/11	< 20	—	—
All other major ions from Schedule 1948	0/10	< 20	—	—
All other trace elements from Schedule 1948	0/8	< 20	—	—

Table A4. Quality-control summary of replicate samples for constituents collected for the Middle Sacramento Valley Groundwater Ambient Monitoring and Assessment (GAMA) study, California, June to September, 2006.—Continued

[The laboratory entity codes for the laboratories in the U.S. Geological Survey's (USGS) National Water Infomation System (NWIS) listed in the footnotes are shown in parentheses following the laboratory name. E, estimated value; mg/L, milligrams per liter; pCi/L, picocuries per liter; RSD, relative standard deviation; TU, tritium unit; µg/L, micrograms per liter; <, less than; —, no value]

Constitutent	Number of RSDs greater than 20 percent/number of replicates	Maximum RSD (percent)	Median RSD (percent)	Concentrations for replicates with RSDs greater than zero (environmental, replicate)
Isotopes and radioactivity				
$\delta^{18}O$ of nitrate[2] (per mil)	1/4	84.8	7.2	(0.01, 0.04)
Tritium[3] (TU)	4/12	141.4	10.9	(0.3, 0), (0.3, 0), (1.3, 1.9), (1.3, 0.7)
Gross-beta radioactivity, 72-hour count[4] (pCi/L)	1/2	39.0	39	(E1.12, E1.97)
Gross-beta radioactivity, 30-day count[4] (pCi/L)	1/2	33.8	21.7	(E1.62, 2.64)
All additional isotopes and radioactivity	0/2	< 20	—	—
Microbial indicators				
F-specific and somatic coliphage	0/1	< 20	0	—
E. coli, and total coliforms	0/30	< 20	0	—

Hi Christina,

Thank you very much. I appreciate the follow up.

Best Regards,

Ben

Subject: RE: Arsenic and Connate Sea Water Contamination around the Sutter Buttes

Hi Ben,

Thanks for the information and additional reports. I did reference some of the reports you had sent me earlier in the draft of the HCM for the Butte subbasin. That document will hit the street for public comment later this summer.

I will pass your emails and attachments along to the consultant team (Davids Engineering) for their reference and consideration as they continue supporting GSP development and completion.

I will also forward your emails to Tania Carlone, the facilitator for the Butte Advisory Board (BAB), so she can include it as correspondence in the future to the BAB since this is helpful follow up to the comment you made at their last meeting.

Best,
Christina

Subject: Arsenic and Connate Sea Water Contamination around the Sutter Buttes

ATTENTION: This message originated from outside **Butte County**. Please exercise judgment before opening

attachments, clicking on links, or replying.

I wanted to follow up regarding my public comment on the last Butte Basin call. As mentioned in my call, my concern is that the connate seawater under the Sutter Buttes is contaminating groundwater and drinking water quality.

I have previously sent the SWCB Bulletin No. 6 from 1952 and the PHD Paper by George Curtin from 1971. Bulletin No. 6 reported that pumping depressions were drawing salt brines to the surface causing groundwater contamination. Curtin's paper proposes that the connate seawater is moving laterally through faults around the Buttes and researched several hundred gas well logs to express this opinion.

According to the Sutter County GMP on Page 23 "The Sutter Buttes Rampart consists largely of gravel, sand, silt and clay sediments which were deposited circumferentially around the Buttes as a geologic apron. These sediments may extend up to 15 miles north and west beyond the Sacramento River. " On Page 32 the GMP addresses the arsenic contamination issue - "… recent data analysis suggest a possible correlation between elevated arsenic concentrations and the presence of volcaniclastic material of the Sutter Buttes Rampart formation." Since the Colusa and Butter Basins are within the 15 mile circumference of the Sutter Buttes this would impact the analysis for Lower Water Quality and potentially Seawater Intrusion SGMA Sustainability metrics. I am mentioning the Seawater Intrusion metric because of the hydraulic components of pumping depressions and the physics of natural occurring contaminants moving laterally from higher elevations to lower elevations in combination of the force of pulling water to the surface by the operation of groundwater wells.

You will see the elevated EC levels and arsenic levels in the GMP Figures attachments. On Figure 19, there was an observation at T15NR3E of arsenic at 350 ppm and an EC of 1126. To the south at 14NR2E the observation of arsenic at 370 ppm and an EC of 1400. Since this study was focused on Sutter County there were not observations for Colusa County and Butter County. For Colusa County – the attached report regarding Arsenic contamination in public drinking water systems has the Grimes water district at 23.9 ppm which is the worse levels of toxicity of any public system in the Sacramento Valley. To the northwest of the Buttes there is a USGS Gamma well ESAC 21 which seems to be located in the Colusa County portion of the Butte Basic which has an arsenic reading of 80 ppm. Finally ESAC 11 which is due north of the Buttes and appears to be located in Grey Lodge has an arsenic level of 70.

I can also note that the EPA assessment of the wastewater treatment facility for Yuba City reported that the high levels of arsenic in the wastewater was apparently from the portion of the Yuba infrastructure. Since most of the source of the water for Yuba City is surface water from the Feather River the arsenic contamination is pronounced where ground water is used. Finally as I mentioned in the past you probably are aware that the EPA has entered into an mitigation agreement with Sutter County regarding the arsenic contamination at Robbins. As you know Robins is at lower elevation and due south of the Buttes which would explain the contamination so far away

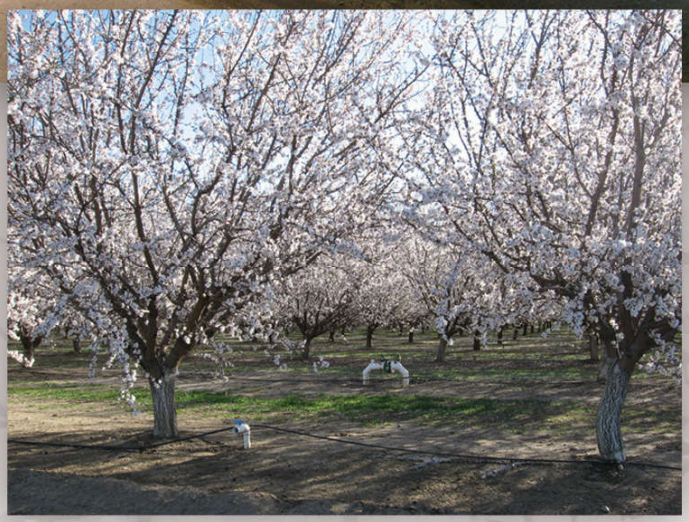
from the Buttes. Robbins arsenic levels are less than the levels observed at Grimes.

I will send the Yuba City EPA report and the USGS Gamma documents next.

My suggestion would be to pick up where the SWRCB left off in 1952 and examine salt water and arsenic levels within a 15 mile circumference around the Buttes and set up a monitoring network to monitor changes in ground water quality going forward. This would not only focus on the southern part of the Buttes but within the whole circumference.

Thank you for your time and consideration.

Best Regards,



Ben

1. INTRODUCTION

1.1. Purpose of Groundwater Management Plan

Sutter County (County) has prepared this Groundwater Management Plan (GMP) with input and direction from County stakeholders, and with financial and technical assistance from the California Department of Water Resources (DWR). Preparing this GMP is one step Sutter County is taking to promote and encourage groundwater users in the County to be responsible stewards of the water resources.

Sutter County's purposes for preparing this GMP are to:

- Summarize the current understanding of the groundwater underlying Sutter County and its role in the County's overall water supply, and make that information publicly available.
- Formulate goals and objectives that can be used as guidelines to help manage groundwater resources to meet current and future demands in Sutter County.
- Establish a plan for the County's involvement in ongoing monitoring and management of groundwater to promote those goals and objectives.
- Maintain eligibility for grant funding administered by the California Department of Water Resources to increase the understanding of the groundwater basins underlying Sutter County.

1.2. Sutter County's Role in Groundwater Management

Sutter County has the authority to adopt and implement this GMP under California Water Code §10750 et seq., which states that a local agency that overlies part of a groundwater basin can "by ordinance, or by resolution…adopt and implement a groundwater management plan…within all or part of its service area," so long as the area is:

- Not served by another local agency, a water corporation regulated by the Public Utilities Commission, or a mutual water company.
- Served by a local agency, when the majority of the agency's governing body declines to exercise its authority to manage groundwater and enters into an agreement with the local agency developing the GMP.

Sutter County's intended role in groundwater management, as discussed in this GMP, is to help coordinate the various groundwater users in the County, and encourage them to be

responsible stewards of the water resources. The County does not have the budget or staff to act as an "enforcer" with regards to groundwater use, and does not intend to do so.

1.3. Plan Area

Sutter County intends this GMP to be relevant for the entire County. Sutter County overlies the south central part of the Sacramento Valley Groundwater Basin, and specifically the Sutter Subbasin and portions of the East Butte and North American Subbasins, as shown in Figure 1. The majority of the County is serviced by water and irrigation districts, reclamation districts, cities, and public utility districts (Figure 2), which have the authority to manage groundwater in their service areas. Unless those entities decline to manage groundwater on their own, and instead enter into agreements with the County, this GMP does not formally apply to those areas. If those entities choose not to adopt their own GMPs, they have the option of taking formal action to adopt the Sutter County GMP for their areas. By doing so, they will fulfill the requirements of the groundwater management provisions of the California Water Code.

Some of the water purveyors in the County have prepared groundwater management plans established under provisions of Sections 10750-10756 of the California Water Code (Assembly Bill 3030). Four of these plans have been submitted to DWR for final adoption.

1.4. Public Involvement in Plan Development

Throughout the development of this GMP, Sutter County solicited public input to help guide the direction and content. Aside from the required public notices and hearings related to the GMP development, Sutter County undertook an extensive public outreach program to encourage public involvement in the GMP development and to solicit public input for the GMP. To help guide the development of the GMP, a Plan Advisory Group (PAG) was formed that included representatives of water purveyors, cities, and the general public (attendance sheets provided in Appendix A)

The Sutter County Water Resource Department and the Board of Supervisors approved a Public Outreach Plan (Appendix B) for the GMP process. The Public Outreach Plan established the following objectives:

- Establish an open process to facilitate stakeholder input.
- Provide information to facilitate stakeholder education on material forming the basis of the GMP.

- Provide a framework by which stakeholders are kept informed of the process, issues, and potential solutions.
- Incorporate public comments throughout the decision-making process.

Various entities – including the Board of Supervisors, Plan Advisory Group, and the general public – were involved in the development, approval, and adoption of the GMP.

While developing the GMP, eleven public meetings were held. The location and time for each of the PAG meetings were advertised in local media. Attendance at each PAG meeting was recorded and a mailing list was created to disseminate meeting times and important information regarding the GMP progress. Participation in the PAG was voluntary and the public was invited to attend and comment at public workshops held in Yuba City. At each of the public workshops, Wood Rodgers, Inc. presented a PowerPoint® presentation of the purpose, scope, and schedule for preparing the GMP, along with educational information related to groundwater, geology, wells, and information about the hydrogeology within the County. The PAG meetings were held in 2008 on June 10, August 14, October 17, and December 9; in 2009 on February 10; in 2010 on June 17, August 19, October 28, and December 15; and in 2011 on April 14[1] and October 20. The Sutter County Water Resources Department hosted a website for the GMP at:

http://www.co.sutter.ca.us/doc/government/depts/pw/wr/gmp/gmphome

All of the presentations and applicable meeting information were posted on the GMP website. Presentations, attendance sheets, and a summary of public comments from the workshops are included in Appendix B.

1.4.1. GMP Survey

The County circulated a voluntary Public Opinion Survey to obtain participation and feedback from stakeholders. The surveys were distributed to interested individuals at the PAG meetings and were also made available for download on the County's website. In order to differentiate between individual well owner concerns and water district concerns, two surveys were distributed. Unfortunately, due to the limited returns, the surveys were not beneficial in identifying countywide concerns related to groundwater.

[1] The reason the meetings extended over four years is that DWR issued a stop work order in 2009 due to uncertainties with the State of California budget. Consequently, the GMP process was temporarily delayed from February 2009 to May 2010. Resumption of the GMP process required approval of a new Notice of Intent and a contract amendment with DWR.

1.5. Issues of Concern

A variety of issues and/or concerns with regard to groundwater and groundwater management have been raised by residents of the County during the development of this GMP. These issues and concerns include the following.

1.5.1. Protect private groundwater rights.

The development of the GMP has raised concerns about how individual groundwater rights will be affected. California State Water Law gives property owners the right to make reasonable and beneficial use of the groundwater resource underlying their property. The GMP does not encroach upon or place any restrictions on groundwater rights. Furthermore, the County does not have the budget or staff to act as an "enforcer" with regards to groundwater use, and does not intend to do so.

1.5.2. Is there enough groundwater to sustain a drought?

Water districts within the County have been able to provide groundwater when surface water supplies were reduced during past droughts. Conversely, the use of groundwater when surface water is in short supply allows the aquifer(s) to recharge when surface water is available and is known as conjunctive use.

Increased use of groundwater in some areas is perceived to be taxing the available supply, and there is concern that wells will go dry during a drought. A related concern is that existing wells may be damaged by increased pumping. This concern is particularly widespread in the southeastern portion of the County, where groundwater is used extensively for irrigation. Additionally, changes in cropping trends to more permanent crops have raised concerns about the ability to reduce groundwater use during drought periods without sustaining substantial economic losses in areas that do not use groundwater conjunctively with surface water.

This concern is understandable given the history of significant groundwater level fluctuations in the southeastern portion of the County during past drought periods. Data also indicate that during wetter periods, or when pumping is reduced, groundwater levels have started to recover. The need for water supply reliability to support water users in the County can be addressed through the conjunctive use/management of available surface water, groundwater, and recycled water supplies. Together, these water sources comprise the irrigation water supply for the County, and can be used in fluctuating proportions to meet demands during different hydrologic (including climatic) and economic conditions. Successful management will also require better coordination among water users, and water users will need to work together to develop strategies for curtailing water use

during drought periods. If intra-county water transfers (transfers from one party to another within Sutter County) are possible, they can become an important water management tool and consideration during these periods.

1.5.3. Are there plans to "export" water out of Sutter County?

There is general concern that projects related to groundwater studies and groundwater management (including this GMP) are somehow related to the desire to "export" water from the County. Those who express this concern feel that the State (and other parties within and outside of the County) cannot be trusted to protect the interests of the community within the County. Currently, under state law, groundwater substitution water transfers are allowed. A groundwater substitution water transfers occurs when an entity with surface water rights makes an agreement to transfer some or all of its surface water to downstream users (by not diverting it), and then pumps groundwater to make up for the "lost source supply" that results from the transfer.

This concern can be somewhat allayed by maintaining local water district control of water management decisions. Also, establishing an open process for discussing groundwater conditions and making management decisions will help the stakeholders within the County have a better understanding of the resources and issues and to voice their concerns and have them addressed.

1.5.3.1. Sutter County Conjunctive Water Use Success (Case Study)

The Department of Water Resources provided the following case study for inclusion in this GMP to demonstrate the effectiveness of conjunctive water use.

"An example of a successful conjunctive use program was implemented by the South Sutter Water District (SSWD or District). The SSWD is located in southern Sutter and western Placer counties, with the Bear River as the northern boundary and stretching southwest between Highway 65 and Highway 70 to Pleasant Grove and Curry Creeks. The District was formed in 1954 to develop, store and distribute surface water supplies and to augment and replenish over-drafted groundwater supplies. Figures 3 and 4 are groundwater level hydrographs illustrating the recovery of groundwater levels after the implementation of the

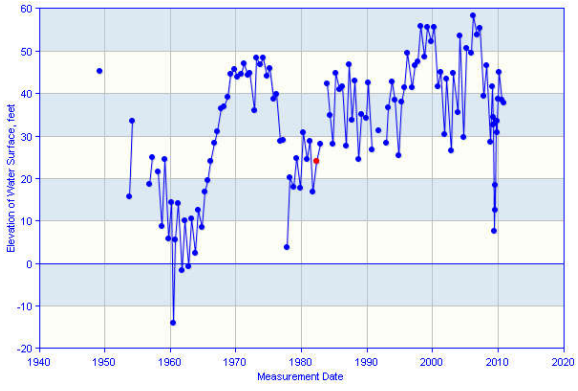

Figure 3 - Hydrograph for Well 13N/5E-30A1M

conjunctive use program. Today SSWD encompasses a total gross area of nearly 64,000 acres, including 57,012 acres that are authorized to receive surface water. According to the District,41,946 acres have actually been irrigated in recent years using a combination of surface and groundwater supplies. By far the majority of those acres grow rice (roughly 34,834 acres, or 83%), while the balance is apportioned between orchards (2,881 acres, or 5%), irrigated pasture (2,088 acres, or 5%), row and field crops (1,742 acres, or 4%) and the remaining 3%, which is fallowed in certain years.

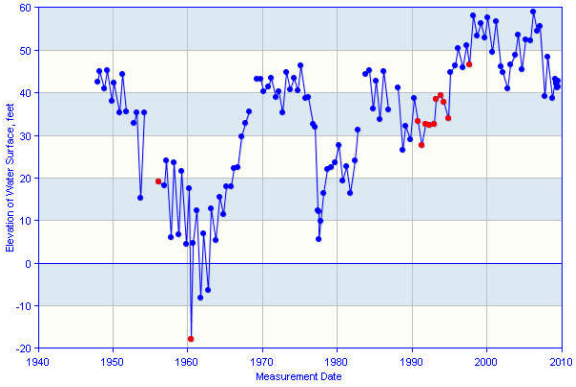

Figure 4 - Hydrograph for Well 13N/4E-13R1M

The enlarged New Camp Far West (NCFW) Reservoir was completed in 1964 with a storage capacity of 104,400 acre-feet (AF). SSWD and Camp Far West Irrigation District (CFWID), formed in 1924, holds the water rights for operating the reservoir. Surface supplies are managed conjunctively with groundwater supplies. The seven (7) megawatts of power generated by the NCFW powerhouse is wholesaled to Sacramento Municipal Utility District. The Federal Energy Commission (FERC) license for NCFW was issued on July 2, 1981.

One and a quarter miles downstream of NCFW Dam (and about 15 miles above the confluence with the Feather River), water is diverted by a diversion dam designed to move 30 cubic feet per second (cfs) north into the CFWID and 380 cfs south into the SSWD. In 1994, SSWD, CFWID, and the Department of Water Resources entered into a settlement agreement to meet the District's obligations under the State Water Resources Control Board's (SWRCB) Water Quality Control Plan for the Bay-Delta. Under the agreement, SSWD agreed to release up to 4,400 AF of water from NCFW, when requested by DWR, in all dry and critical year types. The present water rights require minimum in stream flows below the diversion works of 25 cfs from April 1 through June 30 and 10 cfs from July 1 through March 30. Under the new agreement, SSWD would increase the flow releases to the lower Bear up to 37 cfs in dry and critical years for up to sixty days in July through September.

SSWD receives anywhere from 5,000-20,000 AF of surplus water from Nevada Irrigation District (NID) annually. That water is currently conveyed to SSWD from Rollins Reservoir via the Bear River/Wise Canal system. When completed, SSWD's Canal Expansion project, including related conveyance system improvements, could

well provide previously-unforeseen opportunities for delivering a portion of surplus NID supplies to SSWD directly via the Bear River and NCFW Reservoir."

1.5.4. Will there be taxes or fees for groundwater use?

Concerns have been expressed about the sources of funding for the GMP and other groundwater programs in the County. Funding would be necessary should staff be required to perform new monitoring and evaluation activities or to undertake groundwater investigations. Funding for the latter may be available from DWR and other grant programs, under which this GMP maintains eligibility for the County. Currently, the County assesses fees only for exploratory drilling, well construction, and well destructions, as shown in the following table (Table 1).

Table 1
***Current* Sutter County Fee Assessments (as of January 1, 2012)**

Well Permit	***Fee***
Well Construction	$470.00
Well Destruction	$376.00
Water Exploration and Test Holes	$376.00
Permit Extension (1 year)	$47.00

There is concern about the potential for taxes and fees on groundwater use, and metering of pumps. This GMP does not contain any recommendation to meter groundwater pumping or to enact use-based fees or taxes, although they are considerations and are used in other areas. State law affords property owners the right to make beneficial use of groundwater on their land.

1.5.5. How can we obtain good quality water?

Water quality problems are significant within the County and concerns have been expressed about water quality with regard to salinity, arsenic, and manganese. The hydrogeology of the County as it relates to water quality is not well-understood, and further study will be necessary to develop guidelines for how to obtain good-quality water in different areas of the County, and to determine how to manage groundwater without causing water quality deterioration in areas with otherwise good quality water. As discussed in Section 4.4, this GMP illustrates water quality in different areas of the

County, and shows the geographic areas (and depths) where poorer quality groundwater can be anticipated. As more data becomes available, the County will be able to incorporate it into the existing understanding of the groundwater subbasins.

1.5.6. Is this going to generate new regulations on groundwater?

Concern has been expressed about the potential for additional layers of bureaucracy and regulations on groundwater use. In general, stakeholders recognize a need to better understand and manage groundwater in the County, but have expressed a desire for a "balance" between achieving this objective and minimizing bureaucracy and regulations.

To implement the GMP, an institutional framework (not yet determined) will be needed; however, the intent of this GMP is to minimize the bureaucracy and regulations needed to achieve the goals and objectives of the GMP. The GMP provides a framework and a forum for studying, discussing, and managing groundwater within the County. Ideally, management will be accomplished cooperatively amongst the groundwater users in the County.

2. THE COUNTY

2.1. Physical Setting

Sutter County encompasses approximately 607 square miles (389,443 acres) in the central portion of the Sacramento Valley. As shown in Figure 5, Sutter County is bound by Butte County to the north, Colusa and Yolo Counties to the west, Yuba and Placer Counties to the east, and Sacramento County to the south. The County seat, Yuba City, is located approximately 50 miles north of Sacramento. The 2010 U.S. Census reported that the population of the County in 2010 was 94,737, with the majority of the population residing in Yuba City and Live Oak, and about 25 percent of the population in the rural communities. Land use within the County is principally agricultural, with approximately 318,701 acres in production (Sutter 2010a).

The two main population centers in the County are Yuba City, with 67 percent of the population, and the City of Live Oak, approximately 10 percent of the population (U.S. Census 2010). The remaining County residents live within the small communities of Tierra Buena, Meridian, Rio Oso, Trowbridge, Sutter, Pleasant Grove, Nicolaus, East Nicolaus, Riego, Robbins, or in the vast rural agricultural areas which make up Sutter County. Future major growth areas planned for Sutter County include Sutter Pointe (Measure M). The Sutter Pointe Specific Plan details a large-scale development project that is currently on file with and being processed by Sutter County. This plan area is located in the southern most portion of the County adjacent to the Sacramento County border and a portion of the Placer County border. The plan area includes the development of approximately 7,500 acres into mixed use and residential properties and has been structured to facilitate future incorporation as an independent city (Sutter 2010).

The main transportation routes connecting the County with the region are Highway 99, which runs north-south through the County, California State Route 20, which runs east-west through the County and Highway 113, which runs from the south-west portion of the County and terminates at Highway 99 (connecting Woodland with the County).

Land elevations range between 80 and 20 feet above sea level throughout the County with the exception of the Sutter Buttes, where elevations are more than 2,100 feet above sea level. The lowest land elevations are located towards the southern portion of the County.

Sutter County has abundant surface water, including the Sacramento, Feather, and Bear Rivers, as shown in Figure 5. A number of the water districts in the County (Figure 2) divert and transfer surface water.

2.2. Water Purveyors and Users

Water resources in the County are managed by water purveyors and individual water users who have "hands on" control of both surface water and groundwater for agricultural, urban, environmental, and domestic uses. These water managers represent a complex mix of organized water purveyors, non-organized areas, and areas within National Wildlife Refuges. A brief discussion of each category is presented below.

2.2.1. Water Purveyors

There are 48 water purveyors in Sutter County which provide water service to their customers (Figure 2). These water purveyors include water districts, irrigation districts, reclamation districts, mutual water companies, public utilities districts, and incorporated cities. Additionally, there are many private water users including community service districts (CSD's) and farming interests.

Six water purveyors provide water service not only in Sutter County, but in the counties that share borders with Sutter. They are:

- Reclamation District No. 1004 (Colusa County)
- Biggs-West Gridley Water District (Butte County)
- Butte Water District (Butte County)
- Dry Creek Mutual Water Company (Yuba County)
- South Sutter Water District (Placer County)
- Natomas Central Mutual Water Company (Sacramento County)

2.2.2. Non-Organized Areas

The non-organized areas within the County are not within the boundaries or service area of established water purveyors.

2.2.3. National Wildlife Refuges

The Sacramento National Wildlife Refuge Complex consists of five national wildlife refuges and three wildlife management areas. Portions of Sutter County have been dedicated, both through public and private efforts, as wildlife refuges. Exclusively in Sutter County, the Sutter National Wildlife Refuge has 2,591 total acres, with the majority (83%) located inside the Sutter Bypass. According to U.S. Fish and Wildlife

Service, the refuge "consists of approximately 1,881 acres of seasonal and summer wetlands and approximately 674 acres of unmanaged wetlands, grasslands, and riparian habitats" (USFW 2009).

The Natomas Basin Conservancy also owns nearly 1,000 acres of wildlife habitat/mitigation lands within the southern portion of the County.

2.3. Land Use

The predominant land use within the County is agriculture. The 2008 Sutter County General Plan Technical Background Report estimates that 322,240 acres (83%) of Sutter County is agricultural land. An estimated 44,581 acres (11%) is designated as open space. The remaining 6% of the County is designated as residential, public and vacant, commercial, industrial, and transportation and utilities. As stated above, agriculture dominates land uses within Sutter County. Figure 6 shows the distribution of land uses, with regard to crop type and water source, for the entire County. It is apparent that permanent crops dominate the eastern portion of the County, along the Feather River, while rice and other non-permanent crops dominate the central and western portion of the County.

2.4. Water Use

The amount of water applied for agricultural production and urban or community use has been estimated using information from DWR with respect to unit crop, consumptive use, and applied water, with corresponding losses included and accounted for. Water use within cities and communities was estimated using limited production data from some water purveyors from 2008 to 2010.

2.4.1. Agricultural Water Use

Water use during the 2009 growing season was calculated based on the Sutter County 2009 Crop Report. Estimates of applied water for irrigated agriculture are 1,122,018 AF.

Sutter County's agricultural water usage is approximately 60 percent surface water, 20 percent groundwater, and 20 percent that is irrigated by both surface water and groundwater. Figure 6 illustrates the source of water for crops grown in the County. The predominant source of water for permanent crops is groundwater.

2.4.2. Urban/Community Water Use

Water for urban and community use is from groundwater and surface water. From available DWR records, the minimum urban water use was 1,770 AF in 2010 (records for

all urban water suppliers was not available). Yuba City provides mostly surface water (15,682 AF in 2008) while smaller communities rely exclusively on groundwater.

3. HYDROLOGY AND SURFACE WATER

3.1. Seasonal and Long-Term Hydrology

Annual fluctuations in northern California precipitation directly influence the volume of water flowing in the Sacramento River. Precipitation and climate data from the Western Regional Climate Center (WRCC) suggest the average annual precipitation for the west side of the County (Colusa Station) is 16.40 inches per year and on the east side of the County (Marysville Station), it is 20.96 inches per year. In Nicolaus, the average annual precipitation is 18.27 inches per year. Collectively, average annual precipitation is 18.54 inches per year. Snow-fall within Sutter County is rare, measuring on average 0.01 inches per year. Precipitation is highly variable throughout the State, from year to year. Precipitation usually takes place from October to May and on average no precipitation occurs from June to September. The water year, defined as starting on October 1 and ending September 30, is classified as one of five water year types: critical, dry, below normal, above normal, or wet[2]. Within the past ten years, only two water years were classified as wet and one year was classified above normal. The remaining years were either dry, critical, or below normal. The average annual temperature is approximately 62° F, with an average high of 95.7° F in July and an average low of 37.4° F in January.

Precipitation in the Sierra Nevada, Coast Range, Klamath, and Cascade Mountains contribute to surface water flow and groundwater recharge in the Sacramento River Basin. The general direction of surface water flow is toward the center of the valley, flowing south. Water diversions, evaporation, and groundwater recharge reduce flows as the Sacramento River approaches the Delta.

3.2. Surface Water

Sutter County is located in the Sacramento River Basin, with the Sacramento River on the west and the Feather River on the east. The Sacramento River is the largest river in northern California and drains the northern central part of California. The watershed for the Sacramento River includes tributaries originating in the Sierra Nevada, the Coast Range, and the Cascade Mountains. The main tributaries in Sutter County include the Feather River, Bear River, Dry Creek, Pleasant Grove Creek, Auburn Ravine, and Coon Creek.

During periods of heavy precipitation and runoff, a portion of the flow within the Sacramento River is diverted through the Sutter Bypass. The Sutter Bypass is a man-made feature in Sutter County and was designed to alleviate the flood control system along the Sacramento

[2] http://cdec.water.ca.gov/cgi-progs/iodir/wsihist

River. Aside from the major rivers and tributaries within Sutter County, there are no significant surface water storage reservoirs within Sutter County.

It is important to note that flows in all the major rivers in northern California are managed by dams, e.g. the Feather River by Lake Oroville and the Sacramento River by Lake Shasta. The reservoirs are managed to provide flood protection while collecting runoff from the watershed. Releases from the reservoirs occur from spring through summer to provide irrigation water for agriculture as well as to provide drinking water downstream.

The following discussion provides information on the location, ownership, infrastructure, and an overview of the operational practices of the major water bodies that relate to or are within Sutter County.

3.2.1. The Sacramento River

The Sacramento River is the major surface water feature in Sutter County. Running north-south along the western part of the County, the Sacramento River is the main drainage for the Sacramento Valley Basin on its way to the Delta and the San Francisco Bay. The Sacramento River supports many beneficial uses including recreational, agricultural, and wildlife. The river is currently not used for municipal or domestic water supplies in the County. There are, however, future plans to utilize the Sacramento River, in conjunction with groundwater, to provide municipal water supply to the Measure M Sutter Pointe development (Sutter 2011).

Many tributary streams flow from the mountains on both sides of the valley into the Sacramento River. According to a 2005 report by the Glenn County Department of Agriculture (GCDA), flows in the Sacramento River near Grimes in Southern Colusa County range from 6,500 cfs to 16,900 cfs for the period of record of 1946-2003 (GCDA 2005).

3.2.2. The Feather River

The Feather River is a major tributary of the Sacramento River and outlines a major portion of Sutter County's eastern boundary. The river trends north-south along the northern and central portions of the County to the convergence with the Bear River, where it changes course and flows southwest through the south-central portion of the County until it intersects the Sutter Bypass and the Sacramento River. Like the Sacramento River, the Feather River provides beneficial uses including recreation, agricultural, and wildlife. Yuba City obtains a large portion of its annual water supplies for municipal and domestic use from the Feather River.

3.2.3. The Bear River

The Bear River is a tributary of the Feather River and enters Sutter County from Placer County near the City of Wheatland in Yuba County. It forms the boundary between Sutter and Yuba Counties up to the convergence with the Feather River. The Bear River generally flows west until it converges with the Feather River, approximately one mile upstream from the rural community of Nicolaus. Although smaller than the Sacramento and Feather Rivers, the Bear River also provides beneficial uses that include recreation, agricultural, and wildlife. Discharges within the river are partially controlled by several upstream reservoirs. The Camp Far West Reservoir (located in the counties of Yuba, Placer and Nevada) is the last downstream reservoir on the river and subsequently regulates surface water discharges to downstream users, which has been the source of surface water for a very successful conjunctive water use program for the South Sutter Water District.

3.2.4. The Sutter Bypass

The Sutter Bypass (Bypass) is an artificial flood corridor constructed in the 1930's. As described by the Army Corp of Engineers, "the Sutter Bypass, which began operation in the 1930's, is a leveed portion of the natural floodway in the Sutter Basin. The bypass is south of the Sutter Buttes from Colusa to Verona between the Sacramento and Feather rivers. Flows enter the Sutter Bypass from the Butte Basin at its upper end near Colusa at the Butte Slough. Other flows enter from Wadsworth Canal, interior drainage from pumping plants, and the Sacramento River by way of the Tisdale Weir and Bypass. Flows exit the Sutter Bypass and combine with the Sacramento River, Feather River, Natomas Cross Canal, and Yolo Bypass upstream from the Fremont Weir near the town of Verona"(USACE).

3.3. Seasonal and Long-Term Water Quality

Under the USGS National Water Quality Assessment (NAWQA) Program, the USGS conducted an intensive study of the Sacramento River Basin and collected data between 1995 and 1998. Through the sampling process, the USGS selected indicator streams that were based upon the characterization that "they drain small to intermediate sized watersheds with relatively homogeneous land use and geology" (USGS 1998). The Colusa Basin Drain is located entirely in the Sacramento Valley and was chosen as an indicator stream to determine the impacts of agriculture on stream-water quality (USGS 1998). At the indicator water quality station, Colusa Basin Drain at Road 99E near Knights Landing, it was determined that pH levels were generally on the higher end, with declining suspended sediment concentrations over the two-year sampling period. The higher concentrations of mercury

correlate with suspended sediment because much of the load of total mercury is transported with the suspended material.

The findings of the USGS study also indicated that the water of the Sacramento River and its major tributaries is generally of good quality. As stated in the U.S. Geological Survey Circular 1215:

> "the amount of dissolved solids in the Sacramento River and its major tributaries (Yuba, Feather, and American rivers) was low at all of the sampled locations. Higher median concentrations of dissolved solids occurred at agricultural sites such as the Sacramento Slough and Colusa Basin Drain, but those are diluted upon mixing with Sacramento River water. Nutrient concentrations such as nitrate also were low throughout the Sacramento River Basin, and drinking-water standards for nitrate were not exceeded during the course of this study. The concentrations of Molinate and other pesticides (used in rice farming) measured during this study in the Colusa Basin Drain or in the Sacramento River, represent a significant improvement over concentrations measured in previous years".

3.4. Surface Water Supply Contracts

3.4.1. Settlement Contracts

USBR currently contracts with approximately 145 water districts, water purveyors, or private users for water rights to the Sacramento River. The total amount of water under the settlement contracts is approximately 2.2 million acre-feet and cover a total of almost 440,000 acres of land bordering the Sacramento River and its tributaries between Redding and Sacramento. The Settlement Contracts were originally executed in 1964 with a term not to exceed 40 years. New contracts have been executed with approximately 145 existing Sacramento River Settlement Contracts.

The Settlement Contracts include a Base Supply and Project Water. The Base Supply is the amount that reflects the agreed-upon water right of the respective entity. This is generally regarded as pre-1914 water rights and also water rights perfected after 1914 and reflect water that would be available to the respective entities under "natural" conditions. Project Water represents the amount of water the Bureau of Reclamation agrees to provide from its Central Valley Project (CVP) yield. Under the provisions of the Settlement Contracts both the Base Supply and Project Supply could be reduced by 25 percent of the total contract amount, but only in certain water year types.

3.4.2. Long-Term Renewal Contracts

In accordance with the CVP Improvement Act (CVPIA), the USBR negotiated long-term water service contracts in 2007. According to Section 3404c of the CVPIA, Renewal of Existing Long-Term Contracts requires the USBR to renew any existing long-term repayment or water service contract for the delivery of water from the CVP for a period of 25 years and may renew such contracts for successive periods of up to 25 years each. The USBR anticipates that, "as many as 113 CVP water service contracts, located within the Central Valley of California, may be renewed during this negotiation process" (USBR 2007a).

The long-term renewal contracts, unlike the Settlement Contracts, have no specified reduction in delivery; during critically dry or water-short years, the water supply available from the Project will be allocated among the contractors.

Also, the long-term renewal contracts contain a tiered pricing provision. The Base Supply is 80 percent of the total contract amount, and Tier 1 and Tier 2 supplies represent 10 percent each of the remaining contract amount. Each tier has an incrementally higher water cost. The Tier 1 and Tier 2 water, which is available in most years, is not used due to the incremental higher cost of water.

4. GROUNDWATER

4.1. Groundwater Basins and Subbasins

Sutter County is underlain by the Sacramento Valley Groundwater Basin. The Sacramento Valley Groundwater Basin covers a vast area and encompasses the alluvial deposits under the valley floor from the Sierra Nevada Mountains to the east, the Coast Range mountains to the west, the Sacramento-San Joaquin Delta to the south, and the Klamath and Cascade Ranges to the north. The Sacramento Valley Groundwater Basin covers over 5,900 square miles and 10 counties, and has been divided into 18 subbasins. The GMP area is underlain by three groundwater subbasins (Figure 1) as defined by the California Department of Water Resources (DWR) in "California's Groundwater, Bulletin 118 – Update 2003". These subbasins are: the East Butte Subbasin, the Sutter Subbasin, and the North American Subbasin. According to DWR,

"A groundwater basin is defined as an alluvial aquifer or a stacked series of alluvial aquifers with reasonably well-defined […] features that significantly impede groundwater flow such as rock or sediments with very low permeability or a geologic structure such as a fault. […]

"A subbasin is created by dividing a groundwater basin into smaller units using geologic and hydrologic barriers or, more commonly, institutional boundaries […]. These subbasins are created for the purpose of collecting and analyzing data, managing water resources, and managing adjudicated basins."

4.2. Hydrogeology

4.2.1. Overview of Groundwater and Geology

Groundwater is water that is underground and below the water table (saturated zone), as opposed to surface water, which flows across the ground surface. There are three main types of subsurface geology where groundwater can exist:

- Hard Rock – Groundwater can be present in cracks or fractures in the rocks.
- Underground Caverns – Groundwater can fill these underground voids.
- Porous Sediments – Groundwater can fill the pore spaces between grains of sand and gravel.

In Sutter County, groundwater exists in porous sediments, alluvial aquifers, or fractured volcanic rock such as in the vicinity of the Sutter Buttes. Figure 7 shows a simplified surface geologic map with the major faults in the County. Sutter County is situated along

the axial portion of the Sacramento Valley Groundwater Basin. The subsurface aquifers consist generally of layers of gravel, sand, clay, and in some cases volcanic ash. The characteristics of different aquifers, and zones within each aquifer, are related to the aquifer materials (sands, gravels, clays, etc.). Within a single aquifer zone, nearby wells with similar construction can have very similar well yields and water quality. It should be noted that many of the geologic formations that make up the alluvial aquifers are continuous units that are also present in other counties as discussed.

In the northern portion of Sutter County, the geologic setting changes rapidly from the stratigraphic succession observed in the rest of the County. A thick sequence of volcaniclastic sediments derived from the Sutter Buttes volcanic epoch form a volcanic fan apron of alluvial deposits around its perimeter. These deposits have been characterized recently by DWR as consisting largely of gravel, sand, silt, and clay. These deposits are observed at ground surface around the Buttes, and may extend up to a 15 mile radius in the subsurface (Springhorn 2008). Sediments deposited under marine sedimentary processes are also observed at ground surface and at shallow depths in the subsurface around the Buttes. These deposits were elevated from depth to their current position during the emplacement of the volcanic intrusion which formed the Sutter Buttes. Water quality in these sediments is generally poor and deteriorates with depth.

There is a large amount of hydrogeologic data available in the Sacramento Valley which has been widely studied, and groundwater is continuous within specific aquifer zones (although discontinuous between different aquifer zones) over large areas within the Sacramento Valley.

4.2.2. Status of Understanding of Regional and Local Geology

The geology of the Sacramento Valley has been studied for at least 95 years, and much has been learned over this time. However, there are still many areas of active study and debate. In Sutter County, areas that are not well-understood and/or are actively being studied include:

- The connection between the Coast Range-sourced Tehama Formation and the analogous Sierra Nevada-sourced deposits, and where this interaction occurs.
- The possible existence of subsurface barriers to groundwater flow within the County.
- The source of poor water quality in parts of the County.

4.2.3. Regional Geology and Structure

The Sacramento Valley Groundwater Basin is a north-south trending structural trough which is filled with layers of sediments. The stratigraphic succession of the basin deposits, from oldest to youngest (deep to shallow), depict a regional change in depositional environment from one dominated by marine sedimentary processes to that of continental (alluvial) processes. The deepest portions of the basin generally consist of marine sedimentary rocks, ranging in age from Late Jurassic to early Miocene (160 million years ago to 24 million years ago). These marine deposits are overlain by younger alluvial and locally prominent volcanic rocks of early Miocene to Holocene age (Harwood and Helley 1987). Within the Basin, these deposits are disrupted by deformational stresses derived from east-west compressional forces associated with regional uplift along the western margin of the valley and extensional forces to the east, within the Basin and Range Provenance (Harwood and Helley 1987). Over time, these forces have applied great stresses and strain on valley deposits, creating complex and diversely-oriented fold and fault structures.

The prominent fault system that occurs in Sutter County is the Willows Fault. The Willows Fault is an active northwest-trending fault that dips steeply to the east and shows reverse displacement, meaning the ground east of the fault has moved up relative to the west side. The Willows Fault enters into the County from Colusa County southwest of the Sutter Buttes and extends to the southeast portion of the County towards Sacramento.

The most prominent and recognizable geologic feature in Sutter County are the Sutter Buttes. The Sutter Buttes are composed of late Cenozoic volcanic rocks that rise over 2,000 feet above the Sacramento Valley floor. The Sutter Buttes formed between 2.4 and 1.4 million years ago as magma at depth was injected into the overlying Cretaceous and Tertiary rocks, causing deformation in the form of faulting, folding, and uparching (Harwood and Helley 1987).

4.2.4. Regional Stratigraphy

The prominent non-marine, fresh water-bearing stratigraphic units found within the East Butte, Sutter, and North American Subbasins include (from youngest to oldest):

- Recent Alluvial Deposits (stream channel, basin, and flood plain);
- the Modesto Formation;
- the Riverbank Formation;

- the Sutter Buttes Rampart;
- the Victor Formation;
- the contiguous Laguna, Tuscan, and the Tehama Formations;
- the Mehrten Formation; and
- the informally named Sutter Formation (Springhorn 2008).

Except for the Sutter Formation, the stratigraphic descriptions presented herein are based upon the California Department of Water Resources "Bulletin 118 – California's Groundwater" and are shown in the geologic cross-sections (Figure 8). The location of the cross-section is shown in Figure 7.

Locally, the stratigraphic succession observed in each subbasin differs slightly; therefore, each subbasin and its associated geologic setting are described separately with regard to their relative positions and occurrences in the specific subbasin.

4.2.4.1. East Butte Subbasin (Basin Number 5-21.59)

The northern section of Sutter County is underlain by the East Butte Subbasin. The East Butte Subbasin is bounded by the Sutter Buttes to the south, Butte Creek to the west and northwest, the Cascade Mountain range to the northeast, and the Feather River to the southeast. The East Butte Subbasin aquifer system consists of late Tertiary to Quaternary aged deposits comprised of Sierra and Cascade sourced material, and in the southern portion of the subbasin around the Sutter Buttes, by volcanic and volcaniclastic rocks. The geologic formations that comprise the East Butte Subbasin are (from youngest to oldest):

- Recent Alluvial Deposits;
- the Pleistocene aged Modesto and Riverbank Formations;
- the Sutter Buttes Rampart; and
- the Tertiary aged Laguna and Tuscan Formations.

Recent Alluvial Deposits

Stream channel deposits are Holocene in age and were deposited between 11,000 years ago and present day. The stream channel deposits occur along the current and ancestral paths of streams and rivers in Sutter County. Where present, the stream channel deposits extend from ground surface up to a depth of 80 feet below ground surface (Helley and Harwood 1985). The stream channel deposits consist of unconsolidated gravels, sand, silt, and clay, derived from the erosion and reworking of the Modesto and Riverbank Formations (described below). This unit is moderately to highly permeable, but because of its shallow depth and limited thickness, it possesses limited water-bearing capacity.

Basin deposits are Holocene in age and, like the stream channel deposits, were deposited between 11,000 years ago and present day. Basin deposits occur where sediment-laden floodwaters breached natural stream and river levees and spread across lower-lying topography. Where present, the basin deposits extend from ground surface up to a depth of 150 feet. The basin deposits consist mainly of silt and clay. These units have low permeability and generally yield small quantities of water to wells.

The Modesto Formation

The Modesto Formation is Pleistocene in age and is a stream terrace deposit that was deposited between 12,000 to 50,000 years ago (Helley and Harwood, 1985). Within this subbasin, the Modesto Formation consists of poorly indurated gravel and cobbles, sand, and clay and is derived from the reworking and deposition of the Riverbank Formation, Laguna Formation, and Tuscan Formation (DWR 2004). The Modesto Formation was likely deposited by the same stream and river systems that flow today, because it generally borders existing channels (Blake et. al. 1999). This formation may extend across the entire subbasin and where present, may range in thicknesses from 50 to 150 feet (DWR 2000). The sediments of the Modesto Formation are moderately to highly permeable and can yield moderate quantities of water to wells.

The Riverbank Formation

The Riverbank Formation is Pleistocene in age and was deposited between 120,000 and 500,000 years ago (Helley and Harwood, 1985). The Riverbank Formation consists of gravel and small cobbles, and is interbedded with reddish-clay, sand and silt. Like the Modesto Formation, the Riverbank Formation is a stream terrace deposit. However, the Riverbank Formation is older than the Modesto Formation. The

Riverbank Formation may extend across the entire subbasin, underlying the Modesto Formation, with thicknesses ranging from 50 to 200 feet. The Riverbank Formation is poorly to highly permeable and can yield moderate quantities of water to wells.

Sutter Buttes Rampart

The Sutter Buttes Rampart was deposited during the Middle to Lower Pleistocene period and is encountered in the southern portion of the subbasin. This unit is up to 600 feet thick in the subsurface (DWR 2000). In several studies (William and Curtis 1977, Springhorn 2008) the Sutter Buttes Rampart has been separated into two distinct units: the Rhyolitic Rampart and the Andesitic Rampart. The Andesitic Rampart phase of volcanism was much larger than the Rhyolitic phase. All the large peaks of the Sutter Buttes are andesitic domes and comprise the majority of the Rampart on the surface and the subsurface. The Sutter Buttes Rampart consists largely of gravel, sand, silt, and clay sediments which were deposited circumferentially around the Buttes as a geologic apron. These sediments may extend up to 15 miles north of the Sutter Buttes and west beyond the Sacramento River. Certain zones within these units yield large quantities of water (DWR 2004).

Laguna Formation

The Laguna Formation is Plio-Pleistocene in age and was deposited between 4 million and 2 million years ago. The Laguna Formation is comprised of Sierra Nevada sourced sediments, consisting of consolidated alluvial gravel, sand, and silt, comprised of granitic, metamorphic, and volcanic material. Estimates of the thickness of the Laguna Formation range from 180 feet (Helley and Harwood 1985) to 1,000 feet (Olmstead and Davis 1961). The Laguna Formation is characterized as being moderately consolidated and poorly to moderately cemented. Because of this, the permeability of formation is generally low to moderate. Wells completed in this formation have been observed to yield only moderate quantities of water (DWR 2003).

Tuscan Formation

The Tuscan Formation has been the subject of much interest in recent years. The Tuscan Formation is a regional aquifer system wholly or in parts of Tehama, Butte, Glenn, Colusa, and Sutter County. Within Sutter County, there has been limited analysis done on the subsurface extent of the Tuscan Formation. It is likely that the Tuscan Formation is only present in the northern portion of the County and consequently is not a major water resource for the County.

The Tuscan Formation is Plio-Pleistocene in age and was deposited between 4 million and 2 million years ago. The Tuscan Formation was derived by alluvial deposition associated with the erosion of volcanic material derived from Cascade volcanism. The formation outcrops from Red Bluff, in the northern part of the Sacramento Valley, to Oroville, southeast of Chico, and has been recognized in the subsurface at a distance of about 15 miles west of the Sacramento River (DWR 2003a). The deposits of the Tuscan Formation thin from east to west, from about 1,600 feet thick in the foothills of the Sierra Nevada to about 300 feet thick in the subsurface of the Sacramento Valley (Lydon 1969). In surface outcrops, the exposures of the Tuscan Formation are described as four separate, but lithologically similar units: Units A through D (Helley and Harwood 1985). Units A, B, and C are found within the subsurface in the northern part of the subbasin and units A and B are found in the southern part of the subbasin (DWR 2004). All of the units of the Tuscan Formation contain stratigraphic sequences of volcanic mudflows, volcanic conglomerates, volcanic sandstones, siltstones, and tuff deposits. In the subsurface, the Tuscan Formation consists largely of black volcanic sand and gravel, with interbedded layers of tuff breccias and tuffaceous clays (Ferriz, H. 2001). Unit A is the oldest (deepest) water-bearing unit and is distinguished from Units B and C by the presence of metamorphic clasts. Unit B contains equal distributions of volcanic mudflows, conglomerates, and tuffaceous sandstones. Units A and B are referred to as the "Lower Tuscan Formation". Unit C is capped by massive volcanic mudflows with some interbedded conglomerates and sandstones. In the subsurface, the volcanic mudflows of Unit C act as a confining layer to groundwater flow, separating the more permeable deposits of the Lower Tuscan Formation (Helley and Harwood 1985).

4.2.4.2. Sutter Subbasin (Basin Number 5-21.62)

The Sutter Subbasin underlies the central portion of Sutter County and is wholly within the boundaries of the County. The subbasin is bound by the confluence of Butte Creek with the Sacramento River and the Sutter Buttes to the north, by the Feather River to the east, by the confluence of the Sutter Bypass and Sacramento River to the south, and by the Sacramento River to the west. The Sutter Subbasin aquifer system consists of late Tertiary to Quaternary aged deposits comprised of Sierra-sourced (Sierra Nevada) detritus and volcanic and clastic rocks in the northern portion of the subbasin around the Sutter Buttes. The identified geologic formations that comprise the Sutter Subbasin are (from youngest to oldest):

- Recent Alluvial Deposits;
- the Pleistocene aged Sutter Buttes Rampart and Victor Formation;
- the Pliocene Laguna Formation; and
- the informally named Sutter Formation.

Recent Alluvial Deposits

The Holocene aged stream channel and flood plain deposits occur along the current and ancestral paths of streams and rivers in Sutter County. The stream channel and flood plain deposits consist of unconsolidated gravel, sand, silt, and clay. Both thickness and grain size decrease as the distance increases from their source. Where present, the stream channel and flood plain deposits extend from ground surface to an estimated depth of 100 feet (Helley and Harwood 1985). These units are highly permeable and provide for large amounts of groundwater recharge within the subbasin. This unit is highly permeable, and yields significant quantities of water to wells (DWR 2000).

Sutter Buttes Rampart

The Sutter Buttes Rampart is Middle to Lower Pleistocene aged alluvial deposit that is encountered in the northern portion of the subbasin. This unit can be up to 600 feet thick in the subsurface (DWR 2000). In several studies (William and Curtis 1977, Springhorn 2008), the Sutter Buttes Rampart has been separated into two distinct units: The Sutter Buttes Rhyolitic Rampart and the Sutter Buttes Andesitic Rampart. The deposition and composition of Rhyolitic Rampart reflects the initial stages of volcanism and deposition around the Sutter Buttes, while the Andesitic Rampart reflects the later stages. These fan deposits form an apron around the Buttes and consist largely of gravel, sand, silt, and clay, and may extend up to 15 miles north of the Sutter Buttes and west beyond the Sacramento River. Certain zones within these units yield large quantities of water (DWR 2004).

Victor Formation

The Pleistocene aged Victor Formation is comprised of alluvial fan deposits composed of Sierra-sourced loosely consolidated gravel, sand, and silt. The Victor Formation has an estimated thickness of 100 feet (DWR 2004). This unit is observed to have an impermeable surface due to the presence of hardpan and clay pan soils (DWR 2003). At its base, the Victor Formation has been observed to have moderate

permeability and provides most of the groundwater for domestic and shallow irrigation wells in Sutter County (DWR 2003). Wells completed in this unit have been reported to have yields as high as 1,000 gpm.

Laguna Formation

The Laguna Formation is comprised of Sierra sourced, consolidated alluvial gravel, sand, and silt, which consist of granitic, metamorphic, and volcanic material. Estimates of the formations thickness range from 180 feet (Helley and Harwood 1985) to 1,000 feet (Olmstead and Davis 1961). The Laguna Formation is characterized as being moderately consolidated and being poorly-to-moderately cemented, because of this, the formation generally has a low to moderate permeability. Wells completed in this formation have been observed to yield only moderate quantities of water (DWR 2003).

Sutter Formation

The Mio-Pliocene aged Sutter Formation is an informally named stratigraphic unit that underlies the area around the Sutter Buttes and the central portion of Sutter County. The extent of the deposits have been characterized on a local to sub-regional scale and have been generally classified as volcanic and epiclastic[3] sediments derived from volcanic sources located to the east in the Sierra Nevada, western Nevada, and the southern Cascade Volcanic Province (Springhorn 2008). Due to the complexity of identifying distinguishable characteristics within these deposits, informal and formal stratigraphic units within this region have been grouped together. Some of the major regional stratigraphic units that have been included in the Sutter Formation (from youngest to oldest) are the Tuscan, Mehrten, and Princeton Valley fill deposits.

4.2.4.3. North American Subbasin (Basin Number 5-21.65)

A portion of the North American Subbasin underlies the southeastern section of Sutter County. The North American subbasin is bound by the Bear River to the north, the Feather River to the west, the Sacramento River to the south, and in the east by a north-south trending line that represents the approximate edge of the alluvial basin (DWR 2004). The North American Subbasin is dominated by late Tertiary to Quaternary aged deposits consisting of Sierra-sourced volcanic sediments and alluvial derived sediments. The identified geologic formations that comprise the North American Subbasin are (from youngest to oldest):

[3] Consisting of fragments of preexisting rocks

- Recent Alluvial Deposits;
- Older alluvial deposits (the Pleistocene aged Modesto, Riverbank, Victor, and Laguna Formations); and
- the Mio-Pliocene aged Mehrten Formation.

Recent Alluvial Deposits

Stream channel deposits are Holocene in age and were deposited between 11,000 years ago and present day. The stream channel deposits occur along the current and ancestral paths of streams and rivers in Sutter County. The stream channel deposits consist of unconsolidated gravels, sand, silt, and clay, derived from active stream deposition, overbank sedimentation, and the erosion and deposition of existing Quaternary stream terrace deposits such as the Modesto and Riverbank Formations. Where present, the stream channel deposits extend from ground surface to a depth of 100 feet (Helley and Harwood 1985). This unit is highly permeable, and yields significant quantities of water to wells (DWR 2000).

The flood plain deposits consist primarily of silt and clay size sediments, with intermittent lenses of stream channel deposits. These deposits are generally observed along the flanks of existing and ancestral stream and river systems. These deposits have an estimated thickness up to 100 feet. Being that this unit is primarily comprised of finer-grained material, permeability is generally poor and generally yields low quantities of water. Brackish water is commonly encountered within this unit (DWR 2000).

Older Alluvial Deposits

Within this subbasin, a number of geologic formations have been assigned to the category "older alluvium" including: the Modesto, Riverbank, Victor, and Laguna Formations (DWR 2004). These deposits generally underlie the Recent Alluvial Deposits and consist of loosely to moderately compacted gravel, sand, silt, and clay size sediments that were derived and deposited under alluvial conditions. The thickness of these units ranges from approximately 100 to 650 feet (DWR 2004).

Mehrten Formation

The Mehrten Formation is Mio-Pliocene in age and consists of a sequence of volcaniclastic and volcanic rocks. In the subsurface, the Mehrten Formation ranges in thickness from 200 feet to 1,000 feet along the axis of the Sacramento Valley (DWR

2003). The Mehrten Formation is comprised of two distinct geologic units. The first unit consists of sediments deposited under alluvial and fluvial conditions and are comprised of gravel, sand, silt, and clay size sediments. This unit is highly permeable and wells constructed within this unit have been observed to produce yields exceeding 1,000 gpm (DWR 2003). The second unit consists of dense volcanic flows of tuff breccias with some interbedded conglomerates and sandstones. This unit acts as a confining layer between sand intervals and has a thickness that ranges from 200 to 1,200 feet in the subsurface (DWR 2003).

4.2.5. Areas Outside a Designated Groundwater Basin

The only part of the County that is not within a designated groundwater basin is the area consisting of the Sutter Buttes. Groundwater is likely found in the subsurface in fractures of the volcanic rock; however, historic groundwater levels and water quality were not reviewed in the preparation of this GMP. There are no local entities, aside from private domestic water users, that utilize groundwater resources in this area.

4.3. Groundwater Levels

DWR does not currently consider any of the groundwater subbasins underlying the County to be in overdraft. Overdraft is characterized by a declining trend in groundwater levels over multiple years without recovery during recharge events. Historic groundwater level data were reviewed for each of the subbasins within the County. DWR maintains a publicly available on-line database, which includes groundwater level data for the County. The DWR Water Data Library (WDL) website can be found at http://www.wdl.water.ca.gov. Wells monitored by DWR and cooperating agencies are identified by the State Well Number (SWN). Data can be obtained for specific wells by means of a map interface, by groundwater basin, or by the assigned SWN.

A 79-year period of record for water level measurements in Sutter County depicts a groundwater system that has experienced changing conditions over time. A number of DWR monitored wells were selected throughout the County to represent these changes. The locations of these wells, along with their associated hydrographs illustrating the historic groundwater levels, are shown in Figure 9. Groundwater level data from well 10N/4E-12A1, a 290-foot-deep well located in the southeast portion of Sutter County, and well 13N/3E-32N1, a shallow (less than 100 feet deep) well located in the southern portion of the County show the groundwater levels typical of different areas of the County. Groundwater levels in well 10N/4E-12A1 are characteristic of areas of high groundwater use and differing water conditions. Water levels fluctuate, sometimes dramatically, in response to changes in groundwater use and hydrologic conditions. This well is located in an area where agricultural

demands are supplied entirely with groundwater. The Sacramento County Department of Water Resources website includes published groundwater elevation maps and indicates that this well is in close proximity to a large pumping depression in northern Sacramento County. Groundwater levels in well 13N/3E-32N1 are characteristic of areas with lower groundwater use and more stable water conditions, and as such, water levels have not exhibited significant fluctuations over times. This well is located in an area where agricultural demands have been met almost entirely with surface water and groundwater demands have consequently been small.

Groundwater levels in well 10N/4E-12A1 have varied from 20 to 80 feet below ground surface over time. The combination of high groundwater use, the close proximity to a pumping depression, and changing climatic conditions has led to significant declines in groundwater levels from the early 1950' through the late 1970's. In the middle to late 1970's, drought conditions increased the rate of decline of groundwater levels on an even larger scale. In the mid 1980's and early 1990's, private and municipal water agencies in a collaborative effort started to implement conjunctive water use programs. With the availability of surface water, and the decrease in groundwater pumpage, groundwater levels have been steadily recovering from the early 1980's through present. Groundwater levels in this well are currently about 35 to 40 feet higher than they were in the late 1970's.

Groundwater measurements in well 13N/3E-32N1 shows very stable groundwater levels since measurements began in 1942. Groundwater levels have remained virtually unchanged, with water levels within 5 to 6 feet of ground surface and seasonal fluctuations of less than 10 feet.

The direction of groundwater flow during the fall season within the County has not changed significantly from 1912-1913 (Bryan 1923) to 2007; with the exception of the southeastern portion of the County. Contours of equal groundwater levels from fall 1912-1913 and fall 2007 were compared to identify changes over the 95 year period. Figure 10 depicts changes in groundwater levels over the aforementioned period. In most areas within the County, groundwater levels were not dramatically different in 2007 than they were in 1912-1913. In the central portion of the County, an increase in groundwater levels is observed in the data, which may be likely due to applied surface water for irrigation. In the southeastern portion of the County, a significant decline in groundwater levels is observed, which can be related to the high usage of ground water for irrigation of crops, and the influence of the large pumping depression in the northern portion of Sacramento County.

Fall and spring contour maps of equal groundwater elevation for 2007, 2008, 2009, and spring 2010 were reviewed (Figures 11 through 17) to determine groundwater gradient and

flow direction. The fall 2009 and spring 2009 groundwater contours generally follow the topography of the County and indicate that groundwater flows from the Sierra Nevada toward the Sacramento Valley (east to west), and north to south within the Valley. The fall 2007 contour map of equal groundwater elevations indicates a few locations where small pumping depressions are present, but in general, suggests the same direction of groundwater flow as seen in the spring 2007 groundwater contour map. Differences in groundwater levels between fall and spring appear to be a result of normal fluctuations in groundwater conditions from seasonal pumping and from wet and dry climatic cycles.

Data from the nested monitoring well at the extensometer site in the southern portion of the County indicates that, for the 14 years of available data, the spring groundwater levels in the monitored aquifer zones have been very similar, within a few feet of one another; except for the deepest completion where groundwater levels are approximately 10 feet lower than the shallower completions.

4.4. Groundwater Quality

The quality of groundwater is a product of the material through which it flows, or that flows into it. Local variations in the quality of the County's groundwater can limit its use for either potable water supply and/or agricultural applications. Groundwater contamination is a result of naturally occurring, point source contamination, and/or regional contamination. Naturally occurring contaminants of concern include dissolved salts [as measured by the specific conductance or electrical conductance (EC)], boron, nitrate, manganese, arsenic, and mercury. Point source contamination typically involves solvent releases originating mostly from gas stations and dry cleaners. Regional sources of contamination include applied fertilizers, salts, and leaky septic systems (nitrate and salt loading).

Historic and current water quality data (collected by the DWR, USGS, and local water purveyors) for wells located within the County were analyzed to characterize spatial and depth dependent water quality trends within the County's groundwater subbasins. The data was separated by well depth into the following three categories: less than 150 feet deep, 150 to 400 feet deep and more than 400 feet deep, as shown in Figures 18 through 23. The categories were chosen based on the occurrence at which certain stratigraphic units are observed in the subsurface in Sutter County.

4.4.1. Specific Conductance

Specific conductance was selected as an indicator of overall water quality. Specific conductance is a property of groundwater that is relatively simple to collect in the field at the well head and can help identify and characterize the condition of the non-marine fresh water

bearing aquifer system. Specific conductance is a measure of how effectively water will conduct electricity and is reported in micro Siemens (µS/cm) per centimeter and provides for the indirect measurement of the amount of dissolved solids (salts) in the groundwater. Lower specific conductance generally indicates better water quality (fresh water) while higher specific conductance generally indicates poorer water quality (brackish to saline water).

Applied irrigation and fertilizers can add salts to the water that percolate into the hydrogeologic system, increasing the specific conductance of the groundwater. Increased specific conductance values of the groundwater can also be attributed to naturally occurring brackish or saline water, such as geologic formations (aquifers) which are, or have been in the past, directly connected to a salt water body or where geologic formations were deposited under marine (salt water) conditions and which have inherently high dissolved salt concentrations. As shown in Figures 18 and 19, specific conductance values within the County are generally acceptable for agricultural and domestic use east of Highway 99 and in the northern half of the County. Elevated values for specific conductance are near to and/or exceed the recommended maximum contaminant level (MCL)[4] for domestic use in the shallow aquifers near the Sacramento River and in the aquifers below 900 feet. The elevated specific conductance could potentially be problematic for agricultural use. It is unclear why there is elevated specific conductance in this area.

4.4.2. Boron

Boron is a naturally occurring element. As shown in Figure 20, boron concentrations in the County are generally acceptable. Some deeper wells, which likely encounter more marine sediments, do contain elevated boron concentrations. Boron is a necessary element for agriculture, but may become toxic to crops above 500 micrograms per liter (µg/L). For public drinking water systems, the California Department of Public Health (CDPH) has established a notification level of 1,000 µg/L for boron. Increased concentrations of boron are observed in wells greater than 400 feet as well as in the southwestern portion of the County.

4.4.3. Nitrate

Nitrate is a contaminant which does not naturally occur in the subsurface. Elevated concentrations of nitrate are widespread in the Sacramento Valley. As shown in Figure 21, concentrations of nitrate in the populated areas of Sutter County are near or above the MCL for nitrate (as NO_3). The CDPH has established a primary MCL of 45 milligrams per liter (mg/L) for nitrate (as NO_3). Near the Sutter Buttes and Yuba City, nitrate concentrations in several wells (less than 150 feet) exceed the MCL. Where present, elevated concentrations of

[4] Recommended CDPH MCL for Specific Conductance is 900 µS/cm; upper limit is 1,600 µS/cm; short term is 2,200 µS/cm

nitrate are likely a result of overlying land uses, such as septic systems, animal enclosures, or applied fertilizers.

4.4.4. Manganese

Manganese is a naturally occurring element found in rocks and minerals. Its presence in groundwater is a result of the dissolution of the naturally occurring element in sediments containing minerals composed of manganese. As illustrated in Figure 22, manganese concentrations are elevated in all portions of the County, at levels that may cause aesthetic problems (odor or staining) for domestic and municipal uses, but generally below levels that could represent a health risk. There are, however, a few locations where manganese concentrations are near or exceed the CDPH established Notification Level of 50 µg/L, and may pose a health risk.

4.4.5. Arsenic

Arsenic is a naturally occurring element commonly found in alluvial sediments. Its presence in groundwater is a result of the dissolution of the element in sediments containing minerals containing arsenic. The CDPH has established a primary MCL of 10 µg/L for arsenic. As illustrated in Figures 19 and 23, arsenic concentrations are near to or above the CDPH MCL throughout the County in each of the aquifer zones assessed; conversely, concentrations of arsenic below the CDPH MCL are also present throughout the County in each of the aquifer zones assessed. Countywide, arsenic concentrations do not appear to be isolated to any one specific aquifer zone in the subsurface. However, recent data analysis suggests a possible correlation between elevated arsenic concentrations and the presence of volcaniclastic material of the Sutter Buttes Rampart formation. Concentrations of arsenic in the stratigraphic units that occur above and below the Rampart are generally less than 10 µg/L, whereas concentrations of arsenic within the Rampart material are between 10 to 370 µg/L (Springhorn, 2008). Concentrations of arsenic tend to be under the CDPH MCL southeast of Highway 99 and in the shallow aquifers.

4.4.6. Mercury

Historic gold mining processes and operations introduced toxic mercury into the surface water system throughout Northern California in the late 1800's. Due to the proximity of these operations to Sutter County, the PAG requested an assessment of the concentrations of mercury in the groundwater. A limited number of wells have been sampled within Sutter County for mercury, and as such, concentrations of mercury in the groundwater within Sutter County can not be well characterized. The few wells that have been sampled for mercury

indicate that mercury concentrations were low. In most cases, the concentrations were below the analytical detection limit (not detectable by the laboratory method used at the time).

4.5. Land Subsidence

Land subsidence is the gradual or sudden lowering of the land surface due to compaction of the underlying sediments. Two types of land subsidence are observed within alluvial sediments: inelastic and elastic. Inelastic land subsidence is a result of the compression of geologic formations and is irreversible. Inelastic land subsidence can be caused by excessive extractions of groundwater, oil, or natural gas. In discussing land subsidence, it is important to note that elastic (reversible) land subsidence is a normal occurrence, whereas inelastic land subsidence has associated negative impacts.

Although there are several causes of inelastic land subsidence, the compression of clay as a result of groundwater extraction is considered the most likely cause of subsidence north of the Sacramento-San Joaquin Delta (Page 1998). Once water is removed (mined) from compressible clay, the clay compresses and cannot accept water again, thus resulting in the permanent lowering of the overlying land surface (inelastic land subsidence). Clay compression has occurred in several locations in California, including the San Joaquin Valley. Compressible clay, such as the Corcoran Clay member of the Tulare Lake Formation, has been mapped over much of the western side of the San Joaquin Valley and can be over 130 feet thick. The subsidence documented in the San Joaquin Valley extends over a very large area, with over 30 feet of subsidence recorded in some areas.

North of the Sacramento-San Joaquin Delta in the Sacramento Valley, inelastic land subsidence, which has been directly related to clay compression as a result of groundwater extraction, has occurred in portions of Solano, Yolo, and Colusa Counties (Page 1998). Recorded land subsidence of more than two feet, and possibly as much as five feet, has occurred in this area. Subsidence in the Sacramento Valley appears to extend from Davis to Arbuckle. The area of subsidence appears to follow a local geologic feature known as the Zamora Syncline. A syncline is a structural fold that is formed by compressional forces which cause the sedimentary layers to have a concave, or a bowl-like geometry. Lakebeds are often associated with structural lows such as synclines. Lakebed deposits typically consist of fine-grained, clayey sediments, which settle out to the bottom of standing bodies of water and of which can include large volumes of freshwater diatoms[5]. Along with sediments, the microscopic diatoms settle and collect on the bottom of a lakebed. In Yolo County, diatomaceous (diatom rich) clay sediments have been identified within the geologic formations of Zamora Syncline. These diatomaceous clay sediments were identified to be

[5] Diatoms are unicellular aquatic algae, typically 20 to 200 microns (Prothero, 1998)

highly compressible (Page 1998). Although diatomaceous clay has been identified in numerous boreholes drilled in Sutter County, there have not been any recorded land subsidence issues.

Elastic land subsidence is observed to be cyclical and does not result in permanent compaction of subsurface materials. One example of elastic land subsidence is seasonal fluctuations in ground surface elevations that coincide with fluctuations in groundwater levels (and associated aquifer pressure). In elastic land subsidence, the subsurface pressures acting on the aquifer do not decrease enough so that subsurface materials permanently compact.

The DWR, in cooperation with federal, state and local agencies, installed and surveyed Global Positioning System (GPS) monuments to be able to measure and monitor ground surface elevations over time in the Sacramento Valley. The project, titled "The Sacramento Height-Modernization Project", consists of 339 monuments, spaced approximately 7 kilometers apart, in 10 counties. There are 32 monuments located in Sutter County. The GPS monuments will augment the existing network of extensometers which DWR currently monitors for land subsidence. In total, there are 13 extensometers located in Glenn, Colusa, Butte, Yolo, and Sutter Counties. The land subsidence monitoring network is shown in Figure 24. Only one of these extensometers, State Well Number 11N/4E-04, is located within Sutter County. It is located in the south-central part of the County along Highway 99, and extends to a depth of 1,003 feet, extending over a large portion of the fresh-water formations. The extensometer is installed in a dedicated monitoring well and is designed to measure any change in distance between the bottom of the well and the ground surface. DWR reports the accuracy of the extensometer to be ±0.001 feet. The extensometer provides for ongoing, real-time data collection, of land surface elevation changes. The Sutter County extensometer has been recording data since early 1994. In the 14 years since it began recording, the extensometer in Sutter County has recorded seasonal (cyclic) elastic land subsidence of approximately 0.03 feet (approximately one-third inch). There has been no indication over the period of record that any inelastic subsidence has occurred.

4.6. Groundwater-Surface Water Interaction

Several clustered monitoring wells located throughout the county adjacent are used to monitor changes in surface flow or quality that directly affect the groundwater system (levels or quality), and/or to monitor changes in surface flow or quality that are caused by groundwater pumping. These monitoring wells are adjacent to surface water bodies, and have a river stage gage located in the immediate vicinity.

Several of the network wells are located along the banks of the Sacramento, Feather, and Bear Rivers, as shown in Figure 25. The relationship between the volume of water flowing in the major rivers/streams and the influence the surface water imparts on groundwater elevation are being monitored with a combination of nested monitoring wells and river stage gages. Four stations exist in the County for observing this interaction: on the Sacramento River below Wilkins Slough (WLK), on the Bear River at Pleasant Grove Road (BPG), on the Sutter Bypass at RD 1500 pump (SBP), and along the Feather River above Star Bend (FSB). Sutter County also monitors a river stage gage at Boyd's Landing (FBL). At stations BPG and FBL, observations of water surface/groundwater elevations trend closely during high flow/stage events in the rivers, suggesting a significant hydrologic connection between the groundwater in the shallow aquifers and the surface water.

4.7. Groundwater Recharge

Groundwater recharge is the process in which groundwater is replenished. The geologic formations that comprise the aquifer system underlying the County extend well beyond the County's jurisdictional boundaries. Several processes are responsible for recharge of the groundwater basin. On a regional scale, surface water flowing over the surface expression of the geologic formations (surface outcrops) allows for direct infiltration into the hydrogeologic system. Figure 26 depicts contours of equal groundwater elevations, superimposed over the surface geology, for the Sacramento Valley Groundwater Basin. Groundwater flow is perpendicular and down gradient to the contour interval. On the east side of the Sacramento Valley Groundwater Basin, the groundwater contours become parallel to and follow the margin of the valley, indicating groundwater is moving through the subsurface from the east to the west. Locally, groundwater recharge occurs where surface water flows over permeable sediments (gravel and sand) in the river channels, allowing for the direct infiltration of surface water. Deep percolation of applied irrigation water also recharges the groundwater basin. Additionally, surface water deliveries have increased the quantity of water flowing down the river, adding available water to recharge the underlying aquifers helping to improve groundwater elevations.

The amount of groundwater recharge is dependent on the available storage space within the aquifer(s). Depending on the degree of separation between the elevation of the bottom of the river or stream and that of the groundwater, streams can either "lose" water into the underlying aquifer(s) or "gain" water. Where groundwater levels are at or above the elevation of surface water, groundwater will discharge into the stream (gaining stream). Where there is a separation between the groundwater and surface water, water flowing downstream will recharge into (losing stream) the groundwater basin (although the contribution has not been

studied). Conversely, if groundwater levels are at land surface, there will be refusal of any "new" water into the subsurface.

The State Water Resources Control Board has identified hydrogeological vulnerable areas, meaning vulnerable to groundwater contamination, where geologic conditions allow recharge to the underlying aquifers. Generally, these areas include the coarse deposits associated with the Feather River.

4.8. Groundwater Infrastructure

According to DWR records, 6,742 well completion reports have been filed for wells constructed in Sutter County. Well completion reports are not always filed with DWR, even though they are required by law, so the number of reports likely under-represent the actual total for the County. Of the wells for which well completion reports have been filed:

- 3,344 are domestic wells
- 1,167 are irrigation wells
- 854 have unknown or other uses
- 308 are monitoring wells
- 75 are municipal wells
- 34 are industrial wells
- 13 are test wells
- Seven (7) are stock-watering wells
- 12 are fire or frost protection wells
- Two (2) are cathodic protection wells

Figure 27 shows the number of DWR well completion reports filed for Sutter County from 1928 through 2007. The figure only illustrates wells that were classified as either: domestic, irrigation, or public supply. Domestic wells were constructed at a rate of approximately five per year from 1941 through 1950, but have been constructed at a rate of approximately 59 per year since then. Irrigation wells tend to be constructed more frequently during drought periods, in the mid-1970's and early 1990's. On average, 16 irrigation wells are constructed per year; however, significantly more wells are constructed during droughts. Municipal well construction has averaged two-and-a-half per year. Of the wells for which records exist, approximately 700 wells are classified as either abandoned or destroyed.

Figure 28 shows the average depth of wells constructed from 1950 through 2005. The average depth of domestic wells has fluctuated since the 1930's, but has generally been about 100 feet deep. The average depth of irrigation wells has fluctuated significantly, but has been about 160 feet deeper than the average depth of domestic wells in any give year, or an average of about 260 feet deep. Municipal well depths are inconsistent and vary widely in

depth, from about 50 to 700 feet deep. Combined with the small number constructed annually, calculation of an average depth of new municipal wells would not be meaningful.

5. GROUNDWATER MANAGEMENT PLAN REQUIRED, VOLUNTARY, AND RECOMMENDED COMPONENTS

California Water Code §10750 et seq., as amended by Senate Bill (SB) 1938, defines the required and voluntary components of a GMP and establishes procedures by which they must be developed. DWR recommends additional elements to include in a GMP in Bulletin 118 Update 2003, Appendix C. The Sutter County GMP includes the components required in the Water Code and has been developed in accordance with the required procedures. This GMP also includes many of the voluntary and recommended GMP components. This GMP also includes components designed to address the requirements of California Water Code §10920 et seq., which establish requirements for groundwater monitoring that affect eligibility for grant funding.

5.1. California Water Code Requirements

Section 10750 et seq. of the California Water Code, as amended by SB 1938, requires GMPs to include six mandatory components to be eligible for the award of funds administered by DWR for the construction of groundwater projects or groundwater quality projects. These components are listed below.

Description	*GMP Section*
Make available to the public a written statement describing the manner in which interested parties would be allowed to participate in the development of the GMP.	1.4
Include Basin Management Objectives (BMOs), including components relating to the monitoring and management of groundwater levels, groundwater quality degradation, inelastic land subsidence, and changes in surface flow and surface water quality that directly affect groundwater levels or quality or are caused by groundwater pumping.	6.2
Prepare a plan that involves other agencies that enables Sutter County to work cooperatively with other public entities whose service area or boundary overlies the groundwater basin.	7.1.5
Prepare a map that details the area of the groundwater basins, Sutter County's boundaries, and other local agencies within the groundwater basins.	Figure 1

Description	*GMP Section*
Adopt monitoring protocols to detect changes in groundwater levels, groundwater quality, inelastic surface subsidence, and flow and quality of surface water that directly affects groundwater levels or quality or are caused by groundwater pumping.	7.1
For areas outside the groundwater basins, use geologic and hydrologic principles appropriate to those areas.	4.2.5;7.1.4

5.2. DWR Bulletin 118 Recommended Components

DWR's Bulletin 118 recommends other components that may voluntarily be included in a GMP. These are listed below.

Description	*GMP Section*
Establish an advisory committee of stakeholders to help guide the development and implementation of the plan and provide a forum for resolution of controversial issues.	1.4
Describe the area to be managed under the GMP.	1.3
Describe how meeting each BMO will contribute to a more reliable long-term groundwater supply, and describe management actions to achieve each BMO.	6.2
Describe GMP monitoring program.	7.1
Describe integrated water management planning efforts.	7.1.5
Periodically report groundwater basin conditions and management activities.	7.1.6
Evaluate GMP periodically.	7.1.6

5.3. California Water Code Voluntary Requirements

California Water Code §10753.8 lists twelve issues of groundwater management which may voluntarily be included in a groundwater management plan.

Description	*GMP Section*
Control of saline water intrusion.	6.1.3
Identification and management of wellhead protection areas and recharge areas.	4.7; 6.1.3
Regulation of the migration of contaminated groundwater.	N/A
Administration of well abandonment and well destruction program.	6.1.3
Mitigation of conditions of overdraft.	4.3
Replenishment of groundwater extracted by water producers.	N/A
Monitoring of groundwater levels and storage.	4.3; 5.4
Facilitating conjunctive use operations.	6.1.3
Identification of well construction policies.	6.1.3
The construction and operation of groundwater contamination cleanup, recharge, storage, conservation, water recycling, and extraction projects.	N/A
The development of relationships with state and federal regulatory agencies.	7.1.5
Review of land use plans and coordination with land use planning agencies to assess activities which create a reasonable risk of groundwater contamination.	7.1.6

5.4. California Water Code Groundwater Monitoring Components

On November 4, 2009 the State Legislature amended the Water Code with Senate Bill SBx7-6, which mandates a statewide groundwater elevation monitoring program to track seasonal and long-term trends in groundwater elevations in California's groundwater basins. To achieve that goal, the amendment requires collaboration between local monitoring entities

and DWR to collect groundwater elevation data. Collection and evaluation of such data on a statewide scale is an important fundamental step toward improving management of California's groundwater resources.

In accordance with this amendment to the Water Code, DWR developed the California Statewide Groundwater Elevation Monitoring (CASGEM) program. The intent of the CASGEM program is to establish a permanent, locally-managed program of regular and systematic monitoring in all of California's alluvial groundwater basins. The CASGEM program will rely and build on the many, established local long-term groundwater monitoring and management programs. DWR's role is to coordinate the CASGEM program, to work cooperatively with local entities, and to maintain the collected elevation data in a readily and widely available public database. DWR will also continue its current network of groundwater monitoring as funding allows.

The law anticipates that the monitoring of groundwater elevations required by the enacted legislation will be done by local entities. The law requires local entities to notify DWR in writing by January 1, 2011 if the local agency or party seeks to assume groundwater monitoring functions in accordance with the law (Water Code §10928).

Additionally, on or before January 1, 2012, the law requires that Monitoring Entities shall begin reporting seasonal groundwater elevation measurements to DWR (Water Code §10932).

Local entities in Sutter County that have submitted official notifications to DWR to be considered for CASGEM Monitoring Entities include:

- Sutter Extension Water District
- Feather Water District
- Reclamation District 1500 (including RD 1500, Pelger Mutual Water Company and Sutter Mutual Water Company)
- Natomas Central Mutual Water Company
- South Sutter Water District

Garden Highway Mutual Water Company has shown interest in participating in CASGEM but has not yet completed the official notification submittal process include.

Local entities that submit complete Monitoring Entity notifications and adequate groundwater monitoring plans and well networks will be officially designated by DWR to be

the Monitoring Entities for their respective subbasin or portion of a subbasin for the purposes of the CASGEM Program. However, if no local monitoring entity volunteers or is identified for a particular area or groundwater basin, DWR may assume the monitoring and reporting duties and certain entities in the basin may not be eligible for water grants or loans administered by the state.

Sutter County is severely limited in its ability to take a lead in groundwater monitoring because of budget and staff shortages. Furthermore, the County does not own any groundwater monitoring wells and does not conduct any groundwater monitoring on its own. For this reason, Sutter County does not seek to assume groundwater monitoring functions under California Water Code §10920 et seq. However, the County does promote the coordinated collection of groundwater elevation data through its Groundwater Monitoring Program, discussed in Section 7.1 of this GMP.

6. GROUNDWATER MANAGEMENT GOALS AND BASIN MANAGEMENT OBJECTIVES

6.1. Groundwater Management Goals

Sutter County's groundwater management goals represent the overarching intent of the County with regard to groundwater management. Basin Management Objectives (BMOs) and Management Actions must be consistent with these Groundwater Management Goals, and must contribute to achieving the goals. Sutter County's goals for groundwater management (as developed with input from the public through PAG meetings and workshops) are:

- To promote responsible groundwater use in Sutter County so groundwater is available to meet present and future demands.
- To provide groundwater users with information and guidance to help them be responsible stewards of the groundwater resources in Sutter County.
- To discourage activities that could reduce the long-term availability of high-quality groundwater in Sutter County.

Each of the Groundwater Management Goals is discussed below.

6.1.1. To Promote Responsible Groundwater Use in Sutter County So Groundwater is Available to Meet Present and Future Demands.

One of Sutter County's main goals for groundwater management is to ensure that a reliable water supply is available so that water users in the County can be confident that water will be available to meet domestic, irrigation, and other demands on an ongoing basis.

The goal to promote responsible groundwater use in Sutter County is intended to provide the County with useable groundwater resources now and in the future. This is important because the socio-economic well being of the County could be adversely affected if the groundwater supply becomes less useable from a supply or quality standpoint. Ensuring responsible groundwater use will help protect groundwater rights and maintain local control because adjudication of the groundwater basin will not be warranted if long-term groundwater sustainability can be achieved.

6.1.2. To Provide Groundwater Users with Information and Guidance to Help Them Be Responsible Stewards of the Groundwater Resources in Sutter County.

It is important to understand that in order to responsibly manage groundwater to ensure long-term groundwater sustainability, it is necessary to thoroughly understand the groundwater system underlying the County, along with its capabilities and limitations. Sutter County's water resources should be viewed as a dynamic system with the amount of available surface water and groundwater varying over time with fluctuations in hydrologic and climatic conditions. The implementation of a surface/groundwater monitoring program to observe and document the County's resources is essential to provide the community with the necessary information to accomplish this management objective.

6.1.3. To Discourage Activities that Could Reduce Long-Term Availability of High-Quality Groundwater in Sutter County.

It is important to recognize that this management objective is not intended to restrict the users within the community from exercising their legal rights to groundwater. Groundwater is a resource that should remain available for the people of the County to use beneficially on their property. The intent of this objective is for groundwater management to be accomplished in a way that minimizes activities that could potentially reduce the long-term availability of high-quality groundwater in Sutter County. There are a number of management practices that can be utilized to accomplish this goal. Two of the main practices that should be considered are conjunctive use programs and improving County well standards.

The goal of optimizing the conjunctive use of surface water and groundwater will enhance the County's water supply reliability and maximize the available water supply. The term "conjunctive use" basically means using surface water and groundwater together to meet water demands, using different proportions of each depending upon availability. For example, in years of reduced surface water availability, more groundwater would be used and groundwater levels might decline. Conversely, in years of full surface water availability, less groundwater would be used and groundwater levels would be allowed to recover. Optimizing conjunctive use generally means that, whenever possible, surface water is used to the fullest extent with groundwater serving as a "back-up" supply. This maximizes the available water supply because unused surface water generally flows downstream and is lost, but unused groundwater remains in the ground and would be available for later use.

On the other hand, the potential may exist in some areas of the County where groundwater levels are (and have historically been) high, to utilize more groundwater and thus induce more recharge (by creating additional storage space within the aquifer) thereby increasing the total water supply available in the County.

A related goal is to "even out" water availability in the County. There are cases when surplus water is available in some areas of the County, but other areas have inadequate supplies. For example, an area with high groundwater levels may have adequate or excess surface water, while another area may have low groundwater levels and inadequate surface water. In this case, groundwater could be pumped in the area with high groundwater levels, and their surface water could be transferred to the area with low groundwater levels so that area does not have to rely as much on groundwater. If possible, undertaking such projects will help improve the overall water supply reliability in the County.

The goal for updating the County's well standards is to add additional levels of protection to ensure that the design of new well structures prohibit the downward migration of surface/shallow contaminants or cross contamination of aquifers. The County has adopted standards as set forth in Chapter II of the State Department of Water Resources Bulletin 74-81, and as supplemented by Bulletin 74-90, entitled "Water Well Standards: State of California", except as otherwise provided in Section 700, Chapter 765 "Water Wells" of the Sutter County Municipal Code[6]. Some amendments that could be made to the existing well standards are: (1) require the use of geophysical surveys for all new well projects, (2) increase the required minimum sanitary seal depths, (3) institute water quality sampling during cable tool well drilling, (4) institute well restriction zones where poor water quality is known, and (5) improve/implement well destruction programs.

Requiring the use of geophysical surveys (spontaneous potential, 16- and 64-inch resistivity) in all new boreholes can help to enhance groundwater protection by identifying the zone(s) of poor water quality, as well as the depths of confining layers, which can be used to design adequate sanitary/annular seals. With this data, future wells can be designed to effectively seal against poor water quality while providing adequate measures for aquifer protection.

Increasing the minimum sanitary seal depth required for new wells is a proactive measure that can effectively increase aquifer protection. Increasing the required sanitary seal to a minimum depth of 50 feet for all new wells can seal off shallower aquifers with poorer water quality from the deeper aquifers with better water quality, as well as impede the

[6] http://www.co.sutter.ca.us/doc/government/bos/ordinance

downward migration of surface contaminants. Currently, the standards in force require a minimum 50-foot sanitary seal for municipal supply wells and 20-foot sanitary seal for all other wells (Bulletin 74-90).

Many wells in Sutter County have been drilled and constructed utilizing the cable tool drilling method. One of the main troubles with cable tool wells is that they usually are constructed across, and connect, multiple aquifer zones. Some of these well structures likely have become conduits for the downward migration and cross contamination of aquifer zones. Water quality sampling during the drilling of these wells (field tests for TDS or specific conductance) would delineate between problematic and non-problematic aquifer zones. If an existing well is deemed problematic (i.e. poor water quality), corrective measures through well modification or even well destruction could help mitigate the movement of poorer water quality between aquifer zones.

Implementing well restriction zones where water quality contamination is known to exist in specific aquifers can aide in protecting aquifers with acceptable water quality. Restricting the construction of wells or requiring specific seal intervals can provide an additional level of aquifer protection. Certain areas within Sutter County have localities of poorer water quality. It may be beneficial to assess the risk of drilling and constructing new wells within these areas. If adequate aquifer protection can not be achieved during construction activities, it may be warranted to designate well exclusion zones.

Unused, unsecured, abandoned, or improperly destroyed wells can act as a direct conduit for surface water infiltration or degradation of one or more aquifers, if they are connected by the well structure. Well destruction requirements adopted by the County currently require abandoned wells to be destroyed. Currently, these requirements require the uppermost 20 feet of the well/borehole be filled with impervious material. Special situations, in the case where vertical movement of poor water quality could contaminate an aquifer with good water quality, require impervious sealing material to be placed adjacent to confining layers. Increasing oversight of the permitting process during the planning and design of well destruction programs can ensure added protection against the vertical migration of poor water quality.

6.2. Basin Management Objectives

Basin Management Objectives (BMOs) are guidelines established to ensure that the County's basin management goals are being fulfilled. BMOs create a systematic method for collecting and monitoring data for specific components of the groundwater system and to provide for the dissemination of such information to the public. The objective of the BMOs is not to assign a fixed value, or level, to each parameter, but to allow for the early identification of

potential problems with sufficient time for the County and its groundwater users to formulate an action plan to mitigate adverse effects to its groundwater resource.

Sutter County's BMOs address the following parameters:

- Groundwater levels
- Groundwater quality
- Inelastic land subsidence
- Surface water
- Coordination

6.2.1. Groundwater Levels BMO

There are three BMOs for groundwater levels:

- *Avoid ongoing declines in groundwater levels during water year types identified by DWR to be "above normal" or "wet" for the Sacramento Valley.*
- *Avoid problematically high groundwater levels.*
- *Provide assistance with assessing problems and resolve disputes related to groundwater levels.*

Groundwater levels are to be managed to ensure adequate water supplies while avoiding adverse impacts and mitigating them if and when they do occur. Adverse impacts related to groundwater levels can occur from excessively high or low groundwater levels. What constitutes an excessively high or low groundwater level may change over time, and will also vary by land use and hydrologic and climatic conditions.

Excessively high groundwater levels are problematic in some areas of the County. High groundwater levels in Sutter County are often naturally occurring. However, groundwater levels can be raised by application of water to the ground surface through irrigation, surface storage, or recharge projects. When groundwater levels are high, there is no storage capacity available in the underlying aquifer for groundwater recharge from precipitation, stream flow, or excess applied irrigation water. This represents a lost opportunity to capture recharge and increase the overall water supply for the County. Adverse impacts related to high groundwater levels include:

- Damage to foundations, roads, and other infrastructure.

- Water-logging the root zone of certain crops.

Groundwater levels decline when pumping exceeds recharge and rise when recharge exceeds pumping. It is important to note that periodic short-term declines in groundwater levels (during drought periods and/or increased pumping), which are then followed by recovery to at or near historic highs (during wet periods and/or decreased pumping), are normal and do not represent overdraft. Excessively low groundwater levels that are caused by long-term declines without recovery, thus overdraft, can be avoided by reducing pumpage. This can be accomplished by expanding the conjunctive use with surface water. Adverse impacts related to low groundwater levels include:

- Infrastructure problems when lowered groundwater levels dewater pumps or wells, so groundwater cannot be extracted using existing infrastructure even though it is available at greater depths.
- Depleted available groundwater supply.
- Inelastic land subsidence.
- Riparian and/or native vegetation destroyed.
- Reduced surface water flow due to increases in streambed infiltration, or increases in the capture of groundwater that otherwise would have contributed to increasing the base flow of a surface water system.

6.2.2. Groundwater Quality BMO

The BMO for groundwater quality is to:

- *Improve the understanding of groundwater quality in Sutter County.*
- *Maintain or improve groundwater quality.*

Adverse impacts to groundwater quality most commonly occur when degradation of groundwater renders groundwater unsuitable for intended uses. Accordingly, what constitutes a significant adverse impact to groundwater quality is related to the purposes for which groundwater is used, and may change over time as land uses and water quality regulations change. Groundwater quality degradation can occur when groundwater pumping causes poor quality water (surface water or groundwater) to migrate into areas with good quality groundwater. It can also occur when surface contaminants migrate into groundwater. As a consequence, it is important to coordinate land use planning and

resource management activities in order not to create opportunities for water quality deterioration. Adverse impacts related to groundwater quality include:

- Degradation of groundwater quality so that yields are reduced for crops irrigated with groundwater.
- Degradation of groundwater quality so that it does not comply with drinking water quality standards.
- Degradation of groundwater quality so that it is no longer suitable for beneficial uses.

There are some areas in Sutter County that currently have problems with groundwater quality (particularly arsenic and salinity) that appear to be naturally-occurring. The BMO of maintaining or improving groundwater quality reflects the County's desire to improve the quality of naturally-occurring groundwater where possible, so that it is more useful as a water supply.

6.2.3. Inelastic Land Subsidence BMO

The BMO for inelastic land subsidence is to:

- *Avoid inelastic land subsidence that is linked to declines in groundwater levels.*

Inelastic land subsidence is the permanent compaction of the subsurface. In Sutter County, the activities that have the most potential to cause inelastic land subsidence are withdrawals of groundwater or natural gas from the subsurface. Adverse impacts related to inelastic land subsidence include:

- Reduction in the volume of the subsurface that results in a permanent loss in aquifer storage.
- Damage to foundations, roads, bridges, and/or other infrastructure.
- Change in surface topography that reverses the gradients in canals and ditches, and/or changes floodplains.

6.2.4. Surface Water

There are three BMOs for surface water:

- *To improve the understanding of the relationship between surface water and groundwater.*

- *To avoid changes in surface water flow and surface water quality that adversely affect groundwater levels or are caused by groundwater pumping.*
- *Avoid changes in surface water flow and water quality that adversely affect groundwater quality.*

Pumping from very shallow aquifer zones or poorly sealed wells has the potential to affect surface water or wetlands. Adverse impacts related to surface water or wetlands include:

- Depletion of surface flows and/or degradation of water quality.
- Destroying riparian and/or native vegetation and habitat.

6.2.5. Coordination

This BMO for coordination is to:

- *Coordinate County groundwater management efforts with other groundwater management efforts within and surrounding Sutter County.*

This BMO establishes the importance of local coordination of groundwater management and sharing of hydrogeologic data. To make effective and relevant decisions, the County must rely on current data regarding the quality and quantity of the underlying groundwater.

7. PLAN IMPLEMENTATION

Sutter County intends to implement this GMP through a Groundwater Monitoring Program and an Action Plan. In order to recognize and mitigate adverse impacts to the underlying groundwater system, a system is required to collect and disseminate information to the appropriate groundwater users and agencies.

7.1. Groundwater Monitoring Program

The role of monitoring is essential to implementing the BMOs. Monitoring is the process of collecting data that is used to better understand the groundwater basin underlying the County, evaluate groundwater conditions, facilitate groundwater management, and other related activities. In order for the County to promote sustainable groundwater management, as well as for groundwater users to make effective and relevant decisions, the data needs to be made publicly available.

7.1.1. Groundwater Level Monitoring

There is an extensive network of DWR monitored wells, both dedicated monitoring wells and wells with other uses, within Sutter County. Additionally, several water purveyors within the County monitor groundwater levels within their service areas by means of dedicated monitoring wells and production wells. There is an extensive inventory of wells with groundwater measurements within Sutter County. Historically, DWR and its partners have monitored 172 wells in Sutter County, including 15 dedicated monitoring wells. The earliest recorded DWR water level measurement in Sutter County took place in 1929. Wells accessible to DWR are typically agricultural or domestic wells in which the land owners have previous agreements with DWR to allow access for measurements. Overall, the County has adequate spatial distribution of its current network to obtain groundwater level measurements. For this GMP, DWR utilized 122 of the 172 wells to produce groundwater contour maps of equal elevation.

Water level measurements are generally made two times each year, in spring and fall. Measurements have been made at some monitoring wells on an almost-monthly basis. Twice-annual (spring/fall) water level measurements are generally sufficient for the purpose of determining changes in overall groundwater conditions over time. However, these measurements should reflect the annual high (spring) and low (fall) water levels. More frequent (i.e. at most monthly) measurements are necessary to confirm that the months chosen for spring and fall measurements reflect the months with the highest and lowest groundwater elevations, on average. Water level data is currently available from DWR's Water Data Library, at: http://well.water.ca.gov.

7.1.1.1. Vertical Groundwater Gradients – Nested and/or Clustered Monitoring Wells

The vertical gradients between aquifer zones are important because they give an indication of the direction (up or down) that groundwater will migrate if a pathway, such as a well that connects multiple aquifer zones, is present. To evaluate the vertical gradient between aquifer zones, data for the different aquifer zones at a single location is needed. The preferred way to obtain this data is with nested and/or clustered monitoring wells. Nested monitoring wells have multiple wells within a single borehole, with each well isolated from the others by annular seals. Clustered monitoring wells have a single well in each borehole, with the boreholes in close proximity to one another. Figure 19 shows the locations of the 15 nested and/or clustered monitoring wells in Sutter County. Eleven of these wells are in the DWR monitoring network with measurements taken twice a year, in spring and fall. The remaining four nested monitoring wells are pending inclusion into the network because they were constructed by private parties. All of these wells are dedicated monitoring wells.

7.1.1.2. Groundwater Flow Direction – Contour Maps

The direction of groundwater flow is evaluated with groundwater level contour maps. Groundwater contours are created which connect surfaces of equal elevation (or levels). Figure 17 illustrates the contours of equal groundwater elevation for measurements taken in the spring of 2010.

The current water level monitoring network spacing is suitable for contouring groundwater elevations. Additionally, it would be beneficial to include data from nearby monitored wells in Butte, Yolo, Sacramento, and Yuba Counties to better characterize the groundwater flow direction at the County lines.

7.1.2. Water Quality

Water quality samples from wells within the County have, in the past, been obtained either by local water purveyors, the DWR, or the USGS. Currently, the County only samples groundwater in Robbins, its only public water supply system. Groundwater samples have been collected for analysis in a total of 133 wells. The DWR has sampled 34 of these wells in Sutter County, fifteen of which are nested multiple-completion monitoring wells, as shown in Figure 19. The USGS has sampled 94 of these wells, and the remaining wells were sampled by water purveyors which have shared their data. The DWR expects to conduct water quality sampling of these wells every three years, or as funds are available. The water quality data is disseminated on the DWR WDL.

The results for the USGS water quality sampling are available on the National Water Information System (NWIS) website[7]. The USGS sampled these wells as part of a larger investigation to document the condition of the groundwater throughout the valley. It is not expected that the USGS will routinely sample these wells.

The current water quality monitoring network consists of DWR owned multiple-completion monitoring wells with a sparse distribution covering the entire County. Routine sampling of these wells will allow for water quality trends to be identified. As stated within this GMP, the County does not own any dedicated monitoring wells. In conjunction with DWRs efforts to collect and distribute water quality information of the groundwater resource, the County encourages private water purveyors to disseminate their water quality data to aid in documenting depth specific and County-wide water quality trends.

7.1.3. Land Subsidence

Land subsidence has not been historically reported or documented within Sutter County. Nevertheless, DWR installed an extensometer and began monitoring for ground surface displacement in 1994. Measurements are recorded on a daily basis, offering real-time and site specific measurements. On a more regional scale, DWR and its cooperating agencies, have implemented the Sacramento Valley GPS Height Modernization Project which will provide significant enhancements to a Sacramento Valley subsidence monitoring program. It is reported by DWR that the GPS monuments will be re-surveyed approximately every three years. The monitoring of land surface elevations will allow for periodic measurements of permanent land subsidence induced by groundwater pumping and/or natural processes. The surveys will be conducted in accordance with the National Geodetic Survey Standards for two centimeter accuracy.

When used in conjunction with surface subsidence survey data (GPS), the extensometer data could aide in identifying whether subsidence is occurring over the total depth of the monitoring well.

7.1.4. Future Groundwater Monitoring

The County's existing monitoring network is described above. Groundwater monitoring within the County is currently conducted by DWR and local water purveyors. The County will continue to cooperate with DWR and encourage the local water purveyors to continue to monitor groundwater levels. Under the voluntary guidelines of SBx7-6, selected local water purveyors will continue to monitor groundwater elevations for their

[7] http://waterdata.usgs.gov/nwis

respective service area(s), along with the DWR, under protocols established by DWR. The possibility exists that in the future, DWR may cease their monitoring if they lose funding for groundwater level measurements, and the responsibility of groundwater level monitoring will be entirely upon the local water purveyors.

All new wells should be sampled for basic water chemistry (i.e. specific conductance, arsenic, manganese, and nitrate). Although not required, the County may, in the future, consider requesting copies of laboratory reports to be submitted through the permit process. Water quality results from wells sampled by DWR are routinely placed on the WDL, and are often sampled every three years, or as funding allows.

The overall subsidence monitoring program should continue to be monitored by the extensometer and GPS monuments throughout the County. The Sacramento Valley GPS Network incorporates existing GPS networks and monuments to create a regional network that covers part or all of Colusa, Sutter, Glenn, Butte, Yolo, Yuba, Tehama, and Placer Counties.

For the area encompassing the Sutter Buttes, which is outside of a DWR delineated groundwater basin, groundwater is likely contained in the fractures of the volcanic rock as well as in the marine sands that compromise the Sutter Buttes. The area encompassing the Sutter Buttes is primarily privately owned and groundwater use is unknown but is likely limited to domestic wells or stock watering wells. It is suggested that private well owners monitor groundwater levels at least twice a year (fall and spring) in order to realize changing conditions. It is also good practice to test the quality of the groundwater for health based constituents.

7.1.5. Local and Regional Groundwater Management Coordination

Coordinating local and regional groundwater management is important to meeting Sutter County's Groundwater Management Goals because groundwater, like other resources, does not respect administrative/jurisdictional boundaries, and actions outside the County can affect groundwater in the County. Further, in order to achieve the Groundwater Management Goals, the County needs to be an "effective participant" in local and regional management efforts and work cooperatively with water managers to conduct effective groundwater management. To be an "effective participant", the County needs to be informed of its groundwater conditions and activities underway or planned, which may affect the resources positively or negatively. With time and appropriate documentation of water management activities and monitoring, an understanding of the resources can be obtained so that groundwater conditions can be the result of deliberate water management choices.

Coordinating groundwater management across local and regional jurisdictions will contribute to ensuring a reliable water supply by working towards management of entire groundwater basins, not just the portions underlying the County. Involvement in regional activities will help ensure that activities outside of Sutter County that affect the reliability of the groundwater supply in the County can be addressed through regional management actions. This involvement will also help protect water rights because the County's involvement with regional groundwater management will allow it to be part of a larger group that can exert more influence in preserving water rights north of the Delta. Finally, regional coordination will help the County maintain local control by ensuring that the County's interests are represented in regional groundwater management activities.

Sutter County recognizes the importance of regional coordination, collaboration, and communication and is signatory to the "Four-County Group," which has evolved into the "Northern Sacramento Valley – Integrated Regional Water Management Group", consisting of Butte, Glenn, Colusa, Tehama, Shasta, and Sutter Counties.

In addition to the water management coordination addressed above, which is more at a technical and operational level, it is important that coordination occur at the policy level as well. This is especially important for effective and consistent operations within water purveyors whose geographic jurisdiction extends beyond Sutter County. The processes to addressing water transfers, in particular, are different in each of the three counties. It would be important, as the GMP is implemented and the institutional structure and management processes become solidified, that a dialogue be established with the neighboring counties to address the need for developing consistency in processes that affect the management and operation of the respective water purveyors.

7.1.6. State of the Basin Report - Groundwater Condition and Groundwater Management Plan Evaluation

In the future, Sutter County and local water purveyors may benefit from preparing an annual report of the conditions of its groundwater basin. However, the present County staffing and funding levels are unable to accommodate this work effort. Groundwater elevation data for the County will be available through the CASGEM program and continued DWR monitoring. Additionally, new and/or current water quality data is periodically submitted and is available through the DWR Water Data Library. The County encourages cooperation among all groundwater users to share data (groundwater level and/or quality) which is not reported or what is readily available through the Water Data Library. Water quality data is also accessible through the Department of Public Health for permitted public water systems. Through this report, the County will encourage its groundwater users to be responsible stewards of the County's resources.

This GMP prepared by the County is not intended to be a static document. As conditions change, such as population, land uses, or climate, it may be warranted to revisit the County's goals and BMOs to ensure that the overall goals of sustaining its groundwater resources to meet current and future demands for the County are being satisfied. The County encourages cooperation among its groundwater users to keep these goals in mind. It is not Sutter County's intent of this GMP to be an enforcer with regards to groundwater use; however, as climatic and groundwater usage change in the future, it may be necessary to "check in" and adjust or expand this GMP.

7.2. Action Plan

7.2.1. Actions for Groundwater Levels BMO

To avoid ongoing declines in groundwater, to avoid abnormally high groundwater levels, the County has taken and will take the following actions:

Action	*Frequency*	*Status*
Participation in the "Northern Sacramento Valley – Integrated Regional Water Management Group"	As needed	2008 - Present
Maintain relationships with state and federal agencies	Annual	1850 - Present
Promote conjunctive use through public outreach	Annual	2008 - Present
Coordination with local and regional jurisdictions on groundwater.	Annual	2008 - Present
Ensure compliance with adopted policies in 2008 General Plan (Goal ER 6)	Annual	2008 - Present
Review groundwater contour maps prepared by DWR	Annual	2008 - Present
Disseminate groundwater level data on County's website	As needed	2010 - Present

7.2.2. Actions for Groundwater Quality BMO

To improve the understanding of groundwater quality, the County has taken and will take the following actions:

Action	*Frequency*	*Status*
Cooperate with DWR in its monitoring efforts	Annual	2010 - Present
Maintain relationships with neighboring counties	Annual	1850 - Present
Ensure compliance with adopted policies in 2008 General Plan (Goal ER 6)	Annual	2008 - Present
Ongoing coordination with local and regional jurisdictions on groundwater	Annual	unknown - Present

7.2.3. Actions for Inelastic Land Subsidence BMO

To avoid inelastic land subsidence that is linked to declines in groundwater levels, the County has taken and will take the following actions:

Action	*Frequency*	*Status*
Cooperate with DWRs monitoring efforts	Annual	2010 - Present
Participate in the "Northern Sacramento Valley – Integrated Regional Water Management Group"	Annual	2008 - Present
Establish and update a groundwater management plan website	Annual	2008 - Present
Review data from the extensometer installed in Sutter County	6 months	2010 - Present
Maintain relationships with state and federal agencies	Annual	1850 - Present

7.2.4. Actions for Surface Water BMO

To improve the understanding of the relationship between surface water and groundwater; to avoid changes in surface water flow and surface water quality that directly affect groundwater levels or are caused by groundwater pumping; and to avoid changes in surface flow and surface water quality that directly affect groundwater quality, the County has taken and will take the following actions:

Action	*Frequency*	*Status*
Engage in the "Northern Sacramento Valley – Integrated Regional Water Management Group"	Annual	2008 - Present
Establish a groundwater management plan website	Annual	2008 - Present
Maintain relationships with state and federal agencies	Annual	1850 - Present
Ensure compliance with adopted policies in 2008 General Plan (Goal ER 5)	Annual	2008 - Present

7.2.5. Actions for Coordination BMO

To coordinate County groundwater management efforts with other groundwater management efforts within and surrounding Sutter County, the County has taken and will take the following actions:

Action	*Frequency*	*Status*
Engage in the "Northern Sacramento Valley – Integrated Regional Water Management Group"	Annual	2008 - Present
Maintain relationships with state and federal agencies	Annual	1850 - Present
Establish and update a groundwater management plan website	As needed	2008 - Present

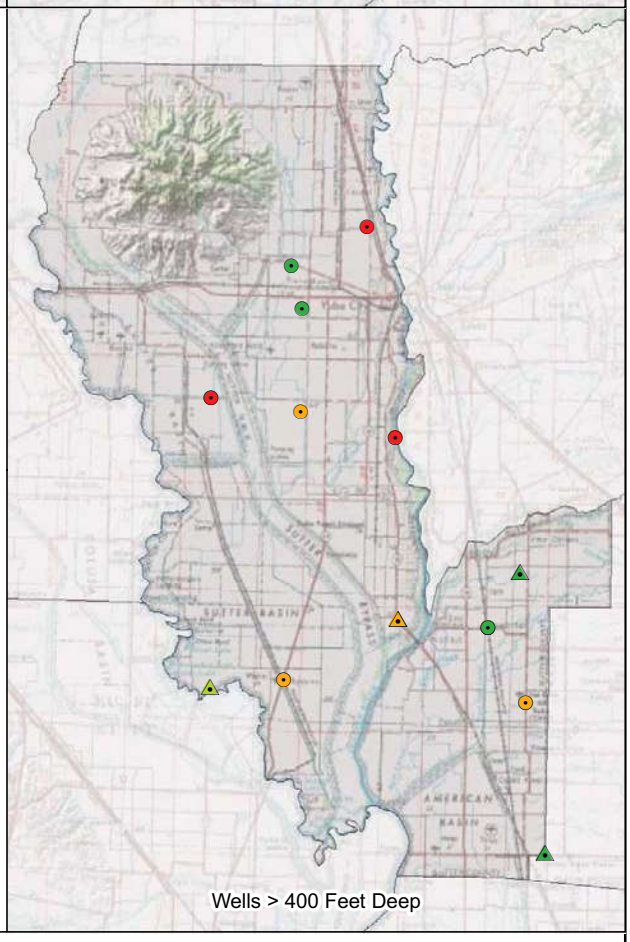
EC in DWR Wells (µmhos/cm)

- < 600
- 600 - 900
- 900 - 1600
- > 1600

EC in USGS Wells (µmhos/cm)



- < 600
- 600 - 900
- 900 - 1600
- > 1600

Note:
"EC" is an abbreviation for specific conductance, which is related to the salt content of a water sample.

For public drinking water systems, the secondary (aesthetic) maximum contaminant levels for EC are 900 micromhos/centimeter (µmhos/cm) (recommended), 1600 µmhos/cm (upper), and 2200 µmhos/cm (short-term).

For irrigation, crop yields decrease above a threshold EC value, which is crop-dependent. Crop yield potential decreases above these threshold levels:

Almonds - 1000 µmhos/cm
Beans - 700 µmhos/cm
Rice - 2000 µmhos/cm
Squash - 2100-3100 µmhos/cm
Tomatoes - 1700 µmhos/cm
Wheat - 4000 µmhos/cm

Wells < 150 Feet Deep

Wells 150 - 400 Feet Deep

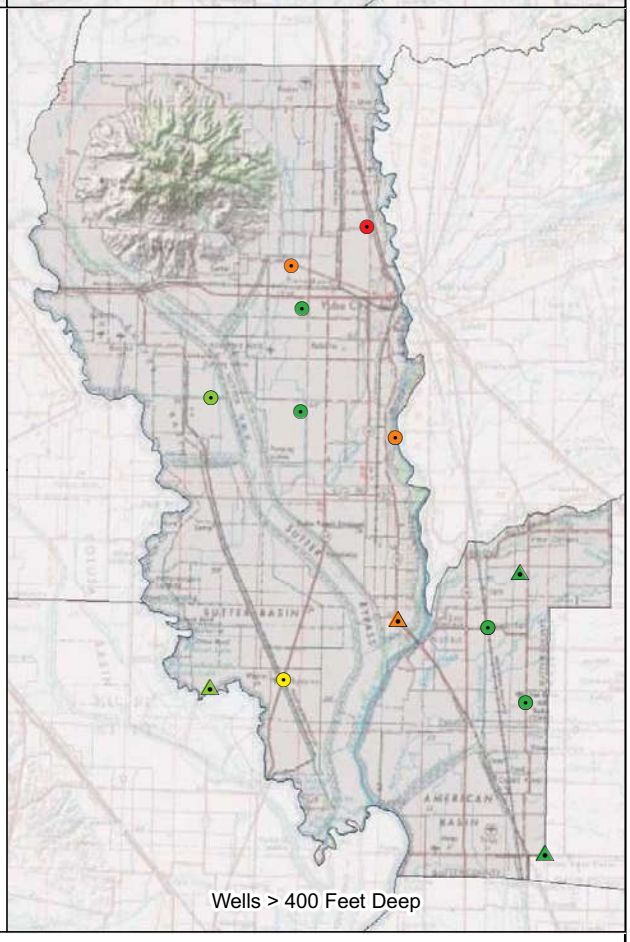
Boron in DWR Wells (µg/L)

- < 500
- 500 - 750
- 750 - 1000
- 1000 - 2000
- > 2000

Boron in USGS Wells (µg/L)

- < 500
- 500 - 750
- 750 - 1000
- 1000 - 2000
- > 2000

Note:
Boron is naturally occurring and leaches from aquifer materials into groundwater.



For public drinking water systems, there is a notification level for boron of 1000 micrograms/liter (µg/L).

For irrigation, boron is necessary for crop growth but becomes toxic to the point that yields may decrease above these threshold levels:

Beans - 750 - 1000 µg/L
Grapes - 500 - 750 µg/L
Squash - 2000 - 4000 µg/L
Tomatoes - 4000 - 6000 µg/L
Walnuts - 500 - 750 µg/L
Wheat - 750 - 1000 µg/L

Many other trees are vulnerable to boron toxicity above 500 - 750 µg/L.

SOURCES: USGS, DWR, SEWD, DHS, FAO, EPA

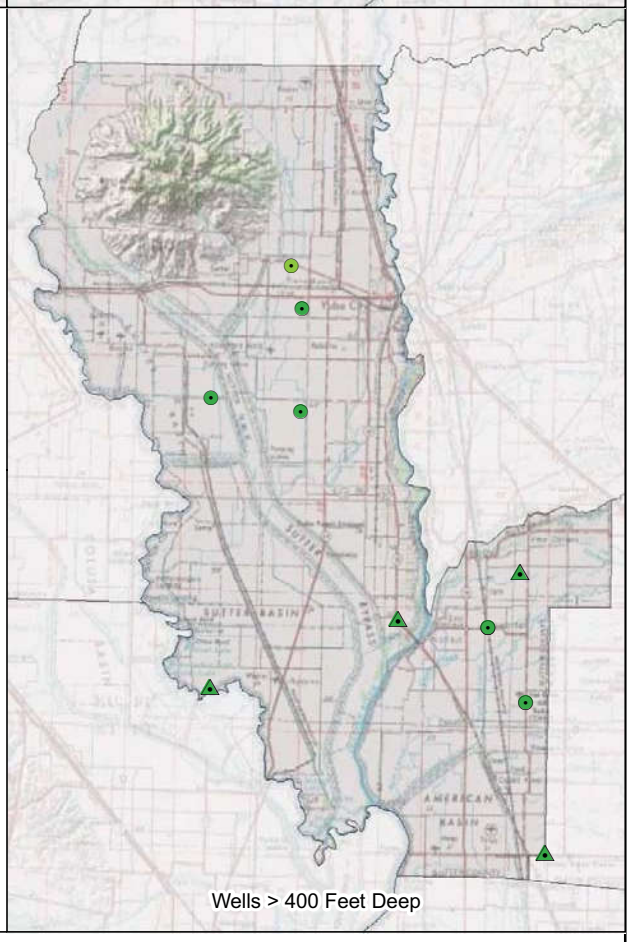
Nitrate in DWR Wells (mg/L)

- < 5
- 5 - 15
- 15 - 30
- 30 - 45
- > 45



Nitrate in USGS Wells (mg/L)

- < 15
- 5 - 15
- 15 - 30
- 30 - 45
- > 45

Note:
Nitrate is generally introduced into groundwater by septic systems, fertilizers, or confined animal operations.

For public drinking water systems, the primary (health-based) maximum contaminant level for nitrate as NO3 is 45 milligrams/liter (mg/L).

At concentrations exceeding the maximum contaminant level, nitrate can interfere with the blood's ability to carry oxygen. This effect can be especially pronounced in infants, where it is known as "blue baby syndrome".

SOURCES: USGS, DWR, SEWD, DHS, FAO, EPA

Manganese in DWR Wells (µg/L)

- < 25
- 25 - 50
- 50 - 150
- 150 - 500
- > 500

Manganese in USGS Wells (µg/L)

- < 25
- 25 - 50
- 50 - 150
- 150 - 500
- > 500

Note:
Manganese is naturally occurring and leaches from aquifer materials into groundwater.

For public drinking water systems, the secondary (aesthetic) maximum contaminant level for manganese is 50 micrograms/liter (µg/L). There is also a notification level for manganese of 500 µg/L. Notification levels are health-based advisory levels for chemicals that do not have primary maximum contaminant levels.

Manganese can cause staining of plumbing and fixtures, and can contribute a metallic odor to water. At very high concentrations (above the notification level) manganese may cause neurologic problems.

Analysis for manganese is very sensitive to turbidity of samples - turbid samples will often have artificially high results for manganese.

SOURCES: USGS, DWR, SEWD, DHS, FAO, EPA

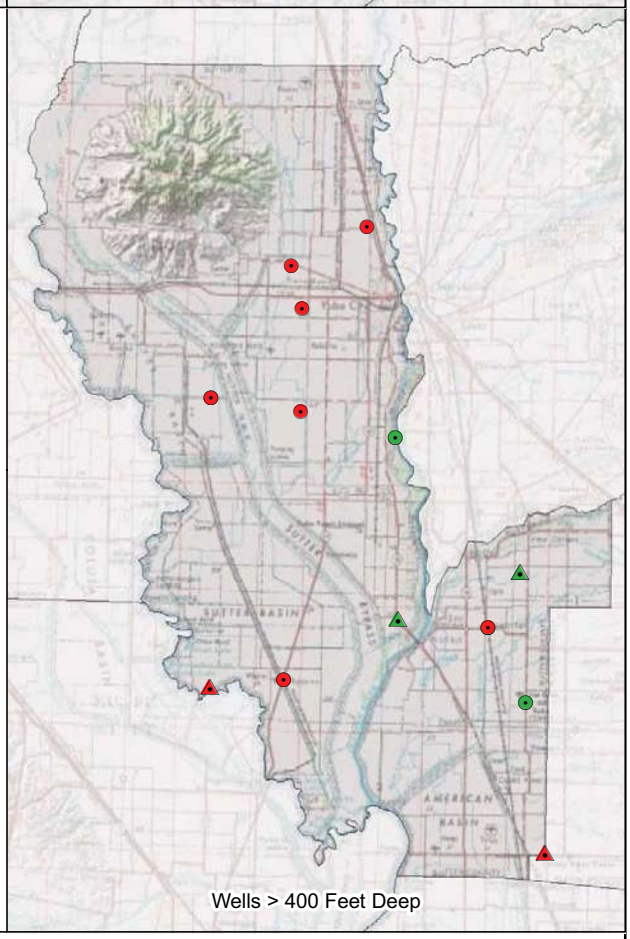
Arsenic in DWR Wells (µg/L)

- < 5
- 5 - 10
- > 10

Arsenic in USGS Wells (µg/L)



- < 5
- 5 - 10
- > 10

Note:
Arsenic is naturally occurring and leaches from aquifer materials into groundwater.

For public drinking water systems, the primary maximum contaminant level for arsenic is 10 micrograms/liter (µg/L).

Exposure to arsenic can cause both short and long term health effects. Long term exposure to arsenic has been linked to cancer of the bladder, lungs, skin, kidneys, nasal passages, liver and prostate. Short term exposure to high doses of arsenic can cause other adverse health effects.

Analysis for arsenic is very sensitive to turbidity of samples - turbid samples will often have artificially high results for arsenic.

ARSENIC IN CALIFORNIA DRINKING WATER

Three Years After EPA Notice of Noncompliance to State, Arsenic Levels Still Unsafe in Drinking Water for 55,000 Californians

ENVIRONMENTAL INTEGRITY PROJECT

SEPTEMBER, 2016

ACKNOWLEDGEMENTS

This report was researched and written by Tom Pelton, Courtney Bernhardt, and Eric Schaeffer of the Environmental Integrity Project. The map was created by Kira Burkhart and the graphics by Alana Natke.

THE ENVIRONMENTAL INTEGRITY PROJECT

The Environmental Integrity Project (http://www.environmentalintegrity.org) is a nonpartisan, nonprofit organization established in March of 2002 by former EPA enforcement attorneys to advocate for effective enforcement of environmental laws. EIP has three goals: 1) to provide objective analyses of how the failure to enforce or implement environmental laws increases pollution and affects public health; 2) to hold federal and state agencies, as well as individual corporations, accountable for failing to enforce or comply with environmental laws; and 3) to help local communities obtain the protection of environmental laws.

For questions about this report, please contact EIP Director of Communications
Tom Pelton at (202) 888-2703 or
tpelton@environmentalintegrity.org.

Arsenic in California Drinking Water

More than three years after the U.S. Environmental Protection Agency found California in noncompliance with the federal Safe Drinking Water Act, 95 community water systems in the state, serving more than 55,000 people, are still providing water with illegal levels of arsenic, according to an examination of state data for the last two years.[1] Arsenic occurs naturally in the soil and groundwater in parts of California and is a known carcinogen that may also damage the developing brains of children and cause other health problems.[2] Many of the people drinking excessive levels of arsenic are poor and/or Latino or African-American, with a cluster in the San Joaquin Valley.[3] Nearly all have been exposed to excessive arsenic levels for at least five years and probably longer.[4]

California requires public water systems to notify their customers when arsenic fails to meet federal health standards. But strangely, the state's language for mailed advisories suggests the water is still safe to drink no matter how high the contimation levels or how long they persist, with the notices telling residents: "You do not need to use an alternative water supply (e.g., bottled water)." [5] That advice conflics with what California tells private well owners (who aren't covered by federal standards) on a state website: "If you suspect that your well may have arsenic, you should not use the water until it is tested, and you take appropriate measures to protect yourself and your family from potential chronic health effects if arsenic is present."[6] Whatever the intention, California's language for people on public water systems is likely to encourage them to drink contaminated water. (For the full text of the California's language, see Appendix A). As the state continues a multi-year effort to solve the contamination problem, it should immediately fix a communications problem so that it clearly warns people not to drink arsenic-tainted tap water.

The highest levels of arsenic in drinking water in California from 2011 through 2015 were in a group home for troubled teenage boys, the Valley Teen Ranch in Madera County. About 50 boys assigned by the courts to the facility have been living in a home with water that has arsenic at concentrations averaging more than 12 times the federal limit (10 parts per billion, or ppb) over these five years, according to state records.[7] "Nobody wants to drink the water because it's brown and nasty,"said Connie R. Clendenan, CEO of the nonprofit organization that runs the group home.[8] "It looks bad."

It is bad. Although California has made substantial progress in addressing

drinking water problems, the state still has 13 school districts, serving a total of 8,822 students, with arsenic in their drinking water that exceeded the federal limit from 2011 to 2015.[9] Twelve mobile home parks in California, serving 889 people, had arsenic in their tap water that averaged up to five times the legal limit. The average annual concentrations of arsenic in the drinking water of 58 residential communities (other than trailer parks) exceeded the legal limit during this time period, as did a military base, three wineries, two food preparation businesses and two campgrounds.

In many of the schools, the group home and military base, administrators say they verbally warn people not to drink tap water. They also provide bottled water as an alternative. But in the residential neighborhoods and trailer parks, it is not clear what warning – if any -- people are receiving. "There is no warning not to drink it. There is no 'non-drink' order out there," said Robert Johnson, President of the Shaver Lake Point 2 Mutual Water Company, which supplies 210 homes in Fresno County with tap water that has seven times the legal limit of arsenic. When asked if these residents should drink bottled water instead of his arsenic-tainted tap water, Johnson said: "It's one of those things, if you want to do it, that's your deal. It's not being recommended. We're not suggesting it. This is per the state of California. We are following their guidance."
